## **Abstract**

Density measurements of the systems CO<sub>2</sub> + CH<sub>4</sub> at  $T = 304.21\text{ K}$  and CO<sub>2</sub> + CO at  $T = 304.21$  and  $308.15\text{ K}$  were carried out at pressures and compositions of interest in the process of transport and storage of CO<sub>2</sub> (CCS Technology):  $P = 0.1$  to  $20\text{ MPa}$ , and  $x_{\text{CO}_2} \geq 0.97$ . From the experimental  $P$ - $\rho$ - $T$ - $x_{\text{CO}_2}$  data, we have studied the dependence of the isothermal compressibility, the excess molar volume, and the partial molar volume of the solute with composition, pressure and temperature within the critical region. We have modelled the volumetric behaviour of these systems with Peng-Robinson, PC-SAFT and GERG Equations of State, thus validating these equations under the conditions considered. Furthermore, we have confirmed the weakly attractive behaviour of these systems by performing a study of the interactions between solvent molecules, CO<sub>2</sub>, and those of the solute, CO or CH<sub>4</sub>, using the Krichevskii Function concept and the Kirkwood-Buff Theory. Finally, we have quantified the influence of small amounts of CH<sub>4</sub> and CO in the transport of anthropogenic CO<sub>2</sub> through several normalized parameters, related to the design and operation of the fluid transport process.

## **1. Introduction**

Nowadays new technologies are being developed in order to reduce CO<sub>2</sub> emissions originated from industrial processes. For instance, CO<sub>2</sub> capture by algae and subsequent transformation into biomass in a process similar to photosynthesis (Ramachandriya et al., 2013); obtaining combustible materials or other high added value substances from its photocatalytic and electrochemical reduction (Ghasemi et al, 2013); purification and treatment of drinking water (Vo et al., 2013) and food preservation, (Al-Nehlawi et al., 2013). However, the technology that will furthest reduce carbon dioxide in the atmosphere is the capture, transport and storage of CO<sub>2</sub> (CCS technology). According to the International Energy Agency (IEA / CSLF, 2010), the contribution of this technology to atmospheric CO<sub>2</sub> reduction by 2050 is expected to be of the order of 20% and the reduction achieved by greater energy efficiency of 36% (*horizon 2050*). In CCS, anthropogenic CO<sub>2</sub> (CO<sub>2</sub> from human activity) is processed in order to increase its CO<sub>2</sub> content (to 85 - 99.5% CO<sub>2</sub>), then transported to a storage site and injected and stored in the chosen reservoir.

The phase diagram of a pure compound shows that at temperatures and pressures above its critical point (for pure CO<sub>2</sub>,  $P_c = 7.383$  MPa,  $T_c = 304.21$  K (Gil et al., 2008)), the gas and liquid phases are indistinguishable and there is only one phase present, known as a supercritical phase, which exhibits viscosity and density values intermediate between the values of liquids and gases. If we consider that the volume occupied by CO<sub>2</sub> under supercritical conditions is about 350 times smaller than that occupied in gas phase, and that the viscosity under these conditions is relatively small, the most economical means of transporting CO<sub>2</sub> through pipelines is going to be either

as a supercritical fluid or as a dense fluid. The supercritical region lies above the critical temperature and pressure and the "dense phase region" is located above the critical pressure, but below the critical temperature.

However, the transported fluid is not pure CO<sub>2</sub>, as it contains other compounds derived from both the emission sources and the capture and conditioning processes. The presence of these "impurities" in CO<sub>2</sub> changes its thermodynamic properties: the position of the critical point is affected and the line of liquid-vapor equilibrium is transformed into a phase envelope, enclosing a biphasic region; thus fluid composition determines the minimum pressure necessary to ensure transport in supercritical or dense phase. There are different reasons why transport, and, in general, any operation should be avoided under two-phase flow in this technology (Knoope et al., 2013): (i) cavitation produced by bubble implosion in the biphasic region generates shock waves which may cause cracks in the pipeline; (ii) turbulence caused by the bubbles hinder the work of compressors and pumps; and (iii) two-phase flow reduces the quantity of fluid transported. Anyway, multiphase flow conditions seem to be unavoidable at startup/failure modes. An equation of state for solid CO<sub>2</sub> has been recently published (Trusler, 2011; Trusler, 2012) that can be solved simultaneously with an equation for the fluid phases to obtain solid-vapour and solid-liquid equilibria, which can be of practical importance when calculating the discharge rate in the event of pipeline failure.

