Abstract: The aim of this study was to evaluate the occurrence, infection level and distribution of ascaridoid larvae in cephalopod products sold in Italy. Data on the species most commonly commercialized as whole and fresh on the Italian market were collected. After comparing commercial and literature data, *Eledone* spp., comprising *E. cirrhosa* and *E. moschata* (horned octopus and musky octopus, respectively) and *Doryteuthis pealeii* (Longfin inshore squid) were selected, also considering that they had been rarely investigated. Overall, 75 *Eledone* spp. caught in the Mediterranean Sea (FAO area 37) and 70 *D. pealeii* from the Northwest Atlantic Ocean (FAO area 21) were examined by visual inspection and artificial digestion (viscera and mantle separately). Parasites were submitted to morphological and molecular analysis. Prevalence (P), mean intensity (MI) and mean abundance (MA) were calculated. In *Eledone* spp. 9 nematodes morphologically resembling *Lappetascaris* spp. were found in the mantle of 5 specimens (P: 6.7%; MI: 1.8; MA: 0.12). However, the molecular identification did not allow to confirm this identification due to lack of reference sequences. In *D. pealeii*, 2 nematodes molecularly identified as *Anisakis simplex* s.s. were found in the viscera and in the mantle (P: 2.8%; MI: 1; MA: 0.028) of two specimens. All the larvae were detected after artificial digestion. This is the first report of *A. simplex* s.s. in *D. pealeii*. Despite the low prevalence, the potential public health risk should not be disregarded, considering the zoonotic potential of *A. simplex* s. s. larvae and their localization in the edible part (mantle). The presence of larvae resembling *Lappetascaris* spp., although not considered to represent a public health hazard, paves the way for further studies to investigate the phylogenetic relationship within the family Raphidascarididae. Considering also the increasing economic value of cephalopods, both Food Business Operators and control authorities must put in place procedures to prevent the commercialization of products at risk due to the presence of larval ascaridoid nematodes.

Data will be made available on request

Pisa, 27<sup>th</sup> November 2019

Dear Editor,

please find enclosed the manuscript entitled **“Larval ascaridoid nematodes in horned and musky octopus (*Eledone cirrhosa* and *E. moschata*) and longfin inshore squid (*Doryteuthis pealeii*): safety and quality implications for cephalopod products sold as fresh on the Italian market”** to be considered for publication in the International Journal of Food Microbiology.

The commercial importance of cephalopods has risen significantly in the last decades, following an increased request from the market due to an excellent palatability, a high nutritional value and the continuously growing popularity of Japanese sushi and sashimi that may also include raw octopus, squid or cuttlefish. The global production largely depends on Asian, North African, North and South American countries. In addition, they are highly traded and appreciated in southern Europe, such as in Spain and Italy.

Among the most important biohazards related to the consumption of cephalopods is the presence of viable zoonotic nematode larvae belonging to the *Anisakis* genus. Although the parasitological risk associated to the presence of such larvae can be prevented applying a freezing treatment, the presence of dead visible parasites represents a defect that alters the overall quality, causes consumers' rejection and damage of the reputation of the brand. In addition, the allergenic potential of dead larvae is still debated.

Considering the rising market request and value of cephalopods and the scarcity of data on the presence of parasitic nematodes in products commercialized in Italy, the aim of this study was to evaluate the occurrence, infection intensity and distribution of parasitic nematodes in edible and non-edible parts of cephalopod species selected among those most commercialized as fresh and whole on the Italian market.

Firstly, the cephalopods species most commonly sold as fresh whole were identified by a market survey. At the same time, a revision of the existing literature on nematodes in cephalopods was performed, to select the less investigated host species. After the comparison of commercial and literature data, the Mediterranean horned and musky octopus (*Eledone cirrhosa* and *E. moschata*, respectively) and the longfin inshore squid (*Doryteuthis pealeii*), imported from the North-west Atlantic, were selected as target species for the present study, as they had been rarely investigated. Overall, 75 *Eledone* spp. caught in the Mediterranean Sea (FAO area 37) and 70 *D. pealeii* from the Northwest Atlantic Ocean (FAO area 21) were examined by visual inspection and artificial digestion (viscera and mantle separately). Parasites were submitted to morphological and molecular

analysis. Prevalence (P), mean intensity (MI) and mean abundance (MA) were calculated. In two specimens of *D. pealeii*, 2 nematodes molecularly identified as *Anisakis simplex* s.s. were found in the viscera and in the mantle (P: 2.8%; MI: 1; MA: 0.028), respectively. In the mantle of 5 specimens of *Eledone* spp. 9 nematodes morphologically resembling *Lappetascaris* spp. were found (P: 6.7%; MI: 1.8; MA: 0.12). Unfortunately, the molecular identification did not confirm this identification, due to the lack of reference sequences. Interestingly, all the larvae were detected after artificial digestion.

The present study represents, to the best of our knowledge, the first report of *A. simplex* s.s. in *D. pealeii* and also the first study investigating parasitic nematodes in this Atlantic species of relevant commercial interest in Italy. Despite the low prevalence of *A. simplex* s.s., the aroused public health risk should not be disregarded, considering its zoonotic potential and the fact that one larva was found in the edible part (mantle). As regards the larvae resembling *Lappetascaris* spp. found in *Eledone* spp., which had already been described in cephalopods from the Mediterranean Sea, they are not considered to represent a public health hazard, but their presence calls for further studies to better investigate the phylogenetic relationship within the family Raphidascarididae.

Overall, the present study provides data on the distribution of ascaridoid larvae in cephalopod products sold on the market that may be of interest for both the seafood industry and the health authorities. In fact, considering also the increasing economic value of cephalopods, the results of the present study suggest that both Food Business Operators and control authorities must put in place procedures to prevent the commercialization of products at risk due to the presence of larval ascaridoid nematodes.

