Title: Hyperthermic intraperitoneal chemotherapy (HIPEC) for ovarian cancer recurrence: systematic review and meta-analysis

Corresponding author: Stefano Cianci

Dear Dr. Cianci,

The proof of your manuscript is attached on the following pages. Please read through the document carefully to check for accuracy, reference citations, and figures and tables. Please also be aware a professional copyeditor may have edited your manuscript to comply with the GS style requirements.

In addition to proofing the article, the following queries have arisen during the preparation of your paper. Please address the queries listed below by making the appropriate changes in the text.

If you have any other revisions that you would like to make, this will be the last opportunity to do so before the article is published. In particular, please ensure that the author's names and affiliations have been identified correctly, and the address of the corresponding author is correct.

If the changes cannot be easily described through email, please annotate this proof according to the annotation guidelines as detailed on the following page.

Query reference	Query	Author's response
Q1	Please note that alterations cannot be made after you have approved for publication, irrespective of whether it is Online First.	
Q2	Author SURNAMES (family names) have been highlighted in red - please check that these are correct.	
Q3	Please check affiliations, correspondence details.	
Q4	Please check acknowledgements section and confirm the conflict.	
Q5	Please note that the link with the doi number for the manuscript should be valid only after the whole issue is official published.	
Q6	Line 52: Please confirm does "supplement M1" refer to the supplement of ref 8.	
Q7	Abstract and Line 163: $I^2=54\%$ seems to be inconsistent with Figure 3. Please confirm.	
Q8	Please check and confirm all highlighted contents in the text.	

Once you have completed your revisions and/or addressed all the queries, or if you are satisfied with the proof in its existing form, please email: e-proof@amegroups.com.

**To ensure the timely publication of your article,
please respond within 48 hours.**

Making corrections

Use Adobe Reader – available for free from <http://get.adobe.com/reader/> – to open the attached document.

Background: Ovarian cancer is the first cause of death among gynecological malignancies with a high incidence of recurrence. Different treatment options are suitable to prolong the survival rate of these patients. Over the last years, one of the most intriguing methods, adopted in different oncologic centers worldwide, is the hyperthermic intraperitoneal chemotherapy (HIPEC).

Methods: A meta-analysis was performed to value the role of HIPEC for ovarian cancer recurrence. Search strategy was conducted with a combination of the following keywords: “ovarian recurrence, ovarian cancer recurrence, peritoneal cancer recurrence, ovarian recurrence AND HIPEC, secondary cytoreduction HIPEC”. Seven studies were selected for analysis.

Results: In women with recurrent ovarian cancer (ROC), the use of HIPEC in addition to cytoreductive surgery and chemotherapy significantly improved 1-year overall survival (OS) when compared to protocols without HIPEC (OR 2.42; 95% CI, 1.06–5.56; P=0.04; I²=4%). The improvement in OS was maintained significant also after 2, 3 and 5 years respectively (OR 3.33; 95% CI, 1.81–6.10; P<0.01; I²=0%), (OR 4.22; 95% CI, 2.07–8.60; P<0.01; I²=54%), (OR 5.17; 95% CI, 1.40–19.09; P=0.01; I²=82%).

Conclusions: HIPEC seems to have an effective role to prolong survival in patients affected by ROC.

Keywords: Ovarian cancer; hyperthermic intraperitoneal chemotherapy (HIPEC); loco-regional treatment; peritoneal carcinosis; recurrence; chemotherapy

1 Introduction

2 Ovarian cancer is the first cause of death among gynecologic
3 malignancies (1). The surgical treatment represents the
4 first option with the aim to achieve the optimal debulking,
5 followed by systemic chemotherapy (2). However, even
6 achieving complete cytoreduction the majority of patients
7 at stage III-IV develops a recurrence in a few years (3). To
8 date, different treatment options are suitable to prolong
9 the survival rate of these patients as monoclonal antibodies
10

and targeted therapies as bevacizumab or PARP inhibitors, 11
and biological therapy. However, the results obtained are 12
still partial and not completely effective (4). One of the 13
most attractive methods, currently available in several 14
oncologic centers, is the hyperthermic intraperitoneal 15
chemotherapy (HIPEC). It is an effective method to 16
deliver antitumor drugs directly in the abdomen at the 17
time of surgery, moreover the hyperthermia addition 18
allowed to enhance the tissue absorption, that is different 19
depending on different factors as drugs administered and 20

