

26 **1. Introduction**

27 In recent years, food products produced by unsustainable and intensive production methods have
28 had negative impacts on human well-being, society and the environment. Therefore, the demand towards
29 more sustainable food production systems and sustainable food consumption is becoming fundamental
30 to sustainable development. The United Nations firstly put forward the concept of sustainable
31 development, including sustainable agriculture in the 1990s, and the goal of sustainable agriculture is to
32 meet society's food and textile needs without compromising the ability of future generations to meet
33 their own needs (Brundtland, 1987). The concept of sustainable food is complex and encompasses issues
34 relating to biophysical, social, and economic environments (Brklacich et al., 1991). Sustainable
35 agricultural production is a systematic concept, which integrates three main objectives: a healthy
36 environment, economic profitability, social & economic equity. More specifically, food should be safe,
37 delicious, naturally ripened, healthy, nutritious, acceptable, and affordable for consumers. It should also
38 guarantee fair profits for farmers, workers, and retailers, enabling a high welfare state and wellbeing. In
39 addition, sustainable food production should be beneficial to the environment, by reducing energy
40 consumption, respecting animal welfare, using environmentally friendly agricultural technology that
41 reduces the use of chemicals, protecting citizens' health and maintaining human and rural communities.

42 Consumers are demanding products with high sustainable standards. Thus, the sustainability
43 concept within the food systems is becoming a prominent and politically complex issue that has received
44 attention from policymakers and researchers. In fact, consumers have increasingly paid attention to the
45 wider ethical issues and sustainable food products. Local products, animal welfare products, fair-trade
46 products, seasonal agricultural products, and more globally, carbon footprints products are just a few
47 examples of this growing trend (Codron et al., 2006). Measuring willingness to pay (WTP) is an
48 acceptable tool to understand consumers' attitudes and opinions towards sustainable attributes in food
49 products. The WTP estimates represent the price premium or the maximum amount that a current or
50 potential consumer is willing to pay for a product or good (Tully and Winer 2014). Understanding
51 consumers' WTP will allow policymakers and multi-agents stakeholders to carry out and design more
52 socially acceptable policy actions that ensure sustainable food production. The changes in consumers'
53 attitudes towards sustainable food will also bring changes in consumers' behavior and consumption
54 patterns. Changes in human behavior could encourage, attain or maintain sustainable systems (Brklacich
55 et al., 1991).

56 As a result, to promote sustainable agriculture, an abundance of empirical studies has attempted to
57 investigate consumers' WTP for sustainable food products. The main results showed that the majority
58 of consumers were willing to pay a premium price for sustainable products (Laroche, Bergeron, and
59 Barbaro 2001). For example, a study showed that the premium that Chinese consumers WTP for
60 sustainable milk reached an additional 40% on the average conventional milk price (Gao et al., 2016).
61 Another study revealed that most Spanish consumers were willing to pay a higher price for sustainable
62 wines (Sellers, 2016), while the WTP values were heterogeneous depending on market segments.
63 Additionally, some studies showed that the consumers who were willing to pay more for
64 environmentally friendly products were more likely to be females, married and with at least one child
65 living at home (Laroche, Bergeron, and Barbaro 2001). Vecchio and Annunziata (2015) indicated that
66 female consumers were willing to pay more for sustainable chocolate bars than male respondents, with
67 a premium of 14, 13 and 9 cents respectively for Fair-trade, Rain Forest certified and Carbon Footprint
68 products.

69 In this context, there are some literature reviews focusing on consumers' WTP for sustainable food
70 products (Katt & Meixner, 2020; Schäufele & Hamm, 2017). However, integrating different literature
71 adopting systematic review and meta-analysis for consumers' WTP towards sustainable food products
72 from a wider range has not been conducted. In addition, meta-analyses literature of WTP for animal
73 welfare products (Clark et al., 2017) and organic food (Xia & Zeng, 2008) have been studied, but
74 focusing on only one specific sustainable attribute. To fill this gap, this research helps to broaden the
75 study of WTP for sustainable food products from a broad area, including different sustainable attributes
76 simultaneously, by extracting data from the previous literature using a meta-analysis. Furthermore, the
77 result will be more accurate using meta-analysis and provide reliable evidence for policymakers and
78 sustainable food producers.

79 In this context, the main objective of this study is twofold: firstly, to synthesize consumers' WTP
80 studies regarding sustainable food products; and secondly, to measure and compare the average WTP
81 towards sustainable food products worldwide and its heterogeneity.

82 This paper is organized as follows. Section 2 is Data and Method and it presents the concept of
83 meta-analysis, selection criteria related to the empirical studies, and how the data collected for the
84 analysis. Section 3 describes the empirical results of descriptive statistics, overall estimates, subgroup
85 analysis and meta-regression models. Section 4 is the discussion and conclusion.

