**ABSTRACT**

**Objectives:** The obstetric conjugate (OC) represents the shortest anteroposterior diameter of the birth canal and it reflects the capacity of the pelvic inlet to allow the passage and the engagement of the fetal head. The antepartum evaluation of this parameter may be attempted at digital examination to predict the risk of cephalopelvic disproportion but the accuracy of clinical pelvimetry is notoriously poor. The aim of our study was to describe the sonographic measurement of the OC at transabdominal 2D-ultrasound

**Methods:** This is a prospective cohort study conducted at a tertiary University hospital. A non-consecutive series of pregnant women with uncomplicated singleton pregnancies attending at the antenatal clinic for routine booking from 34 weeks of gestation onward were included. The ultrasound probe was longitudinally placed above the level of the symphysis and the interpubic fibrocartilaginous disk was visualized. Then the promontory was identified as the most prominent segment of the sacral vertebral column. The OC was measured as the distance between the inner edge of the interpubic disk and the promontory. The intra- and interobserver repeatability of this measurement was calculated using the intraclass correlation coefficient (ICC) and the Bland-Altman method.

**Results:** 119 women were considered eligible for the study purpose. Overall, 111/119 (93.3%) women were included in the analysis with a median gestational age of 36.0(35.0-37.0) weeks. The mean OC measurement was 11.4±0.93 mm for the first operator and 11.4±0.91 mm for the second operator. The overall interobserver ICC was 0.95(95% CI 0.92-0.96) while the overall intraobserver ICC was 0.97(95%CI 0.96-0.98). The degree of reliability was also analyzed for women with a BMI  $\geq 30$  and for women with a gestational age  $\geq 37$  weeks. The inter and intra-observer ICCs were respectively 0.97(95% CI 0.90-0.98) and 0.98(0.95-0.99) in the former group and 0.96(95% CI 0.93-0.98) and 0.97(95%CI 0.95-0.98) in the latter one

**Conclusion:** Our study demonstrated that among pregnant women at term gestation the sonographic measurement of the OC is feasible and reproducible

## 86 INTRODUCTION

87 Pelvimetry is the biometric evaluation of the birth canal and it has been historically used to identify  
88 those women at higher risk for labor dystocia due to cephalo-pelvic disproportion. The clinical  
89 pelvimetry is based on the measurement of the main diameters of maternal pelvis either at external  
90 or at internal digital examination. Among them the obstetric conjugate which is the linear distance  
91 between the sacral promontory and the internal edge of the pubic bone may be assessed at vaginal  
92 examination<sup>1</sup>. This is the shortest anteroposterior diameter of the birth canal and it is believed to  
93 reflect the capacity of the pelvic inlet to allow the passage and the engagement of the fetal head<sup>2</sup>.  
94 Traditionally it is reported that the digital palpation of the promontory is suspected to herald a  
95 narrower inlet of the birth canal and to anticipate the occurrence of cephalopelvic disproportion<sup>3</sup>.

96 However, the digital measurement of the obstetric conjugate at vaginal examination and the clinical  
97 prediction of a narrow pelvic inlet is considered to be inaccurate and of limited reproducibility<sup>1,4</sup>.  
98 Also, the combination of vaginal findings with more objective maternal anthropometric parameters  
99 such as height, BMI, shoulder diameter, lower limbs length has been investigated and has shown to  
100 yield a poor sensibility and specificity in predicting the risk of obstructed labor<sup>5-7</sup>.

101 The use of imaging techniques (X-ray, MRI and CT) has been claimed to provide accurate  
102 measurements of pelvic diameters with a low intra and inter-observer variability<sup>8-10</sup>. However, the  
103 routine use of imaging techniques in the antepartum assessment of pelvic capacity is highly  
104 controversial and not supported by rigorous randomized controlled trials. A recent Cochrane review  
105 found that women who undergo an X-ray pelvimetry may be more likely to have a CS and concluded  
106 that there is not enough evidence to support the use of X-ray pelvimetry for deciding on the mode of  
107 delivery<sup>11</sup>. Lastly, concerns have arisen regarding the fetal risks from radiation exposure and cost-  
108 benefit analysis especially in low-resource settings<sup>8,12</sup>.