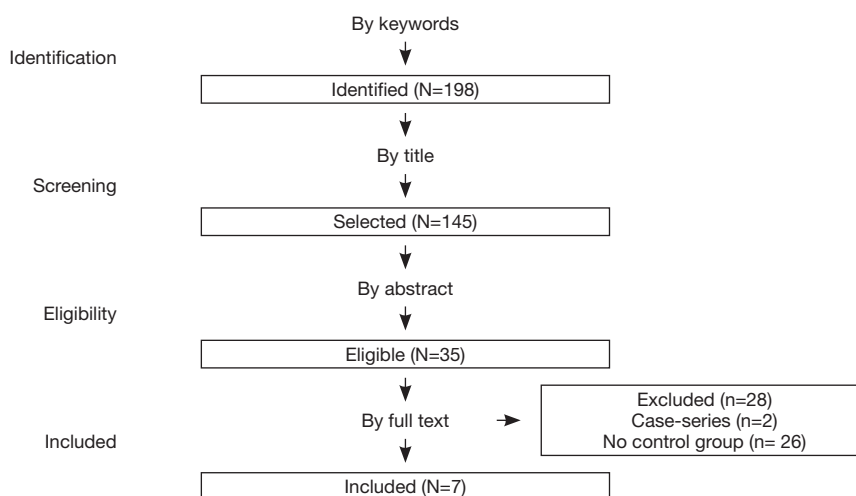

Figure 1 Study selection search strategy.

21 temperature reached, and consequently the cytotoxic action
 22 of chemotherapeutic drugs that reach the maximum effect
 23 between 40 and 43 centigrade (5). HIPEC treatment is
 24 adopted in different kind of cancer as gastric, colorectal and
 25 primary peritoneal carcinosis. For ovarian cancer treatment,
 26 this technique, was for a long time debated, however after
 27 the results of a randomized trial by van Driel *et al.* (6)
 28 HIPEC was inserted in NCCN guidelines as an optional
 29 treatment for interval debulking surgery (NCCN clinical
 30 practice guidelines Version 1.2019–March 8, 2019 OV-2).

31 The role of HIPEC in treatment of primary ovarian
 32 cancer (POC) and recurrent ovarian cancer (ROC) is
 33 actually under study. Different series could be found
 34 in literature, and different on-going trials (HORSE
 35 NCT01539785, CHORINE NCT01628380, HIPOVA-
 36 01NCT03220932). However, the heterogeneity of the
 37 population and the different drugs administered did not
 38 allow to draw definitive conclusions.

39 The present study aims to explore whether the addition
 40 of HIPEC in ROC patients could improve clinical outcome.
 41 A systematic review of the literature and meta-analysis was
 42 performed. We present the following article in accordance
 43 with the PRISMA reporting checklist (available at <http://dx.doi.org/10.21037/gs-20-335>).

46 **Methods**

47
 48 We performed our meta-analysis following the Preferred
 49 Reporting Items for Systematic reviews and Meta-Analyses
 50 (PRISMA) (7) and the Meta-analysis Of Observational

51 Studies in Epidemiology (MOOSE) statement guidelines
 52 (supplement M1) (8). The research protocol was designed
 53 a priori, defining methods for literature search, article
 54 examination and inclusion criteria, data extraction and
 55 analysis.

56 **Search strategy**

57
 58 Searches were performed using PubMed, Scopus, and
 59 Cochrane from the inception of all databases until March
 60 2020. We searched the databases with a combination of
 61 the following keywords and Medical Subject Headings
 62 (MeSHs): “ovarian recurrence, ovarian cancer recurrence,
 63 peritoneal cancer recurrence, ovarian recurrence AND
 64 HIPEC, secondary cytoreduction HIPEC”, without
 65 restricting our search geographically or linguistically. The
 66 PRISMA based flow-diagram in *Figure 1* depicts our search
 67 strategy. If it was necessary, we obtained unpublished data
 68 by contacting authors of the original papers whenever
 69 methodology indicated that further outcome data were
 70 recorded.

71 **Study selection and outcomes**

72
 73 We included all studies with more than ten patients
 74 comparing women with a diagnosed first recurrent ovarian
 75 epithelial cancer treated with cytoreductive surgery and
 76 HIPEC protocols versus cytoreductive surgery without
 77 HIPEC.

78
 79 Moreover, we excluded commentaries, editorials, reviews,
 80

81 letters and abstracts.

