Title: The Soap Box as a Black Box: Regulating Transparency in Social Media Recommender Systems

Author: Paddy Leerssen

Contact: p.j.leerssen@uva.nl

Date: 24 February 2020.

Abstract:

Social media recommender systems play a central role in determining what content is seen online, and what remains hidden. As a point of control for media governance, they are subject to intense controversy and, increasingly, regulation by European policymakers. A recurring theme in such efforts is transparency, but this is an ambiguous concept that can be implemented in various ways depending on the types of accountability one envisages. This paper maps and critiques the various efforts at regulating social media recommendation transparency in Europe, and the types of accountability they pursue.

This paper identifies three different categories of disclosure rules in recent policymaking: (1) user-facing disclaimers, (2) government auditing and (3) data-sharing partnerships with academia and civil society. Despite their limitations and pitfalls, it is argued, each of these approaches has a potential added value for media governance as part of a tiered, variegated landscape of transparency rules. However, an important element is missing: public disclosures. Given the deeply political and value-laden context of media governance, it is argued, this field cannot rely exclusively on technocratic, institutionalized forms of transparency emphasized in current proposals. The final section articulates the distinct benefits of public disclosures as a supplement to existing transparency measures, and suggests starting points for their design and regulation.

1. Introduction

Social media platforms have become central actors in media governance. One of their most powerful means of influence is their content recommender systems, which determine the ranking of content as it is presented to users. Their design can therefore have significant effects on what is seen online, and what remains hidden. Accordingly, content recommender systems have a gatekeeping function, implicating urgent public interests including the freedom of expression and media pluralism and swiftly becoming a key point of control and contention in ongoing debates about online content regulation.¹

In this otherwise contentious debate, a rare point of consensus for both scholars and policymakers appears to be the need for greater transparency. At present, social media recommendation systems operate largely as ‘black boxes’, guided by complex, confidential machine-learning algorithms whose operations are inscrutable to outside observers.² “A system must be understood to be governed”, as Mike Ananny and Kate Crawford observe, and there is broad agreement amongst scholars and policymakers that recommender systems must be more

transparent – if not as a sufficient condition for holding them accountable then at least as a first step.³

This paper analyses recent policymaking in Europe that attempts to regulate transparency in social media content recommendations. Not yet a cohesive framework, we see various overlapping standards at the national, EU and Council of Europe level, each furthering particular visions of what ‘transparency’ entails, and what types of accountability it should serve. This paper critiques these various efforts, drawing on critical literature on transparency regulation and platform governance, and questions how, and under which conditions, they can contribute to holding social media recommender systems accountable for their impact on online content distribution.

The paper proceeds as follows: Section 2 offers an overview of governance debates about gatekeeping through social media recommenders, and how these have given rise to calls for greater transparency. As will be seen, the issue of transparency in social media recommendations is multifaceted and relates not only to the algorithm but to the performance and operation of these sociotechnical systems more broadly. Section 3 describes recent European policymaking around recommendation transparency, identifying three general categories of disclosure rules: user-facing disclaimers, government oversight and civil society partnerships. Each of these methods has a potential added value for media governance, despite their respective limitations and pitfalls, as part of a tiered, variegated approach to transparency. Yet, an important element is missing: public disclosures. Section 4 articulates the distinct advantages of public disclosures as a supplement to existing transparency measures, and suggests starting points for their design and regulation.

2. Social media recommenders systems as opaque gatekeepers for online content

2.1 What are social media recommender systems?

Platforms use recommender systems to determine the manner in which content is presented to their users. Their recommendations typically take the form of pages or lists, often referred to as ‘feeds’, in which the order of content is determined by ranking algorithms. These ranking algorithms can take any number of forms, from simple reverse chronology to complex machine-learning solutions. Recommender systems can also include user customization options, such as the ability to ‘like’ or ‘follow’ specific content sources, to block or filter certain content sources, or to switch between entirely different ranking logics. Recommender systems are commonly understood as optimizing for user attention, or ‘relevance’, but in practice, as will be unpacked further below, recommender design may also follow other economic and political imperatives.

Recommendations are not the only way to access social media content, but they are nonetheless influential. Users can typically also reach content through search functions, user profiles,

³ Mike Ananny & Kate Crawford (2016), ‘Seeing without knowing: Limitations of the transparency ideal and its application to algorithmic accountability’, *New Media & Society* 20:3.

hotlinking and embedding. But content recommenders commonly take up a central position in platform interfaces: Facebook's Newsfeed and YouTube's Autoplay and Recommended Videos, for instance, are some of the key content discovery features on their respective platforms. YouTube recently stated that 70% of user viewing is accessed through recommendations.⁴ Since Facebook's Newsfeed being is even more central to the platform's interface, the percentage here could plausibly be even higher.

It is important to note that content recommendations are not fully controlled by their operators, but are co-determined by platform users, who influence outcomes in several ways. Firstly, users are responsible for uploading content from which content recommendations draw their recommendations. Secondly, users' behavior provides feedback signals, including explicit feedback such as rating, following or subscribing, as well as implicit feedback such as scrolling and clicking.⁵ Since recommender systems commonly rely on machine-learning processes to optimize the algorithm, these user signals can also serve to shape the weighting of the algorithm over time. Conversely, the recommender system can also shape users' behavior over time, in terms of their preferences, habits and expectations they form in relation to the service. These complex interactions between the recommendation algorithm and its users make making for a recursive and unpredictable system, with the potential for unexpected feedback loops and path dependencies.

Given the central role of user behavior in steering recommendation outcomes, it is important to emphasize that platform recommendations are not fully pre-determined or controlled by their operators. The effects of a given recommender architecture cannot be understood independently from the preferences and biases exhibited by its userbase. Kevin Munger & Joseph Philips warn that decontextualized or monocausal understandings of 'the algorithm' shaping online media consumption overestimates the role of their designers and undervalues the relative influence of user communities which shape content supply and demand.⁶ Similarly, Rebecca Lewis' study of far-right content on Youtube emphasizes the role of well-organized "influence networks" of content creators and audiences, who used guest appearances and other forms of referral and collaboration to create a pipeline or 'rabbit hole' of gradually escalating extremism.⁷ In other words, the problem may not just be with the algorithms.⁸

A more refined view of platform recommendation systems, then, recognizes that they are neither objective or unmediated reflections of users' preferences (if such a thing is even possible), nor top-down impositions by the platform. Rather, platform recommendations

emerge from complex and recursive interactions between the system and its userbase. As Natali Helberger et al observe, governance of these systems therefore requires close attention to “the complex dynamics between the gatekeepers and the gated”.⁹ Or, as Philip Napoli puts it, gatekeeping on social media is performed by “individual media users working in conjunction with content recommendation algorithms”.¹⁰ Building on this perspective, Bernhard Rieder, Ariadna Matamoros-Fernandez and Oscar Coromina argue for a shift from studying ranking algorithms to ‘ranking cultures’, acknowledging ‘the realities of an intricate mesh of mutually constitutive agencies’.¹¹

2.2 Recommendation gatekeeping: from the attention economy to attention politics

Given their role in shaping online media consumption, content recommendations from dominant social media platforms exercise a gatekeeping function with implications for online freedom of expression and media pluralism.¹² As information gatekeepers, recommender systems have important policy implications related to media governance, and raise deeply divisive questions about the types of values and interests their design should serve. As several scholars have observed, their function is comparable to editorial decisions in the mass media, in the sense that they reflect an ultimately subjective (and typically commercially motivated) judgement on what content is ‘relevant’ to their audience.¹³

Of course, the gatekeeping function exercised traditional editors and social media recommendations differ in important ways. On the one hand, content recommendations do not determine *access* to content, like a traditional editor would, but rather *exposure* - a function that Natali Helberger, Katharina Kleinen-Von Königslow and Rob von der Noll describe as ‘indirect editorial influence’.¹⁴ Gillespie makes a similar comparison, noting that “[t]his may be a gentler intervention than an editor deciding what is a front page story and what isn’t worth reporting at all, but it is selection nonetheless, and it matters in many of the same ways”.¹⁵ Another distinction is that platforms tend to process user-generated content, rather than editorially selected content. Even when media organizations use algorithms to personalize content selections, as the New York Times does for instance, they are still drawing from a smaller, pool of vetted content than, for instance, YouTube’s Recommended Videos. In this regard, Jennifer Cobbe & Jatinder Singh distinguish ‘open recommending’ of user-generated content by

platform services, which is the focus of this paper, as distinct from ‘curated recommending’ of walled garden services such as Netflix, or ‘closed recommending’ of in-house content by media organizations such as the New York Times.¹⁶ Whilst all these services use complex algorithmic systems to generate personalized content recommendations, the ‘open recommending’ performed with user-generated content operates at the largest scale and with the greatest diversity of content, serving an essential or even quasi-infrastructure role in many media ecosystems.¹⁷ Given their open nature, they also offer the greatest risk of surfacing harmful or illegal content. In this light, social media recommender systems afford a form of gatekeeping which may at first seem relatively indirect and light-touch, but has the potential for systemic effects across online media ecosystems.¹⁸

Social media recommender systems are also embedded in different organizational and commercial structures than the mass media’s editorial selections.¹⁹ Unconstrained by professional standards of journalism, social media platforms are incentivized to optimize their recommendations primarily for *engagement*.²⁰ By encouraging users to spend time on the platform, engaging content recommendations can enable platforms to monetize more of their attention and behavioral data. This ‘attention economy’ logic of recommender systems has been criticized extensively in academia, the press, and public policy, who have highlighted the potential harms that may arise from recommendations optimized for engagement and are increasingly forcing platforms to incorporate alternative design values.