The manuscript has not been published elsewhere nor is it being considered for publication elsewhere. All authors have approved this manuscript, agree to the order in which their names are listed, declare that no conflict of interests exists and disclose any commercial affiliation.

Yours sincerely,  
Andrea Armani and co-authors

- *Doryteuthis pealeii* and *Eledone* spp. were selected as they are sold whole fresh in Italy
- All the specimens were analysed by visual inspection and by digestion
- Two *Anisakis simplex* larvae were found in the 70 *Doryteuthis pealeii* examined
- Nine larvae resembling *Lappetascaris* spp. were isolated from the 75 *Eledone* spp.
- The finding of *A. simplex* in *Doryteuthis pealeii* represents a new host record

## 53 **1.Introduction**

54 Cephalopods are characterized by a rapid growth, short lifespan and strong life-history  
55 plasticity; thus, they are quickly adaptable to changing environmental conditions. A global  
56 increase of their populations has been observed over the last sixty years: the factors influencing  
57 such phenomenon are likely to be complex, but ocean warming and the decrease of fish  
58 competitors and predators due to intensive fishery practices are believed to have played a role  
59 (Doubleday et al., 2016).

60 The commercial importance of cephalopods has risen significantly in the last decades  
61 (Hunsicker et al. 2010), thanks to an increased request from the market due to an excellent  
62 palatability and an high nutritional value. In fact, their high-protein content, the abundance of  
63 essential amino acids, and the low-fat content make cephalopods an ideal component of healthy  
64 and balanced diets (Vieites et al., 2019).

65 According to recent data from the Food and Agriculture Organization of the United Nations  
66 (FAO), cephalopods constituted 6.4% (live weight) of the total world trade of fish and fish  
67 products in 2016 (FAO, 2018). The world cephalopod production has shown a relatively stable  
68 growth since 1950, reaching a peak in 2014, then dropping in 2016 (Peng & Mu, 2019). Also in  
69 2018 octopus and squid catches have been poor (FAO, 2019a). However, the global demand is  
70 high and this production decrease is causing a strong rise in trading prices (FAO, 2018; FAO,  
71 2019a).

72 The species of main economic interest belong to two distinct superorders (Decapodiformes  
73 and Octopodiformes) and, for commercial and catch statistics purposes, they are grouped in three  
74 macro categories: squids (shortfin; longfin and bobtail squids), cuttlefish and octopus (Arkhipkin  
75 et al., 2015; FAO, 2018). Squids' category was the most represented on the global market (total  
76 production of 3385003 tons) in 2015, followed by octopus (400404 tons) and cuttlefish (331824  
77 tons) (<http://www.fao.org/fishery/topic/16140/en>). Similar proportions were reported in 2017  
78 (FAO, 2019a).

79 The global production of cephalopods largely depends on Asian (China, Vietnam, Thailand,  
80 Indonesia, India), North African (Morocco, Mauritania), North American (California) and South  
81 American (Argentina, Mexico and Peru) countries (FAO, 2016). Although traditionally they  
82 have represented a minor catch in European waters, they are particularly important in southern  
83 countries (Lougovois et al., 2008), being an important element of the Mediterranean diet (Picó-  
84 Durán et al., 2016). In particular, Spain and Italy are the most important consumer markets  
85 (FAO, 2018): squid flows from the first to the latter country were among the top 15 of the total  
86 intra-EU exchanges in terms of value and showed an upward trend since 2014 (EUMOFA,  
87 2017). In addition, the recent growing worldwide popularity of Japanese sushi and sashimi, as  
88 well as Spanish tapas, has helped to further boost demand for cephalopods (FAO, 2018). In a  
89 recent survey conducted in Italy it was found that common octopus (*Octopus vulgaris*), squid  
90 (*Loligo vulgaris*) and cuttlefish (*Sepia officinalis*) are currently used for the preparation of such  
91 Japanese recipes (Armani et al., 2017).

92 Interest in the parasite communities associated with cephalopods is growing (Guillén-  
93 Hernández et al., 2018), and several studies investigating biological/ecological aspects and  
94 public health issues are available (Table 1). In fact, it is well documented that cephalopods act as  
95 intermediate, paratenic, or definitive hosts with a variable role that depends on the type of  
96 parasite and the specific life cycle (Guillén-Hernández et al., 2018). Nematodes from the  
97 superfamily Ascaridoidea belonging to the families Anisakidae and Raphidascarididae  
98 (according to the classification of Fagerholm, 1991) are common parasites in the marine  
99 environment (Picó-Durán et al., 2016). Larval ascaridoid nematodes may be found in  
100 cephalopods' viscera and mantle (Roumbedakis et al., 2018) and they are commonly generically  
101 referred to as anisakids (Picó-Durán et al., 2016). The most relevant anisakids from a public  
102 health point of view belong to the genera *Anisakis* and *Pseudoterranova* (family Anisakidae)  
103 (EFSA, 2010). In particular, *Anisakis* sp. is the most studied in cephalopods (Roumbedakis et al.,  
104 2018). The life cycle of this genus is indirect, with crustaceans acting as first intermediate hosts,

105 fishes and squids as intermediate and/or paratenic hosts and marine mammals as definitive hosts.  
106 Fish and cephalopods generally host the third larval stage (L3) of *Anisakis* spp. encysted on the  
107 visceral organs, although L3 migration into the muscle or mantle is possible. If live larvae are  
108 accidentally ingested when eating raw, marinated or undercooked seafood infected by L3, human  
109 infection can occur (Mattiucci et al., 2018). Other ascaridoid larvae have been described in  
110 cephalopods, such as *Contracaecum* spp. (family Anisakidae), as well as the genera  
111 *Hysterothylacium* and *Lappetascaris* (family Raphidascarididae) (Table 1). While zoonotic  
112 infections by *Contracaecum* spp. are uncommonly described (Nagasawa, 2012),  
113 *Hysterothylacium* spp. is generally believed to be not zoonotic (Cipriani et al., 2019). To the best  
114 of our knowledge, no human cases due to *Lappetascaris* spp. have been reported.

