**ABSTRACT:** The strategies of the syntheses of various (thio)ureas, semicarbazides, thiosemicarbazides, thiazolidones, and oxadiazole derived from the [2.2]paracyclophane molecule are achieved starting with 4-(2.2)paracyclophanyl)isocyanate. The structures of the obtained products were elucidated by NMR, mass spectrometry, and infrared (IR) spectroscopy in addition to high-resolution mass spectrometry (HRMS). X-ray structure analysis was also used to prove the assigned structure.

## 1. INTRODUCTION

[2.2]Paracyclophane (PC) chemistry has evolved from the functional molecules to functional materials and from the synthetic curiosity to emerging applications in asymmetric synthesis, energy materials,  $\pi$ -stacked polymers, and functional parylene coatings (i.e. polymer made by polymerization of PC induced by vapor-phase pyrolysis).<sup>1–4</sup> [2.2]Paracyclophane is also described as a rigid molecule within the interior of the conjugated segment with an otherwise similar aspect ratio to the phenylene unit. The intermolecular interactions in PC involving aromatic rings are the key processes in both chemical and biological recognition.<sup>5</sup>

Recently, it has been shown that connecting heterocycles with the PC moiety showed anticancer activity as in the case of paracyclophanyl-dihydronaphtho[2,3-*d*]thiazoles and paracyclophanyl-thiazolium bromides.<sup>6</sup> Among the following three assigned series I–III of the synthesized paracyclophanyl-heterocycles (Figure 1), series I having 1,4-dihydronaphthoquinone, was found as more active as antiproliferative agents than their naphthalene-containing congeners (series II and III) toward the SK-MEL-5 melanoma cell line.<sup>6</sup>

Previously, we reported the various classes of connection between PC and heterocycle moieties.<sup>7</sup> Aly et al. synthesized heterocycles conjugated to [2.2]paracyclophane such as five-membered rings (i.e., imidazolinone,<sup>8</sup> pyrrole,<sup>9</sup> triazolethiones, and substituted oxadiazoles<sup>10</sup>) together with six-membered rings (i.e., pyridine).<sup>11,12</sup>

It was reported that some marketed drugs had been found to contain the *N*-acylhydrazone motif in their structures, e.g.,

azumolene, carbazochrome, dantrolene, nitrofurantoin, nitrofurazone, nifuroxazide, and testosterone 17-enanthate 3-benzilic acid hydrazone.<sup>13</sup> More specifically, acylhydrazone-based compounds have shown antioxidant activities.<sup>14</sup> Hydrazides and carbohydrazides have been described as useful building blocks for the assembly of various heterocyclic rings.<sup>15–19</sup> Ureas and thioureas in combination with benzothiazoles were reported that they produced DNA topoisomerase or HIV reverse transcriptase inhibitors.<sup>20–22</sup> 1,3,4-Oxadiazole heterocyclic ring is one of the most important heterocyclic moieties due to its versatile biological actions.<sup>23</sup> Based upon the aforementioned, we are encouraged to incorporate a PC molecule to (thio)urea, semicarbazides, thiosemicarbazide, thiazolidone, and oxadiazole groups.

## 2. RESULTS AND DISCUSSION

**2.1. Synthesis of 1*N*-Benzyl-3-*N*-[2.2]-paracyclophanyl)urea (6) and *N*-(4'-[2.2]Paracyclophanyl)hydrazinecarboxamides 7a, 7b.** The strategy of preparing compounds 6, 7a, and 7b was divided into two parts: First, starting with the parent hydrocarbon 1 as a commercial

Scheme 1. Synthesis of 1*N*-Benzyl-3-*N*-[2.2]paracyclophanylurea (**6**) and *N*-(4'-[2.2]Paracyclophanyl)hydrazinecarboxamides **7a** and **7b**<sup>a</sup>

<sup>a</sup>Reagents and conditions: (A)  $(\text{COCl})_2/\text{AlCl}_3$ ,  $-10$  to  $5$  °C, 20 min; (B)  $\text{PhCl}$ ,  $\Delta$ , 40 h; (C)  $\text{NaN}_3$ , acetone/water, r.t., 2 h; (D) toluene,  $80$  °C, 1 h; (E)  $\text{PhCH}_2\text{NH}_2$ /fusion,  $100$  °C, 10 h; (F)  $\text{NH}_2\text{NH}_2$  as a solvent,  $\Delta$ , 20 h; (G)  $\text{PhNHNH}_2$ , toluene, 20 h.