Engagement-optimized social media recommendations are alleged to contribute to a range of harms (though some critiques have more empirical grounding than others). To name a few: content recommenders have been accused of accelerating extremist content and disinformation²¹; polarizing audiences and pushing users into homogenous ‘filter bubbles’ or ‘echo chambers’²²; underserving content on certain social movements and news events²³; exposing children and other vulnerable groups to harmful content²⁴; and for reflecting or

amplifying societal prejudices and biases against marginalized groups.²⁵ They have also been accused of intentional political bias and censorship, where platforms allegedly intervened with content on specific issues, though many of these claims remain unverified.²⁶ Such critiques serve to problematize and politicize the supposed neutrality or objectivity of platform information flows and their determinations of relevance.²⁷

Alternative design principles for social media recommendations are now being devised, and, increasingly, implemented in practice. Academics have articulated a range of different values for content recommenders, including ‘serendipity’²⁸, ‘diversity’²⁹, ‘neutrality’³⁰, ‘user choice’ and ‘user control’³¹, and ‘agonism’.³² Each reflects different judgements about the particular risks and opportunities posed by recommender systems, and can be operationalized in countless different ways. But what these proposals have in common, is that they depart from the basic commercial logics of the attention economy, and instead would use social media recommenders to reflect public interests or values.³³ Indeed, several governments across Europe have over the past years proposed to regulate social media recommendations through public law, based on a variety of public interest principles and definitions.³⁴ And platforms are starting to take note.

Since 2016, major social media platforms claim, ostensibly in response to concerns over the spread of harmful content, to have altered their recommender systems in ways that depart from a strictly engagement-driven design. In particular, these changes tend to address content which is not explicitly prohibited by the platform but is nonetheless considered undesirable or unwelcome, such as disinformation and political extremism. Facebook has announced a bevy of responses. In early 2018, the platform changed their recommendation algorithm to promote content shared by friends and reduce the reach of news pages (described as “meaningful engagement”).³⁵ In 2019, Facebook announced that it would downrank anti-vaccination content and other “borderline content” which falls short of violating company policies.³⁶ In May 2019,

Facebook announced its new ‘click-gap’ program to suppress “low-quality content”, which is achieved by analyzing the relative popularity of a given item on Facebook compared to its overall web traffic.³⁷ YouTube also claims to be experimenting intensively with methods to improve recommendation quality and to reduce the spread of harmful and misinforming content. A 2019 blog post claimed that “in the last year alone, we’ve made hundreds of changes to improve the quality of recommendations”.³⁸ Those concerned with harmful speech online may welcome these interventions, while those concerned with free speech might balk at them. In any case, as discussed below, these decisions and their effects are largely opaque to outside stakeholders.

As these examples show, recommender systems are increasingly used as a tool for content regulation. A variety of different methods are in play: some interventions target specific speakers or posts, such as Facebook’s downranking of false headlines, whereas more fundamental changes to the algorithm have the potential to affect all rankings across the system. Some interventions are decided on a case-by-case basis by human actors, whereas others are automated to a large degree, such as the blacklisting and whitelisting of accounts, keywords or phrases, or analysis of content metadata as in Facebook’s aforementioned ‘Clickgap’ program.³⁹

These content-related interventions may be motivated by any number of (perceived) demands or pressures, including political pressures and the threat of government regulation.⁴⁰ Social media platforms are embedded in complex governance structures and accountability relationships with a range of different stakeholders: not only governments but also proactive users, civil society actors, and commercial partners may motivate them to intervene in content flows. In any case, it is clear that their actions cannot be explained solely through ‘attention economy’ narratives. This is not to deny the commercial, profit-seeking nature of social media platforms, but simply to recognize that their economic self-interest may require them to take into account political conditions. In other words: recommendation gatekeeping is not simply a matter of attention economy, but also, and increasingly, of attention politics.

This struggle over the future of recommendation gatekeeping does not appear to have definitive answers or solutions. Public interest concepts such as media pluralism – i.e. the appropriate structure or balance of available media in a given polity – cannot, as Kari Karppinen observes,

be ‘solved’ objectively or definitively.⁴¹ Indeed, it is worth noting the tensions between current design proposals, such as ‘diversity’ and ‘trustworthiness’ on the one hand and ‘non-discrimination’ and ‘neutrality’ on the other.⁴² After all, the former may require recommenders to seek out and prioritize certain content, while the latter could arguably prohibit the drawing of such distinctions. We need not expect a consensus to emerge soon: what types of content should be prioritized across different segments of the population, is a fundamentally political and value-laden question, and will therefore likely continue to be debated for the foreseeable future, as a new frontier in online media governance.⁴³

2.3 ‘Obscured obscuring’: The opacity of social media recommendations

A commonly criticized aspect of recommendation gatekeeping is that it is deeply opaque. While it is clear *that* platforms increasingly curate their recommendations for various forms of content regulation, *how* they do so is difficult to observe and understand. Recommender systems are perceived as ‘black boxes’, whose internal logics are inscrutable and their outputs unpredictable, creating a barrier to holding these systems accountable.⁴⁴ Gillespie memorably warns against “the obscured obscuring of contentious material from the public sphere”, which “raises a new challenge to the dynamics of public contestation and free speech”.⁴⁵ So what makes these systems so opaque? This lack of transparency is multifaceted, and results from both technical and legal factors.

Taken in its most basic sense, transparency can be said to refer to “the disclosure of certain information that may not previously have been visible or publicly available”.⁴⁶ In the context of recommender systems, concerns over transparency often refer to the specific algorithm used to produce recommendations. But other aspects of recommender systems are also opaque, such as the outputs (what recommendations are made?) and inputs (user content & metadata, behavioral data, etc.) In addition, transparency can also refer to the human agents and organizational structures involved in designing and operating this system. At present, many influential content recommenders lack transparency on each of these issues – from the algorithm as such to its inputs and outputs and the surrounding institutions.

See also: Robert Gorwa & Timothy Garton Ash (2020, forthcoming), ‘Democratic Transparency in the Platform Society’, in: Nate Persily & Joshua Tucker (eds.), *Social Media and Democracy: The State of the Field and Prospects for Reform*, Cambridge University Press.

To start with the recommendation algorithm: these are obscure due to their technical complexity as well as intentional corporate secrecy.⁴⁷ Commonly developed with the assistance of complex machine-learning techniques, these algorithms are often ill-suited to ‘human scale comprehension’, and it is difficult even for experts to develop concrete, causal explanations for specific outcomes.⁴⁸ Some platforms now offer individualized ‘explanation’ features, such as Facebook’s Why Am I Seeing This? feature, but such efforts have been criticized for failing to meaningfully describe the full complexity of the algorithm’s operations.⁴⁹ Platforms could in theory publish their algorithms in full and enable outside study, but they have reasons to keep them confidential. Firstly, platforms commonly argue that the recommender system design involves commercially valuable trade secrets.⁵⁰ Secondly, confidentiality of the algorithm may in some cases be necessary to prevent users from ‘gaming’ the system and undermining its gatekeeping function.⁵¹ For instance, if platforms were to publish their keyword blacklists, this could help sophisticated spammers to avoid being downranked in this way.

But a clear view of inputs and outputs is also crucial to understanding recommender systems. As discussed, the effects of a recommender algorithm are very much contextual, and a view of its outputs is necessary to understand its effects in practice. For example, enhancing user customization options in a given recommender system could either increase or decrease the diversity of content consumption, depending on what options users end up selecting. Similarly, a decision to downrank content with a high comment rate could serve to punish controversial and divisive ‘clickbait’, but could also punish desirable forms of exchange and deliberation. In this light, transparency in algorithmic design is not particularly meaningful without a view of their complex, recursive interactions with users in practice. As Rieder, Matamoroz-Fernandez and Coromina write, “access to the mythical source code would not solve this problem.”⁵² Instead, they argue for research methods focused firstly on the *outcomes* of these systems, in terms of what recommendation patterns are generated on particular issues and for particular publics, and how these change over time.⁵³

But the study of recommender system outcomes is restricted in several ways, first and foremost as a result of their personalization. Since each user is served a personalized selection of recommendations, it is difficult for any individual observer to make generalizable conclusions about the performance of the system as a whole.⁵⁴ We only know our own news feeds, and can only guess as to what others are seeing. Researchers have attempted to counteract the obscuring effects of personalization through independent survey techniques, which mobilize a large number of accounts (either bots or human volunteers) to assemble data about the platform’s

⁵⁰ Burrell (2016).