109 The assessment of the pelvic cavity size although not advisable on a routine basis might be of clinical  
110 utility especially among women who seem at higher risk of cephalopelvic disproportion such as those  
111 carrying a large for gestational fetuses or requiring a trial of labor after CS (TOLAC)<sup>13,14</sup>.

112 A pioneer study had proposed to use of 2-Dimensional (2D) transabdominal ultrasound for measuring  
113 the OC and predicting of the risk of CD due to obstructed labor<sup>15</sup>. More recently some Authors have  
114 reported the antepartum assessment of the OC thanks to the use of the tomography<sup>16</sup>. However, the  
115 available data is still limited and the reliability of the sonographic assessment of the OC is still to be  
116 proven.

117 The aim of our study was to describe the sonographic measurement of the OC at transabdominal 2D-  
118 ultrasound and to assess its reproducibility in a group of women close to term of gestation.

119

120

## 121 **METHODS**

### 122 **Study design and population study**

123 This is a prospective cohort study conducted at the tertiary care Maternity Hospital of the University  
124 of Parma from December 2020 to February 2021.

125 A non-consecutive series of pregnant women with uncomplicated singleton pregnancies attending at  
126 the antenatal clinic for routine booking from 34 weeks of gestation onward were considered eligible  
127 for the study purposes.

128 Inclusion criteria were: age between 18 and 45 years, singleton gestation with fetus in cephalic  
129 presentation, absence of indications to scheduled CS delivery.

130 Exclusion criteria were: low lying placenta, uterine fibroids, history of pelvic bone fractures.

131 With the woman lying supine with a moderately repleted bladder, the ultrasound probe was  
132 longitudinally placed on maternal abdomen above the level of the symphysis. This structure was  
133 sonographically visualized as a hypoechoic oval with an internal echogenic core representing the  
134 interpubic fibrocartilaginous disk. Then the promontory was identified as the most prominent  
135 segment of the sacral vertebral column. The OC was measured as the distance between the inner edge  
136 of the interpubic disk and the promontory (fig 1).

137 For the study purpose two ultrasound machines equipped with a transabdominal multifrequency 2D  
138 convex transducer were employed. The standard 3<sup>rd</sup> trimester setting was used for each examination.  
139 In order to have the widest view of the maternal pelvis, the ultrasound probe sector was increased to  
140 a maximum of 120° while the probe frequency was turned down at 2.5 mHZ to increase the  
141 penetration of the ultrasound beam.

142 To assess the intra- and interobserver reproducibility of the sonographic measurements, all the  
143 ultrasound examinations were performed twice by the operator 1 (N.V.) and once by operator 2

1  
2  
3 144 (C.L.). Operator 1 had >10 years' experience in prenatal ultrasound while operator 2 was a resident  
4  
5 145 with <2 years' experience.  
6  
7

8 146 The ultrasound measurements of the OC were not used for clinical purposes and the clinicians who  
9  
10 147 were in charge of the management of the women were blinded to the values obtained by the study  
11 148 investigators  
12  
13

14 149 Clinical data regarding pregnancy, labor and neonatal outcomes were obtained in all pregnancies  
15  
16 150 from medical records.  
17  
18