One of the characteristic properties of supercritical fluids in the region near the critical point is the wide variation caused in the density and compressibility values when small changes in pressure, temperature and composition occur. These

properties, in turn, influence various parameters that affect the process of transport, having an impact on the overall economic cost of the facilities (ElementEnergy, 2010; Knoope et al., 2013): pipeline diameter, pressure drop, erosional velocity, capacity of the booster stations, etc. As for the injection and storage processes, the density variation due to the presence of impurities affects parameters such as injection flow, solubility parameter, storage capacity and rising velocity of the plume (Blanco et al., 2012).

The variety of emission sources, capture and conditioning processes as well as the storage reservoirs, can cause the composition of the stored fluid to be quite varied. In particular, CH<sub>4</sub> is a likely impurity in the CO<sub>2</sub> capturing process from natural gas sweetening, and is present in significant quantities in some reservoirs (reservoirs exhausted of coal and natural gas); CO is a likely impurity in processes from heavy oil production and upgrading, and both are expected impurities from power plants using pre-combustion capture. Additionally, there is a significant legislative gap regarding the range of compositions allowed in anthropogenic CO<sub>2</sub>. As a consequence, the experimental study and thermodynamic modelling of these systems have become important: we must understand how the composition of these systems affect their behaviour and make technology profitable while ensuring maximum safety.

Knoope et al. 2013 recognize a significant knowledge gap in the calculation of the economic costs of the process since none of the models used take into account the impact of impurities on the various design parameters. Moreover, the shortage of experimental data, especially of volumetric properties under conditions relevant to CCS technology, means that there is not a preferred thermodynamic model to predict

the behaviour of the fluid to be transported and stored (Li et al., 2011a; Li et al., 2011b; Sánchez-Vicente et al., 2013). The most common models are based on the use of equations of state of different nature: cubic (Peng-Robinson, Patel-Teja...), those derived from statistical mechanics (SAFT versions, CPA...) or multiparameter approaches (GERG). However, all of them should be validated with experimental data of mixtures, under conditions at which transportation and storage of anthropogenic CO<sub>2</sub> take place: compositions rich in carbon dioxide,  $x_{\text{CO}_2} > 0.85$ , and pressure and temperature values corresponding to the critical region.

It is also important to know the nature of the interactions between CO<sub>2</sub> molecules and those of compounds which may appear in the capture and storage processes, since they may alter the selectivity in the capturing process or induce additional phenomena during storage. This study can be performed from ab-initio calculations (Liu and Wilcox, 2013), molecular dynamics (Lachet et al., 2012) and statistical mechanics (Blanco et al., 2009).

In our current work we have studied the volumetric behaviour of mixtures of carbon dioxide with small amounts of methane or carbon monoxide, at compositions, temperatures and pressures of interest in CCS technology (ElementEnergy, 2010; Li et al., 2011; ENCAP Project, 2008):  $x_{\text{CO}_2} \geq 0.97$ ,  $T = 304.21$  and  $308.15$  K, and  $P = 0.1\text{-}20$  MPa. The CO<sub>2</sub>+CH<sub>4</sub> and CO<sub>2</sub>+CO systems have been modelled using three different Equations of State, EoS: PR (Peng and Robinson, 1976), EoS widely used in engineering for their acceptable results despite the simplicity in implementation; PC-SAFT (Gross and Sadowskii, 2001 and 2002), EoS nowadays used in various applications including the study of the supercritical fluids; and GERG-2008 (Kunz and Wagner, 2012), EoS

developed for mixtures containing components of natural gas. The three EoS have been validated for these systems under the aforesaid conditions. We have performed a theoretical study of the interactions that occur between the molecules involved in these mixtures near the critical point of the solvent, showing the affinity of the solvent molecules, CO<sub>2</sub>, for the solute, CH<sub>4</sub> or CO. The study has been conducted using the Krichevskii function concept (Levett Sengers, 1994 and Japas et al., 1998) and the Kirkwood-Buff Theory (Kirkwood and Buff, 1951). Finally, we have calculated the effect of CH<sub>4</sub> and CO as impurities on various operating transport parameters in CCS technology, by comparing the physicochemical properties of the mixtures with those of pure CO<sub>2</sub>. This aspect has not been well studied in the literature. To this end, we have used equations which have been reviewed and widely accepted for modelling by the industrial and engineering community (ElementEnergy, 2010).

## 2. Materials and methods

### 2.1. *Chemicals*

Carbon dioxide (mole fraction > 99.998 %), methane (mole fraction > 99.995 %) and carbon monoxide (mole fraction > 99.997 %) were obtained from Air Liquide and used without further purification.