115 To manage the parasitological risk, Food Business Operators (FBOs) must submit fishery  
116 products to a visual examination for the detection of visible parasites before commercialization  
117 (Commission Regulation (EC) No. 2074/2005; Regulation (EC) No. 853/2004). However, the  
118 checks performed by FBOs does not ensure that the product is completely free from risks  
119 (D'Amico et al., 2014); thus, products intended for raw consumption must undergo a preventive  
120 freezing treatment (Commission Regulation (EC) No. 2074/2005; Regulation (EC) No.  
121 853/2004). Moreover, the allergenic potential of dead larvae is still debated (Audicana &  
122 Kennedy, 2008; Dashner et al., 2012; EFSA, 2010).

123 In addition, beside public health issues, the presence of parasitic nematodes may also  
124 negatively impact the seafood quality, causing economic losses (Bao et al., 2018). In fact, fishery  
125 products containing live or dead visible larvae are unattractive for consumers and unsuitable as  
126 food (Regulation (EC) No178/2002).

127 Considering that data on the distribution of ascaridoid larvae in cephalopod products sold on  
128 the market are of interest for both the seafood industry and the health authorities, the aim of the  
129 present study was to evaluate the occurrence, infection intensity and distribution of parasitic

130 nematodes in edible and non-edible parts of cephalopod species selected among those most  
131 commercialized as fresh and whole in Italy.

## 132 **2. Materials and methods**

### 133 ***2.1 Species selection: market and literature analysis***

134 The cephalopods species most commonly sold as fresh whole on the Italian market were  
135 identified by contacting national large-scale retailers and import companies, the Border  
136 Inspection Point (BIP) of Malpensa (Milan) and the Wholesale fish market of Milan. At the same  
137 time, a revision of the existing literature on nematodes in cephalopods was performed, to assess  
138 available epidemiological data and select the less investigated species (Table 1). After the  
139 comparison of commercial and literature data, the horned and musky octopus (*Eledone cirrhosa*  
140 and *E. moschata*, respectively) and the longfin inshore squid (*Doryteuthis pealeii*) were selected  
141 as target species for the present study.

### 142 ***2.2 Sampling***

143 The cephalopod specimens were collected as whole fresh at the Wholesale fish market of  
144 Milan and at the distribution platforms of two national leading brands in the organized  
145 distribution. Totally, 145 specimens were collected in June 2019, including 70 *D. pealeii* from  
146 the Northwest Atlantic (FAO area 21) and 75 *Eledone* spp. (36 *E. cirrhosa* and 39 *E. moschata*)  
147 caught in the Mediterranean Sea (FAO area 37.1 and 37.2). The samples collected at the  
148 Wholesale fish market of Milan were immediately submitted to visual inspection (see section  
149 2.3.1), then frozen and transferred to the FishLab for further analysis (see section 2.3.2).  
150 Specimens collected at the platforms were instead directly transferred to the FishLab, where they  
151 were visually examined as fresh and then frozen (see section 2.3). Each specimen was measured  
152 registering the total length (TL) and the dorsal mantle length (DML), which was measured from  
153 the tip of the mantle to the midpoint between the eyes, and weighted (total weight, viscera  
154 weight, mantle weight).

### 155 ***2.3 Parasites detection***

156        *2.3.1 Visual inspection.* A visual inspection under natural light was conducted on both viscera  
157 and mantle of fresh specimens to detect visible parasites (non-encapsulated nematodes longer  
158 than 1 cm or parasites with a capsular diameter of at least 3 mm according to the definition given  
159 by the Codex Alimentarius Commission, 1971) according to the Commission Regulation (CE) n.  
160 2074/2005. In detail, once separated, the viscera and the body (mantle and arms) were both  
161 placed in a Petri dish and left at room temperature for 15 minutes to allow the mobilization of the  
162 larvae. In a second moment, after freezing and defrosting, viscera were also checked under a 365  
163 nm UV-light source (Gómez-Morales et al., 2018; Karl and Leinemann, 1993).

164        *2.3.2 Artificial digestion.* Viscera and mantle of each specimen were separately submitted to  
165 artificial digestion using Trichineasy (CTSV srl, Brescia) slightly modifying the protocol  
166 described in Guardone et al., (2017), which was based on the Commission Regulation (EC) No  
167 2075/2005. Residues from the sieve were transferred to Petri dishes and examined under natural  
168 and UV (365 nm) light.

## 169        ***2.4 Parasites identification***

170        *2.4.1 Morphological identification.* The parasitic nematodes were counted, washed and  
171 maintained in 0.9% NaCl solution for morphological identification. Parasites were observed  
172 under a light microscope at 200×magnifications for identification at the genus and/or species  
173 level on the basis of the following morphological characteristics: the size, the position of the  
174 excretory pore, the shape of the tail, the shape of the cephalic end, the length and shape of the  
175 ventricle, the presence and position of the mucron (Berland, 1961; Fagerholm, 1991; Nagasawa  
176 and Moravec, 1995; 2002). After microscopic observations, larvae were preserved in 70%  
177 ethanol and stored at -20 °C until further analysis.