### 19 151 **Statistical analysis**

20  
21  
22 152 The Shapiro-Wilk test was used to assess the normality of the distribution of the data. Mean±Standard  
23 153 Deviation (SD) or median [IQR] were used to describe continuous data normally and non-normally  
24  
25 154 distributed, respectively. The agreement between the two examiners and between the two  
26  
27 155 measurements made by the first examiner, were expressed using intraclass correlation coefficients  
28  
29 156 (ICCs) for single measurements and 95% confidence intervals (CI). The systematic differences were  
30 157 also computed by means of the paired Student t test. As far as the repeatability is concerned, in order  
31  
32 158 to assess systematic bias between intra-, interobserver measurements, differences between values  
33  
34 159 were plotted against means of the measurements as described by Bland and Altman and the limits of  
35  
36 160 agreement were evaluated together with their 95% CI<sup>17,18</sup>. A p-value<0.05 was considered as  
37 161 statistically significant. Statistical analysis was performed by using SPSS 21.0.  
38  
39

### 40 162 **Ethical approval**

41  
42  
43 163 The study was approved by our local Ethics committee (270/2018/OSS/AOUPR, 24/04/2018).  
44  
45

### 46 164 **RESULTS**

47  
48  
49 165 During the study period, 119 women were considered eligible for the study purpose. In five cases the  
50  
51 166 sacral promontory was not clearly visualized due to shadowing cast from the engaged fetal head, one  
52 167 case was excluded due to a previous trauma involving the sacrum, while in the remaining two cases  
53  
54 168 the correct visualization of the most prominent part of the inner symphysis surface was not possible  
55  
56 169 due to diastasis (figure 2). Overall, 111/119 (93.3%) women at a median gestational age of 36.0 (35.0-  
57 170 37.0) weeks were included in the final analysis. The main characteristics of the study population are  
58  
59 171 summarized in Table 1  
60

1  
2  
3 172 The median maternal age was 33.0 [29.0-36.5], the median OC measurement was 11.4±0.93 mm for  
4  
5 173 the first operator and 11.4±0.91 mm for the second operator (Table 1). No significant relationship  
6  
7 174 was found between the differences of the mean values of the two measurements made twice by the  
8  
9 175 same operator (intraobserver) (p=0.79) and of the measurements made by the first and the second  
10 176 operators (interobserver) (p=0.62) (Table 2).

11  
12  
13 177 The overall interobserver ICC was 0.95(95% CI 0.92-0.96) while the overall intraobserver ICC was  
14  
15 178 0.97(95%CI 0.96-0.98); the Bland-Altman graphs demonstrate the degree of intra and inter-observer  
16  
17 179 concordance (Figure 3 a and b). The degree of reliability was also analyzed for women with a BMI  
18 180  $\geq 30$  at the enrollment and for those with a gestational age  $\geq 37$  weeks. The inter and intra-observer  
19  
20 181 ICCs were, respectively, 0.97(95% CI 0.90-0.98) and 0.98(0.95-0.99) for the first group and  
21  
22 182 0.96(95% CI 0.93-0.98) and 0.97 (95%CI 0.95-0.98) for the latter group thus indicating a substantial  
23 183 good degree of reliability (Table 2).

## 24 25 26 184 **DISCUSSION**

27  
28  
29 185 Our study demonstrated that among pregnant women close to term gestation the measurement of the  
30  
31 186 OC at TA 2D-ultrasound is feasible and reproducible. In particular, we found that the sonographic  
32  
33 187 OC had an overall high intra-observer and interobserver agreement; and that this was not impacted  
34 188 by the more advanced gestational age and increased maternal BMI. We have also provided original  
35  
36 189 data on the ultrasound measurement of the OC in a population of singleton pregnancies > 34 weeks  
37  
38 190 and this may offer the opportunity to build specific references charts.

39  
40  
41 191 The development of the ultrasound technique has enormously improved our ability to recognize the  
42 192 bony structures of the birth canal.

43  
44  
45 193 Compared to X-ray and MRI pelvimetry the ultrasound evaluation of the OC has many advantages  
46  
47 194 as fetal safety, low costs and the possibility to be performed at bedside evaluation also in low-  
48  
49 195 resources settings<sup>19,20</sup>.