product, which was then converted into the acid chloride derivative **3**<sup>24</sup> by the procedure described in Scheme 1. At the beginning, compound **1** was converted into **2** during reaction with oxalyl chloride/aluminum trichloride. Then, heating **2** in refluxing chlorobenzene caused decarbonylation to give **3**. Subsequently, the resulting acid chloride **3** was subjected toward  $\text{NaN}_3$ /acetone to give compound **4**<sup>24</sup> (Scheme 1). Heating **4** in toluene at  $80$  °C provided the corresponding isothionate **5**<sup>24</sup> in 70% yield (Scheme 1). Second, fusion of **5** with benzylamine gave the corresponding urea **6** in 87% yield (Scheme 1). Based on NMR, IR, mass spectra, as well as HRMS, the structure of compound **6** was satisfactorily proved. As the  $^1\text{H}$  NMR spectrum indicated the appearance of the  $\text{CH}_2$  protons of compound **6** as a doublet at  $\delta_{\text{H}} = 4.26$  ( $J = 6.0$  Hz). Whereas, the two NH protons appeared as two singlets at  $\delta_{\text{H}} = 7.73$  and  $6.75$  ppm. In  $^{13}\text{C}$  NMR, the  $\text{CH}_2$  and the carbonyl carbon signals resonated at  $\delta_{\text{C}} = 42.9$  and  $158.1$  ppm, respectively. On subjecting **5** with hydrazines by the procedure mentioned in Scheme 1, *N*-(4'-[2.2]paracyclophanyl)hydrazinecarboxamides **7a** and **7b** were obtained in very good yields (Scheme 1). The structure of the newly prepared compound **7a** was established by IR, NMR, mass spectra, as well as HRMS. The IR spectrum revealed a diagnostic broad band at  $\tilde{\nu} = 3352$ – $3214$  for NH groups, whereas the carbonyl group appeared at  $\tilde{\nu} = 1632$   $\text{cm}^{-1}$ . The  $^1\text{H}$  NMR spectrum

exhibited the NH-2 and NH-1 protons at  $\delta_{\text{H}} = 7.59$  and  $6.88$  ppm, respectively. In addition, the characteristic hydrazine-NH<sub>2</sub> resonated in the  $^1\text{H}$  NMR spectrum at  $\delta_{\text{H}} = 4.72$  ppm. The  $^{13}\text{C}$  NMR spectrum displayed the carbonyl-carbon at  $\delta_{\text{C}} = 157.3$ , whereas the four distinctive  $\text{CH}_2$ -bridged carbons of PC resonated at  $\delta_{\text{C}} = 35.4$ ,  $35.1$ ,  $32.9$ , and  $32.3$  ppm. HRMS proved the chemical formula of **7a** as  $\text{C}_{17}\text{H}_{19}\text{N}_3\text{O}$ .

For compound **7b**, HRMS confirmed the molecular formula of compound **7b** as  $\text{C}_{23}\text{H}_{23}\text{N}_3\text{O}$ . The  $^1\text{H}$  NMR spectrum revealed the NH protons as three singlets at  $\delta_{\text{H}} = 8.36$  (for NH-2),  $7.97$  (for NH-1), and  $6.60$  ppm for (NH-3). The  $^{13}\text{C}$  NMR spectrum of compound **7b** revealed the carbonyl carbon at  $\delta_{\text{C}} = 155.8$ , whereas the carbon signal of C-Ph was observed at  $\delta_{\text{C}} = 149.1$  ppm (see the Experimental Section). The four carbon signals of the  $\text{CH}_2$ – $\text{CH}_2$  appeared at  $\delta_{\text{C}} = 36.4$ ,  $36.1$ ,  $35.7$ , and  $32.2$  ppm.