82 Two authors (C.R. and G.R.) reviewed and classified all
83 abstracts independently. The agreement about potential
84 relevance was reached by consensus of the researchers;
85 the same two authors were able to obtain full-text copies
86 of those papers and separately extracted relevant data
87 regarding study characteristics and outcomes. Later, the two
88 reviewers discussed all the inconsistencies; and, if needed, a
89 third author (S.C.) decided if no consensus was reached.

90 If more than one study was published on the same
91 cohort and with the same identical endpoints, population
92 overlapping was avoided considering only the article with
93 the most comprehensive information.

94 Two different authors (G.R. and A.S.) assessed the risk
95 of bias of all studies included in this review. The Modified
96 Newcastle-Ottawa Scale for case-control studies was used
97 for observational studies; The Cochrane risk of bias tool
98 was used to assess the risk of the included RCTs. In case
99 of disagreement, a third reviewer (S.C.) judged. Potential
100 publication bias was assessed by the Egger's test. The
101 articles remained were then filtered according with the
102 availability for meta-analysis.

103 The primary outcome of the meta-analysis was the one-
104 year overall survival (OS). Secondary outcomes explored
105 were the two, three and five-year OS.

106

107

108 *Statistical analysis*

109 Pooled odds ratios (ORs) and 95% confidence interval
110 (CI) were calculated using the Der Simonian and Laird
111 random-effects model. We quantified heterogeneity to
112 describe the percentage of total variation across studies
113 attributable to heterogeneity rather than by chance by
114 means of Higgins I^2 -statistic. In our meta-analysis, I^2 -values
115 of 25%, 50% and 75% corresponded to cut-off points for
116 low, moderate and high degrees of heterogeneity. We used
117 Review Manager 5.3 (The Nordic Cochrane Centre 2014,
118 Copenhagen, Denmark) and Stata 14.1 (Stata corp., College
119 Station, TX, 2013) to analyze data. For studies in which
120 the corresponding results were not shown, the Engauge
121 Digitizer v.4.1 software was used to extract survival data
122 obtained from the Kaplan-Meier curves.

123

124

125 **Results**

126 *Study selection and study characteristics*

127

128 We identified and assessed 198 initial studies (*Figure 1*). Of
129 those, 26 studies were considered pertinent for the study

130 criteria, seven of them were considered available for meta-
131 analysis. Depicts summary characteristics of included studies
132 *Table 1*. Those seven studies regarded women with ROC
133 treated with or without HIPEC. Concerning the included
134 studies, they were conducted in France, Spain, Italy, Israel,
135 Brazil and Egypt between 2009 and 2019. We identified one
136 RCT (9), one prospective (10) and five retrospective case-
137 control studies (11-15).

138 Drugs used for HIPEC chemotherapy, as well as
139 temperature and duration, were described in every study.
140 The most used HIPEC chemotherapy was cisplatin. It was
141 used in combination with other agents such as doxorubicin,
142 mitomycin-C or paclitaxel. One study used carboplatin
143 in combination with paclitaxel or doxorubicin (12). One
144 research involved the use of oxaliplatin alone (10). Mean
145 temperature for HIPEC was between 41–41.5 °C.

146 Quality assessment of studies, with the Newcastle-
147 Ottawa Scale and the Cochrane Tool, showed an overall
148 good score regarding the selection and comparability of the
149 study groups, as well as for ascertainment of the outcomes
150 of interest in case-control studies. For the RCT (9) quality
151 assessment revealed a low risk of bias in 5/7 analyzed
152 elements (*Tables S1,S2*).

153 *Synthesis of the results*

154 The data are summarized in *Table 2*. In women with ROC,
155 the use of HIPEC in addition to cytoreductive surgery
156 and chemotherapy significantly improved 1-year OS when
157 compared to protocols without HIPEC (OR 2.42; 95% CI,
158 1.06–5.56; $P=0.04$; $I^2=4\%$) (*Figure 2*). The improvement
159 in OS was maintained significant also after 2, 3 and 5 years
160 respectively (OR 3.33; 95% CI, 1.81–6.10; $P<0.01$; $I^2=0\%$),
161 (OR 4.22; 95% CI, 2.07–8.60; $P<0.01$; $I^2=54\%$), (OR 5.17;
162 95% CI, 1.40–19.09; $P=0.01$; $I^2=82\%$) (*Figure 3*). For the
163 primary outcome, between-studies heterogeneity was
164 referred as low.