### 2.2. *Apparatus*

Density measurements were carried out using an experimental setup described in a previous work (Velasco et al., 2011). The apparatus was designed and built by ARMINES and the Laboratoire de Thermodynamique des Equilibres entre Phases de l'École Nationale Supérieure des Mines de Paris (France) for fast, reliable and accurate generation of  $P\rho T$  data for pure compounds and mixtures over the whole state surface of a fluid encompassing the liquid and vapour compressed phases, and the saturation

curve in the (253 to 423) K  $\pm$  0.006 K temperature range, up 70 MPa pressure with a precision of 0.025% FS.

The main component of the system is a vibrating tube densimeter Anton Paar DMA HPM which includes the measuring cell and an interface module. Increases or decreases in pressure inside the cell are obtained through mass transfers with respect to the measurement circuit. Connecting the unit to a mPDS 2000V3 evaluation unit allows quasi-continuous data acquisition. A schematic diagram is shown in Fig. S1 (Supporting Information).

### 2.3. *Experimental procedure*

A variable-volume cell is used for loading mixtures into the measurement circuit. Successive introduction of compounds allow the preparation of mixtures of accurately determined composition due to successive weighing of the cell on a mass comparator from Sartorius, model CCE 2004, with maximum masses of 2500 g and typical repeatability better than 0.0001 g. The components are introduced in order of increasing volatility and the mixture formed is homogenized through efficient stirring and kept at pressures higher than its bubble pressure.

The fluid is transmitted from the loading cell to the measurement circuit through a manual pump, which makes it possible to achieve pressures up to 70 MPa inside the measurement circuit (in this work, the maximum operating pressure was 20 MPa). When the fluid to be studied exhibits phase transition within the operating range of temperature and pressure, the density measurement is performed in two stages: (i) ascending from atmospheric pressure to the pressure corresponding to phase transition; and (ii) descending from the maximum operating pressure down to

the pressure of the phase transition. However, when the fluid exhibits no phase transition, as is the case in this work, the measurement is only carried out with descending pressure.

Since we must ensure a quasi-static equilibrium, the pressure changes have been kept sufficiently low; they are usually below  $0.005 \text{ MPa.s}^{-1}$ . Thus, each isotherm in the range of 0.1 to 20 MPa consists of about 4,000 density-pressure points, which are evenly reduced to about 1,000 points for easier handling in subsequent calculations. This large number of points makes quasi-continuous isotherms available along subcritical, critical and supercritical regions, and allows the accurate determination of density derivative properties.

#### 2.4. *Calibration and uncertainty*

The general principle of the vibrating tube densimeter is based on the application of the relation between the vibrating period of a one-dimensional resonator and its vibrating mass. This system has a transversal stiffness  $K = K(T, P)$  and is vibrating with a period ( $\tau$ ) in an undamped harmonic way under the effect of a mechanical excitation. Considering the vibration period,  $\tau$ , as a pseudo state variable, the  $P\tau T$  variables can describe the  $P\rho T$  state surface as long as a calibration may provide a direct relation between  $\tau$  and  $\rho$  (Appendix A, Eq. A1 and A2). In this work, Forced Path Mechanical Calibration Model, FPMC (Bouchot and Richon, 2001), has been used. This model includes realistic mechanical considerations and forces representing the stress and strain behaviour of the tube material.

In order to evaluate the precision in density results,  $\rho = \rho(\rho_{ref}, \tau, P, T)$ , uncertainty propagation law has been used (Appendix A, Eq. A3). The reference fluid to calibrate was pure CO<sub>2</sub> and the estimated uncertainty in  $P$  and  $T$  were  $u(P) = \pm 0.008$  MPa and  $u(T) = \pm 0.006$  K (Velasco et al., 2011). From those and  $u(\rho_{ref}) = 0.03\%$  (Span and Wagner, 1996) and  $u(\tau) = \pm 2 \times 10^{-5}$  ms (Bouchot and Richon 2001), the expanded ( $k=2$ ) uncertainty in the density has been calculated for our mixtures:  $U(\rho) = 0.4 - 0.7$  kg.m<sup>-3</sup>. On the other hand, the repeatability of the density measurements for mixtures, expressed as relative mean standard deviation (Appendix A, Eq. A4-A6), is  $\bar{S}_{\rho}^r = 0.13\%$  (Velasco et al., 2011).

### 3. Results

#### 3.1. Experimental density

$P$ - $\rho$ - $T$ - $x_{CO_2}$  measurements for {CO<sub>2</sub> + CH<sub>4</sub>} ( $x_{CO_2} = 0.9719, 0.9809, 0.9902, 0.9932, 0.9961$ ) at  $T = 304.21$  K (critical temperature of pure CO<sub>2</sub>, Gil et al., 2008) and {CO<sub>2</sub> + CO} ( $x_{CO_2} = 0.9700, 0.9810, 0.9902, 0.9930, 0.9960$ ) at  $T = 304.21$  and 308.15 K were carried out in the pressure range from 0.1 to 20 MPa.