50  
51  
52 196 While pubic symphysis may be easily visualized at both transperineal and transabdominal  
53 197 ultrasound<sup>21-22</sup>, the sonographic demonstration of the sacrum promontory is much more challenging  
54  
55 198 especially at advanced gestational ages when the interposition of the fetal head may not allow the  
56  
57 199 correct visualization of this structure. In our series we found that if transabdominal ultrasound is  
58  
59 200 performed between 34-36 weeks the promontory can be visualized in most cases. In addition, using  
60

1  
2  
3 201 our approach the whole inner margin of the pubic symphysis is visualized leading to the correct  
4  
5 202 measurement of the OC.

6  
7  
8 203 To our knowledge, Katanozaka et al.<sup>15</sup> firstly described the measurement of the OC by means of  
9  
10 204 transabdominal ultrasound. More specifically, they investigated 209 women and found that the OC  
11 205 assessed by ultrasound normally ranged from 10.7 to 15.1 cm; those women with an OC <12 cm had  
12  
13 206 a higher rate of Cesarean Section due to labor dystocia compare to those women with an OC >12 cm  
14  
15 207 (50% vs 5.7% p<0.001). Interestingly, they also reported a positive correlation between ultrasonic  
16  
17 208 OC and X-Ray OC ( $r = 0.91$ ;  $p < .0001$ ) thus concluding that ultrasonic OC measurement is a safe  
18 209 and useful procedure in the prediction of dystocia. The most important limit of this study was that the  
19  
20 210 authors measured the antero-posterior diameter between the upper bone of the pubic symphysis and  
21  
22 211 the promontory of the sacrum, and this was improperly defined OC while it corresponded to the  
23 212 anatomic conjugate<sup>1</sup>. Due to the technical limitations of the ultrasound equipment that were available  
24  
25 213 at that time they were not able to visualize the most prominent part of the inner symphysis surface  
26  
27 214 which is one of the reference landmarks for the correct measurement OC. Furthermore, the authors  
28  
29 215 did not evaluate the inter and intraobserver agreement of their method in the sonographic assessment  
30 216 of the conjugate.

31  
32  
33 217 Beside this single report on the ultrasound evaluation of the OC, the assessment of other anatomical  
34  
35 218 landmarks for the evaluation of maternal pelvimetry has been attempted with the aim to predict the  
36  
37 219 risk of obstructed labor.

38  
39 220 Some Authors have reported the sonographic measurement of the pubic arch angle (PAA) at  
40  
41 221 transperineal 2D ultrasound and found that its width was inversely correlated with the risk of cesarean  
42  
43 222 of delivery in a group of women with prolonged 2<sup>nd</sup> stage of labor<sup>22</sup>. A significant positive correlation  
44  
45 223 was found by the same research group between the 2D sonographic measurement of the PAA and the  
46  
47 224 OC measured on three-dimensional computed tomography<sup>23</sup>. In 2015, a study by Ghi et al.<sup>24</sup>  
48 225 demonstrated the reproducibility of a new 3-D transperineal ultrasound technique supported by a  
49  
50 226 specific contrast-enhancing technique in the measurement of the Subpubic arch angle (SPA) among  
51  
52 227 a group of women at term gestation. Subsequent studies evaluated the usefulness of the antenatal  
53 228 assessment of this parameter in predicting the likelihood of an obstetric intervention. Youssef et al.<sup>25</sup>  
54  
55 229 among 145 nulliparous with uncomplicated pregnancies demonstrated that the SPA was significantly  
56  
57 230 narrower in the women submitted to obstetric intervention compared with those undergoing  
58  
59 231 spontaneous vaginal delivery ( $116.8 \pm 10.3^\circ$  vs.  $123.7 \pm 9.6^\circ$ ,  $p < 0.01$ ). Another study on 368  
60

1  
2  
3 232 nulliparous women at term found that a narrow SPA was associated with a higher risk of persistent  
4  
5 233 Occiput Posterior position at delivery and of operative delivery also<sup>26</sup>.

6  
7  
8 234 Similarly, the clinical usefulness of antepartum US pelvimetry has been assessed in particular  
9  
10 235 conditions such as in women carrying a suspected LGA fetus.