⁵¹ Pasquale (2015) argues that platform’s claims in this context should not be taken at face value; only under certain conditions will transparency enable ‘gaming’, and platforms’ claims may in fact be motivated by proprietary concerns.

⁵² Rieder, Matamoroz-Fernandez & Coromina 2017.

outputs.⁵⁵ However, these methods can only provide snapshots and do not come close to a comprehensive or systematic view of platform traffic flows. Worse still, platforms can and have restricted these processes contractually in their Terms of Service, and technically by blocking such tools. For instance, Facebook recently blocked a popular data scraping tool by ProPublica, citing violations of its Terms of Service.⁵⁶

Besides independent surveying, one of the most important sources of data regarding recommender systems has been their public APIs, through which outside researchers can download platform data in bulk. But these have come under significant pressure over the past years. Since the Cambridge Analytica scandal, in which academics helped to leak and abuse large sets of user data from Facebook, important APIs have incurred major restrictions in their functionality. This development, which Axel Bruns has described as the ‘APIcalypse’, has caused many widely-used research tools, both commercial and academic, to be shuttered.⁵⁷ Of course, the quality of API access differs between platforms; for instance, YouTube and Twitter offer relatively generous public research APIs, whereas Instagram’s was recently shut down entirely.⁵⁸ Regardless of what information is currently available, Deen Freelon argues that, since platforms have no binding obligation to maintain these systems in any consistent manner, the situation is fundamentally precarious: “we find ourselves in a situation where heavy investment in teaching and learning platform-specific methods can be rendered useless overnight”.⁵⁹

Through such interventions, platforms are able to leverage law and technology to obstruct independent study of their recommender systems, leaving even the basic outputs unclear.⁶⁰ In this sense, platform content recommenders can be even less transparent than the prototypical ‘black box’: not only is it unclear *why* certain decisions are being made, it is simply unclear what decisions are being made in the first place. This is an important contrast with other areas of algorithmic governance such as, for instance, judicial sentencing algorithms, where the algorithm may be secret but the ultimate decisions are still a matter of public record.⁶¹ It is also a noteworthy contrast with mass media content distribution of press, radio and television, whose outputs are equally a matter of public record and thus make the editorial line of a given outlet

readily identifiable for any and all audience members.⁶² The personalized gatekeeping of recommender systems, by contrast, is difficult for any outsider to observe at a systemic level.

Finally, the organisation surrounding social media recommender systems also tends to be poorly documented. As mentioned, speculation abounds regarding the possibility of human interventions in important content recommender systems, such as YouTube's Trending Videos and Facebook's Newsfeed, but there are few conclusive or authoritative sources of information about these platforms' internal operations. In their absence, conjectural 'folk theories' and 'algorithmic lore' proliferate.⁶³ Occasional announcements are made, such as Facebook's aforementioned fact-checking partnership, which enables third parties to mark false or misleading content for downranking. Their basic modus operandi is outlined on the website, but there is no public registration of *which* particular pieces of content are being downranked under this system, making the actual impact of these partnerships difficult for outsiders to evaluate. This is but one example of potential manual interventions by engineers. How else are platforms and their affiliates intervening? In the most extreme cases, recommendations may not be automated at all, but instead are curated entirely by human operators. In the case of Facebook's by-now notorious Trending Topics, reporters showed in 2016 that this system, despite appearances, was in fact manually curated by Facebook staff, rather than by an automated algorithmic process, and these revelations quickly prompted accusations of political bias.⁶⁴ In practice, many or even most algorithms likely combine human and algorithmic decision-making. As such stories illustrate, the opacity of social media recommendations relates not only to technical specifications, but also the organizational structures in which they are embedded. In the words of Ananny & Crawford, transparency in algorithmic systems should take into account "not just code and data but an *assemblage* of human and non-human actors."⁶⁵

All this means that the quasi-editorial influence exercised by platforms recommendations is difficult for outside stakeholders to study, much less evaluate or hold accountable. How platforms tweak and their algorithm is effectively hidden from public knowledge – much less the actual impact of their choices. Even simply observing trends or patterns in recommendations is made all but impossible, and worse still, any observed trend or pattern must account not only for complex machine-learning algorithms but also for highly unpredictable and dynamic user behavior.

Though platforms have devised a number of self-regulatory transparency measures, these have broadly failed to assuage criticisms. Relevant efforts include user-facing notices (e.g. Facebook's 'Why Am I Seeing This' feature discussed above) as well as data sharing projects with civil society. They tend to be met skepticism for several reasons. Firstly, creating meaningful transparency arguably runs counter to platforms' incentives: they have a commercial interest in monetizing traffic data and insights, and thus in keeping this information

⁶² This comparison has been made in numerous commentaries on news personalization, e.g.: Bodo et al (2018); Yochai Benkler, Robert Faris & Hal Roberts (2018). *Network Propaganda: Manipulation, Disinformation, and Radicalization in American Politics*. Oxford University Press.

exclusive, as well as a political interest in avoiding negative publicity.⁶⁶ Indeed, the flagship Social Science Initiative has been marred with delays and controversies; whilst Facebook cites legal concerns over data protection compliance, others blame a lack of incentives and political will.⁶⁷ Even the European Data Protection Supervisor recently argued as much: “It would appear therefore that the reluctance to give access to genuine researchers is motivated not so much by data protection concerns as by the absence of business incentive to invest effort in disclosing or being transparent about the volume and nature of data they control.”⁶⁸ Such considerations may explain the recent attention for government regulation of transparency.

3. State of play: Regulating recommendation transparency in Europe

The law and policy literature displays a strong consensus around the need for greater transparency in platform gatekeeping, particularly as regard content recommender systems.⁶⁹ Yet it is also widely acknowledged that “transparency” is an ambiguous concept that can be operationalized in numerous ways, particularly as regards such complex technological systems as platform content recommenders. Crucial questions include: Which stakeholders should transparency address? And what information should they receive? In this regard, as argued by Ananny & Crawford, the design of transparency interventions should always be tied to a clear vision of accountability which it is intended to serve.⁷⁰ In this sense, the debate around transparency in recommender systems is inextricably linked to a broader and more fundamental debate about social media accountability.⁷¹ As Robert Gorwa & Timothy Garton Ash argue, “transparency in practice is deeply political, contested, and oftentimes problematic” – or, more bluntly by Amitai Etzioni, “a form of regulation by other means”.⁷²

The following section reviews European plans to regulate transparency in social media recommender systems, and the types of accountability they pursue. In the past years, policymakers have undertaken several different initiatives to regulate the transparency of social media recommendations. This by now complex and fragmented landscape includes horizontal instruments, such as competition law and data protection law, which are not tailored to social media governance in particular but may still have some spillover benefits for its purposes. More recently we also see the emergence of several sectoral proposals that lay out a specific vision for transparency for social media recommendations in particular. Most of the latter instruments

are rooted in media pluralism policy, but they also target other public interest considerations such as the combating of online disinformation.

Despite the variety of rules in play, the transparency measures contained in these instruments can be grouped into three general categories, pursuing accountability towards three different sets of stakeholders: (1) user-facing disclosures, which aim to channel information towards individual users in order to empower them in relationship to the content recommender system, (2) government oversight, which appoints a public entity to monitor recommender systems for compliance with publicly regulated standards, and (3) and partnerships with academia and civil society, which enable these stakeholders to research and critique recommender systems. Each of these is discussed below.

Disclosure audience	Platform users (incl. audience and speakers)	Public authorities	Academia and civil society
Disclosure type	Disclaimers, notices, ‘explanations’	Audits, reporting requirements	Data-sharing ‘partnerships’, ‘initiatives’, observatories, etc.
Associated Accountability Standard(s)	User choice / revealed preference	Public standard setting (e.g. non-discrimination, pluralism, trustworthiness)	Various/undefined (e.g. public deliberation, evidence-based policymaking).

Table 1: Typology of disclosure rules for social media recommenders in Europe

At the outset, it should be noted that these different types of transparency are by no means mutually exclusive; each has distinct benefits and shortcomings, and these may overlap or even synergize. Many scholars of algorithmic governance and platform governance recommend such a variegated or tiered approach to transparency regulation, with notable examples including Frank Pasquale’s ‘qualified transparency’ model and Andrew Tutt’s ‘Spectrum of Disclosure’.⁷³ Indeed, what appears in the following section is that emerging standards seem to approximate Pasquale’s model of ‘qualified transparency’, in which understandable, simplified information is channelled towards individual end-users, and detailed, sensitive information is shared confidentially with experts in government in civil society.⁷⁴ Such a tiered approach to transparency also comports with a broader view of social media governance as not depending exclusively on a single source of accountability or regulation, but rather on more complex and multistakeholder systems of governance.⁷⁵ For instance, Helberger, Pierson and Poell argue that “the realization of public values in platform-based public activities cannot be adequately

⁷³ Pasquale (2015). Andrew Tutt (2017), *An FDA for Algorithms*, 69 Administrative Law review 83. Tal Zarsky (2013), *Transparent Predictions*, University of Illinois Law Review 1503. For overview and analysis, see: Kaminski (2020).

achieved by allocating responsibility to one central actor (as is currently common practice)”, and instead envisage a “dynamic interaction between platforms, users, and public institutions”.⁷⁶ However, although such involvement of civil society and academia may at first blush seem relatively uncontroversial, it is in the definition and institutionalization of these groups that problems are likely to emerge. Given the difficulty of maintaining inclusiveness and independence of stakeholders in such efforts, it is argued, policymakers should also turn their attention towards developing a robust vision for *public* disclosures about recommender systems – which is lacking from the current framework.