86 **2. Data and Method**

87 **2.1 Meta-analysis**

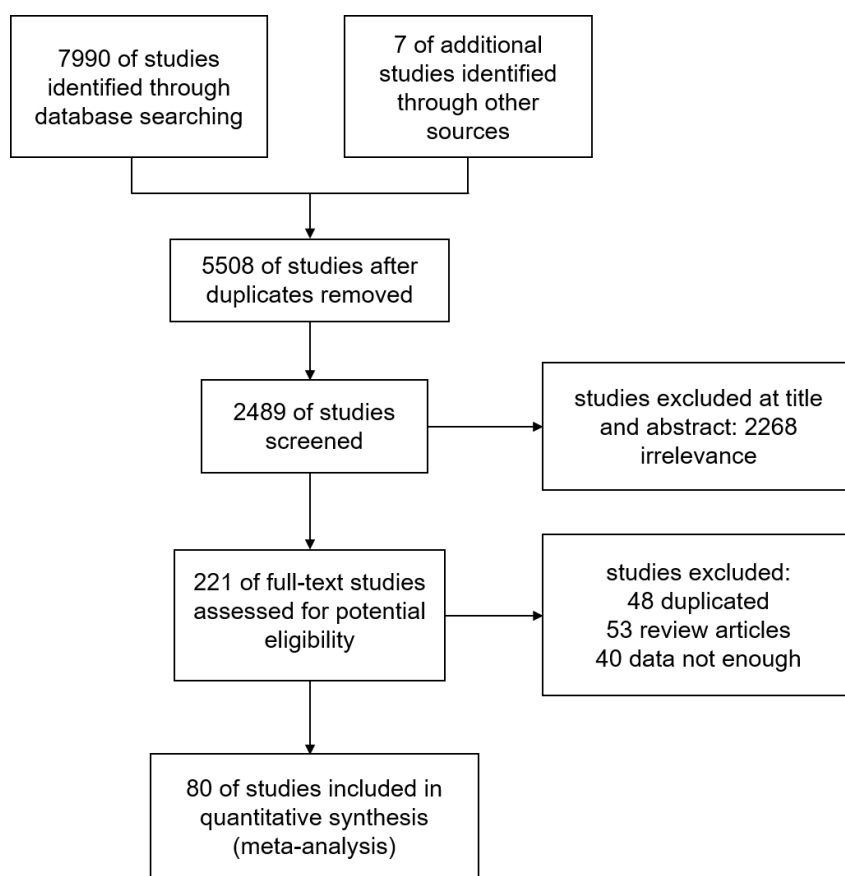

88 Glass (1976) defined meta-analysis for the first time as “the statistical analysis of a large collection
89 of analysis results from individual studies to integrate the findings”. Meta-analysis is widely used by
90 researchers in many fields, such as psychology, education, marketing and social sciences. In addition,
91 meta-analysis is a good method of understanding variation in WTP across different products and types
92 of social responsibility (Tully and Winer 2013). This study made a broader generalization about WTP
93 for sustainable products using meta-analysis from a wider perspective by jointly including different
94 sustainable attributes.

95

96 **2.2 Strategy of literature search**

97 The available studies relevant to consumer’s preferences and WTP for sustainable food products
98 (from 2000 to 2020) were identified from the electronic databases of Google Academic search and the
99 Web of Science. We used the following keywords: “consumer preferences”, “willingness to pay”,
100 “WTP”, “consumer behavior”, and “sustainable food products”. In order to reduce publication bias
101 (Rothstein et al., 2006; Stanley, 2011), we also searched unpublished literature by scanning some
102 researchers’ and institution websites. Included studies were based on “English”, “mainly a choice
103 experiment (CE) or contingent valuation method (CVM)”, “willingness to pay or price premium or
104 preferences”. The CE method is a valuation method based on Lancasterian consumer theory and random
105 utility theory (Lancaster, 1966). It consists of several choice sets with two or more alternative goods
106 described by their attributes and the respondents are asked to choose one of the alternatives hereby,
107 revealing trade-offs between the attributes of the goods (Holmes et al., 2017; Koistinen et al., 2013).
108 CVM is a survey-based method, which is often used to evaluate the monetary value of environmental
109 goods and services that are not traded in the market (Carson, 2000). In the CVM, researchers develop a
110 survey for a hypothetical market and ask a survey participant to make an economic decision (i.e., to buy
111 or not to buy) (Yi, 2019). CE and CVM are both stated preference approaches, and concerns about
112 strategic behavior or hypothetical bias arise (Holmes et al., 2017). Finally, 80 papers were included
113 based on three criteria: firstly, the topic of research was consumers’ WTP for sustainable food products
114 or sustainable attributes. Secondly, the study reported the average consumers’ WTP value for sustainable
115 food, whether it was in monetary form or percentage form. Thirdly, studies adopting stated-preferences