Experimental results are shown in Fig. 1 for the CO<sub>2</sub> + CH<sub>4</sub> system and Fig. 2 ( $T = 304.21$  K) and 3 ( $T = 308.15$  K) for CO<sub>2</sub> + CO mixtures. Full numerical data are included in Tables S1-S3 in the Supporting Information. As shown in Fig. 1-3, at the studied temperatures the densities of all mixtures change continuously with pressure, and an inflection point appears in the isotherms; that is, the systems are at a supercritical temperature for any composition, a fact which is consistent with literature data on critical locus of these systems (Donnelly and Katz, 1954; Bian et al., 1993; Ke et al., 2001): the critical temperatures of all mixtures under study range from 302.6 K to

303.9 K. At the same temperature (304.21 K) the influence of the presence of CO on the density of the mixtures is higher than those of CH<sub>4</sub>. For a given system (CO<sub>2</sub> + CO or CO<sub>2</sub> + CH<sub>4</sub>), the influence of the presence of solute on the density of the mixtures is higher at 304.21 K ( $T_c$  of pure CO<sub>2</sub>) than at 308.15 K (for CO<sub>2</sub> + CH<sub>4</sub> at 308.15, see Blanco et al. 2012).

Table 1 lists literature references for the volumetric properties of the two systems as well as the  $T$ - $P$ - $x_{\text{CO}_2}$  ranges of each study. As can be seen, the system CO<sub>2</sub> + CH<sub>4</sub> has been widely studied, however there are only eight studies in which the values of temperature, pressure and composition are of interest in CCS technology, and solely the data published by Zhang et al. (2002) and Blanco et al. (2012) analysed the region of infinite dilution, IDS, the region that has been studied in our current work. Our experimental data are consistent with those but not directly comparable since temperature do not match. We have carried out a comparison between the experimental density data from Blanco et al. (2012), used further in this study, for the mixture of composition  $x_{\text{CO}_2} = 0.9961$  and those published by Zhang et al. (2002) for the mixture  $x_{\text{CO}_2} = 0.997$ , both at  $T = 308.15$  K, obtaining a mean relative deviation (Appendix A, Eq. A7):  $MRD_\rho = 2.2\%$

For the CO<sub>2</sub> + CO system the extent of literature data is rather small. Mallu et al. (1987) and Cipollina et al. (2007) have studied its volumetric behaviour, and our experimental data are consistent with those but not directly comparable, since the compositions do not match.

### 3.2. *Isothermal compressibility*

From the  $P$ - $\rho$ - $T$ - $x_{\text{CO}_2}$  experimental values of the mixtures studied, we have evaluated the effect of pressure on density at the critical temperature of pure solvent,  $T = 304.21$  K, by means of the isothermal compressibility,  $\kappa_T$ , defined as:

$$\kappa_T = \left(\frac{1}{\rho}\right) \left(\frac{\partial \rho}{\partial P}\right)_T \quad (1)$$

Fig. 4 and 5 show the  $\kappa_T - x_{\text{CO}_2} - P$  representations for  $\text{CO}_2 + \text{CH}_4$  and  $\text{CO}_2 + \text{CO}$  mixtures, respectively. It can be seen that the dependence of the isothermal compressibility on pressure and composition is similar for both systems: (i)  $\kappa_T$  varies with pressure, going through a maximum; (ii) the maximum value of  $\kappa_T$  increases as the composition of  $\text{CO}_2$  goes up, since the critical temperature of the increasingly  $\text{CO}_2$  rich mixture approaches the critical temperature of  $\text{CO}_2$ ; and (iii) the pressure at which the maximum in  $\kappa_T$  occurs decreases as the composition of  $\text{CO}_2$  rises, since the critical pressures,  $P_c$ , of both systems decrease when  $x_{\text{CO}_2}$  increases (Donnelly and Katz, 1954; Bian et al., 1993; Ke et al., 2001). Moreover, when comparing the mixture compressibility for the two systems with the same concentration, we observe if  $x_{\text{CO}_2} < 0.99$ , the maximum value for the isothermal compressibility of the  $\text{CO}_2 + \text{CH}_4$  system is higher than that for  $\text{CO}_2 + \text{CO}$  and when  $x_{\text{CO}_2} > 0.99$ , this trend is reversed.