11  
12 236 In 2017 a study on 129 nulliparous at higher risk of having a LGA fetus found that the SPA was  
13  
14 237 narrower among those women who underwent to unplanned obstetric intervention (vacuum delivery  
15  
16 238 or cesarean section) due to prolonged or arrested labor compared with those who achieved a  
17  
18 239 spontaneous vaginal delivery (107.9 13.4 vs 120.7 9.4 p<0.001); in addition, they found a smaller  
19 240 SPA to be independent predictor of operative delivery (OR 1.09 95%CI 1.05-1.13)<sup>27</sup>.

20  
21  
22 241 The clinical usefulness of antepartum pelvimetry in anticipating the labor outcome has been  
23  
24 242 suggested also by the use of non-ultrasound imaging techniques.

25  
26  
27 243 A randomised controlled trial of magnetic-resonance pelvimetry on 235 women with breech  
28  
29 244 presentation at term showed that the emergency cesarean-section rate was significantly lower in the  
30 245 study group (pelvimetry results were reported to the responsible obstetricians, who used them as the  
31  
32 246 basis for decisions on whether to schedule elective cesarean or trial of labor) than in the control group  
33  
34 247 (pelvimetry results were not disclosed until 8 weeks post partum, and decisions about obstetric  
35 248 management were made on the basis of clinical factors)<sup>28</sup>. More recently, a large study conducted in  
36  
37 249 the Frankfurt maternity on 365 women with fetuses in breech presentation has demonstrated that an  
38  
39 250 increasing OC assessed by MRI pelvimetry was significantly associated with an increasing rate of  
40  
41 251 successful vaginal deliveries; based on this data it is claimed by the Authors that the OC may be used  
42 252 to counsel the women carrying a breech fetus on the mode of delivery <sup>29</sup>.

### 43 44 45 253 **Clinical implication and future research**

46  
47  
48 254 The WHO guidelines recommend against the routine use of antenatal pelvimetry <sup>30</sup>. On note, this  
49  
50 255 recommendation is based on the Cochrane systematic review including 5 RCTs comparing X-ray  
51  
52 256 pelvimetry with no pelvimetry, 2 of them including women candidate to TOLAC.

53  
54 257 This systematic review found that women undergoing X-ray pelvimetry were more likely to have a  
55  
56 258 CS (risk ratio (RR) 1.34, 95% CI 1.19 to 1.52) compared to women receiving clinical pelvimetry or  
57  
58 259 no pelvimetry. In addition, no significant differences were found between groups for the following  
59  
60 260 clinical outcomes: perinatal mortality (RR 0.53, 95% CI 0.19 to 1.45), perinatal asphyxia (RR 0.66,  
261 95% CI 0.39 to 1.10), and admission to special care baby unit (RR 0.20, 95% CI 0.01 to 4.13)<sup>11</sup>.

1  
2  
3 262 However, as mentioned above, the growing interest towards the antepartum assessment of pelvic  
4  
5 263 diameters seems justified by the reports showing that pelvimetry impacts the prediction of labor  
6  
7 264 outcome<sup>31-36</sup>. Of course, our demonstration that an accurate measurement of the OC is achievable by  
8  
9 265 standard transabdominal 2D ultrasound may usher in a new era for the clinical use of antepartum  
10 266 pelvimetry in obstetrics.  
11

12  
13 267 Following the creation of nomograms of the true OC based on 2D ultrasound, it will be necessary to  
14  
15 268 assess if this measurement impacts the labor outcome and more specifically if a shorter OC is  
16  
17 269 associated with an increased risk of cesarean section due to cephalo-pelvic disproportion especially.  
18 270 This approach may turn particularly useful among those groups who seem at higher risk of obstructed  
19  
20 271 labor such as women with diabetes or those carrying a LGA fetus<sup>27</sup>. In addition, women who are  
21  
22 272 willing to undergo a trial of labor after cesarean might also benefit from the antenatal evaluation of  
23 273 the OC.  
24