178        *2.4.2 Molecular identification.* All the collected larvae were submitted to molecular  
179 identification. Total DNA extraction was performed according to the protocol used in Guardone  
180 et al. (2016). DNA concentration and purity were determined by a NanoDrop ND-1000  
181 spectrophotometer (NanoDrop Technologies, Wilmington, DE, USA). A 629-bp fragment of the

182 mitochondrial cytochrome *c* oxidase subunit II (*cox2*) gene was selected as molecular target and  
183 amplified using the primers 211F and 210R (Cipriani et al., 2019). In addition, a fragment of  
184 about 900-bp of the ITS-1 region, the 5.8S gene and the ITS-2 region plus approximately 70  
185 nucleotides of the 28S gene (further as ITS), was amplified according to Zhu et al., (1998). PCR  
186 products were analysed by electrophoresis in 2% agarose gel and those presenting the expected  
187 length were sent for standard forward and reverse Sanger sequencing to an external company.  
188 The obtained sequences were analyzed, edited and assembled with the Geneious R7 software  
189 (Kearse et al., 2012) and compared with sequences deposited in GenBank.

## 190 ***2.5 Statistical analysis***

191 The prevalence (P), mean abundance (MA) and mean intensity (MI) for the investigated  
192 species were calculated (separately for viscera and mantle). To assess the relationship between  
193 the weight and the length of the cephalopod specimens and the parasite number, the Pearson's  
194 correlation coefficient was calculated.

## 195 **3. Results and discussion**

### 196 ***3.1 Species selected after market and literature analysis***

197 According to our analysis, the species most commonly commercialized as whole and fresh on  
198 the Italian market are: *Octopus vulgaris*, *Sepia officinalis*, *Illex coindetii*, *Todarodes sagittatus*,  
199 *Loligo vulgaris*, *E. cirrhosa* and *E. moschata*, commonly sold as *Eledone* spp. and often  
200 appearing mixed on the market  
201 (<https://www.faoadriamed.org/html/Species/EledoneCirrhosa.html>), and *Doryteuthis pealeii*.  
202 While for *S. officinalis*, *I. coindetii*, *T. sagittatus* and *L. vulgaris* data on anisakids occurrence are  
203 available, very few data exist for *O. vulgaris*, *Eledone* spp. and *D. pealeii*. In particular, to the  
204 best of our knowledge, only four studies on parasitic nematodes targeting *Eledone* spp. are  
205 available, while no studies targeting *D. pealeii* have been conducted (Table 1). Therefore, these  
206 species were selected, in order to investigate a product locally fished (*Eledone* spp.) and one

207 imported (*D. pealeii*) belonging to two different superorders (Octopodiformes and  
208 Decapodiformes, respectively).

209 3.1.1. *Eledone* spp. *E. cirrhosa* (superorder Octopodiformes, order Octopoda, family  
210 Eledonidae), also known as ‘curled’, ‘horned’ or ‘lesser’ octopus, is distributed partly in the  
211 North East Atlantic and mainly in the Western part of the Mediterranean Sea (Sealifebase,  
212 2016a), where it is one the most commonly fished benthic cephalopod species. It has a  
213 commercial relevance primarily in the central and southern Adriatic  
214 (<https://www.faoadriamed.org/html/Species/EledoneCirrhosa.html>), as well as in France and in  
215 Tunisia (Souidenne et al., 2016). In Italy, sales of *E. cirrhosa* represent 17% of the total sale  
216 volume of Octopodidae (EUMOFA, 2018) and in the Ligurian Sea and the central Tyrrhenian  
217 Sea it contributes to 50% of total seafood landings (Libralato et al., 2018).

218 *E. moschata* has a smaller geographical range. Although, differently from *E. cirrhosa*, it  
219 extends to the whole Mediterranean Sea (Sealifebase, 2016b), its distribution in the Atlantic is  
220 limited to the southern coasts of Portugal, the west coast of Gibraltar and the Gulf of Cadiz  
221 (<https://www.faoadriamed.org/html/Species/EledoneMoschata.html>). It is a typical commercial  
222 species for the Mediterranean demersal fishery (Belcari and Sbrana, 1999), being particularly  
223 important in the Northern and Central Adriatic (Libralato et al., 2018). In Italy, sales of *E.*  
224 *moschata* represent 15% of the total volume of sale of Octopodidae products (EUMOFA, 2018).

225 3.1.2 *Doryteuthis pealeii*. *D. pealeii* (superorder Decapodiformes, order Teuthida, family  
226 Loliginidae, former name *Loligo pealeii*), commonly known as longfin inshore squid, is mainly  
227 distributed in the North West and Central West Atlantic Ocean, as well as, to a less extent, in the  
228 Western Central Pacific (Sealifebase, 2016c). In fact, it inhabits the continental shelf and upper  
229 slope waters between southern Newfoundland and the Gulf of Venezuela, including the Gulf of  
230 Mexico and the Caribbean Sea. *D. pealeii* is a high valued species that, together with *Illex*  
231 *illecebrosus* (Northern shortfin squid), has been commercially exploited since the late 1800s.  
232 Fishing activities increased rapidly until the 1970s when trawlers from Japan, former USSR and

233 Western Europe, including Italy, targeted both species. This widespread presence of an  
234 international fishing fleets urged the USA to manage the fishery from 1977, imposing catch and  
235 bycatch allocations, gear limitations, and time-area restrictions (Arkhipink et al., 2015).  
236 Currently, most of the landings are sold domestically for food and the rest is exported.  
237 Interestingly, even though this species is available as fresh on the Italian market only for a short  
238 period of time, usually between May and June (authors' personal communication), foreign trade  
239 statistics for the New England and the Mid-Atlantic Customs Districts combined indicate that in  
240 the period 1991-2012 Italy was the first importer of *D. pealeii* products, accounting for 29% of  
241 the exports, followed by China (19%), Spain (16%). Greece (6%), and Japan (4%) (Arkhipink et  
242 al., 2015).