### 3.3. Excess molar volume and solute partial molar volume

From experimental data obtained in this work and literature experimental values for the  $\text{CO}_2 + \text{CH}_4$  system at 308.15 K (Blanco et al., 2012), we have calculated the excess molar volume of the mixture,  $V_m^E$ , using the following expression:

$$V_m^E = V_m - V_1 - V_2 = \frac{x_1 M_1 + x_2 M_2}{\rho_m} - \frac{x_1 M_1}{\rho_1} - \frac{x_2 M_2}{\rho_2} \quad (2)$$

where the subscripts 1, 2 and  $m$  refer to solvent ( $\text{CO}_2$ ), solute ( $\text{CH}_4$  or  $\text{CO}$ ), and mixture, respectively;  $M_i$  is the molar mass of each component  $i$  in the mixture, and  $V_i$ ,  $V_m$ ,  $\rho_i$  and  $\rho_m$  are the molar volume and the density for the pure compounds and the mixture at temperature  $T$  and pressure  $P$ .

Due to the small values of the densities of these mixtures at low pressures, we have calculated the expanded ( $k = 2$ ) uncertainties in the excess molar volumes in the 5 - 20 MPa range. The rules of propagation of errors (Appendix A, Eq. A3) have been used, obtaining the values  $U(V_m^E) = 0.1 - 1 \text{ cm}^3 \cdot \text{mol}^{-1}$ .

Fig. 6 shows the trends in the excess molar volumes,  $V_m^E$ , with pressure and composition for two mixtures,  $x_{\text{CO}_2} \cong 0.971$  and  $x_{\text{CO}_2} \cong 0.993$ , of both systems at the two operating temperatures. They are supercritical mixtures and we observe a peak in the excess molar volume:  $P \cong 7.41 \text{ MPa}$  at  $T = 304.21 \text{ K}$  and  $P \cong 8.15 \text{ MPa}$  at  $T = 308.15 \text{ K}$ . The value of the maximum for  $V_m^E$  decreases with increasing temperature and molar fraction of  $\text{CO}_2$ . Finally, the maxima in  $V_m^E$  for  $\text{CO}_2 + \text{CO}$  mixtures are higher than for mixtures  $\text{CO}_2 + \text{CH}_4$ , which means that the inclusion of a molecule of  $\text{CO}$  in pure  $\text{CO}_2$  disturbs the system to a further extent than when introducing a molecule of  $\text{CH}_4$ . This may be due to either the dipolar moments ( $\mu_{\text{CO}_2} = \mu_{\text{CH}_4} = 0$ ;  $\mu_{\text{CO}} = 0.122 \text{ D}$ ), the sizes of the components of each system (the size difference between the molecules of  $\text{CO}_2$  and  $\text{CH}_4$  is smaller than that between  $\text{CO}_2$  and  $\text{CO}$ ), or both.

From the density data, the partial molar volume of the solute,  $\bar{V}_2$ , has been calculated for the five studied compositions of each system at temperatures of 304.21 and 308.15 K and selected pressures of 7.383 MPa (critical pressure of pure  $\text{CO}_2$ ) and 8.000 MPa (supercritical pressure). To this end we have used the following expression:

$$\bar{V}_2 = V_m + (1 - x_2) \left( \frac{\partial V_m}{\partial x_2} \right)_{P,T} \quad (3)$$

where the subscripts 2 and  $m$  refer to solute ( $\text{CH}_4$  or  $\text{CO}$ ) and mixture respectively, and  $V_m$  is the molar volume of the mixture at temperature  $T$  and pressure  $P$ .  $(\partial V_m / \partial x_2)_{P,T}$  values have been calculated from polynomial fittings of  $V_m$  vs.  $x_2$ , being  $V_m$  the first term in the right side of Eq. 2.

The expanded ( $k=2$ ) uncertainties in  $\bar{V}_2$  have been calculated using the rules of propagation of errors (Appendix A, Eq. A3). The values are  $U(\bar{V}_2) = 3 - 85 \text{ cm}^3 \cdot \text{mol}^{-1}$ .

Fig. 7 shows trends in the partial molar volumes of the solute,  $\bar{V}_2$ , with solute concentration at the above indicated pressures and temperatures. A similar behaviour is observed for the two systems under study: at  $P = P_c(\text{CO}_2) = 7.383 \text{ MPa}$ ,  $\bar{V}_2$  decreases with increasing solute concentration at both working temperatures, with a much smaller slope at  $308.15 \text{ K}$ . By contrast, at the supercritical pressure,  $P = 8.000 \text{ MPa}$ ,  $\bar{V}_2$  increases with increasing solute concentration at  $T = 304.21 \text{ K}$ , and decreases at  $T = 308.15 \text{ K}$ .