**2.2. Reaction of Compound 7a with Dimethyl Acetylenedicarboxylate (8a) and Substituted Isothiocyanates 10a–10e.** In extension to the aforesaid strategy and taking compound **7a**, as an example, in the reaction between **7a** and dimethyl acetylenedicarboxylate (**8a**), the reaction gave compound **9** in 80% yield (Scheme 2). HRMS confirmed the molecular formula of **9** as  $\text{C}_{23}\text{H}_{25}\text{N}_3\text{O}_5$  indicating the addition reaction of compound **7a** to **8a** proceeded without elimination of a MeOH molecule.

Scheme 2. Strategy of Various Reactions of *N*-(4'-[2.2]Paracyclophanyl)hydrazinecarboxamide (7a)<sup>a</sup>

<sup>a</sup>Reagents and conditions: (H) EtOH, reflux 4 h; (I) oil path EtOH, 70 °C, reflux 4–8 h.

To discriminate between the possible structures **9** and **9'**, we analyzed the NMR spectrum. As, the hydrazano-NH appeared in the <sup>1</sup>H NMR spectrum as a singlet at  $\delta_{\text{H}} = 11.01$ , whereas the PC-NH at  $\delta_{\text{H}} = 8.45$ . The two methyl-ester protons appeared as two very close singlets at  $\delta_{\text{H}} = 3.90$  and 3.75 ppm. The <sup>1</sup>H NMR did not reveal any proton for the ethylenic-H, which excluded the formation of the isomeric product **9'** (Figure 2). The CH<sub>2</sub> carbon and its protons attached to the

Figure 2. Additive products **9** and **9'** from the reaction between **7a** and **8a**.

ester group resonated at the same region of the ethylenic-CH<sub>2</sub> of PC. The <sup>13</sup>C NMR spectrum revealed the two methyl-esters at  $\delta_{\text{C}} = 52.5$  and 52.1 ppm (see the Experimental Section). The structure of **9** was unambiguously proved by X-ray structure analysis as shown in Figure 3.

X-ray structure analysis of compound **9** showed different bond lengths of the C–N bonds, as the bond lengths of C16–N17 and C18–N19 are 1.413 and 1.384 Å, respectively. The lengths of the double bonds assigned to the C=O and N=C as in C18–O18 and N20–C21 are 1.225 and 1.272 Å, respectively. Whereas the lengths of the C–C bond assigned to the C21–C22 and C22–C23 are 1.496 and 1.510 Å, respectively.

Figure 3. Molecular structure of compound **9** (displacement parameters are drawn at the 50% probability level).

Surprisingly, when compound **7a** was subjected to substituted isothiocyanates **10a–10e**, the unexpected substituted thiourea derivatives **11a–11e** were obtained in 50–60% yields as the major products, whereas the expected products results in the addition reaction of **7a** to **10a–10e** were obtained in 20–30% yields (Scheme 2). Both products were separated by column chromatography using ethyl acetate–hexane, 10:1. The IR spectrum of compound **11d**, as an example, revealed absorptions at  $\tilde{\nu} = 3296$ –3206 (NH, s), 3091 (aryl-H), 2925 (aliph.-CH), and 1456 cm<sup>-1</sup> (C=S). Additionally, the <sup>1</sup>H NMR spectrum revealed two singlets at  $\delta_{\text{H}} = 8.99$  (NH-1) and 7.50 ppm (NH-3). The ethyl protons

were detected in the  $^1\text{H}$  NMR spectrum as a quartet at  $\delta_{\text{H}} = 3.61$  (for  $\text{CH}_2$ ,  $J = 7.2$  Hz) and as a double-triplet at  $\delta_{\text{H}} = 1.08$  ppm (for  $\text{CH}_3$ ,  $J = 13.2, 7.1$  Hz). The  $^{13}\text{C}$  NMR spectrum presented the  $\text{C}=\text{S}$  and the ethyl carbon signals at  $\delta_{\text{C}} = 180.2$ , 56.5 ( $\text{CH}_2$ -ethyl) and 14.9 ppm ( $\text{CH}_3$ -ethyl), respectively. HRMS confirmed the molecular formula of **11d** as  $\text{C}_{19}\text{H}_{22}\text{N}_2\text{S}$ . Finally, X-ray structure analysis confirmed the structure of compound **11d** as shown in Figure 4.