116 methods and revealed-preferences both were included. The flow chart for the exclusion /inclusion
117 process was presented in Fig. 1.
118

119
120 **Fig.1** The flow diagram of the search and selection process

121
122 **2.3 Data extraction and critical analysis Information**

123 In this meta-analysis, standardized average WTP value in included studies was taken as effect size.
124 This was in agreement with the study of Xia and Zeng (2008). Mean WTP is a measure that involves
125 utility levels subjectively estimated by consumers, which reflects complex, subjective perceptions
126 (Dolgopolova & Teuber, 2018). 53 studies reported WTP estimates in the percentage form, but the others
127 reported WTP in monetary terms. In order to tackle the currency difference issues and different WTP
128 formats (i.e., the weight unit, product unit and category), all WTP estimates were presented in percentage
129 form. The WTP value, represented as the dependent variable in this analysis, was the price premium
130 which meant the percent payment increased over conventional food price (Lagerkvist & Hess, 2011).
131 Therefore, all WTP values in the 80 included papers were presented in the percentage form. For the
132 monetary WTP, the transformation was as follows:

133
$$\text{WTP (\%)} = \frac{\text{WTP}_{\text{sustainable}} - P_{\text{conventional}}}{P_{\text{conventional}}} \times 100\%$$

134 “*P conventional*” denoted the price of conventional food products. Some papers did not mention
135 the price of conventional food product, the value of conventional products were searched, based on the
136 year of data collection (Clark et al., 2017). Moreover, we extracted moderator variables to explain
137 heterogeneity within the data. These were average values (income, age), percentages of the population
138 (female, more than university education) and categorical moderators (sustainable food categories, region
139 of study, sustainable attributes and study method). Income was the annual household income, expressed
140 in dollars, because most papers provided income data in dollars.

141 The data was collected, analyzed and checked according to the requirements of meta-analysis using
142 Review manager 5.3 (Revman 5.3), provided by the Cochrane Collaboration (Higgins & Green, 2011;
143 Leontiadis et al., 2005), and Stata 14.0 software for the econometric modeling and analysis. We adopted
144 the random-effects model rather than the fixed-effects model in Stata to calculate the effect size because
145 of the heterogeneity among the population effects of studies included in the analysis (Hedges & Vevea,
146 1998).

147 The Egger’s test and the funnel plot were conducted to measure the publication bias. Publication
148 bias is a term for what occurs whenever the study that appears in the published literature is systematically
149 unrepresented of the population of completed studies (Rothstein et al., 2006) and it may lead to the
150 overestimation and some unreliable conclusions, so it is vital to test for (Clark et al., 2017). In the
151 absence of publication selection bias, the plot looks like a symmetrical funnel (Dolgoplova & Teuber,
152 2018). Meta-analysts attempted to minimize the publication bias because of including working papers
153 and any other unpublished reports (Stanley, 2011).

154 Furthermore, subgroup analysis was adopted to test deeper heterogeneity of the data. Seven
155 subgroup analyses were conducted according to the year of publication, sustainable food categories,
156 sustainable attributes, method types, region of study and socio-demographic characteristics (age and
157 income). In order to make the subgroup analysis results more visually, two plots were drawn using the
158 Tableau software. The size of the circle means the WTP value of each variable.

159 Finally, the meta-regression was used on a study-level summary data and estimated the between-
160 study variance and coefficients, using weighted least squares when the outcome variable is continuous
161 (Dolgoplova & Teuber, 2018; Harbord & Higgins, 2008). Meta-regression can conduct more complex

162 analyses considering all significant moderators. It also benefits to detecting whether collinearity might
163 provide an alternative explanation for some of the significant results (Xia & Zeng, 2008). In this meta-
164 regression analysis, eight covariates (percentage of female, more than university education, the year of
165 publication, income, region, methods, sustainable attributes and food categories) were introduced so the
166 Monte Carlo permutation test was conducted to reduce Type I error and improve the accuracy of the p-
167 value. In this analysis, dummy variables were used to quantify categorical variables. “Year 1” meant
168 papers published before 2008 (including 2008), and accordingly, “year 2” denoted papers published after
169 2008. “Income 1, 2 and 3” were those with average annual household income of included papers under
170 \$30,000, \$30,001-60,000 and more than \$60,001, respectively. In addition, methods were classified into
171 two types, hypothetical approaches and non-hypothetical methods, coded as “method 1” and “method
172 2”. The “food category 1” meant dairy and “food category 2” represented drinks (wine, beer, coffee).
173 As for “food category 3, 4 and 5”, they were fruit & vegetable, meat and seafood, respectively. “Region
174 1, 2, 3, 4” denoted America, Asia, Europe and Oceania. “Attribute 1, 2, 3, 4 and 5” meant
175 environmentally friendly (EF), local, organic, fair-trade and animal welfare. It was worth noting that
176 year 1 (before 2008), income 3 (more than \$60,000), method 2 (non-hypothetical methods), region 4
177 (Oceania), attribute 4 (fair-trade) and food category 5 (seafood) were dropped because of collinearity.
178 In order to make the results more visually, two visual plots were drawn using the Tableau software to be
179 better understood. Tau2 estimated the size of the variance component between-study. The smaller the
180 value was, the better the model fitted.

