Abstract

For a long time, the systematics of *Atriplex* was based solely on morphological characters and leaf anatomy. The latest worldwide phylogenetic study of *Atriplex* significantly improved our knowledge about the relationships within the genus, but a new classification has not been put forward thus far. Here we re-evaluate the taxonomy of C_4 -species of *Atriplex* that are native to Russia. Seven species are classified into two sections, *A. sect. Obione* (incl. *A. sect. Sclerocalymma*, syn. nov.) (*A. altaica*, *A. centralasiatica*, *A. rosea*, *A. sibirica*, and *A. sphaeromorpha*), and *A. sect. Obionopsis* (incl. *A. sect. Psammophila*, syn. nov.) (*A. fominii* and *A. tatarica*). Although the majority of Eurasian C_4 -species have similar morphology, leafy inflorescence is a typical character for *A. sect. Obione*. The members of *A. sect. Obionopsis* are characterised mostly by aphyllous inflorescences, but some species (*A. laciniata*, *A. pratovii*, and *A. tornabenei*) have leafy inflorescences. Geographically, almost all members of *A. sect. Obione* are confined to Central Asia, although *A. rosea* is a typical Mediterranean element and *A. argentea* occurs in North America. The representatives of *A. sect. Obionopsis* are distributed mostly in the Mediterranean and the Irano-Turanian floristic region. The alien status of *A. rosea*, *A. sibirica* and *A. tatarica* is discussed. *Atriplex flabellum*, a desert species from the Irano-Turanian region, is reported for the first time from Russia (Yamalo-Nenets Autonomous District, North Siberia) as a casual alien. This species occupies a phylogenetic position distant from both aforementioned sections. An identification key to all C_4 -species of the genus growing in Russia is given, and a sectional checklist with updated nomenclature and revised synonymy is provided.

Keywords

Alien species, *Atriplex flabellum*, distribution, Russia, systematics, taxonomy

Introduction

Atriplex L. is the largest genus in the subfamily Chenopodioideae (Amaranthaceae *sensu* APG IV 2016), after *Chenopodium* L. s.l. has been disassembled into several genera of different taxonomic placement within the subfamily (Fuentes-Bazan et al. 2012). It encompasses ca. 260 species distributed worldwide (Žerdoner Čalasan et al. 2022). In Eurasia, many species of *Atriplex* are found in deserts, especially in the Irano-Turanian floristic region, and it was suggested that the genus originated in continental Asia (Žerdoner Čalasan et al. 2022).

The classification system of *Atriplex* had been at first based on morphological characters (e.g., Aellen 1939; Wilson 1984); additionally, leaf anatomy was used as an important character for the delimitation of *Atriplex* species. The genus was divided into two physiological groups: with non-Kranz (C₃) and Kranz (C₄) anatomy (Moser 1934; Carolin et al. 1975; Welsh 2001; Sukhorukov 2006). In the latest treatment for Russia and adjacent countries (Sukhorukov 2006), *Atriplex* was divided into two subgenera based on the fusion of the perianth segments (valves) in the female flowers: *A.* subgen. *Atriplex* with marginally connate valves and *A.* subgen. *Pterotheca* (Aellen) Sukhor. with ventrally fused valves. The valves imitate bracteoles and pairs of them form bract-like covers enclosing each female flower. The type subgenus comprised several sections, characterised by the degree of valve fusion and their sclerification, leaf anatomy, the type of diurnal leaf movements, as well as their fruit and seed characters.

Molecular phylogenetic studies (Kadereit et al. 2010; Žerdoner Čalasan et al. 2022) confirmed a close relationship of many Eurasian C₃-species, especially those of *A.* sect. *Atriplex* and *A.* sect. *Teutliopsis* Dumort. emend. Sukhor. (excl. *A. oblongifolia* Waldst. & Kit.), as well as a distant position of *A. cana* C.A.Mey. from other members proposed by Sukhorukov (2006). All C₄-species of the genus comprise a monophyletic clade (Kadereit et al. 2010; Žerdoner Čalasan et al. 2022) with ca. 180 members distributed in the arid and mountainous regions around the world (Sage 2016).