**Figure 4.** Molecular structure of one of the crystallographic independent molecules of compound **11d** (displacement parameters are drawn at the 50% probability level).

The structures of compounds **12a–12e** were identified as thiamido derivatives of **11a–11e** (Scheme 2). As for example, compound **12d** was proved as *N*-(4'-[2.2]paracyclophanyl)-2-(ethylcarbamothioyl)hydrazine-1-carboxamide. In the  $^1\text{H}$  NMR spectrum, compound **12d** supported the structure, since four singlets for NH protons appeared at  $\delta_{\text{H}} = 9.29$  (NH-3), 8.37 (NH-2), 8.29 (NH-4), and 7.59 ppm (NH-1). The ethyl protons resonated in the  $^1\text{H}$  NMR spectrum as a quartet at  $\delta_{\text{H}} = 3.61$  ( $\text{CH}_2$ ,  $J = 7.2$  Hz) and as a triplet for  $\text{CH}_3$  at  $\delta_{\text{H}} = 1.12$  ppm ( $J = 7.1$  Hz). The  $^{13}\text{C}$  NMR spectrum confirmed the structure of **12d** by the appearance of the  $\text{C}=\text{S}$  carbon signal at  $\delta_{\text{C}} = 182.6$ , in addition to a signal at  $\delta_{\text{C}} = 155.0$  ppm for the carbonyl carbon signal. The ethyl carbon signals were distinguished at  $\delta_{\text{C}} = 39.0$  ( $\text{CH}_2$ -ethyl) and at  $\delta_{\text{C}} = 14.9$  ppm ( $\text{CH}_3$ -ethyl). Mass spectrometry showed the molecular ion peak at  $m/z$  (%) = 368 (20). Besides that, HRMS proved the molecular formula of **12d** to be  $\text{C}_{20}\text{H}_{24}\text{N}_3\text{OS}$ .

The mechanism describes the formation of compounds **11a–11e** and **12a–12e** could be explained as due to the addition of the NH lone pair to the electrophilic center in **10a–10d** in the  $\text{C}=\text{S}$  to form compound **11** (Scheme 3). Rearrangement of **11** involved addition of the NH-PC *via* the bond between NH-PC and  $\text{C}=\text{O}$  to the electrophilic carbon of  $\text{C}=\text{S}$  accompanied by the oxidation process to give the intermediate **12** (Scheme 3). Upon heating,  $\text{N}_2$  and CO would

then be eliminated, as shown in Scheme 3, to produce **11** (Scheme 3).

**2.3. Reaction of Compounds 11a–11e and 12a–12e with Diethyl Acetylenedicarboxylate (8b) and Preparation of 1,3,4-Oxazole Derivative 17.** Further investigation was done toward compounds **11a–11e** and **12a–12e** through their reactions with diethyl acetylenedicarboxylate (**8b**). The corresponding oxothiazoles **14a–14e** and **15a–15e** were obtained and were identified by IR and NMR spectra in addition to HRMS. For example, the structure of compound **14b** was elucidated by  $^1\text{H}$  NMR spectrum *via* the appearance of the aromatic protons as two multiplets at  $\delta_{\text{H}} = 7.58–7.27$  (for 5H) and at  $\delta_{\text{H}} = 6.66–6.22$  ppm (6H), whereas the vinyl-proton of the exocyclic double bond resonated as a singlet  $\delta_{\text{H}} = 6.78$  ppm. A quartet at  $\delta_{\text{H}} = 5.22$  ( $J = 8.2$  Hz, for  $\text{CH}_2$ ) and as a triplet (3H) at  $\delta_{\text{H}} = 1.20$  ( $J = 6.9$  Hz,  $\text{CH}_3$ ) appeared to indicate the ethyl ester protons. The benzyl protons are clearly resonated as a double-doublet at  $\delta_{\text{H}} = 4.17$  ppm ( $J = 14.3, 6.8$  Hz). The  $^{13}\text{C}$  NMR spectrum supported the structure of compound of **14b** *via* the appearance of the carbonyl carbon signals at  $\delta_{\text{C}} = 150.3$  and at 147.5 ppm. The ester carbons and the benzyl carbon signals appeared at  $\delta_{\text{C}} = 61.4$  (ester- $\text{CH}_2$ ), 13.90 (ester- $\text{CH}_3$ ), and 45.9 ppm ( $\text{CH}_2$ -benzyl).