165 *Publication bias*

166 Assessment of publication bias using the Egger's regression
167 model showed that publication bias for small studies was not
168 present for 1-year ($P=0.22$), 2-year ($P=0.38$), 3-year ($P=0.51$)
169 and 5-year ($P=0.10$) OS.

170 *Perioperative mortality and complications*

171 Regarding perioperative mortality between 1 and 30 days
172

1 year overall survival

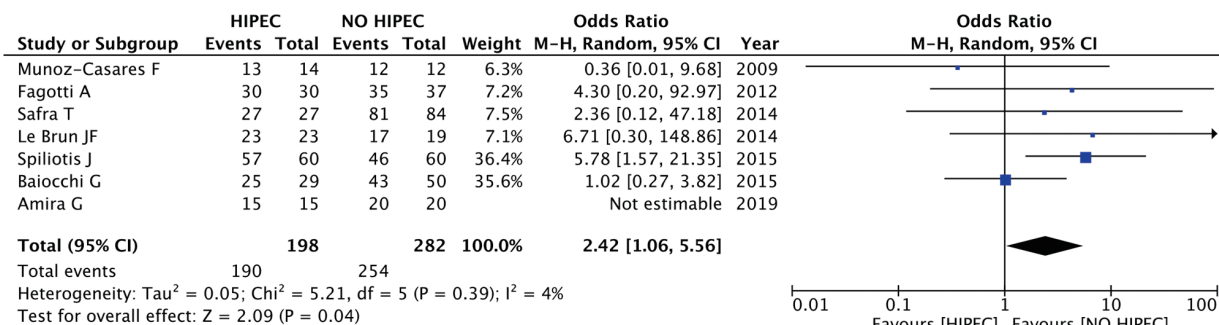

Figure 2 One-year OS forest plot

178 after surgery plus HIPEC, reported rates were 4%
 179 in Baiocchi *et al.* (13), 13.3% in Amira *et al.* (14) No
 180 perioperative deaths were reported in 4 studies (9-12). Post-
 181 surgical hospital stays ranged between 5.1 and 25.8 days,
 182 with a 15.9 day calculated mean.

183 Common adverse reactions after intervention were
 184 reported by two studies without distinction between cases
 185 and controls (11,14). Amira *et al.* (14) reported a 53% of
 186 chemotherapy-related toxicity, followed by pulmonary
 187 complications (33%) need for mechanical ventilation; 13%
 188 chest infections). Almost 20% of women experienced wound
 189 infection after surgery. The most common side effect
 190 reported by Safra *et al.* (11) was related to chemotherapy,
 191 with mild nausea which was successfully treated by anti-
 192 emetics. No complications were reported in other studies
 193 included in quantitative analysis.

194

195 Discussion

196
 197 The role of HIPEC for ovarian cancer treatment, seems to
 198 furnish clear benefits. Even if the literature remains partially
 199 controversial (16).

200 The randomized trial conducted by van Driel *et al.* (6)
 201 demonstrated the effective role of HIPEC to prolong the
 202 survival rate of patients with diagnose of POC submitted to
 203 interval debulking surgery. However, the present study was
 204 focused on a different subset of patients affected by ROC.
 205 Actually, no concrete randomized studies are available
 206 regarding this patient's subset. An Italian randomized trial
 207 HORSE (NCT01539785) is actually in a follow-up phase,
 208 awaiting the results.

209 A randomized trial by Spiliotis *et al.* was published (9);
 210 however, it was not sufficient to furnish concrete
 211 conclusions about the usefulness of HIPEC for ROC.

212 Considering the most relevant literature available about
 213 HIPEC and ROC, in a study by Petrillo *et al.* (17), a long-
 214 term follow-up series of patients with ROC submitted to
 215 secondary cytoreductive surgery and HIPEC was studied
 216 with a median follow up of 5 and 7 years. The results of the
 217 study suggested the benefits of HIPEC in terms of long-
 218 term survival rates.

219 Considering our meta-analysis, the results seem very
 220 encouraging since the OS at 1, 2, 3 and 5 years were
 221 statistically significant in favor of HIPEC groups.
 222 However, the limits are related to the heterogeneity of
 223 treatments in terms of drugs used and protocol adopted for
 224 HIPEC. Moreover, surgical treatment and the achievement
 225 of complete debulking remain a fundamental step. Another
 226 limitation of our quantitative analysis is related to the
 227 design of included studies; the majority were retrospective
 228 case-control studies and only one research was a prospective
 229 randomized trial. Moreover, the small number of samples in
 230 selected studies should be taken into account.