In Eurasia, the majority of C₄-species were traditionally united into *A.* sect. *Sclerocalymma* (Asch.) Asch. & Graebn. and *A.* sect. *Obione* (Gaertn.) Reichenb., differing mainly by the degree of valve fusion (Iljin 1936; Aellen 1939; Medvedeva 1996; Sukhorukov 2006). *Atriplex* sect. *Sclerocalymma* included annual species with the valves fused to (nearly) half of their length (*A. altaica* Sukhor., *A. fominii* Iljin, *A. kalafganica* Podlech, *A. laciniata* L., *A. megalotheca* Popov, *A. olivieri* Moq., *A. pallida* (Moq.) Sukhor. [= *A. schugnanica* Iljin], *A. pamirica* Iljin, *A. paradoxa* Nikitina, *A. pratovii* Sukhor., *A. pungens* Trautv., *A. recurva* D'Urv., *A. rosea* L., *A. sphaeromorpha* Iljin, *A. tatarica* L., *A. tianschanica* U.P.Pratov, and *A. tornabenei* Tineo). *Atriplex* sect. *Obione* comprised *A. belangeri* (Moq.) Boiss., *A. centralasiatica* Iljin and *A. sibirica* L. (Sukhorukov 2006, 2014).

Nearly all of the aforementioned species (except *A. belangeri* and *A. tianschanica*) were included in the latest molecular phylogenetic study of the genus, and they fell into two phylogenetic lineages with different positions on the tree within the large *C₄*-group (Žerdoner Čalasan et al. 2022). The previous morphology-based classification (Sukhorukov 2006, 2014) only partly agrees with the phylogenetic relationships. Thus, the systematics of *Atriplex* needs to be revised, with the re-evaluation of its section-level taxonomy.

The present article is dedicated to a new sectional subdivision of the *C₄*-species of *Atriplex* growing in Russia as the first step towards a new taxonomic classification of *Atriplex* worldwide. It summarises the distributional data for all its members including new, unexpected alien occurrences, with further notes on geographical patterns revealed in the new classification.

Materials and methods

Our new classification of *C₄-Atriplex* taxa occurring in Russia is based on the most recent phylogenetic study (Žerdoner Čalasan et al. 2022) and follows the principle of strict monophyly.

Historical taxonomic literature was examined for infrageneric classifications in *Atriplex*. A section-level taxonomic and nomenclatural checklist was compiled in order to evaluate the infrageneric names used to classify the species under study. Taxonomic literature was screened for protologues, which were evaluated according to the current rules of botanical nomenclature (Turland et al. 2018).

We used the distribution data for each species given by Hedge (1997) and Sukhorukov (2006, 2014), which were complemented by our recent field and herbarium studies. Herbarium collections from LE, LECB, MHA, MW, MSK, MSKU, MWG, NS and NSK were critically revised for taxonomic identifications and screened for new records.

Distribution maps were prepared using SimpleMappr online tool (<http://www.simplemappr.net>) based on the literature data and the examined specimens. The results were generalised and schematically presented over the basemap of first-level administrative subdivisions of Russia. Distribution areas were evaluated for their native core and secondary dispersal based on herbarium specimens and our personal observations in the field, thus separating the territories where the species occur in their natural habitats from those where the species are confined exclusively to ruderal or other man-made habitats.

Results and discussion

Taxonomy of the native species

The *C₄*-species of *Atriplex* native to Russia are here classified into two sections, *A. sect. Obione* (Gaertn.) Reichenb. and *A. sect. Obionopsis* (Lange) Dumort., according to their phylogenetic position (Žerdoner Čalasan et al. 2022). The latter sectional

name had been forgotten for a long time but is resurrected here as the earliest name applicable to the group that includes its type species *A. laciniata* and related taxa. In the checklist, previously overlooked protologues are cited for accepted names together with second references (other than protologues) that indicate the works previously considered as places of valid publication.

- ≡ *Atriplex* sect. *Roseae* Aellen, Bot. Jahrb. Syst. 70(1): 39 (1939), “*Rosea*”, nom. illeg. (Art. 52.1). Type species: *Atriplex rosea* L.
- = *Atriplex* [unranked] *Argenteae* Standl. in Britton, N. Amer. Fl. 21: 46 (1916), syn. nov.
- ≡ *Atriplex* subsect. *Argenteae* (Standl.) S.L. Welsh, Rhodora 102: 420 (2001). Type species (Art. 10.8): *Atriplex argentea* Nutt.