3.1 User-facing disclaimers

Perhaps the most common approach to regulating transparency in recommender systems is to require disclosures for individual users. The aim of transparency in this context is to *inform* users about their available options so as to help them realize their own preferences, appealing to such values as individual autonomy, agency and trust.⁷⁷ If platforms fail to do so, users can, in theory, respond by exiting the platform and taking their activity elsewhere. Napoli describes this as the ‘individualist model’ of social media governance, in which platforms are required to ‘provide an enabling environment in which individual responsibility and autonomy can be realized in relation to the production, dissemination, and consumption of news and information’.⁷⁸ It should be noted that ‘users’ in the context of social media platforms includes not only the consumers of content, but also the providers of content, ranging from amateur vloggers to professional influencers and major media organizations. With that in mind, user-facing transparency can also appeal to principles of competition, fairness and diversity in online media markets.

This user-facing approach to transparency can be seen in several European instruments. The General Data Protection Regulation (GDPR) grants platform users a bundle of individual rights. Article 5 lists ‘transparency’ as one of the Regulation’s key principles, and users are granted a bevy of information and notice rights about personal data processing under Article 12-14. More specifically, under Article 22, data subjects may under certain circumstances have the right to opt out of such automated decisions, and also enjoy a bundle of information rights collectively known as the “right to an explanation”.⁷⁹

Given that the GDPR focuses on data protection, rather than media governance or platform gatekeeping per se, the information acquired in this way could be of only tangential relevance to the study of platform gatekeeping. However, expansive interpretations may be possible: Max van Drunen, Natali Helberger and Mariella Bastian have studied this right as it applies to news recommender systems, and conclude that these provisions should be interpreted *contextually* as

⁷⁶ Natali Helberger, Jo Pierson & Thomas Poell (2017), ‘Governing Online Platforms: From Contested to Cooperative Responsibility’, *The Information Society* 34:1.

⁷⁷ Max Van Drunen, Natali Helberger & Mariella Bastian (2019), ‘Know your algorithm: what media organizations need to explain to their users about news personalization’, *International Data Privacy Law* 9:4.

⁷⁸ Napoli (2015).

⁷⁹ Andrew Selbst & Julia Powles (2017), ‘Meaningful information and the right to explanation’, *International Data Privacy Law* 7(4). Margot Kaminski (2019), ‘The Right to Explanation, Explained’, *Berkeley Technology Law Journal* 34: 1.

a means to empower data subjects in their capacity as news consumers.⁸⁰ On this basis, they argue that users of recommender systems are entitled to a range of information about e.g. the parties able to influence editorial decisions, the profiles that the algorithms construct about them, and the algorithm's metrics and factors.⁸¹ In such a reading, the GDPR could in theory be a source of insights about platform gatekeeping decisions. It remains debatable whether such access rights would find much usage with the average end user.

Another relevant horizontal instrument is the Regulation on Promoting Fairness and Transparency for Business Users of Online Intermediation Services (Platform-to-Business Regulation).⁸² This Regulation affects a different category of users: not *consumers* of social media content, but rather *producers*, who are granted certain notice rights in relation to recommender systems under Article 5. This provision requires platforms to disclose, *inter alia*, “the characteristics of the goods and services offered to consumers through the online intermediation services or the online search engine”.⁸³ For sophisticated content providers who rely on social media, such as newspapers and other media outlets, this could be an additional way to adapt to changes in recommendation algorithms, and potentially to detect unlawful or abusive forms of discrimination.⁸⁴

New proposals particular to media governance are also emerging. The *Medienstaatsvertrag*, proposed in 2018 by the German broadcast authority, requires media intermediaries to disclose the selection criteria that determine the sorting and presentation of content. These include “the central criteria of aggregation, selection and presentation of content and their weight, including information about the function of the algorithms used”.⁸⁵ Addressed towards end-users, they must be made in “understandable language”, and in “in easily recognisable, directly accessible and constantly available formats”.⁸⁶ Comparable recommendations are made in the EU Code of Practice on Disinformation, which is a co—regulatory instrument signed by Facebook, Google and Twitter under the guidance of the European Commission.⁸⁷ These companies must “consider empowering users with tools enabling a customized and interactive online experience so as to facilitate content discovery and access to different news sources representing alternative

⁸⁰ Van Drunen, Helberger & Bastian (2019).

⁸¹ Van Drunen, Helberger and Bastian (2019) also recommend disclosures about e.g. sources (the origin of the information) and outputs (possible alterations to the content). However, these arguments appear to focus on recommender systems operated by *news organizations*, which have direct knowledge and control of such elements. Such disclosures do not appear to be feasible in the context of platforms.

⁸² Regulation 2019/1150 of the European Parliament and of the Council of 20 June 2019 on promoting fairness and transparency for business users of online intermediation services (‘P2B regulation’). *OJ L 186*. (‘P2B Regulation’).

⁸⁷ European Commission (2018), Code of Practice on Disinformation. Available at: <https://ec.europa.eu/digital-single-market/en/news/code-practice-disinformation> (‘EU Code of Practice on Disinformation’)

Although this document has been presented at times as self-regulatory, it is better described as co-regulatory, due to the close involvement of the European Commission in its development and implementation. See: Aleksandra Kuczerawy (2020, forthcoming), ‘Fighting Online Disinformation: Did the EU Code of Practice Forget about Freedom of Expression?’, in: Elzbieta Kuźelewska, Georgios Terzis, Daniel Trotter and Dariusz Kloza *Disinformation and Digital Media as a Challenge for Democracy*, Intersentia.

viewpoints, also providing them with easily-accessible tools to report Disinformation.”⁸⁸ A number of Council of Europe recommendations also emphasize the importance of informing and empowering users. For instance, Recommendation 2018-1 on media pluralism and transparency of media ownership calls on states to encourage platforms to “provide clear information to users on how to find, access and derive maximum benefit from the wide range of content that is available”.⁸⁹

Evidently, the notion that individual user rights should ‘empower’ users vis-à-vis social media recommender systems is popular in European policy circles. But there are also important limitations to these user-centric approaches, both practical and principled. As a practical matter, informing users about complex systems such as content recommenders is difficult, and not straightforwardly achieved through disclaimers or notices. Evidence from privacy and consumer protection law scholarship shows that user-facing notices on social media platforms and other websites are routinely neglected by the vast majority of users.⁹⁰ And even where information is made to be ‘simplified’ and ‘understandable’, as media governance instruments are now requiring, these effects are likely to persist -- the most infamous precedent being the cookie consent notices required under EU privacy law.⁹¹

Leaving aside these information asymmetries, individual users may simply lack the market *power* to depart from dominant platform offerings. Due to such well-documented dynamics as market concentration, network effects, and user-lock in, it may be costly or even impossible for users to switch to viable alternative platforms.⁹² In this sense, transparency towards users may not have full effect if it is *disconnected from power* to actually change outcomes.⁹³

In this light, it remains debatable whether fleshed out user transparency rights under would have much impact on the average user. Their impact might be strongest with more sophisticated users, such as content providers who rely on social media to spread content. Also worth noting is that academics and journalists are starting to experiment with access rights under the GDPR (exercised directly or by volunteer participants) as a source of data; in this light, as Jef Ausloos argues, individualized user rights may have unexpected spillovers from user empowerment to independent research by civil society actors.⁹⁴

More fundamentally, the ideal of “user empowerment” can be criticized as overly individualistic, and endorsing a “neoliberal model of agency”.⁹⁵ While informing users may

serve to enhance choice and competition, as Napoli points, media governance has typically not allowed the public interest to be defined exclusively by these market-based ordering principles. The view that “the public’s interest, then, defines the public interest”⁹⁶ is marginal, certainly in the European tradition. Rather, media policy has also relied on public and collective forms of governance, including government oversight and professional self-regulation, in order to safeguard public values that risk being underserved in a laissez-faire environment, such as pluralism, diversity, child protection, and localism.⁹⁷ Of course, individualist values such as choice, autonomy, competition and agency may still be recognized as important within a broader conception of the public interest. But to *equate* them with the public interest, is to oversimplify the challenges of media governance.

3.2 Government oversight

Several European institutions have also proposed government oversight of social media recommendations, in order to safeguard public interest principles such as diversity or child protection,⁹⁸ enforced by independent regulatory agencies. In terms of transparency, this form of governance relies on reporting duties for platforms and/or auditing powers vested in the regulator.⁹⁹ With relevant expertise and the ability to ensure confidentiality of information disclosed, this allows more detailed information to be released than in user-facing notices. Government oversight frameworks for social media recommenders are not yet as commonplace in Europe as user-facing disclaimers, but a number of horizontal instruments apply, and several sectoral proposals have surfaced in recent years.