### 243 **3.2 Parasites detection and identification**

244 A variety of methods, including classical ones such as visual inspection, slicing, candling,  
245 UV-press and chloro-peptic digestion, as well as more innovative imaging technologies (X-rays,  
246 electromagnetism, spectroscopy and Magnetic Resonance Imaging) and, recently, biomolecular  
247 analysis, have been used to recover larvae from fishery products (Bao et al., 2017). However,  
248 nowadays only visual inspection under natural light is included in EU food hygiene and safety  
249 regulations (Commission Regulation (EC) No 2074/2005) while different analytical protocols  
250 are used by the international scientific community (Table 1).

251 Even though chloro-peptic digestion and UV press methods are considered the most sensitive  
252 ones in fish species (Gómez-Morales et al., 2018; Llarena-Reino et al., 2013; parasite-  
253 project.eu), such techniques have not been commonly applied in cephalopods examination. In  
254 fact, only 3 (11%) and 1 (4%) out of the 27 revised studies explicitly mentioned to have used the  
255 digestion or the UV method, respectively (Table 1). On the contrary, the visual inspection under  
256 natural light (9 studies, 33%), frequently coupled with dissection under a stereomicroscope (12  
257 studies, 44%), was more commonly used. No detailed description of the used methods was  
258 instead provided in 2 studies (7%) that generally referred to “standard procedures”.

259 In the present study the viscera and the mantle of all the 145 collected specimens (70 *D.*  
260 *pealeii* and 75 *Eledone* spp.) were visually examined (under natural and UV light) and digested.  
261 Overall 11 nematode larvae were found: 9 larvae in *Eledone* spp. and 2 larvae in *D. pealeii*  
262 (Table 2). Interestingly, all the larvae were detected after artificial digestion. In addition, 18  
263 cestode plerocercoid larvae were found in *D. pealeii* during visual inspection (see section 3.2.2).

264 3.2.1. *Eledone* spp. During the visual inspection of the 75 specimens of *Eledone* spp. (mean  
265 weight 198.8 g, mean total length 35.8 cm, mean DML 8.3 cm) no nematode larvae were found  
266 (Table 2). The artificial digestion of the viscera was also negative for all the specimens. On the  
267 contrary, 9 nematodes (P: 6.7%, MA: 0.12, MI: 1.8) were found in the mantle of 5 specimens (3  
268 *E. cirrhosa* and 2 *E. moschata*) after digestion. Details of the measured parameters and  
269 parasitological results are reported in Table 3.

270 The body of the collected larvae was elongated, white and measured between 15 and 28 mm.  
271 Microscopic observations, especially of the shape of the cephalic and caudal end, allowed to  
272 observe features different from *Anisakis* spp. In particular, the 9 larvae presented an asymmetric,  
273 obliquely truncated cephalic end and a recurved conical tail with a slightly inflated extremity and  
274 a small spike (Fig. 1). In addition, a very elongated ventricular appendix was visible along the  
275 most part (70-80%) of the body. The morphological features of the larvae found in this study  
276 corresponded to those described by Nagasawa and Moravec (1995) as third-stage larvae of  
277 *Lappetascaris* spp. in *Todarodes pacificus* from the Sea of Japan. The same kind of larvae were  
278 then described as *Lappetascaris* sp. Type A by Nagasawa and Moravec (2002) in the mantle of  
279 four species of squids (*Thysanoteuthis rhombus*, *Ommastrephes bartramii*, *Onychoteuthis*  
280 *boreali-japonica*, and *Gonatopsis borealis*) in Central and Western Pacific Ocean. To the best of  
281 our knowledge, the same type of larvae had been only described once in the Mediterranean Sea,  
282 by Culurgioni et al., (2010) in *Histioteuthis bonnelli* and *H. reversa* caught in the Sardinian  
283 Channel (Western Mediterranean Sea), with prevalence values (4.26% and 1.22%, in *H. bonnelli*  
284 and *H. reversa*, respectively) comparable to the prevalence found in the present study in *Eledone*

285 spp. The molecular analysis of the larvae found in *Eledone* spp. in the present study could only  
286 be based on ITS sequences, as no amplifications were obtained using the primer pair commonly  
287 applied for targeting the mtDNA *cox2* of *Anisakis* spp. (see section 2.4.1). However, the  
288 comparison of the obtained ITS sequences with the sequences in GenBank database did not  
289 allow a specific identification. In fact, the highest identity values (92.92-93.36%) were obtained  
290 with sequences belonging to *Hysterothylacium deardorffoverstreetorum*. Similarly, also in the  
291 study of Setyobudi et al., (2013), the *cox2* sequence of an unknown nematode found in common  
292 squids from the East Sea, showed 83.0-84.0% similarity with *H. deardorffoverstreetorum*.  
293 Interestingly, the RFLP patterns obtained by Setyobudi et al., (2013) for this nematode did not  
294 correspond to any known anisakid. The authors hypothesized that the unknown species could be  
295 *Lappetascaris* sp., also considering that parasites of that genus had been morphologically  
296 identified by Takahara & Sakurai, (2010) from common squids in geographically adjacent  
297 Japanese waters (Table 1). Unfortunately, a morphological examination of the nematode found  
298 in the study of Setyobudi et al., (2013) was not conducted, as the samples had been directly  
299 transferred to molecular analysis. In addition, several confirmed or potential reports from the  
300 Pacific Ocean are cited in Nagasawa and Moravec (1995; 2002). In particular, according to  
301 Nagasawa and Moravec (1995), many previous records of anisakid larvae from the mantle of  
302 squids in the western North Pacific Ocean reported as *Contraecaecum*, *Thynnascaris* or  
303 *Hysterothylacium* were, in fact, identical to *Lappetascaris* sp. (Nagasawa and Moravec, 2002). In  
304 the light of such not fully clear picture, a focused molecular investigation would be needed to  
305 better clarify the phylogenetic relationship of *Lappetascaris* type larvae with other genus of the  
306 family Raphidascarididae, in particular with the genus *Hysterothylacium*, which is known to be a  
307 very abundant and diverse group of marine ascaridoids (Ghadam et al., 2018). In addition,  
308 *Hysterothylacium* larvae are generally believed to not migrate into the fish flesh (Cipriani et al.,  
309 2019), but Picó-Durán et al. (2016) reported the presence of *Hysterothylacium* sp. larvae in the