Description. Annuals; inflorescences leafy; glomerules loosely arranged.

Native distribution and species. Members of the section occur in steppes, semi-deserts and mountains of Central Asia (e.g. *A. altaica*, *A. centralasiatica*, *A. pamirica*, *A. sibirica*), in the Aralo-Caspian floristic region (*A. sphaeromorpha*), in the Mediterranean (*A. rosea*), and in North America (*A. argentea* Nutt.). Five species are native to Russia (*A. altaica*, *A. centralasiatica*, *A. sibirica*, *A. sphaeromorpha*, and *A. rosea*). The Central Asian species (*A. altaica*, *A. centralasiatica*, *A. sibirica*) are mostly confined to mountain steppes and screes in South Siberia, but *A. centralasiatica* and *A. sibirica* can be found also in saline and ruderal habitats. *Atriplex rosea* and *A. sphaeromorpha* are typical lowland species with similar morphology but different distribution patterns. The first species, with predominantly Mediterranean distribution, was considered native in the southern part of Eastern Europe (Medvedeva 1996), whereas we treat it as native only in Krasnodarsky Kray, where it occurs near the shore of the Black Sea and in ruderal places further inland (Sukhorukov 2006; Zernov 2006). *Atriplex sphaeromorpha* is

mainly distributed in steppes and semi-deserts of Kazakhstan, with very scattered records in Orenburg and Saratov Oblast, as well as in the North Caucasus (Sukhorukov 1999, 2006). In these regions, *A. sphaeromorpha* could potentially require conservation action according to the IUCN guidelines (IUCN 2022) because of a high level of anthropogenic disturbance to Eurasian grasslands. The native and alien ranges of all Russian species of *A.* sect. *Obione* are displayed in Fig. 1A–E.

Taxonomic notes. The synonymisation of *Atriplex* sect. *Obione* with *A.* sect. *Sclerocalymma* and *A.* subsect. *Argenteae* is undertaken here for the first time. *Atriplex powellii* S.Watson, previously considered as a close relative of *A. argentea* (Standley 1916; Welsh 2001), occupies a distant phylogenetic position (Žerdoner Čalasan et al. 2022).

Nomenclatural notes. The name *A.* sect. *Obione* has usually been credited to Meyer (1833), who accepted this subdivision in ‘Flora Altaica’. However, the first author who segregated this section within *Atriplex* was Reichenbach (1828). He accepted the name and provided an indirect reference to the basionym as “*Obione*. G.” The