The structure of compound **14b** was totally confirmed by X-ray analysis as shown in Figure 5. X-ray structure analysis also

**Figure 5.** Molecular structure of compound **14b** (minor disordered parts omitted for clarity, displacement parameters are drawn at 50% probability level).

proved the structure of the other thiazole named (*rac*)-ethyl-(*E*)-2-((*E*)-2-(4'-[2.2]paracyclophanyl)imino)-3-cyclopropyl-4-oxothiazolidin-5-ylidene)acetate (Figure 6).

### Scheme 3. Mechanism Describing the Formation of Compounds 11a–11e and 12a–12e

**Figure 6.** Molecular structure of compound **14e** (displacement parameters are drawn at 50% probability level).

On the other side, compound **15c** was obtained in 75% yield and it was identified as (*rac*)-ethyl-(*E*)-2-((*E*)-2-(2-(4'-[2.2]-paracyclophanylcarbamoyl)-hydrazineylidene)-3-allyl-4-oxo-thiazolidin-5-ylidene)acetate. The  $^1\text{H}$  NMR spectrum indicated the NH protons as two singlets at  $\delta_{\text{H}} = 9.25$  (NH-2) and 8.53 ppm (NH-1). The vinyl proton resonated as a singlet at  $\delta_{\text{H}} = 6.80$ . The allyl protons appeared at  $\delta_{\text{H}} = 6.08$  as ddd (CH-allyl,  $J = 22.4, 10.3, 5.2$  Hz), at  $\delta_{\text{H}} = 5.12$ – $4.93$  as a multiplet for  $\text{CH}_2$ -allyl, and at  $\delta_{\text{H}} = 4.29$  ppm as a doublet ( $J = 5.3$  Hz). Finally the ethyl protons appeared, as expected, as a quartet at  $\delta_{\text{H}} = 4.18$  ( $\text{CH}_2$ ,  $J = 7.1$  Hz), and triplet at  $\delta_{\text{H}} = 1.14$  ppm ( $\text{CH}_3$ ,  $J = 7.1$  Hz). Three distinguished carbonyl carbon signals in the  $^{13}\text{C}$  NMR spectrum were present at  $\delta_{\text{C}} = 165.3$  (CO), 165.1 (CO), and 162.9 ppm. Besides that, the allyl

carbons are shown at  $\delta_{\text{C}} = 132.8$  ( $=\text{CH}$ ), 117.6 ( $=\text{CH}_2$ ), and at 44.5 ppm ( $\text{CH}_2$ -).

In the way to synthesize 1,3,4-oxazole derivative **16**, one example, such as **12e**, was chosen (Scheme 4). The disappearance of the carbonyl and  $\text{C}=\text{S}$  carbons in the IR and  $^{13}\text{C}$  NMR indicated that cyclization occurred (Scheme 4). The  $^1\text{H}$  NMR spectrum of **16** showed the two NH protons as two singlets at  $\delta_{\text{H}} = 9.41$  and 8.44 ppm (see the Experimental Section). The allyl protons appeared as a doublet at  $\delta_{\text{H}} = 6.76$  ( $J = 1.4$  Hz), besides two multiplets at  $\delta_{\text{H}} = 5.98$ – $5.90$  and at  $\delta_{\text{H}} = 5.35$  and 5.25. According to the  $^{13}\text{C}$  NMR spectrum of compound **16**, three carbons were distinguished for the allyl carbons at  $\delta_{\text{C}} = 46.3$  ( $\text{CH}_2$ ), 115.8 ( $=\text{CH}_2$ ), and 132.3 ppm ( $=\text{CH}$ -), respectively.