One of the most advanced proposals for public oversight of social media recommendations is Germany’s aforementioned *Medienstaatsvertrag*. Its key requirement would be non-discrimination. Under this framework, social media platforms “may not unfairly disadvantage (directly or indirectly) or treat differently providers of journalistic editorial content to the extent that the intermediary has potentially a significant influence on their visibility”.¹⁰⁰ German broadcast regulators at the federal and local level would be empowered to set detailed standards for social media recommender design, and to request documentation from platforms about their activities.¹⁰¹ In the Netherlands, the Dutch State Commission on the Parliamentary System has proposed a comparable “independent entity” to monitor social media recommenders, but unlike the Germans their mandate would focus not on non-discrimination but rather on maintaining ‘diversity’ and avoiding ‘bias’.¹⁰² “If a strong bias can be observed which does not correspond to the information offered by the users themselves on the platform, or if that bias suddenly

⁹⁹ Caveat: as Kaminski (2020, forthcoming) observes, governments commonly rely on knowledge sourced from other societal actors. Accordingly, transparency measures aimed at other stakeholders may also offer indirect benefits to government oversight.

¹⁰⁰ *Medienstaatsvertrag*, Art. 53(e) (translation mine)

changes during an election period, this entity can remark on this and ask the company for a response”.¹⁰³

At EU level, the main instrument for media regulation is the Audiovisual Media Services Directive. However, it does not contain any particular rules related to recommender systems. More relevant for our purposes is the EU Code of Practice on Disinformation, which requires signatories to “[d]ilute the visibility of disinformation by improving the findability of trustworthy content” and to “invest in technological means to prioritize relevant, authentic, and authoritative information where appropriate in search, feeds, or other automatically ranked distribution channels”.¹⁰⁴ However, this being a non-binding co-regulatory instrument, it lacks any concrete sanctions or enforcement mechanisms; platforms were merely expected to self-report their compliance efforts in the months prior to the European Election of May 2019. In terms of transparency, then, it is not armed with the same investigative powers as a conventional regulatory agency. Binding regulation at EU level appears to be under consideration: leaked policy briefs from the Von der Leyen Commission from 2019 envisages “a dedicated regulatory structure” for the oversight of online platforms, with a particular focus on creating transparency.¹⁰⁵

The Council of Europe has also developed standards on the need for government oversight of content recommenders, emphasizing diversity or pluralism as a guiding principle. Their Committee of Ministers has recommended that “[s]tates should encourage social media, media, search and recommendation engines and other intermediaries which use algorithms ... to engage in open, independent, transparent and participatory initiatives that seek to improve these distribution processes in order to enhance users’ effective exposure to the broadest possible diversity of media content.”¹⁰⁶ In contrast to the foregoing examples, this wording does not expressly refer to regulatory agencies but instead describes in more general terms a need for ‘open’ and ‘participatory’ institutions or initiatives, suggesting a more co-regulatory or multistakeholder approach. The state’s more modest role lies in ‘encouraging’ such efforts.

Government oversight of platform recommender can also be found in horizontal instruments in data protection and competition law. The General Data Protection sets limits and conditions on the processing of personal data by content recommender systems, which constrains their ability to personalize content. These rules can be enforced privately by data subjects, but also by national data protection authorities (DPAs). Likewise, competition law constrains dominant platforms in their ability to discriminate between commercial actors on their platform, if this constitutes an abuse of a dominant position.¹⁰⁷ This standard is most relevant for vertically integrated platforms, who also produce their own content and thus have an incentive to discriminate against rival content providers.¹⁰⁸ Both data protection and competition authorities are vested with a bevy of investigative powers, such as requesting documentation and

¹⁰⁸ Helberger, Kleinen-Von Konigslow, von der Noll (2015).

performing audits. These frameworks do not directly address the same public interest concerns as media policy, so it is unlikely that these efforts will be targeted directly at studying media governance issues such as pluralism or disinformation. Nonetheless, their research may still have spillover effects, for instance if important findings are made public, or if data is shared sharing between different regulators -- as is currently envisaged in the European Data Protection Supervisor's ongoing plans for a 'Digital Clearing House'.¹⁰⁹

Government oversight of social media recommendations faces many significant challenges, both practical and principled. Most straightforward is the fact that government authorities are capacity-constrained, particularly as regards the technical expertise required to perform complex algorithmic auditing. This is especially true for horizontal agencies such as competition and data protection authorities, for whom recommender systems risk being overshadowed and overlooked in an extensive, economy-wide portfolio. Sectoral proposals, on the other hand, would in many cases require the creation of *entirely new* oversight bodies, or for traditional broadcast regulators to develop radically new forms of expertise. What makes this particularly challenging is that, in Europe, media policy is largely a national affair, without a clear institution at EU level capable of performing a monitoring role. Indeed, EU governments have repeatedly shot down proposals for creating a supranational media authority.¹¹⁰ National-level action in this space, on the other hand, could result in a duplication and fragmentation of efforts.

Given these capacity constraints on government monitoring, government agencies commonly rely on knowledge sourced from other societal actors, through such formats as public consultations, expert hearings, and complaint procedures. Therefore, as Margot Kaminski observes, transparency measures aimed at third parties such as users, civil society and other stakeholders can also serve indirectly to enhance accountability to public regulation.¹¹¹

Principled objections to government monitoring as a form of transparency are also possible. As discussed, public standard setting for recommender systems necessarily involves (quasi-)editorial judgements, which are not readily quantifiable or 'solvable' in any objective manner.¹¹² Such editorial judgements in the mass media have historically been protected against direct government regulation, given the threats to freedom of expression,¹¹³ and attempts to regulate recommendations may raise similar concerns. From this perspective, government attempts to prescribe what is downranked risks becoming a form of censorship – and what is promoted, a form of propaganda.¹¹⁴ How can a government agency make such essentially political assessments in a legitimate and trustworthy manner?

Put differently, government auditing powers continue to raise issues of what Kaminski terms 'second-order accountability': is the governance system itself sufficiently open to outside

scrutiny?¹¹⁵ If government determinations rely on privileged access to confidential data, which is not accessible to broader publics, it may be difficult for citizens to scrutinize and contest government policy in this space.

This critique of second-order accountability are in line with constitutional principles on the rule of law, due process and open government, which reflect broad agreement that government action should be documented publicly inasmuch as possible.¹¹⁶ Also relevant is the Council of Europe’s emphasis that oversight of social media recommendations should itself be conducted through “open” and “transparent” initiatives.¹¹⁷ In line with such perspectives, the legitimacy of government action regarding content recommendations very much relies on its ability to publicize their actions in a meaningful way. However, publicly documenting algorithmic gatekeeping involves significant technical and operational challenges (as discussed in Section 4 below), and has unfortunately not received detailed attention in relevant standards to date.

A final note the transparency of government relates to the *informal* government action. It is by now well-documented in platform governance that governments can and have used informal means of persuasion and coercion, including the *threat* of regulation, to persuade platforms to adopt certain policies – a stratagem also known as ‘jawboning’, ‘power laundering’ or ‘regulation by raised eyebrow’.¹¹⁸ As a result, it can be difficult to disentangle public and private sources of influence in online content moderation; what is presented as a private platform policy may in fact be inspired or compelled by governments, whose role is effectively obscured. Indeed, such an informal approach seems to be exemplified in the ongoing reliance on quasi-voluntary ‘Codes’ by the European Commission.¹¹⁹ These informal dimensions of public power risk sidestepping safeguards applicable to formal government action, including transparency principles.¹²⁰ In this light, transparency obligations focusing solely on formal government action may fail to capture the full picture. This is where independent disclosure obligations imposed on the platforms may be useful: they may offer a useful starting point not only for holding the platform itself accountable, but also for detecting and contesting informal government action.

3.3 Research partnerships with academia and civil society

Recent European standards increasingly emphasize the role of independent researchers from academia, civil society, and related designations such as “the research community” or “media organizations”. The types of accountability envisaged with these measures are various: in some

¹²⁰ Tambini, Leonardi & Marsden (2008).

cases, these actors are formally incorporated in (co-)regulatory decision making processes, and serve clearly designed accountability processes such as fact-checking or informing action by a regulatory agency. In other cases, the aims of involving independent researchers appear to be more open-ended, treating independent research and reporting as an end in itself.