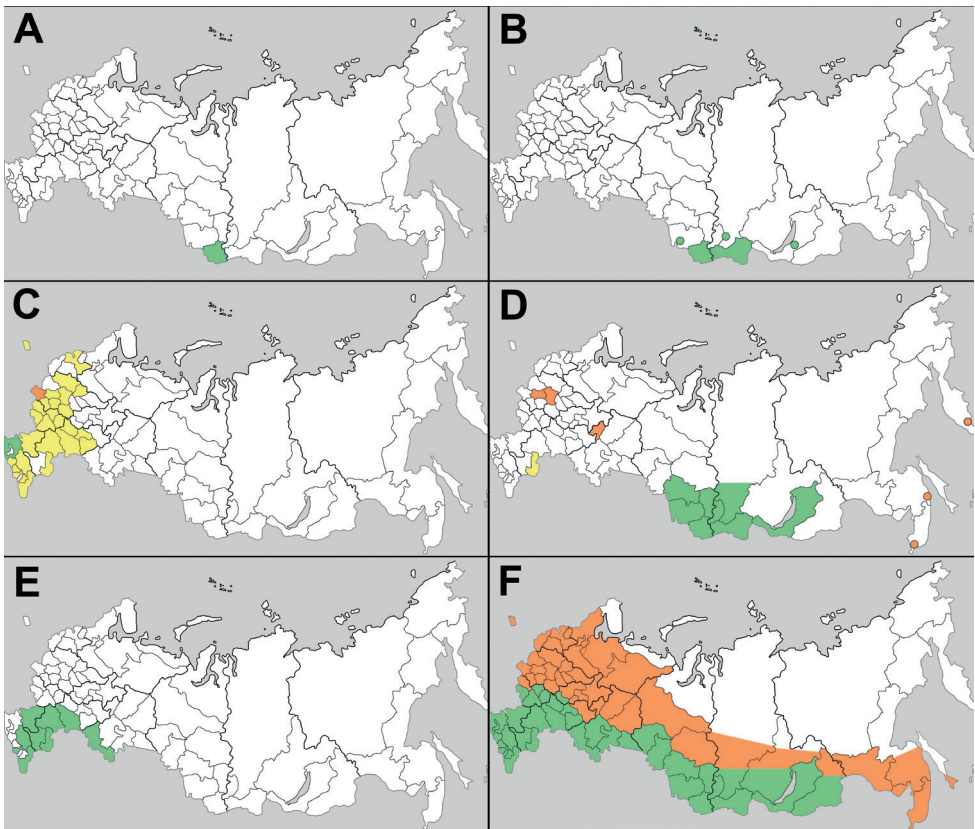

Figure 1. Schematic distribution areas of C₄ species of *Atriplex* native to Russia **A** *A. altaica* **B** *A. centralasiatica* **C** *A. rosea* **D** *A. sibirica* **E** *A. sphaeromorpha* **F** *A. tatarica*. Green – native distribution range, yellow – alien distribution not confirmed after 1930s, orange – alien distribution confirmed after 1930s.

infrageneric taxa accepted by Reichenbach (1828) were explicitly ranked as sections, as evidenced by a footnote on page 184 in this work. Similarly, Hooker (1870) was the first to accept *A.* subgen. *Obione*, which was explicitly ranked by him. On the contrary, Ascherson (1864) developed complex infrageneric systems that included at least three ranks, with names at all of these ranks, and made no note of their ranking; such classifications are to be treated as unranked (Art. 37.3).

***Atriplex* sect. *Obionopsis* (Lange) Dumort., Bull. Soc. Bot. Fr. 20: xiii (1873).**

≡ *Atriplex* [unranked] *Obionopsis* Lange, Haandb. Danske Fl., ed. 2, [7]: 635 (1859).

Type species: *Atriplex arenaria* J.Woods 1849, non Nuttall 1818 (= *Atriplex laciniata* L.).

= *Atriplex* sect. *Psammophila* Sukhor., Ann. Naturhist. Mus. Wien 108 B: 388 (2006), syn. nov. Type species: *Atriplex dimorphostegia* Kar. & Kir.

Description. Annuals; inflorescences aphyllous or bracteate, rarely leafy in the lower and middle parts; glomerules loosely or densely arranged.

Species. This section includes *A. dimorphostegia* Kar. & Kir., *A. fominii* Iljin, *A. kalafganica* Podlech, *A. laciniata* L., *A. lasiantha* Boiss., *A. olivieri* Moq., *A. ornata* Iljin, *A. paradoxa* Nikitina, *A. pratovii* Sukhor., *A. pungens* Trautv., *A. recurva* d'Urv., *A. schugnanica* Iljin, *A. tatarica* L., and *A. tornabenei* Tineo.

Native distribution. Members of this section are distributed mostly in the Irano-Turanian floristic region, with extensions into the Mediterranean and Western Europe. *Atriplex paradoxa* is the only species native to Central Asia (Tian-Shan Mountains). Two species are present in Russia: *A. fominii* (not shown on the map), which is restricted to the western shore of the Caspian Sea in Dagestan and Azerbaijan (Iljin 1936; Sukhorukov 2006), and the widely distributed *A. tatarica* (Fig. 1F). In the steppe and desert zones of Russia, *A. tatarica* is considered native based on its presence in natural landscapes (mostly on saline soils).

Nomenclatural notes. Lange (1859) used unranked infrageneric categories in his classification, whereas Du Mortier (1873) was apparently the first to explicitly rank *Obionopsis* as a section of *Atriplex*, but the nomenclatural significance of Du Mortier's publication was overlooked.