181

182 **3. Results**

183 **3.1 Descriptive statistics**

184 In 80 included studies, 34 were from Europe, 21 were conducted in Asia, 21 were from America
185 and the remaining 4 were from Oceania. Diverse WTP estimates for sustainable food products and
186 attributes were measured. The sample sizes of individual literature were also different. The maximum
187 size was 4103, which was studied in 8 European countries. Whereas, the minimum size was only 60
188 studied in Ukraine. The typical sample sizes ranged from 200 to 400 (Xia & Zeng, 2008). Regarding
189 valuation methods, 31.3% of the studies were CE, with 2 papers using non-hypothetical CE and 33.8%
190 were CVM. Only 8.8% of papers were using an auction experiment. 23.8% of the studies were other
191 valuation methods. The lowest mean percentage WTP was 1.7% from Loureiro (2003), who studied

192 sustainable wine in America, while the highest one was 91.0%, studied in Iran for organic milk by
 193 Amirnejad and Tonakbar (2015), followed by tomato, which was studied by Cicia et al. (2006) in Italy
 194 and Skreli et al. (2017) in Albania with 86.0% and 85.0% WTP premium respectively. These results are
 195 clearly related to the baseline of the conventional product category. Wine is more expensive than milk
 196 and tomatoes and therefore, the percentage of expensive products is lower compared with the cheaper
 197 ones. Annex 1 presented the characteristics of the studies included in the research.

198

199 3.2 Overall results

200 It showed that the overall quality was high in the included papers, according to the graph of quality
 201 assessment (Fig. 2), which denoted the risk of bias item for each included study.

202

203 **Fig. 2** Risk of bias across included studies

204

205 Note: It was judgements about each risk of bias item for each included study. This figure was generated
 206 in Revman, which denoted the risk of bias of included papers, according to criteria of quality assessment
 207 from Cochrane. It showed that the overall quality was high of the included papers.

208

209 In addition, we also checked for publication bias using Egger's test method (Table 2). The existence
 210 of publication bias in favor of studies with positive WTP for sustainable food products was confirmed
 211 by visual inspection of the funnel plot (Fig.4) and results of the Egger's tests (Table 2) ($p = 0.00 < 0.01$).
 212 Whereas, this asymmetry might be caused by true empirical effects observed in the literature
 213 (Dolgoplova & Teuber, 2018).

214

215

215

216

Table 2 Result of Egger’s test (N = 80)

Std_Eff	Coef.	Std. Err.	t	P> t	Lower 95% CI	Upper 95% CI
slope	0.03	0.04	0.87	0.39	-0.04	0.11
Bias	13.12	2.64	4.96	0.00***	7.82	18.38

217 Note: *** Significance level: 0.01. $P = 0.00 < 0.01$, denoting that there is a significant difference, which
218 means significant existence of publication bias.

219

220

221

Fig. 4 Funnel plot of study

222 Note: ES means effect size (standardized average WTP value in this research) and s.e. of ES denotes
223 standard error of effect size. In the absence of publication selection bias, the plot looks like a symmetrical
224 funnel. This funnel is not symmetrical, indicating the existence of publication bias.

225

226 3.3 Subgroup results

227 The summary of results for different subgroup analyses could be found in Table 3, Fig. 5 and Fig.

228 6. As can be seen, the WTP estimates of all subgroups were positive. The overall WTP estimate was

229 0.295 (29.5%), with 95% CI (0.251, 0.338). With regard to the results of the subgroups for socio-

230 demographic characteristics (age, income) and the date of publication, it should be noted that the average

231 age of only 2 articles was over 56. The results of age showed that the younger generation had a higher

232 WTP value with 34.6%, while the 56 and older had the lowest WTP with 29.5%. Fig.5 clearly proved

233 the result. Regarding the results of the subgroup for average annual household income, it demonstrated

234 that those whose income was over \$60,001 had the highest WTP with 30.7%, while those whose income
 235 was between \$30,001 and 60,000 got the lowest WTP with 25.5%. With respect to the subgroup of date
 236 of publication, it showed that the WTP value of papers published before 2008 was lower (21.6%) than
 237 those after (31.0%). It should be noted that there were only 13 papers before 2008 (including 2008) (the
 238 financial crisis), meaning that the results should be interpreted with caution. The I^2 values of all three
 239 subgroups were over 90.0%, which demonstrated the existence of high heterogeneity.