231 However even, acknowledging such limitations, the
 232 results of the meta-analysis were statistically significant
 233 in favor of HIPEC, especially for the two years follow-up
 234 (P<0.0001).

235 In a similar meta-analysis published in 2015 by Huo
 236 *et al.* (18) the authors obtained similar conclusions.
 237 Considering this aspect, the accordance of two different
 238 studies performed in different periods reinforce the
 239 scientific evidence.

240 Some relevant studies reported an average of 60 months
 241 survival rate for selected patients submitted to secondary
 242 cytoreductive surgery for ovarian cancer (19,20); these data
 243 are in line with our results.

244 The complexity of surgery can be related to the disease
 245 dissemination influencing the surgical invasiveness and the

2 year overall survival

3 year overall survival

5 year overall survival

Figure 3 Two, 3, 5 years OS forest plot.

246 risk of complications. Considering that even if the HIPEC
 247 treatment seems to be safe in terms of intra-operative and
 248 post-operative complications; however, it represents an
 249 additional risk, especially related with bowel anastomosis
 250 leakage, often related to the number of surgical procedures
 251 performed. The surgery for ROC could be often less
 252 invasive than primary surgery (21,22), especially for isolated
 253 abdominal relapse (23), if compared with POC. In this
 254 context, the HIPEC addition during ROC, especially for
 255 isolated relapse, could reduce the risk of complications.

256 However, the ROC could not be the only time to
 257 perform HIPEC, in fact, as demonstrated in some studies,

the HIPEC procedures can be administered even more
 times during the disease history (24).

Another essential aspect that should be acknowledged
 is the approach adopted for HIPEC administration. In a
 recent study by Petrillo *et al.* (25), the authors completed
 a pharmacokinetic study in which they demonstrated that
 the HIPEC drugs absorption was statistically significant
 enhanced in patients underwent laparoscopic procedures.
 Probably it was related to the enhanced intra-abdominal
 pressure and the reduction of pressure dispersion warranted
 by laparoscopy. However, considering that the endoscopic
 approach is not always feasible, especially for ovarian cancer

270 treatment, some novel technologies are available and in an
271 experimental phase (26-28).

272

273 Conclusions

274

275 The present systematic review and meta-analysis suggest
276 that the HIPEC addition during cytoreductive surgery for
277 ROC treatment can give a survival rate benefit that was
278 recorded even after five years of follow-up.

279 However, the heterogeneity of the series studied cannot
280 allow providing definitive conclusions. To date, several
281 randomized trials are on-going with the aim to give a
282 definitive answer to this aspect.

Supplementary

Table S1 Quality scores of the case-control studies included in the meta-analysis, assessed by the Newcastle-Ottawa scale

Author	Year	Outcome	Selection				Comparability		Exposure			Overall quality
			Case definition	Representative-ness of the cases	Selection of controls	Definition of controls	Control for the most important factor	Control for any additional factors	Ascertainment of exposure	Same method for cases and controls	Non-response rate	
Safra T	2014	Overall survival	*	*	0	0	*	*	*	*	0	6
Fagotti A	2012	Overall survival	*	*	*	*	*	*	*	*	0	8
Baiocchi G	2016	Overall survival	*	*	*	*	*	*	0	*	*	8
Muñoz-Casares FC	2009	Overall survival	*	*	0	0	*	*	0	*	0	5
Le Brun JF	2014	Overall survival	*	*	0	*	*	*	*	*	*	8

Newcastle-Ottawa scale for assessment of quality of included studies - Case-control studies (each asterisk represents if individual criterion within the subsection was fulfilled).

Table S2 Quality assessment for RCTs (method: Cochrane collaboration's tool for assessing risk of bias)

Author	Selection bias		Performance bias	Detection bias	Attrition bias	Reporting bias	Other bias	Total
	Random sequence generation	Allocation concealment	Binding of participant and personnel	Blinding of outcome assessment	Incomplete outcome data	Selective reporting	Anything else, ideally prespecified	Low on risk of bias
Spiliotis J	Low	Low	Low	Low	Unclear	Unclear	Low	5/7

RCTs, randomized controlled trials.