The second edition of Lange's 'Haandbog i den Danske Flora' was published in 7 parts during 1856–1859 (Staffeu and Cowan 1979). These parts were distributed separately by commercial publishers and are therefore effectively published, and the nomenclatural novelties in this work should be cited as published in its parts. The complete book bears no note on the parts and their dates, and no information on the book's structure and dates is publicly available. According to contemporary announcements of book sales, the concluding part 7 of Lange's book (with the treatment of Chenopodiaceae) was published in 1859 and consisted of 172 pages, which agrees with the printer's signatures.

Morphological notes on the members of *Atriplex* sect. *Obione* and *A. sect. Obionopsis*

Considering the latest phylogenetic results, many morphological characters like annual life form, \pm significant fusion of the valves enclosing the female flowers, indurated lower part of the bract-like cover and heteromorphic seeds, which have been traditionally used in sectional delimitation (e.g., Aellen 1939; Sukhorukov 2006), should be considered as convergent and thus unreliable for the delimitation of *Atriplex* sect. *Obione* and *A. sect. Obionopsis*.

The fusion of the valves of the female flowers can vary considerably within a single species as observed, e.g., in *A. centralasiatica* (Grubov 1966). This species is characterised by dimorphic bract-like and smooth covers (with and without dorsal outgrowths), with the latter ones being less fused. The valve fusion was examined in other annual species of both sections (Sukhorukov 2006). In *A. sect. Obione*, the valves are connate to 1/3–1/2 of their length in most species, but to 2/3 or higher in *A. sibirica*. In *A. sect. Obionopsis* the valves are usually fused to 1/3–1/2 of their length, but in *A. dimorphostegia* and *A. ornata* they are free (except the stalks, which are always fused), herbaceous and not inflated.

Seeds are usually dimorphic, red and brown in most members of both sections (Sukhorukov 2006). In light of the recent phylogenetic results (Žerdoner Čalasan et al. 2022), the trimorphic (black, red and brown) seeds mentioned by Sukhorukov (2006) as a key character for *A. sect. Psammophila* (now included in *A. sect. Obionopsis*) as well as the stalked and herbaceous valves should be re-evaluated as rare synapomorphies among the *C₄*-species of the genus.

Leafy inflorescences, which were considered characteristic of *A. sect. Obione* (Sukhorukov 2006), are also present in several species of *A. sect. Obionopsis* (*A. dimorphostegia*, *A. laciniata*, *A. ornata*, *A. pratovii*). We conclude that there are no specific morphological traits that can distinguish both sections.

Notes on alien status of the species under consideration

From all the *C₄*-species of *Atriplex* growing in Russia, only *A. tatarica* (Fig. 2A) seems to be able to spread continuously to the north reaching the forest zone (Fig. 1F). It is found in almost all regions of European Russia and Siberia up to 60°–65°N (e.g., Lomonosova 1992; Medvedeva 1996; Uotila 2011), with potential outposts in the Russian Far East (Ignatov 1988). In the forest zone, *A. tatarica* is usually found along the railway tracks on gravelly soil, where it can be classified as a typical “railway-wandering plant” (terminology after Kornaś et al. 1959). Nevertheless, sometimes it can also be encountered in towns as a ruderal plant (Sukhorukov 2014). In the northern part of Central Russia, it is a neophyte (Vinogradova et al. 2009) rather than a native species or an archeophyte as proposed by Uotila (2011). *Atriplex tatarica* was included in the “Black Book [Invasive and naturalized alien plants] of the flora of Middle Russia” (Vinogradova et al. 2009), but its invasive status was apparently exaggerated,

at least for the provinces situated in the forest zone, due to a limited number of suitable habitats in this area. In steppes of European Russia, *A. tatarica* seems to be native (but allochthonous) and can be found in a wide range of habitats including saline soils, same as in more southern regions of temperate Eurasia.