240

241

Table 3 Summary of the results from subgroup analysis

Subgroup	WTP estimate	Lower 95% CI	Upper 95% CI	Study Numbers	p-value	I^2	
18-30 years old	0.298	0.250	0.346	7	0.015	99.7%	Subgroup of age (excluding outlier)
31-55 years old	0.346	0.067	0.625	61	0.000	99.4%	
56 and older	0.295	0.251	0.338	2			
< \$30,000	0.275	0.159	0.390	25	0.301	90.6%	Subgroup of annual income
\$30,001-60,000	0.255	0.168	0.341	18	0.000	99.2%	
> \$60,001	0.307	0.206	0.409	6	0.047	98.1%	
Year < 2008	0.216	0.137	0.296	13	0.000	99.2%	Subgroup of date of publication
> 2008	0.310	0.259	0.360	67	0.000	99.5%	
America	0.255	0.175	0.335	21	0.010	99.5%	Subgroup of region
Europe	0.319	0.256	0.382	34	0.000	99.3%	
Asia	0.318	0.206	0.431	21	0.020	99.7%	
Oceania	0.172	0.049	0.295	4	0.006	98.0%	
drinks	0.253	0.183	0.322	19	0.000	99.2%	
seafood	0.166	0.111	0.221	10	0.023	82.3%	
dairy	0.349	0.145	0.553	8	0.001	99.2%	
fruit & vegetable	0.388	0.266	0.511	20	0.062	99.6%	
meat	0.294	0.198	0.391	15	0.000	99.3%	
EF	0.213	0.165	0.261	25	0.030	98.9%	Subgroup of sustainable attributes
Local	0.211	0.122	0.300	11	0.000	98.2%	
Organic	0.381	0.282	0.480	29	0.028	99.6%	
Fair-trade	0.305	0.164	0.446	9	0.006	99.6%	
Animal welfare	0.295	0.252	0.339	6	0.104	98.9%	
CE	0.383	0.284	0.481	25	0.009	99.7%	Subgroup of methods types
CVM	0.279	0.207	0.351	27	0.000	99.5%	
non-hypothetical	0.267	0.165	0.370	9	0.001	94.9%	
others	0.213	0.147	0.280	19	0.000	98.9%	
Overall	0.295	0.251	0.338	80	0.000	99.5%	Overall estimate

242 Note: I^2 means the variation in ES (effect size) attributable to heterogeneity and all values are more than
 243 80.0%, indicating the existence of high heterogeneity. EF: environmentally friendly. There are 7
 244 subgroups, with age, annual income, date of publication, region, food categories, sustainable attributes

245 and methods types, excluded outlier because of the limitation of numbers included papers. The subgroup
 246 analysis is conducted in Stata.
 247

248

249

Fig. 5 Results of subgroup analysis

250 Note: The y-axis represents the size of WTP estimates and the x-axis shows each subgroup. The size of
 251 the circle means the WTP value of each variable. The figure was drawn using the Tableau software.

252

253

254

Fig. 6 WTP estimates of Regions

255 Note: Circle sizes demonstrate the overall combined WTP value of studies in each region. This map
 256 indicates that WTP estimates from highest to lowest are Europe (0.319), Asia (0.318), America (0.255)
 257 and Oceania (0.172). The figure was drawn using Tableau software.

258

259 As for the results of the subgroup for region, almost half of the research (42.5%) was conducted in
 260 Europe. While it should be noted that only 4 studies were from Oceania so the evidence was not
 261 conclusive. The results of the region subgroup (Table 3 and Fig. 6) demonstrated that the lowest WTP
 262 was in Oceania (0.172, 98.0%), followed by America (0.255, 99.5%) and Asia (0.318, 99.7%), and the
 263 largest in Europe (0.319, 99.3%). The Asian WTP estimate was very similar to Europe both higher than
 264 America. Additionally, a large heterogeneity existed among studies because I^2 were above 98% for all
 265 four regions.

266 With respect to food categories, the data of dairy was only obtained from 8 studies. Analysis
 267 showed that seafood with 16.6%, obtained the lowest WTP estimate and the highest one was for fruit &
 268 vegetable, with 38.8%. The WTP estimates of drinks, meat and dairy was 25.3%, 29.4% and 34.9%,
 269 respectively. I^2 value (82.3%) of seafood was the lowest, indicating that the heterogeneity was less
 270 compared with other food categories.