We have compared (Fig. S2, Supporting Information) the values of  $\bar{V}_2$  calculated in this work for the  $\{0.9961\text{CO}_2 + 0.0039\text{CH}_4\}$  mixture with those calculated by Zhang et al. (2002) for the  $\{0.997\text{CO}_2 + 0.003\text{CH}_4\}$  mixture at  $308.15 \text{ K}$ , observing good agreement, especially in the dense region. The mean relative deviation, calculated with Eq. (1), at the point corresponding to the maximum value of  $\bar{V}_2$  is  $MRD_{\bar{V}_2} < 6\%$ .

The strong dependence of  $V_m^E$  on pressure and composition (Fig. 6) demonstrates the non-ideality of the studied systems. However, the greater values of  $V_m^E$  and

$(\partial \bar{V}_2 / \partial x_2)$  exhibited by the  $\text{CO}_2 + \text{CO}$  system suggest that this system deviates from ideality further than  $\text{CO}_2 + \text{CH}_4$ .

#### 4. Modelling

Due to the variety of compositions that the transported and later stored fluid can present, as well as the pressure and temperature operational ranges within CCS technology, it is interesting to develop effective working tools which will allow to correctly predict the phase and volumetric behaviour of the fluid. To do this, our experimental  $P - \rho - T$  results have been compared, in terms of relative mean deviation,  $MRD_X$  (Appendix A, Eq. A7), with those calculated using three different types of equations of state, validating them for these experimental conditions.

(i) Peng-Robinson EOS (Peng and Robinson, 1976). The cubic equations are the simplest EoS which predict the existence of a critical point and quantitative representation of VLE. Their simple structure, which requires little input information, make them popular for engineering applications.

The parameters used for the pure components, as well as the binary interaction parameter,  $k_{ij}$ , included in the mixing rule of a van der Waals fluid, are shown in Table 2. A comparison between our experimental data and those calculated with the PR EoS are shown in Table 3. Despite its simplicity, the agreement with experimental data is good at pressures below the critical pressure,  $MRD_\rho = 1.8\%$  for both systems, and acceptable at higher pressures:  $MRD_\rho(\text{CO}_2 + \text{CH}_4) = 4.4\%$  and  $MRD_\rho(\text{CO}_2 + \text{CO}) = 4.1\%$ .

(ii) PC-SAFT EoS (Gross and Sadowski, 2001, 2002). In this model, based on Wertheim's first order thermodynamic perturbation theory, the reference fluid is the hard-chain fluid. Attractive intermolecular forces are further separated into different contributions, so that the Helmholtz energy,  $a$ , is written as the sum of the ideal-gas contribution,  $a^{id}$ , a hard-chain term,  $a^{hc}$ , a contribution for the dispersive attraction,  $a^{dis}$ , and several terms for associating, dipolar and quadrupolar interactions. In this work, we have not taken into account the polar and association contributions, therefore the terms contributing to the Helmholtz energy are as follows:

$$a = a^{id} + a^{hc} + a^{dis} \quad (4)$$

For the non-polar pure compounds, three parameters are needed: the segment number,  $m$ , the segment diameter,  $\sigma$ , and the segment energy parameter,  $\varepsilon$ . These parameters provide an accurate representation for both volumetric and VLE properties if they are obtained from vapor pressures and liquid densities; however, they always overestimate the critical properties. In order to describe the critical region, different authors (Cismondi et al., 2005; Blanco et al., 2009; Gil et al., 2010, 2012) perform a rescaling of pure-compound parameters using their  $T_c$  and  $P_c$ . In this work we have applied PC-SAFT EoS to our systems with both options, using pure compounds parameters ( $m$ ,  $\sigma$ ,  $\varepsilon$ ) original and rescaled. Moreover, in both cases, we have adjusted the experimental density values of pure CO<sub>2</sub> and CO using volume shift,  $\Delta\nu_c$ .

The parameters used for the pure components, the mixing parameters and a comparison between our experimental data and calculated values are found in Tables 2 and 3 respectively. When the original parameters for the pure compounds are used (Gross and Sadowski, 2001, 2002), the model predicts in the vicinity of the critical pressure,  $P_c$ , an erroneous subcritical state for many of our mixtures when in reality

those are at supercritical conditions. Mean relative deviations in this region ( $P = 7 - 9$  MPa) are  $MRD_\rho(\text{CO}_2 + \text{CH}_4) = 12.8\%$  and  $MRD_\rho(\text{CO}_2 + \text{CO}) = 8.1\%$ . However, the agreement outside the critical region is much better:  $MRD_\rho(\text{CO}_2 + \text{CH}_4) = 0.5\%$  and  $MRD_\rho(\text{CO}_2 + \text{CO}) = 0.8\%$ . On the other hand, if the parameters used are rescaled using the critical points of the pure compounds, the model predicts supercritical state for all mixtures and represents the critical region more accurately, with  $MRD_\rho(\text{CO}_2 + \text{CH}_4) = 5.7\%$  and  $MRD_\rho(\text{CO}_2 + \text{CO}) = 5.6\%$ , although the deviation for the remaining pressures is higher:  $MRD_\rho(\text{CO}_2 + \text{CH}_4) = 2.5\%$  and  $MRD_\rho(\text{CO}_2 + \text{CO}) = 2.4\%$ .