310 mantle of *I. coindettii*. Further investigations could thus also help in defining preferred  
311 localization of Raphidascarididae.

312 In the few other available studies on nematodes in *Eledone* spp., no parasites were found by  
313 Goffredo et al. (2019) in 5 specimens of *E. moschata* from the South Adriatic and Ionian Sea  
314 examined by visual inspection of the celomic cavity and candling technique under  
315 stereomicroscope. Also, a single *E. cirrhosa* from Sardinia examined by visual inspection and  
316 digestion (of the body cavity and viscera) was negative (Angelucci et al., 2011). In two older  
317 studies a low prevalence (1.5% out of 67 specimens) of *Anisakis simplex* s.l. was found along the  
318 Spanish coasts of Galicia (Atlantic Ocean) with visual and stereomicroscopic examination  
319 (Abollo et al., 1998), and a prevalence of 28% of *Hysterothylacium* spp. was found in 25  
320 specimens from the northern Tyrrhenian Sea (Gestal et al., 1999) (Table1). However,  
321 considering that mantle digestion was never conducted in these previous studies, their results are  
322 not fully comparable with ours, and the absence of *Lappetascaris* spp. and of other anisakids in  
323 some studies might be related to the different techniques applied.

324 Finally, as regards the sizes, the total weight and the mantle weight as well as the total length  
325 and the DML of the positive specimens of *E. cirrhosa* were higher than the average of that  
326 species; on the contrary, in the case of *E. moschata*, the total and the mantle weight and the total  
327 length were lower than the species average, while the DML was lower or equal. The calculation  
328 of Pearson's coefficient showed a moderate positive relationship between total weight, total  
329 length, DML of *Eledone* spp. (the two species were analysed together due to the number of  
330 samples) and number of found larvae (0.5; 0.5; 0.7), and a weak positive relationship between  
331 the mantle weight and the number of larvae (0.2). No comparison with the previous works on  
332 *Eledone* spp. can be conducted as sizes of the examined specimens were not reported.

333 *3.2.2 Doryteuthis pealeii*. During the visual inspection of the 70 specimens of *D. pealeii*  
334 (mean weight 106.5 g, mean total length 41.2 cm, mean dorsal mantle length 16.8) no nematodes  
335 were found, while 18 visible cestode plerocercoid larvae were found in the visceral cavity in 10

336 specimens (P: 14.28% MA: 0.26; MI: 1.8). Since the aim of this paper was to investigate the  
337 occurrence of nematode larvae and also considering the lack of previous reports of larval  
338 cestodes in *D. pealeii*, data regarding these parasites will be discussed in a dedicated article.

339 The artificial digestion instead allowed to detect 2 nematodes (1 in the viscera and 1 in the  
340 mantle) in 2 specimens of *D. pealeii* (P: 2.8%; MA: 0.01; MI: 1). Details of the measured  
341 parameters and parasitological results are reported in Table 3. The body of the recovered third-  
342 stage larvae was white, cylindrical in shape, attenuated at both ends, and measured 15 - 30 mm  
343 in length and approximately 0.40–0.60 mm in width. The larvae were covered with a rigid  
344 cuticle with an annular transverse striation beginning from the cephalic region to the anus and  
345 ending with a short mucron. Based on the microscopic observations both larvae were identified  
346 as *Anisakis* sp. Amplicons and sequences were obtained for both isolated larvae for both genes  
347 (ITS and COX2). The comparison of the obtained sequences with GenBank database allowed to  
348 identify both larvae at species level as *A. simplex* s.s. (100% identity for both markers with  
349 sequences of *A. simplex* deposited in GenBank).

350 A wide variety in the prevalence values of *Anisakis* spp. can be observed in cephalopods  
351 (Table 1). In the revised studies, the squid category was the most represented with 14 analysed  
352 species belonging to three different families (Ommastrephidae, Loliginidae, Histioteuthidae),  
353 followed by cuttlefish and octopus, with 4 species and one family each (Table 1SM).  
354 Noteworthy is the fact that the squids' category is also the most represented on the global market,  
355 followed by octopus and cuttlefish. However, since no data are available for *D. pealeii*, a  
356 comparison can only be made with other squid species. In particular, by uniquely observing the  
357 10 studies analysing species belonging to the Loliginidae family (namely *Alloteuthis* spp.,  
358 *Doryteuthis* spp. and *Loligo* spp.), it may be noted that nematode larvae were only detected in the  
359 co-generic *D. gahi* (1 study conducted in the South Atlantic Ocean reporting a prevalence of  
360 *Anisakis* spp. of 2.46% for 1096 analysed specimens) and in *Loligo vulgaris* (2 studies conducted  
361 in Galicia, Atlantic coast of Spain, with prevalence values of 16% out of 50 specimens and