25  
26 274 Besides the assessment of the risk of obstructed labor, a correlation between the pelvic diameters  
27  
28 275 assessed at postpartum MRI and the five types of Levator ani muscle (LAM) injury has been recently  
29  
30 276 reported<sup>37</sup>. Based on these experiences, the antenatal sonographic evaluation of the OC may be  
31  
32 277 finalized at the prevention and prediction of major perineal injuries.  
33

### 34 278 **Strengths and limitations**

35  
36  
37 279 The prospective design and the originality in describing the transabdominal ultrasound technique to  
38  
39 280 evaluate the true OC represent the main strengths of the present study. Furthermore, potential  
40  
41 281 confounders as maternal BMI or advanced gestational ages have been considered in the analysis.  
42

43 282 The small number of women and the fact that this data have not been validated in clinical practice  
44  
45 283 are to be acknowledged among the main study limitations.  
46  
47

### 48 284 49 50 285 **CONCLUSION**

51  
52  
53  
54 286 In conclusion, our study has provided original data on the OC values measured at transabdominal 2D  
55  
56 287 ultrasound. It is still to demonstrate if the use of the antepartum evaluation of the OC alone or in  
57  
58 288 combination with other fetal parameters might help the clinician in identifying women at high risk  
59 289 for and adverse labor outcome. Further studies on larger low-risk population or in women with  
60

1  
2  
3 290 specific risk factors are required to investigate the clinical usefulness of this new ultrasound  
4  
5 291 parameter.

41 442 primiparous women using 3 Tesla magnetic resonance imaging. *Neurourol Urodyn.* 2018  
42 443 Aug;37(6):1950-1956. doi: 10.1002/nau.23537. Epub 2018 Feb 21. PMID: 29464757.

**Table 1.** Maternal characteristics and Obstetric conjugate (OC) measurements obtained twice by operator 1 and once by operator 2

	N=111
Maternal age (years)	33.0 [29.0-36.5]
Caucasian	83(74.8)
Nulliparous	52(46.8)
Gestational Age (weeks)	36.0[35.0-37.0]
Gestational Age $\geq 37$ weeks	35(31.5)
BMI at the enrollment (Kg/m <sup>2</sup> )	23.7[20.4-27.0]
BMI $\geq 30$ Kg/m <sup>2</sup>	15(13.5)
Mean value operator 1a (mm)	11.4 $\pm$ 0.93
Median value operator 1b (mm)	11.4 $\pm$ 0.94
Median value operator 2 (mm)	11.4 $\pm$ 0.91

Numbers are expressed as median [IQR] or mean $\pm$ SD or n(%)

**Table 2.** Summary of intra- and interobserver reliability measurements of the Obstetric Conjugate

	Interobserver	Intraobserver
Mean difference $\pm$ SD	-0.02 $\pm$ 0.42	0.008 $\pm$ 0.32
Limits of agreement	-0.80 to 0.84	-0.62 to 0.63
Systematic difference (p-value)	0.62	0.79
Overall ICC	0.95(0.92-0.96)	0.97(0.96-0.98)
ICC for BMI $\geq$ 30 Kg/m <sup>2</sup>	0.97(0.90-0.98)	0.98(0.95-0.99)
ICC for GA $\geq$ 37 weeks	0.96(0.93-0.98)	0.97(0.95-0.98)

ICC=Interclass Correlation Coefficient; BMI=Body Mass Index; GA= Gestational Age

**Figure 1.** Ultrasound evaluation of the Obstetric Conjugate (OC). The ultrasound probe is longitudinally placed above the level of the symphysis and the **interpubic fibrocartilaginous disk (S)** is visualized. Then the **promontory (P)** was identified as the most prominent segment of the sacral vertebral column. The OC is measured as the distance between the inner edge of the interpubic disk and the promontory