A formalized role for civil society actors can be found in in the Council of Europe’s 2018 Recommendation on Media Pluralism, which proposes “open, independent, transparent and participatory initiatives by social media, media actors, civil society, academia and other relevant stakeholders” which would be tasked not only with enabling independent research but also with devising new strategies to ensure diversity and other public interest principles in online content distribution.¹²¹ In France, a 2019 report for the Secretary for Digital Affairs similarly recommends a permanent convening of a “political dialogue with social networks involving the regulator and civil society”, including “NGOs, regions and the educational and academic communities” with the government tasked with ensuring transparency for the stakeholders involved.¹²² Academia and civil society are also increasingly represented in the voluntary self-regulatory organs devised by major social media platforms, from the long-standing Global Network Initiative, which conducts audits of platform content moderation practices, to Facebook’s novel and widely-publicized Oversight Board.¹²³

More open-ended calls to enable independent research can be found in the EU Code of Practice on Disinformation. Its signatories have committed to “empower the research community”, which includes “sharing privacy protected datasets, undertaking joint research, or otherwise partnering with academics and civil society organizations if relevant and possible”; and to “convene an annual event to foster discussions within academia, the fact-checking community and members of the value chain”.¹²⁴ In late 2019, the European Commission also issued a call for tenders for a new European Digital Media Observatory, which would allow “fact-checkers and academic researchers, to bring together their efforts and actively collaborate with media organisations and media literacy experts”, with the aim to “fight disinformation online”.¹²⁵ To this end, the Observatory would also “help design a framework to ensure secure access to platforms’ data for academic researchers working to better understand disinformation”.¹²⁶ The UK’s DCMS White Paper would task the government with ‘encouraging’ the creation of “access for independent researchers”, with the aim of “ensure that academics have access to company data to undertake research, subject to suitable safeguards” in order to “help the regulator to assess the changing nature of harms and the risks associated with them”.¹²⁷

Whether it is for independent research or as part of some more formalized co-regulatory process, it is noteworthy that all of the transparency arrangements in this space tend to emphasize the sharing of data with specific institutions -- as ‘partners’ or ‘initiatives’, or ‘observatories’. No explicit attention is paid to creating robust systems of *public* disclosure, available to academia and civil society at large. This preference for partnerships appears to be motivated by the risk of abuse of sensitive data, as highlighted in Cambridge Analytica scandal.¹²⁸ By selecting and vetting trustworthy civil society ‘partners’, and imposing binding conditions and sanction mechanisms on their access to research data, partnerships have a clear utility in enabling research into sensitive data while reducing the risk of its abuse.

But this selecting and vetting of eligible civil society participants brings challenges of its own. Compared to public datasets, one necessarily reduces the number of stakeholders who can access relevant data and perform research – limiting the potential uptake and impact of disclosures. More fundamentally, the selection of eligible participants raises difficult questions about the inclusiveness, diversity and independence of the access framework. The Council of Europe recommends that data access initiatives should be “open, independent, and participatory”, as mentioned previously, but what does this look like in practice? For academia but especially for civil society in a broader sense, there is a very clear tension between these ideals of openness and inclusiveness on the one hand, and the push to restrict access to trusted participants on the other hand. As will be argued below, European governments will face significant challenges in instituting such social media watchdogs – and public disclosures can help to address relevant concerns.

Academics make promising candidates for research access, not only given their professional expertise and ethical standards, but also due to the university system allowing for a relatively stable and objective means of accreditation. Where self-regulatory efforts in this space such as Social Science One been criticized for slow rollout, a lack of (perceived) independence, and a lack of diversity in its leadership, binding regulation could play an important role in addressing relevant concerns and facilitating access for even the most critical research perspectives.¹²⁹ This would require neutral and impartial processes for vetting researchers and holding them accountable to data protection and research ethics standards, perhaps in co-regulation with academic institutions themselves. A useful starting point for such efforts is the European Data Protection Supervisor’s recent Preliminary Opinion on Data Protection and Scientific Research, which envisages the creation of a co-regulatory accreditation scheme and Code of Conduct for research integrity under the guidance of Data Protection Authorities.¹³⁰

Despite the clear benefits of such academic research frameworks, they cannot necessarily make up for the full breadth of civil society watchdog functions in media governance, which have also been performed by journalists, activists, NGOs and political campaigners. For instance, academia tends to have slow turnover times, and may therefore ill-suited to perform real-time, large-scale tasks such as fact-checking. For instance, one recurring controversy in recommender

¹³⁰ European Data Protection Supervisor (2020), A Preliminary Opinion on data protection and scientific research. Available at: https://edps.europa.eu/press-publications/press-news/press-releases/2019/edps-publishes-new-proportionality-guidelines_en

governance has been the prospect of sudden changes during election periods.¹³¹ The academic publishing cycle seems ill-suited to hold such developments to account in a timely manner, and this would likely be better placed with other civil society actors. Yet for these non-academics fields of civil society, such as activism and journalism, accrediting eligible participants is even more challenging, since their professional boundaries are more porous and politically contested.

The difficulties in defining ‘civil society’ are evident in Facebook’s self-regulatory attempts to create civil society partnerships. For instance, Facebook’s fact-checking program, which partnered with an independent journalists through the Poynter Institutes’ International Fact-Checking Network, drew extensive criticism for including US-based Daily Caller as a partner.¹³² This website has been accused by many left-leaning outlets of playing a key role in spreading disinformation and hate speech, arguably invalidating their position as a reliable fact-checker.¹³³ The point was even raised during CEO Mark Zuckerberg’s testimony before Congress.¹³⁴ Ultimately, the partnership was terminated in November 2019.¹³⁵ A comparable controversy occurred when another the Weekly Standard, another right-leaning fact-checking partner, rated an article from the left-leaning ThinkProgress as false.¹³⁶ Facebook’s widely-publicized Oversight Board also bears mention: though its membership has not yet been announced, with the exception Thomas Hughes, former executive director of free speech NGO Article 19,¹³⁷ they will likely face comparable controversies and contestations. Such cases illustrate the difficulty, amidst the ongoing decline in mainstream media and established knowledge institutions in general, of arriving at generally accepted definitions and configurations of ‘civil society’.

If European governments are to carry the flag for civil society research partnerships, then they would most likely face comparable accusations about bias and inclusiveness. Attempts could be made to devise clear and objective processes for accreditation, which, as in academia, could connect to existing self-regulatory bodies in the field of journalism such as the European Federation of Journalists. But even this approach may be at once too broad and/or too narrow: On the one hand, if the goal is indeed to limit disclosures of confidential data to a restricted group of trusted and accountable actors, such broad professional structures might be overly broad and enable abuse. And on the other hand, these professional structures could still be considered too restrictive since they still exclude a range of non-traditional watchdogs such as

citizen journalists, activists, influencers, bloggers or NGOs. In essence, what is at stake here is a tension between the practical need to restrict sensitive data access to vetted actors, and conceptions of the fourth estate and civil society as open and participatory institutions.

It is worth noting that the regulation of civil society research access is in a less advanced stage compared to user-facing disclaimers and government oversight; it is largely limited to soft law, and no binding legislation has yet been proposed in this space. It remains to be seen whether and how relevant legislators will take up their cause in upcoming rounds of legislation. Existing standards do suggest, however, a focus on vetted partnerships for privileged data access, as outlined above, as opposed to the creation of public datasets.

In sum, the push to create vetted research access programs has important advantages in enabling in-depth investigative work, but also has limitations. There are important trade-offs between the vetting of eligible researchers for sensitive data access, on the one hand, and the potential scale and diversity of such programs on the other hand. Forthcoming plans for regulated research access will require careful attention to institutional design so as to manage relevant trade-offs for such programs, and ensure their independence and credibility (real and perceived). Overall, such access programs may be well suited for in-depth academic research, but less so for real-time monitoring and reporting by journalists, activists and other non-academic actors in civil society.

4. The case for public disclosures

The above has shown that the emergent European framework for transparency in social media recommendations focuses on channelling information towards user-facing notices, government authorities, and civil society research partners. In this landscape, precious little information is publicly available. Firstly, independent observation of platforms' personalized recommendations is obstructed by their technical and legal design. Secondly, user-facing information, whilst public, is typically simplified and individualized. Thirdly, detailed data is accessible only to a privileged few in government and selective research partnerships.

A robust regime for public disclosures, I argue, would contribute not only to the first-order goal of making oversight of platforms more effective, but also to the second-order goal of making the governance system as a whole open more accountable to outside critique.¹³⁸ This section articulates these potential benefits associated with public disclosures, and suggests some starting points for their design and regulation. In particular, these recommendations focus on the high-level, real-time, and anonymized documentation of recommendation system outputs, audiences, and institutions.

4.1 The pros and cons of public disclosures

The main drawback of public records, compared to confidential disclosures such as data sharing partnerships and government auditing, is their limitations in sharing sensitive data: public

¹³⁸ This distinction between first- and second-order accountability is drawn from the work of Kaminski (2020, forthcoming). See also section 3.2 *supra*.

disclosures require a trustless design that pre-empts abuse by malicious actors. In the context of platform recommender systems, disclosures would need to contend with threats to user privacy, and, according to platforms, the integrity of the service (i.e. by enabling third parties to ‘game’ the algorithm).¹³⁹ Privacy-by-design techniques such as anonymization and differential privacy can go some way in mitigating these concerns. Nonetheless, publicity places hard limits on what can be disclosed and thus on the ultimate research utility of public disclosures.