362 62.5% out of 8 for *Anisakis* spp., respectively) (Table 1). On the contrary, *L. vulgaris* was found  
363 to be negative in studies conducted in the Mediterranean Sea (Angelucci et al., 2011; Gestal et  
364 al., 1999; Goffredo et al., 2019; Graci et al., 2019; Picó-Durán et al., 2016), while all samples of  
365 the genus *Allotheuthis* resulted negative, both in the Mediterranean area (Gestal et al., 1999;  
366 Goffredo et al., 2019) and in the North East Atlantic (Abollo et al., 1998; Abollo et al., 2001).  
367 Besides the family Loliginidae, discussed above, species of the family Ommastrephidae have  
368 been investigated in a large number of studies, which frequently include the three major market  
369 squid species: *D. gigas*, *I. argentinus* and *T. pacificus*. The most relevant data is that prevalence  
370 for *Anisakis* spp. higher than 20%, reaching 50-100% in some geographical areas, were observed  
371 only for species of Ommastrephidae family, namely *T. sagittatus*, *T. pacificus*, *I. coindettii* and  
372 *T. eblanae*. However, in a study on 615 specimens of *T. pacificus*, very different prevalence  
373 values have been found in the different geographical areas and were attributed to different  
374 migration patterns and different prey items, as already indicated by several authors (Setyobudi et  
375 al., 2013).

376 Beside the origin and the analytical method, another important factor to considered is the host  
377 body size. In fish species, large piscivorous fish hosts such as European hake (*Merluccius*  
378 *merluccius*), European anchovy (*Engraulis encrasicolus*), Atlantic herring (*Clupea harengus*),  
379 haddock (*Melanogrammus aeglefinus*), whiting (*Merlangius merlangus*) and Atlantic cod  
380 (*Gadus morhua*) typically present much higher *Anisakis* spp. infection levels compared to strict  
381 plankton feeders fish (Cipriani et al., 2019). In the case of many Ommastrephids an ontogenetic  
382 shift in preferred food source occurs at around 200 mm DML: squid below that size feed  
383 primarily on crustaceans (amphipods and euphausiids) whereas fish and other squids become the  
384 most prevalent prey items in larger host size (Cipriani et al., 2019). In the work of Cipriani et al.,  
385 (2019), in fact, highest *A. pegreffii* abundance was observed in squids >200 mm DML. Similarly,  
386 also Setoybudi et al. (2013) states that the prevalence in the Yellow Sea and the East Sea  
387 generally increased with the host body size, due to the fact that common squid juveniles usually

388 prey on crustaceans and switch to fish and cephalopods as they grow. However, in the present  
389 study the DML of the two positive species was shorter than the average of all the analysed  
390 specimens as well as of that reported by other sources  
391 (<https://www.sealifebase.ca/summary/Doryteuthis-pealeii.html>), while the other parameters did  
392 not show a clear tendency. However, considering the low number of positive samples in the  
393 present study and the absence of literature data for *D. pealeii*, additional observations would be  
394 required to investigate this aspect. Finally, the very broad feeding pattern of *D. pealeii* should  
395 also be taken into account. Larger specimens may be at higher risk of harbouring L3, as it has  
396 been shown that adults between 12 and 16 cm long feed on fish and squid larvae or juveniles,  
397 while adults larger than 16 cm feed on fish and squid (Jacobson, 2005).

### 398 **3.3 Parasite in cephalopods: implication for food quality and safety**

399 The present survey provides data on the occurrence and distribution of molecularly identified  
400 larvae of *A. simplex* in *D. pealeii* from the Northwest Atlantic Ocean and of larvae  
401 morphologically resembling *Lappetascaris* sp. in *Eledone* sp. from the Mediterranean Sea.

402 To the best of our knowledge, this is the first report of *A. simplex* s.s. in *D. pealeii*, both in the  
403 viscera and in the mantle. Considering that this species is sold as fresh to the final consumers and  
404 that *A. simplex* s.s., together with *A. pegreffii*, is a well renowned zoonotic species (Guardone et  
405 al., 2018; Mattiucci et al., 2013; 2018), findings of our work are of interest both for the seafood  
406 industry and for the control authorities. Despite the low prevalence value observed in the present  
407 study, the potential public health risk should not be disregarded, as this study showed that *D.*  
408 *pealeii* is able to harbour *Anisakis simplex* s.s. also in the mantle that represents the main edible  
409 part of cephalopod body sold to the final consumers. As a newly described proven host for *A.*  
410 *simplex* s.s., this squid should thus be considered at risk of anisakiasis transmission if consumed  
411 raw or not well cooked. In fact, considering that in Korea and Japan anisakid nematodes were  
412 isolated from patients who had eaten raw common squid, cuttlefish and octopus (Hibi et al. 2009;  
413 Im et al.1995; Setyobudi et al., 2013), and that cephalopods are increasingly consumed as raw in

414 typical Asian dishes also in Europe, the public health risk posed by cephalopod consumption  
415 should not be underestimated. A recent study showed that octopus and squid are used in sushi  
416 preparation in Italy (Armani et al., 2017). Even though the species found did not include *Eledone*  
417 spp. or *Doryteuthis pealeii*, the use of other kind of cephalopods cannot be excluded. Such  
418 practices have already been observed in Japan, where due to poor catches and consequent  
419 market shortage, *Todarodes pacificus* is being replaced by jumbo flying squid (*Dosidicus gigas*)  
420 in some sushi products (FAO, 2019b).