Atriplex sibirica is native to Central Asia and South Siberia (Sukhorukov 2006) where it grows in steppes, on loamy or stony soils, or as a ruderal plant. Surprisingly, this species is rarely found as an alien taxon in other regions despite the presence of suitable habitats, and almost all of the several recent findings outside of Siberia (Fig. 1D) are located along railway tracks. For example, in the Russian Far East it was found for the first time in 1973 in Kamchatka Kray (MHA0303450, as *A. rosea*) and correctly identified by Ignatov (1988), then collected once in Khabarovskiy Kray in 1990 (MHA0303451). The first record of *A. sibirica* in Primorsky Kray is reported here: “Vladivostok town, Ugol’naya railway station, gravely substrate, 9 Aug 1988, *T. Nechaeva s.n.*” (MHA0303481, as *A. tatarica*). Among several sheets collected from this locality by T. Nechaeva, only one specimen belongs to *A. sibirica*, whereas all other specimens were correctly identified as *A. tatarica*. In European Russia, *A. sibirica* was known only from two provinces (Sukhorukov 2014; Fig. 1D in the present paper). Because of its scattered records in both Far East and European Russia, *A. sibirica* should be considered a casual alien without naturalization potential.

Contrary to *A. sibirica* and *A. tatarica*, the secondary range of *A. rosea* (Fig. 2B) in Eastern Europe has dramatically declined (Sukhorukov 2006). Almost all the recent claims about its wide distribution in the central and south parts of European Russia are erroneous, and since the 1930s there were no new records of *A. rosea* except the oc-

Figure 2. General view of the plants: **A** *A. tatarica* **B** *A. rosea*. Photographs by A. Sukhorukov (**A** Russia, Tambov Oblast, Uvarovo, 20 September 2008) and M. Chambouleyron (**B** Morocco, Jerada, 23 August 2019).

currences in Krasnodarsky Kray, Crimea (MW! MHA! see also Sukhorukov 2006) and Bryansk Oblast (MSK!), the territories with mild climatic conditions. The causes of its disappearance are still unknown, and further observations are needed to revise the distribution and ecological preferences of *A. rosea* in the countries bordering the Black Sea.

A new record of an alien *C₄*-species from Russia

Among the Russian specimens of *Atriplex prostrata* Boucher ex DC. (*A. sect. Teutliopsis* Dumort.: Sukhorukov 2006; Žerdoner Čalasan et al. 2022), which are deposited at MW, an unusual plant was found that readily differs from this species by its (sub)opposite leaves with crenate blades and by the leaf venation with remarkable chlorenchyma stripes that is peculiar for the atriplicoid Kranz anatomy. These features indicate that this plant is actually *A. flabellum*, a desert species from Central Asia, Iran and Afghanistan, which has never been reported for Russia (Lomonosova 1992; Sukhorukov 2006). This record is treated in detail here, separate from the other *C₄*-species because of its novelty and casual non-native origin.

Atriplex flabellum Bunge in Boiss., *Fl. Orient.* 4: 912 (1879).

≡ *Obione flabellum* (Bunge) Ulbr. in Engler & Prantl, *Nat. Pflanzenfam.*, ed. 2, 16c: 506 (1934). Type: Iran. “Persia, in montosis salsis ad orientem urbis Meschhed, inter Faz et Tabatkuh prov. Khorassan”, *A. Bunge* (LE!), lectotype designated by Sukhorukov (2006: 408)).

Morphology. For a detailed description, see Iljin (1936), Hedge (1997) and Sukhorukov (2006). The species is recognisable in all stages by its (sub)opposite crenate leaves with the Kranz-type anatomy, and flabellate and stalked bract-like covers of the female flowers with ventrally fused valves. The (sub)opposite leaves are very rarely found in the *C₄*-clade of *Atriplex*, and the ventral valve fusion is present only in two Eurasian species of the genus, *A. flabellum* and *A. moneta*.

Specimen seen (Fig. 3). Russia, Tyumen Oblast, Yamalo-Nenetsky Autonomous District, Novy Urengoy Town, Aug 199X [year unknown], *P. Zhmylyov* & *S. Elansky s.n.* (MW0058941!). Image available at <https://plant.depo.msu.ru/public/scan.jpg?rcode=MW0058941>.

Habitat. In Russia, the species occupies ruderal habitats. Within its native distribution range, it occurs in the desert zone on sandy and loamy soils in lowlands and foothills.

Introduction status. Casual alien. *Atriplex flabellum* is a typical desert plant, and its populations cannot become established in the extreme north of the boreal zone. For this reason, we presume that this population is most likely extinct now.

Native distribution. Afghanistan, Iran, Kazakhstan (south and south-east), Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan.

Alien distribution. Russia (Tyumen Oblast) (Fig. 4).