271 As for the result of sustainable attributes, the WTP estimates of EF (environmentally friendly)

272 attribute and local attribute were similar, with 21.3% and 21.1%, respectively. The highest one was for
273 organic attribute with 38.1%, followed by fair-trade and animal welfare attributes with 30.5% and 29.5%.

274 Regarding the subgroup analysis of method types, the result indicated that the WTP estimate of CE,
275 was the highest (0.383), followed by CVM (0.279). Non-hypothetical methods (e.g., non-hypothetical
276 choice experiment, auction experiment and real buying data) got 0.267. The category of Others has the
277 lowest estimate, with 0.213. I² of CE and CVM were more than 99.5%, indicating relatively high
278 heterogeneity in the data, while the heterogeneity of non-hypothetical methods and others were a little
279 lower (94.9% and 98.9%).

280 In addition, Table 3 showed that the overall effect size was 0.29 (95% CI 0.251, 0.338), which was
281 considered as a medium estimate in the sustainable food products. The overall I² statistics was 99.5%.
282 I² statistics indicated the percentage of variance due to heterogeneity (Dolgoplova & Teuber, 2018). If
283 this value is higher, it means heterogeneity is more significant. 99.5% demonstrated that significant
284 heterogeneity indeed existed within studies in this research. In general, the source of high heterogeneity
285 did not be found using subgroup analysis.

286 **3.4 Meta-regression results**

287 Meta-regression was conducted to further identify the source of heterogeneity. The results were
288 presented in Table 4. Results indicated the Coefficient (Coef.), standard error (Std. Err.), p-value and
289 Monte Carlo permutation adjusted p-value of included variables. The overall p-value equaled 0.042 <
290 0.05, which denoted significant differences at the significance level of 0.05. I² equaled 96.26% and it
291 measured residual variation due to heterogeneity, while 81.73% was the proportion of between-study
292 variance explained. Tau² equaled 0.008, demonstrating the regression model fitted well. Monte Carlo
293 permutations were also conducted to avoid Type I error and to get a more reliable assessment. The results
294 reported that all p-values increased compared with unadjusted p-values and it meant that Type I error
295 existed.

296 _____

Table 4 Results of the Meta-Regression (excluding outlier)

	Coef.	Std. Err.	P> t	Monte Carlo permutation test	
				Unadjusted p-value	Adjusted p-value
female	0.467**	0.226	0.044**	0.045	0.048**
university	-0.100	0.212	0.652	0.662	0.744
Year < 2008	-0.002	0.145	0.991	0.991	0.100
< \$30,000	-0.082	0.160	0.617	0.701	0.756
\$30,001-60,000	0.008	0.129	0.954	0.954	0.988

298 Notes: *** Significance level: 0.01; ** Significance level: 0.05; * Significance level: 0.1.

299 The joint test gives a p-value of 0.042 < 0.05, denoting there is a significant difference, which means
300 some evidence for an association of at least one of the covariates. I² equaled 96.26% and it measured
301 residual variation due to heterogeneity, while 81.73% was the proportion of between-study variance
302 explained. Tau² equaled 0.008, demonstrating the regression model fits well. The results of the meta-
303 regression indicated that the percentage of female, region, sustainable attributes and food categories
304 were the sources of high heterogeneity in this study and they significantly influenced variations in WTP
305 estimates across studies.

306 Female & university: the percentage of female and more than university education.

307 Year < 2008: it was coded as year 1 in this regression.

308 < \$30,000: it was coded as Income 1. \$30,001-60,000: it was coded as Income 2.

309 hypothetical: codes as Method 1.

310 dairy, drinks, fruit & vegetable, meat: coded as Food category 1, 2, 3 and 4, respectively.

311 America, Asia, Europe: coded as Region 1, 2 and 3 in the meta-regression.

312 EF means environmentally friendly, coupled with local, organic and animal welfare, coded as attribute
313 1, 2, 3 and 5.

315 The results of the meta-regression indicated that the percentage of female, region, sustainable
316 attributes and food categories were the sources of high heterogeneity and they significantly influenced
317 variations in WTP estimates across studies. However, we found non-significant differences among the
318 percentage of more than university education, income, date of publication and methods of studies. First,
319 the percentage of females ($p = 0.048 < 0.05$) highlighted a significant difference, showing that it was
320 the source of heterogeneity. Second, regarding food categories, the results demonstrated that for drinks
321 products ($\beta = -0.618$), WTP estimates were significantly lower than dairy and fruit & vegetable
322 products. This was in line with the result of the subgroup analysis above. Third, the p-values of America,
323 Asia and Europe were 0.038, 0.042 and 0.048, showing significant differences among studies and
324 confirming this subgroup as a source of heterogeneity. This result corroborated the findings of (Clark et
325 al., 2017), who found significant differences across regions, especially Europe, America and Asia.
326 Finally, the environmentally friendly attribute ($\beta = -0.314$) reported statistically significant lower WTP
327 values, which was also similar to the result of the subgroup analysis above. However, results indicated
328 non-significant differences among studies for local, organic and animal welfare attributes.