421 While the viscera contamination could be controlled by a rapid evisceration of the specimens,  
422 the reduction of the parasite burden in the edible part is quite challenging. In fact, while the  
423 removing of belly flaps in fish is a routine practice that does not reduce the fish value, the setup  
424 of trimming procedures, aimed at removing the “most contaminated part” of the cephalopods  
425 body, could result in a drastic reduction of their commercial value. In addition, the elective site  
426 of parasites embedding in the mantle is still unclear, as only few studies described this aspect.  
427 Cipriani et al., (2019) found each of the three mantle-infecting *A. simplex* larvae in the posterior  
428 half of the mantle (the hind part, roughly mirroring the most common larval infection site in the  
429 viscera) in the Argentinian shortfin squid. Interestingly, the larvae were embedded in the  
430 muscular tissue and were not readily recognizable neither by plain visual inspection (whitish  
431 larvae in whitish muscular tissue), nor candling, but only by UV fluorescence. Thus, even though  
432 the dorsal part of the cephalopods (adjacent to the viscera) is a potential “election site of  
433 localization”, further studies would be required to confirm this localization.

434 Finally, while the presence of *A. simplex* s.s. in *D. pealeii*, although with very low prevalence  
435 values, suggests that preventive measures should be put in place to avoid anisakiasis risk in the  
436 case of raw or undercooked longfin inshore squid consumption, the presence of *Lappetascaris*  
437 spp. larvae should not represent a public health risk. However, as in the case of other  
438 Raphidascarididae larvae, the possibility of causing allergic syndromes still needs to be clarified.

#### 439 **4. Conclusions**

440 The present study contributes to describe the contamination level of cephalopod products of  
441 commercial interest for the Italian market sold as whole fresh in terms of anisakids infection, as  
442 requested by the European Food Safety Authority, recommending research on the prevalence,  
443 intensity, and anatomical location of parasites of public health importance in wild caught fishery  
444 products (EFSA, 2010). Unfortunately, the methodology used in the different studies in the  
445 literature varies, hampering direct comparison of the epidemiological data. In addition, most of the  
446 studies used visual inspection. Although frequently coupled with stereomicroscopic dissection, this  
447 technique may not always be adequate to detect nematode larvae, especially in the mantle, which is  
448 however the edible part. Standardization is thus highly need to provide new data for risk analysis, in  
449 order to better implement Food Business Operators inspection procedures aimed at guaranteeing  
450 products' quality and consumers' safety.

451

#### 452 **Declarations of interest**

453 None.

454

#### 455 **Funding source**

456 This work was supported by the 2019 Visiting Fellow Program of the University of Pisa,  
457 which financed a period of research of Dr. Ewa Bilaska-Zajac at the FishLab, Department of  
458 Veterinary Science, University of Pisa.

459

#### 460 **Acknowledgments**

461 The authors wish to thank Dr. Culurgioni for the support in the morphological analysis of the  
462 larvae found in *Eledone* spp. in the present study.

**Table 1SM.** List of species investigated for the presence of nematod larvae (divided by categories octopus, cuttlefish and squid). CD: commercial designation

| Category   | Order      | Family            | Genus               | Species                | CD                        |                       |
|------------|------------|-------------------|---------------------|------------------------|---------------------------|-----------------------|
| octopus    | Octopoda   | Octopodidae       | Eledone             | <i>E. cirrhosa</i>     | horned octopus            |                       |
|            |            |                   |                     | <i>E. moschata</i>     | musky octopus             |                       |
|            |            |                   | Octopus             | <i>Octopus sp.</i>     | -                         |                       |
|            |            |                   |                     | <i>O. maya</i>         | Mexican four-eyed octopus |                       |
|            |            |                   |                     | <i>O. vulgaris</i>     | common octopus            |                       |
| cuttlefish | Sepiida    | Sepidae           | Sepia               | <i>S. elegans</i>      | elegant cuttlefish        |                       |
|            |            |                   |                     | <i>S. esculenta</i>    | golden cuttlefish         |                       |
|            |            |                   |                     | <i>S. officinalis</i>  | common cuttlefish         |                       |
|            |            |                   |                     | <i>S. orbignyana</i>   | pink cuttlefish           |                       |
|            |            |                   |                     | <i>H. bonnellii</i>    | umbrella squid            |                       |
| squid      | Teuthida   | Histioteuthidae   | Histioteuthis       | <i>H. reversa</i>      | elongate jewell squid     |                       |
|            |            |                   |                     | <i>Alloteuthis sp.</i> | -                         |                       |
|            |            | Loliginidae       | Alloteuthis         | <i>A. media</i>        | -                         |                       |
|            |            |                   |                     | <i>A. subulata</i>     | European common squid     |                       |
|            |            |                   |                     | Doryteuthis            | <i>D. gahi</i>            | Patagonian squid      |
|            |            |                   | Loligo              | <i>L. bleekeri</i>     | spear squid               |                       |
|            |            |                   |                     | <i>L. vulgaris</i>     | European squid            |                       |
|            |            |                   | Dosidicus           | <i>D. gigas</i>        | jumbo flying squid        |                       |
|            |            | Ommastrephidae    | Illex               | <i>I. argentinus</i>   | Argentine shortfin squid  |                       |
|            |            |                   |                     | <i>I. coindetii</i>    | shortfin squid            |                       |
|            |            |                   |                     | Ommastrephes           | <i>O. bartramii</i>       | neon flying squid     |
|            |            |                   |                     | Todarodes              | <i>T. pacificus</i>       | Japanese flying squid |
|            |            |                   |                     | <i>T. sagittatus</i>   | European flying squid     |                       |
|            | Todaropsis | <i>T. eblanae</i> | lesser flying squid |                        |                           |                       |