However, public disclosures also have an important advantages over data partnerships in terms of increasing inclusiveness and broadening access. By simply making information publicly accessible, one side-steps the pitfalls of needing to define, accredit or otherwise institutionalize such factious and amorphous categories as ‘civil society’ or ‘academia’. Public disclosures would be available to every researcher with the time and interest – not the lucky few with the wherewithal and *bona fides* to engage in protracted negotiations, tender procedures or other forms of partnership arrangements. In particular, public disclosures open the doors to civil society actors that do not have an institutional means of accreditation, such as many independent journalists, NGOs, activists, and even sophisticated social media users themselves. In this way, public records offer the prospect of broader and more diverse uptake. Public access can also mitigate (perceived) threats to researchers’ independence, since it leaves its users free to pursue critical lines of research without needing to appease their benefactors -- be they platforms in as self-regulatory setting, or governments in a regulated setting. In this way, public records avoid many of the aforementioned problems with more institutionalized ‘partnerships’ models for civil society data access.

In this light, public records could be instrumental for purposes of real-time, high-level monitoring by media watchdogs such as journalists, activists, and NGOs. As discussed in Section 3.3, academics and others performing more in-depth research may be relatively better-served by privileged research partnerships. But even here it is worth considering that public records can offer a low-cost starting point for more in-depth research. For instance, public records may not suffice to conclusively demonstrate bias or discrimination in a recommendation algorithm, but at a minimum they could offer a starting point for such investigations by making visible disparate outcomes in the system’s recommendation outputs. Such evidence can then be used to request further clarification from the platform,¹⁴⁰ or investigate with more fine-grained tools, such as algorithmic auditing approaches,¹⁴¹ data surveys¹⁴² or GDPR data access requests.¹⁴³ In other words, public disclosures can serve as a first-warning system for more targeted efforts.

The open nature of public disclosures means that they can contribute to the second-order goal of holding the governance system *itself* accountable – i.e. Kaminski’s ideal of ‘second order accountability. As discussed, direct government regulation of social media recommendations is problematic from a fundamental rights perspective, since it applies opaque, technocratic methods to a highly contentious and politically sensitive field of governance. Even if

¹⁴³ Ausloos (2019).

multistakeholder perspectives from civil society or academia are incorporated in relevant oversight structures, such institutions run the risk of capture or bias. Releasing public information about content recommendation trends can help to critique such governance structures, and potentially even provide a starting point to identify more informal ‘jawboning’ relationships between platform power and public power.

A similar argument about second-order accountability may also apply to other platform *users*, insofar as they also co-determine harmful outcomes in recommender systems; for instance, the discovery that certain harmful channels are being disproportionately recommended towards children could warrant intervention from platforms or from governments, but one might also appeal to the responsibilities of the content provider in question. Public disclosures could ideally accelerate such media criticism by providing the necessary evidence of relevant recommendation trends. In sum, then, public records can assist civil society actors in holding not only platforms accountable but the governance system as a whole.

The benefits of public disclosures not only pertain to civil society, but may also spill over to government oversight. Since regulatory auditing and other investigative powers can be slow and costly to perform, publicly available data can cut down on such costs and help agencies to perform high-level monitoring and more efficiently prioritize their in-depth investigative efforts. Perhaps more important, however, is the point raised earlier that regulatory enforcement commonly relies on knowledge sourced from third parties, e.g. through consultation responses, complaints and referrals, and scientific literature.¹⁴⁴ In this light, public records can also help such third parties in monitoring social media recommendation systems and referring cases to competent government agencies. For instance, content providers who depend on platforms to disseminate their content, have incentives to monitor recommendations trends and check for potentially unlawful or anticompetitive patterns of discrimination. Public records could help them in such efforts, whereas government auditing places the onus entirely on the government itself.

Of course, all of these potential benefits related to public disclosures are still largely speculative, and their realization depends on whether they are implemented effectively so as to offer meaningful and accessible information. The operational and technical challenges in designing such a regime are not to be underestimated, and require further research and debate. The above is simply intended to articulate the distinct benefits of public disclosures, relative to narrower, institutional or user-facing approaches currently seen in Europe policy. These benefits are particularly salient, it is submitted, in the politically sensitive context of media governance, where scepticism of both market and public ordering are uniquely strong and the demands of broad and inclusive second-order accountability are therefore particularly urgent.

4.2 Designing public disclosures

So what information, specifically, should public disclosures offer? This is a complex question and it is outside the scope of this paper to offer an exhaustive answer. What follows is intended as exploratory, offering some starting points for further research and debate. In terms of format, public disclosures about recommender systems should include real-time, high-level,

¹⁴⁴ Kaminski (2020, forthcoming).

anonymized data access through public APIs and browser interfaces. In terms of content, public should include the documentation of recommendation outputs and their audiences; content-specific ranking decisions and other interventions by the operator's in recommendation system performance; and the organizational structures that control recommendation systems.

At the outset, an important starting point for existing best practices is public research APIs; As discussed in Section 2.3, many social media platforms already offer some level of real-time public access through these systems, and public regulation can draw and build on this prior art. As discussed, the functionality of these systems has been reduced significantly in recent years, nominally in response to privacy concerns resulting from the Cambridge Analytica scandal, but communications researchers argue that there is evidence of a disproportionate overreaction; for instance, Instagram's API has been shut down entirely. Binding public regulation could provide an impetus for (privacy-compliant) reform. To this end, policymakers can draw on expertise from communications science and adjacent fields, who have extensive experience with the design and usage of such public APIs.

As for the substance of public disclosures about content recommendations, one particularly salient aspect of their design which could be eligible for disclosure is content-specific ranking interventions. Platforms routinely intervene in recommender systems to alter specific outcomes, and such information could be eligible for disclosure. For instance, as mentioned in Section 2.2, Facebook currently partners with third-party fact-checkers to identify and downrank 'false headlines' from untrustworthy news sources. At present, it is not clear which headlines and sources in particular have been targeted under this regime. To evaluate the impact of these programs, and hold them accountable, comprehensive documentation of their decisions in a publicly accessible database could be valuable asset. This need not require full disclosure of the recommendation algorithm as a whole, which could undermine service integrity and enable gaming of these systems by spammers and other malicious actors.¹⁴⁵

A comparison with transparency for content removal decisions is instructive: for content removal, such comprehensive, content-level transparency has been denied because the content at issue is expected to be illegal or otherwise unsuitable for publication.¹⁴⁶ But this rationale does not apply when it comes to downranking decisions, which are expressly intended for content that platforms do *not* wish to remove. In this light, there appears to be no compelling reason why these downranking decisions should not be made public.

More broadly, it is worth investigating a best effort documentation requirement for other human-coded aspects of recommender algorithms. While many aspects of these algorithms are the product of complex machine-learning processes and therefore difficult to understand or explain even for their makers, other elements are human-coded and therefore easier to shed light on. One example is Facebook's Click-Gap initiative, which identifies low-quality based on the ratio of engagement on Facebook versus overall popularity across the web and thus

¹⁴⁵ e.g. Pasquale (2015).

¹⁴⁶ q.v. Heidi Tworek & Paddy Leerssen (2019), *An Analysis of Germany's NetzDG Law*, Transatlantic High Level Working Group on Content Moderation Online and Freedom of Expression. Available at:

Daphne Keller & Paddy Leerssen (2020, forthcoming), 'Facts and Where to Find Them: Empirical Research on Internet Platforms and Content Moderation', in: Persily N. and Tucker J (eds), *Social Media and Democracy: The State of the Field and Prospects for Reform* (Cambridge University Press).

serves to privilege more ‘mainstream’, established media outlets.¹⁴⁷ It is to Facebook’s credit that this update has been announced publicly.¹⁴⁸ But this is arguably the exception proving the more fundamental rule that conscious and explainable interventions are taking place, without any guarantee that these will necessarily be disclosed to the public. How else have platforms intervened to curate their recommendations? Indeed, as mentioned, YouTube boasts that it has made ‘hundreds’ of changes in 2018 alone, and it is unclear what these entail.¹⁴⁹ A legal requirement that such interventions in the algorithm must be disclosed systematically would help to prevent any important omissions and underwrite the credibility of platform disclosures. Of course, an important limitation is the risk of gaming in the algorithm, which may counsel against overly detailed specification of such changes: for instance if the specific keywords of an anti-spam blacklist were to be disclosed. Such defences may need to be evaluated on a case-by-case basis.

Secondly, it is important to keep in mind that public documentation of recommender systems need not focus exclusively on the *algorithm*. As discussed in Section 2.3, the algorithm as such cannot account fully for the effects and outcomes of recommender systems, and this requires reference to users’ and their activity. As argued by Rieder, Matamoroz-Fernandez, and Coromina argue, this can best be approached through the study of recommendation *outcomes*, in terms of what content is recommended, and to whom.¹⁵⁰ At present, social media recommendations are scarcely documented many important platforms. What are the most recommended pieces on content on YouTube or Instagram on a given day? In a given country? For a given age group? Some knowledge can be gleaned through independent observational methods, but, as discussed in Section 2.3, such methods have major operational challenges and necessarily produce incomplete and time-lagged datasets. Perhaps the most ambitious project in this space, Algotransparency.org, only covers YouTube recommendations made by 1000 selected channels and on a limited set of keywords.¹⁵¹ While such methods have already led to important insights about social media recommendations,¹⁵² far more comprehensive and systematic data could be published with the (regulated) cooperation of platforms themselves.¹⁵³ In essence, these output disclosures would serve to recreate, to some degree, the baseline publicity or ‘visibility’ that was inherent in mass media content distribution, and has been lost through personalization.¹⁵⁴ Even if the precise motives and decisions of our gatekeepers remains secret, at least the overall outcomes in terms of content distribution can then start to be observed.