### 3. EXPERIMENTAL SECTION

Uncorrected melting points were taken in a Gallenkamp melting point apparatus (Weiss-Gallenkamp, Loughborough, U.K.). The infrared spectra were determined with a Bruker Alpha ATR instrument. The NMR spectra of the title compounds described herein were recorded on a Bruker Avance 400 NMR instrument at 400 MHz for  $^1\text{H}$  NMR and 101 MHz for  $^{13}\text{C}$  NMR; the references used were the  $^1\text{H}$  and  $^{13}\text{C}$  peaks of the solvents, *d*<sub>6</sub>-dimethyl sulfoxide (( $\text{CD}_3$ )<sub>2</sub>SO-*d*<sub>6</sub>): 2.50 ppm for  $^1\text{H}$  NMR and 39.4 ppm for  $^{13}\text{C}$  NMR. For the characterization of centrosymmetric signals, the signal's median point was chosen; for multiplets, the signal range was given. The following abbreviations were used to describe the proton splitting pattern: d = doublet, t = triplet, m = multiplet, dd = doublet of a doublet. The following abbreviations were used to distinguish between signals:  $H^{\text{Ar}}$  = aromatic-CH,  $H^{\text{Pc}}$  = [2.2]paracyclophane- $\text{CH}_2$ . Signals of the  $^{13}\text{C}$  NMR spectra were assigned with the help of DEPT90 and DEPT135 and were specified in the following way: + = primary or tertiary

**Scheme 4.** Synthesis of Thiazoles **14a**–**14e** and **15a**–**15e** in Addition to 1,3,4-Oxadiazole Derivative **16**<sup>a</sup>

carbon atoms (positive DEPT signal), – = secondary carbon atoms (negative DEPT signal), C<sub>q</sub> = quaternary carbon atoms (no DEPT signal). Mass spectra observed by fast atom bombardment (FAB) experiments were recorded using a Finnigan, MAT 90 (70 eV) instrument. TLC silica plates coated with fluorescence indicator from Merck (silica gel 60 F254, thickness 0.2 mm) were used to purify the crude products; flash chromatography with silica gel 60 (0.040 mm × 0.063 mm, Merck) was used.

**3.1. General Procedures.** Compounds 2–5 were prepared according to the literature.<sup>23</sup>

**3.2. Synthesis of Compound 6.** Isocyanato[2.2]-paracyclophane (**5**)<sup>23</sup> (1.00 g, 4.1 mmol, 1.00 equiv) was fused with benzylamine (5 mL) at 100 °C for 10 h. The reaction mixture was then cooled to room temperature until a precipitate was formed (24 h). The precipitate of **6** was filtered and washed with 150 mL of hexane (three times) and then was dried.

*(rac)*-1-(4'-[2.2]Paracyclophanyl)-3-benzylurea (**6**). *R<sub>f</sub>* = 0.30 (cyclohexane/ethyl acetate, 4:1). Colorless crystals (EtOH), 310 mg (87%). **3.10. Crystal Structure Determinations.** The single-crystal X-ray diffraction study were carried out on a Bruker D8 Venture diffractometer with a PhotonII detector at 123(2) K or 173(2) K using Cu- $K\alpha$  radiation ( $\lambda = 1.54178$  Å). Dual space/intrinsic methods<sup>25</sup> were used for structure solution, and refinement was carried out using SHELXL-2014 (full-matrix least-squares on  $F^2$ ).<sup>26</sup> Hydrogen atoms were localized by difference electron density determination and refined using a riding model (H(N) free). Semiempirical absorption corrections were applied. For **14b**, an extinction correction was applied. In **14b**, the ethyl moiety is disordered (see the *cif* files for details). **14e** was refined as a twin with two domains.

## 4. CONCLUSION

In the current study, a novel series assembly of thio(ureas), semicarbazides, thiosemicarbazides, thiazoles, and oxadiazole derived from [2.2]paracyclophane were effectively synthesized. Therefore, it would be potentially applied to the symmetrical disubstituted PC. We are encouraging to synthesize numerous new heterocycles derived from [2.2]paracyclophanes aiming to increase attention on that important asymmetric molecule toward biological activity. Previous reports have dealt with effective biological activities resulting from conjugation between paracyclophane and heterocycle molecules. That might led to the discovery of promising novel hybrids of interesting heterocyclic/paracyclophanes as a starting point in medicinal chemistry art that warrants further research and development as potential biological active candidates.