329

330 **4. Discussion and conclusion**

331 It is necessary to find systematic evidence on consumers' WTP for sustainable food products. For
332 this purpose, 80 publications are included and analyzed using meta-analysis. This study is focused on a
333 broad area of sustainable food products and attributes. It is, to our knowledge, the first meta-analysis
334 jointly assessing different sustainable attributes and the number of included papers is the largest in this
335 field. The meta-analysis focuses on the literature of consumer behavior with respect to average WTP
336 estimates towards sustainable food products and it attempts to fill the gaps in meta-analysis for
337 consumers' WTP for sustainable food products. Although high heterogeneity exists, this research
338 summarizes the efforts performed so far and provides some stylized facts that may be employed to
339 determine the directions for future analysis (Dolgopolova & Teuber, 2018).

340 Firstly, our results show that the WTP value of the studies adopting hypothetical approaches (CE
341 and CVM) is higher than non-hypothetical methods. This was consistent with the conclusion of
342 Dolgopolova and Teuber (2018), who suggested that hypothetical elicitation methods resulted in higher
343 WTP than non-hypothetical approaches. This result also coincided with the research of Martínez-

344 Carrasco et al. (2015), who found CVM yielded higher values for WTP than the auction because of the
345 hypothetical bias. This is because hypothetical bias leads to overestimation of values. The hypothetical
346 bias was discussed and studied by many researchers in the social and economics.

347 Secondly, the subgroup analysis showed that the younger generation had a higher WTP value, while
348 the 56 and older had the lowest WTP. It was consistent with some studies, which indicated that organic
349 consumers were likely to be younger (Krystallis et al., 2006; Van Loo et al., 2013), and also in line with
350 Carley and Yahng (2018), who found that younger were willing to pay more for sustainable beer.
351 However, it was opposite to the study of Bellows et al. (2008), indicating that older people tended to
352 buy organic food regularly. This divergence could be related to the fact of considering organic products
353 as an environmentally friendly alternative or as a healthy one.

354 Interestingly, Asian WTP estimates, in percentage terms, are higher than those obtained in America
355 and similar to those from Europe, which was different from our expectation. A possible explanation for
356 it might be that sustainable labeling in products is an incomplete marketing tool for products perceived
357 as low quality in America, so there is a need to improve quality perceptions and knowledge for
358 sustainable labels to obtain a premium in differentiated food markets (Loureiro, 2003). Furthermore,
359 this outcome is also related to the fact that the price of American products is more expensive than Asian
360 countries. As for Asia, evidence can be found in the study of Wang and Huo (2016), who indicate food
361 safety certification has increasingly received much attention by Chinese consumers since the melamine
362 milk crisis in 2008. As a result, Chinese consumers had a higher WTP for ensuring food safety compared
363 with any of the other attributes resulting from Chinese poor food safety record, coupled with a low level
364 of trust in government safety certification schemes (Liu et al. 2010; Tait et al. 2016). Another study also
365 suggests that Asian consumers are concerned about food safety and are willing to pay more to assure
366 that their daily food is safe. Accordingly, they are willing to pay a higher premium for environmentally
367 certified products that had reduced levels of pesticides (Aye et al., 2019). In addition, European WTP is
368 similar to the studies conducted in Asia, which is in line with the study of Tait, Saunders, and Guenther
369 (2015), who suggest preferences are very similar towards sustainable food for both UK and Japanese
370 consumers. A similar result is also found in Tait et al. (2016) which indicates that the WTP value of
371 Chinese consumers (7%) for water minimization sustainable food is similar to the UK (6%). The
372 findings of this research can be used as a guide by food producers, marketers and policymakers when
373 making decisions related to the sustainability of food products. Regarding the region, Europe and Asia

374 have high WTP estimates, followed by America and Oceania, suggesting that sustainable food marketing
375 departments could put more sustainable products in Europe and Asia.