Figure 3. The voucher specimen of *Atriplex flabellum* recorded in Russia.

Figure 4. The location of a single alien record of *Atriplex flabellum* in Russia.

Taxonomy. The phylogenetic position of *A. flabellum* is distant to both *A. sect. Obione* and *A. sect. Obionopsis*; this species belongs to the basal grade within a large clade encompassing the majority of the Old World species of the genus (Žerdoner Čalasan et al. 2022). It was assigned to *A. subgen. Pterotheca* (Aellen) Sukhor. (lectotype species: *A. moneta* Bunge (Sukhorukov 2006)), whose monophyly has not been confirmed, and the sectional placement of *A. flabellum* has not been evaluated. A new classification of *Atriplex* is currently in preparation by Sukhorukov et al.

This Russian record of *Atriplex flabellum* is unexpected. Two more species of the C₄-clade of *Atriplex*, *A. dimorphostegia* and *A. pungens* (both belonging to *A. sect. Obionopsis*), occur in West Kazakhstan at their western distribution limit (more detail in Sukhorukov 2006) and can potentially be found in adjacent regions of Russia (e.g., Astrakhan Oblast) as alien or sporadically distributed native plants.

Key to the native and alien C₄-species of *Atriplex* growing in Russia

- 1 Leaves (sub)opposite, crenate; valves at fruiting flabellate, stalked, ventrally fused ***A. flabellum***
- Leaves alternate, of different shape; valves marginally fused..... **2**
- 2 Inflorescence leafy (almost) to the top; leaves rhombic, triangular or spatulate, entire to lobate **3**
- Inflorescence not leafy, sometimes one to several leaves present; leaves of different shape (linear, lanceolate or rhombic), entire to sinuate **7**
- 3 Plants small (up to 20–30 cm), not forming a tumble-weed habit; bract-like cover dorsally without outgrowths..... ***A. altaica***
- Plants forming a tumble-weed or spreading habit; bract-like cover usually with outgrowths..... **4**

- 4 At least some valves of female flowers stalked, with thorn-like outgrowths located along the seed-containing part; plants native to Siberia, rarely found in other regions as aliens.....5
- Valves sessile, with one to several outgrowths located near their centre, rarely smooth; plants native to Europe.....6
- 5 Valves monomorphic, all with thorn-like outgrowths..... *A. sibirica*
- Valves dimorphic, smooth and with thorn-like outgrowths on the same plant.....
.....*A. centralasiatica*
- 6 Inflorescence branches almost filiform; each cluster with 1–3 female flowers; steppe plants *A. sphaeromorpha*
- Inflorescence branches not filiform, stout; each cluster with 3–6 female flowers; ruderal or coastal habitats.....*A. rosea*
- 7 Inflorescence bracteate; bract-like cover not inflated.....*A. tatarica*
- Inflorescence leafy in its lower and middle part; bract-like cover inflated*A. fominii*

Conclusions

A new, phylogeny-based classification of the C_4 -species of *Atriplex* occurring in Russia, places them into two large groups, which are morphologically similar but geographically rather distinct.

The phylogenetic circumscription of these groups shows that many characters that evolved in these lineages are highly convergent; thus it is impossible to find any clear morphological differences between these lineages. They can be characterised by different tendencies in certain diagnostic characters.

This classification is the first step towards a new phylogeny-based revision of the taxonomy of *Atriplex* worldwide. In addition to the gaps in the recent phylogenetic studies, for which some important species have not been sampled yet, a significant difficulty is presented by the vast corpus of old taxonomic literature, which has never been evaluated for the infrageneric nomenclature.

Many *Atriplex* species readily colonise disturbed habitats and spread widely to new territories next to or even far away from their native distribution areas. In addition to the first record of *A. flabellum*, further records of non-native species are expected in Russia, especially those with the ranges located close to the country, e.g. *A. dimorphostegia* and *A. pungens*.

Acknowledgements

The herbarium studies of APS and MK and interpretations of the results were supported by the Russian Science Foundation (project 22-24-00964). We also thank Stephen Boatwright, Nadja Korotkova and one anonymous reviewer for valuable comments and Mathieu Chambouleyron (Emirates Center for Wildlife Propagation, Missouri) for the image of *A. rosea*.