(iii) GERG EoS (Lemmon et al., 2010). International reference equation of state for natural gases based on a multi-fluid approximation. This approximation divides the Helmholtz energy formula into three terms: one term to account for ideal gas behaviour, a second term describing the contributions of pure substances and a third term for the departure function. This equation covers subcritical, critical and supercritical regions as well as liquid-vapor phase boundaries but its accuracy decreases when the GERG database contains few experimental data of the studied system. It should also be noted that the uncertainty increases in both density and VLE calculations of  $\text{CO}_2$ -rich mixtures (Li et al., 2011).

As can be seen from Table 3, a comparison between our experimental data and those calculated with the GERG EoS is very good for both systems; the deviation for  $\text{CO}_2 + \text{CH}_4$  is smaller, since the EoS developed for this system used a larger number of experimental data, covering a wider range of pressures. However, for  $\text{CO}_2 + \text{CO}$ , the EoS GERG database only contains VLE data in the pressure range from 0.1 to 6 MPa.

The deviations obtained are:  $MRD_\rho(\text{CO}_2 + \text{CH}_4) = 0.4\%$  and  $MRD_\rho(\text{CO}_2 + \text{CO}) = 1.0\%$ .

GERG EOS is the equation that best represents our experimental results, although its extension to mixtures with compounds not included in their database is complex. By contrast, PC-SAFT EoS offers slightly higher deviations than GERG, but its use can be extended easily to multicomponent mixtures. Finally, PR EoS may be adequate, depending on the working pressure and the accuracy required.

Fig. 8a and 8b depict the relative deviations between the experimental densities and the values calculated using PR, PC-SAFT and GERG EoS for selected mixtures studied in this work (different solute, composition and temperature). Deviations are similar at both temperatures for pressure values far from the critical, while in the near-critical zone the nearer is the temperature to the critical value the higher the deviations.

## 5. Discussion

### 5.1. Study of the interaction $\text{CO}_2$ - impurity

The efficiency and selectivity of the capture processes are influenced by the type of interactions between the molecules present, that is, by their affinity. Moreover, once the fluid is stored,  $\text{CO}_2$  molecules can interact with other molecules present in the reservoir, consequently modifying the behaviour of the plume (Blanco et al., 2012). In this section we determine the nature of the interactions between solvent molecules,  $\text{CO}_2$ , and those of the solute,  $\text{CH}_4$  or  $\text{CO}$ , through a volumetric study in the critical region of infinitely dilute solutions, IDS, for systems  $\{\text{CO}_2(1) + \text{CH}_4\}$  or  $\{\text{CO}_2(1) + \text{CO}\}$ .

(2)}. We use the Krichevskii function concept (Levelt Sengers, 1994 and Japas et al., 1998) and the Kirkwood-Buff Theory (Kirkwood and Buff, 1951).

### 5.1.1 Krichevskii function.

The Krichevskii function,  $J$ , represents the pressure change that occurs in a system when a molecule of solvent is replaced by one of the solute at constant  $T$  and  $V$  in IDS. When the conditions of  $T$  and  $V$  correspond to critical conditions for the pure solvent, the Krichevskii function,  $J$ , becomes the Krichevskii parameter,  $A_{Kr}$ :

$$J = (\partial P / \partial x_2)_{T,V}^{\infty} \quad (5)$$

$$A_{Kr} = (\partial P / \partial x_2)_{Tc,Vc}^{c,\infty} \quad (6)$$

According to Equations (5) and (6), given a number of volumetric data at infinite dilution, the values for the Krichevskii function (including the parameter  $A_{Kr}$ ) can be calculated from the slopes of the isotherms-isochores  $P - x_2$  when  $x_2 \rightarrow 0$ .

Fig. 9a and 9b show some experimental results on the  $P - x_{\text{CH}_4}$  and  $P - x_{\text{CO}}$  planes at  $T = 304.21$  K for mixtures studied along various isochores, including the critical. The slopes of the  $P - x_2$  graphs increase in both systems with increasing density, being greater when CO is the solute. The slopes along the critical isothermal-isochoric, the Krichevskii parameter, for our systems are shown in Table 4. In the literature we have found some values for the  $A_{Kr}(\text{CO}_2 + \text{CH}_4)$  parameter; the mean relative deviations between our results and the literature are:  $MRD_{A_{Kr}} = 1.6\%$  (Furuja and Teja, 2000) and  $MRD_{A_{Kr}} = 8.0\%$  (Abdulagatov et al., 2007).