376 The subgroup analysis also indicates that fruit & vegetables has the highest WTP estimate while the
377 seafood has the lowest one. The low WTP estimate of seafood (e.g., salmon) could be related to its price,
378 which was more expensive than fruit & vegetable. It also could be related to the presence of many
379 substitutes, which led to a lower price premium for these products particularly consumers who were
380 sensitive to price. As far as it concerns the high WTP value of fruit & vegetable, the main factors for
381 high WTP mostly relied on a perceived increase in food safety and quality, especially for fresh and
382 perishable products (Marchesini et al., 2007). Moreover, Moser, Raffaelli, and Thilmany-McFadden
383 (2011) indicated that consumers perceived sustainable fruit & vegetable as being natural, with higher
384 vitamin and nutrient content, and containing fewer or no pesticides and additives compared to
385 conventional fruit & vegetable. Therefore, they were willing to pay more for fruit & vegetable. The high
386 WTP estimate for fruit & vegetables means the sellers could focus on this food category and advertise
387 more to attract consumers. Also, they could put fruit & vegetables in a conspicuous place in the
388 supermarket or shop. Seafood has the lowest WTP value. For the fishermen, transportation personnel
389 and sales departments engaged in the seafood industry, the price of seafood could be appropriately
390 reduced, so as to encourage consumers to consume seafood and improve their WTP for seafood.

391 In addition, organic food has the highest WTP estimate. It was in line with the study of Zander and
392 Feucht (2018), who concluded that consumers' WTP for organic production (14.8%) was higher than
393 animal welfare (14.0%) and local products (12.6%). Van Loo et al. (2015) also found that WTP of
394 organic food (27.0%) was the highest, followed by Rainforest Alliance (19.5%) and fair-trade products
395 (15.8%). The high WTP value for organic food indicates a clear market consumption potential, which
396 inspires food producers to produce more organic food and marketing strategies should be targeted
397 towards increasing consumption for organic food. For retailers, they could put organic food especially
398 organic fruit & vegetables in the obvious placement (e.g., at the entrance of the supermarket or shops)
399 to sell more organic food and maximize profits. Conversely, they can put local seafood in the far corner
400 of the supermarket. Also, retailers could promote seafood especially local seafood based on ensuring
401 profits to attract more consumers. Van Loo et al. (2011) pointed that a product label is a quality signal
402 for the consumer. Thus, organic labels should be emphasized on the package to attract consumers who
403 care about labels. Also, policymakers could give more subsidies and incentives to organic food

404 producers, which can attract more ordinary food producers to change from conventional agricultural
405 production mode to organic agriculture. The result shows that the WTP estimate for local food is the
406 smallest. As a result, it is necessary to increase consumers' knowledge about local food products and
407 consider how to differentiate them in the market.

408 The results of this meta-regression suggest that female, region, sustainable attributes and variety of
409 studying products influence average WTP estimates and represent major sources of WTP heterogeneity.
410 The overall WTP is 29.5% for sustainable food products, which is consistent with the study of Vecchio
411 and Annunziata (2013), who indicate that consumers' WTP is between 23% and 57%. It is also in line
412 with Yi (2019), who concludes that consumers' average WTP towards sustainable products is 29%.
413 Nevertheless, our result shows significantly lower values than those obtained in Y. C. Yang (2018) in
414 Taiwan, with 254.0% and Skreli et al. (2017), who suggests that the widespread positive preferences is
415 85% of Albanian consumers for sustainable products. The existence of differences may be explained by
416 the fact that Taiwan and Albanian consumers are mainly concerned about food safety and sustainable
417 food can reduce their health risks, so they are willing to pay high premiums to tackle safety and health
418 issues. In all cases, the results of this study show that overall WTP estimates may vary according to
419 specific countries.

420 Additionally, the WTP estimates from our meta-analysis also suggest that positive WTP estimates
421 are shown independent of the food categories, region or methods. This outcome denotes the presence of
422 great market potential for sustainable products worldwide, which can provide a reference for relevant
423 stakeholders to better understand market trends and the government to give more support to sustainable
424 policies.

425 Finally, there are some limitations in this research. While it is relevant to measure consumers'
426 average WTP for sustainable food products, this study mostly focuses on the European countries because
427 many of the previous studies are conducted in Europe. The numbers of research from other regions are
428 not enough to draw a clear differentiation according to region, especially Oceania. In addition, the results
429 explain some of the heterogeneity and maybe there are other factors influencing heterogeneity that have
430 not been considered, measured or studied. Although heterogeneity exists in some data, meta-analysis is
431 still useful for analyzing the data, which provides a more transparent assessment of the consistency of
432 the effect compared to a simple summary of the literature (Clark et al., 2017). In order to improve
433 policies for sustainable food products and obtained more evidence, the research scope and quantity of

434 studies need to be expanded. With the emergence of related papers in the future, more comprehensive
435 and representative papers will be collected for further research and will be better analyzed the WTP
436 heterogeneity.