Such public documentation of outputs would require strong safeguards against potential privacy harms. One important best practice is to limit disclosures to *publicly accessible* content -- as opposed to private content such as personal messages. But this is no panacea: even though such an API would not technically expand access to content, since the content is already public, it would still make the content searchable and measurable in new ways for third parties, which

¹⁵³ Cobbe & Singh (2019).

¹⁵⁴ Section 2.3 *supra*.

may raise privacy issues of its own.¹⁵⁵ In addition, therefore, public disclosures can also apply a *de minimis* rule: only content above a certain threshold of popularity could be included. Such a rule, already commonly seen in public research APIs, would limit the scope to the most important and visible content, and protect more sensitive activity from excessive monitoring. Potentially, content below this threshold could still be described with certain metadata, such as keywords, format, or language, to provide at least some basic insight into content flows without threatening the underlying content.

In designing public disclosures and their privacy safeguards, a relevant precedent is the experience with political advertising archives. Since 2018, major social media platforms have started developing such public archives to document political ads sold on their services.¹⁵⁶ Like the output documentations discussed in this paper, ad archives are similarly concerned with accountability in the algorithmically personalized distribution of content – albeit in the context of advertising rather than organic content. In ad archives, the data is disclosed through searchable web interfaces as well as through APIs, and audience data are anonymized and aggregated to avoid user privacy concerns. It should be noted that present self-regulatory implementations of this API have been criticized extensively, with researchers from Mozilla concluding that it was so bug-ridden as to be effectively unusable – creating a strong argument for regulation in this space.¹⁵⁷ But whilst their research utility is necessarily limited for understanding deeper questions about algorithmic sorting and bias, platform ad archives have already started to see regular use in real-time media monitoring and election coverage.¹⁵⁸ In this light, the experience with ad archives is instructive in two ways: First, it warns against an overreliance on self-regulation, given the critical failures of voluntary initiatives in this space. Second, despite their inadequate implementation in practice, ad archives do provide a basic conceptual blueprint for public transparency in algorithmic content distribution more broadly: real-time, anonymized, output-focused, and accessible to all.

A final point of attention for public disclosures is the organization behind recommender systems. This information is highly relevant to understand how gatekeeping decisions are made, and better outcomes can be ensured. Relevant issues in the context of recommender systems could include the location, demographic background, training, reward schemes, authorizations, and management systems in place for relevant workers. Comparable rules about organizational transparency can already be found in Germany's *Netzwerkdurchsetzungsgesetz*, which includes public documentation requirements for staffing and training of content removal operations related to this law.¹⁵⁹ More broadly, analogies to professional standards for transparency in journalistic organizations can be made.

4.3 Regulating public disclosures

As with other forms of transparency envisaged by European policymakers, public disclosures would likely require a binding legal basis in order to be effective. As discussed in Section 2.3, platforms have a poor track record in their voluntary transparency reforms, and even when delivering results may still be dogged by questions of credibility and independence.¹⁶⁰ Binding transparency obligations can help to address these concerns, and avoid a situation in which “only approved questions get answered”.¹⁶¹ In addition, public regulation of transparency can help to offset legal restrictions on data disclosure, e.g. by providing relevant exemptions under intellectual property law, or processing grounds under data protection law.

Due to platform dominance dynamics,¹⁶² size-based regulation is appropriate; targeting the most influential platforms addresses the major sources of risk while avoiding unnecessary or disproportionate burdens on smaller services. For instance, platform size could be defined based on revenue, user count, view count, or some combination of these metrics. Similar size-based regulation is already common in recent proposals for transparency in social media platforms, such as the EU Code of Practice, the US Honest Ads Act and Germany’s *Netzwerkdurchsetzungsgesetz*.

Given the complexity of designing privacy-compliant disclosure standards, rules for public disclosure will be difficult to capture exhaustively in one-size-fits-all legislation. Not only are social media recommendations technically complex, they are also heterogeneous; each has unique features (types of posts and formats, engagement metrics, et cetera) which may require unique forms of documentation and privacy safeguards. Therefore, a more feasible model may be to set broad disclosure standards in legislation, enforced by an independent public authority with the power to offer case-by-case guidance for particular platforms on what types of disclosures are necessary. Of course, such a body could also be instrumental in achieving other transparency goals in social media governance, such as those related to individual user notices and academic access frameworks.

An ongoing challenge regarding transparency regulation is finding an appropriate regulatory body to enforce these rules. Few national systems have developed agencies equipped to regulate social media, and leaving Member States to each develop their own institutional capacities risks not only a duplication of efforts but also the risk of regulatory and (potentially conflicting) standards. Transparency measures, like most information products, tend to benefit from economies of scale, which argue for uniform regulation at EU level. And yet, a (social) media regulator does not yet exist at the EU level. Indeed, member states have historically resisted the institution of a EU media regulator given the cultural and political sensitivities in this space.¹⁶³

Whilst developing a definitive division of competences is outside the scope of this paper, it is worth emphasizing that the regulation of transparency may in theory be separated from the substantive media policy. Under such an approach, the EU could put its full force behind ensuring access to information, whilst leaving national entities to make use of this data and thus

to realize the *substance* of domestic media policy.¹⁶⁴ This aligns with other proposals to institute government regulators focused on transparency. For instance, Ben Wagner and Lubos Kuklis envisage a “single European institution which could act as an auditing intermediary to ensure that the data provided to regulators by social media companies are accurate”.¹⁶⁵ Their proposal focuses on transparency towards other public regulators, such as data protection and competition authorities, but a similar vision could also apply to public disclosures and their use by a range of governance stakeholders in government and civil society.¹⁶⁶ The ideas about public disclosure regulation outlined in this paper should be considered alongside such broader debates about the need for dedicated regulatory structures for transparency for platforms in general, and social media in particular.

5. Conclusion

These are decisive times for the regulation of social media content recommendations. As the ‘techlash’ moves from the opinion page to public policy, and attempts at regulation begin in earnest, we see a variety of attempts to make social media platforms more transparent and accountable in their content recommendations. A governance landscape is emerging in which users, governments and civil society all have a role to play in holding these systems accountable, and realizing public values in our content feeds. Transparency rules are developing accordingly, with each stakeholder group being associated with its own types of disclosures. As recurring themes in ongoing policy, this paper has identified notices and disclaimers, government auditing, and data access partnerships.

A central component in ongoing efforts is the enabling of independent oversight by academia and civil society. This is laudable given the particular sensitivity of recommender governance from the perspective of democracy and fundamental rights. Yet this paper has cautioned against efforts which pursue transparency towards academia and civil society exclusively through institutionalized systems of privileged data access – seemingly the dominant approach currently pursued in Europe. Whilst such privileged access regimes have important advantages in enabling in-depth scholarly research, there may be low-hanging fruit of non-sensitive data that could find far wider uptake if made public without restriction. This paper has articulated how the real-time, low-cost, high-level access of public disclosures has distinct advantages for accountability in this space. A robust system of public disclosures not only allows for wider uptake and greater impact, but is essential to make the technocratic, expert-driven institutions of recommendation governance accountable to scrutiny and contestation by broader publics and interest groups.

This paper has also provided some starting points for the design and regulation of such public disclosures. Overall, it suggests a reorientation from ‘algorithms’ as objects of transparency towards a broader appreciation of the recommender system as a sociotechnical system and a focus on its outcomes. To this end, fruitful avenues for public disclosure include content-level detail on downranking decisions and other manual interventions in the recommender system,

as well as publicly searchable documentation of recommendation outputs for the most popular content. More generally, policymakers should explore existing best practices in the design and regulation of public research APIs. Given the complexity of these issues, the most promising way to regulate this would be through broad legislative standards, specified and enforced by an authorized regulator. This approach resonates with recent proposals in academia and government to install a dedicated transparency regulator for online platforms.

On a final note: This paper's discussion of transparency has hewed closely to the prevailing vision in European media governance of social media platforms as regulated oligopolists, whose dominance as online speech infrastructure is not to be replaced or contested but rather to be made more transparent and accountable to public interest considerations. It remains to be seen, given the vast power and complexity of these services and the sensitivity of the data they process, whether such a vision can be realized. We may well come to conclude that for-profit stewardship of these influential and opaque systems simply creates unacceptable and unmanageable risks to democracy; that meaningful transparency – much less accountability – in these circumstances is a false hope and that more fundamental changes to ownership or business models may be necessary, such as switching to cooperatively owned or publicly owned social media services.¹⁶⁷ But even for these more radical visions of online media governance, the arguments discussed in this paper may still hold some relevance: what will likely remain is the importance of broad and inclusive scrutiny of algorithmic gatekeeping and the distinct benefits of publicly accessible information to that end.