The values of the  $P - x_2$  slopes on the rest of isochores allow us to complete the study of the behaviour of IDS when expanding it to other states different to the critical point. Fig. 10 shows the evolution of the Krichevskii function,  $J$ , with the density of the pure solvent,  $\rho_{\text{CO}_2}$ , at  $T = 304.21$  and  $308.15$  K for the two systems under study. As can be seen,  $J$  is positive over the entire range of densities and its values are slightly higher and less sensitive to temperature for  $\text{CO}_2 + \text{CO}$  than for the  $\text{CO}_2 + \text{CH}_4$  system.

The partial molar volume of solute at infinite dilution,  $\bar{V}_2^\infty$ , can be expressed in terms of the Krichevskii function,  $J$  (Blanco et al., 2009):

$$\rho_1^0 \bar{V}_2^\infty = [1 + \kappa_T^0 J] \quad (7)$$

Where the superscripts 0 and  $\infty$  denote pure component and infinite dilution, respectively, and  $\rho_1^0$  and  $\kappa_T^0$  are the density and the isothermal compressibility of the solvent.

In the vicinity of the critical point of the solvent,  $J \rightarrow A_{Kr}$  and the compressibility of the pure solvent,  $\kappa_T^0$ , is a divergent function ( $\kappa_T^0 \rightarrow +\infty$ ); therefore, under these conditions, the partial molar volume of the solute at infinite dilution will also be divergent  $\bar{V}_2^\infty \rightarrow \pm\infty$ , and the sign of the Krichevskii parameter will define the sign of such divergence. For the two mixtures studied in this work, the parameter  $A_{Kr} > 0$ , thus at the critical point of the solvent,  $\bar{V}_2^\infty \rightarrow +\infty$ . A representation of  $\bar{V}_2^\infty$  vs  $\rho_{\text{CO}_2}$  can be seen in Fig. S3 (Supporting Information). Table 4 shows the maximum values of  $\bar{V}_2^\infty$  exhibited by our systems at a temperature of  $308.15$  K; these peaks appear in the vicinity of the critical pressure ( $\cong 8$  MPa) and the value is higher for the  $\text{CO}_2 + \text{CO}$  mixture, which suggests that the substitution of a molecule of  $\text{CO}_2$  for one of  $\text{CO}$

results in a bigger change in the volume of the system than if the replacing molecule were CH<sub>4</sub>.

The only value found in the literature for the partial molar volume at infinite dilution of the systems studied has been published by Abdulagatov et al. (2007) for the CO<sub>2</sub> + CH<sub>4</sub> system. These authors find a negative sign for the divergence of  $\bar{V}_2^\infty$ , which is not consistent with the positive sign of their own value of  $A_{kr}$ .

### 5.1.2. Structural Properties.

The study of a fluid structure can be conducted through the so-called Inversion of the Kirkwood-Buff Theory (Kirkwood and Buff, 1951), developed by Ben-Naim in 1977. In it, measurements of thermodynamic properties are used to calculate Kirkwood-Buff integrals,  $G_{ij} = \int_0^\infty [g_{ij}(r) - 1] 4\pi r^2 dr$ , where  $g_{ij}(r)$  is the pair correlation function or radial distribution function for species  $i$  and  $j$ , and represents the probability of finding the particle  $i$  at a distance  $r$  of the particle  $j$ . Strictly speaking, the  $G_{ij}$  integrals are not molecular properties, however, they provide information about the species' local packing.

For a binary mixture at infinite dilution conditions,  $x_2 \rightarrow 0$ , the Kirkwood-Buff equations are simplified (Lee and Cochran, 1994; Chialvo and Cummings, 1995) to:

$$\rho_1^0 \bar{V}_2^\infty = 1 + \rho_1^0 (G_{11}^0 - G_{12}^\infty) \quad (8)$$

$$\rho_1^0 RT \kappa_T^0 = 1 + \rho_1^0 G_{11}^0 \quad (9)$$

Considering Equations 7 and 8:

$$J = \frac{\rho_1^0 (G_{11}^0 - G_{12}^\infty)}{\kappa_T^0} \quad (10)$$

Alternatively, the Kirkwood-Buff equations and the expression for the Krichevskii function can be written in terms of the direct correlation function integral (DCFI),  $C_{ij} = \int c_{ij} dr$  where  $c_{ij}$  represents the direct correlation due solely to the interaction forces exerted between two particles in a system of  $N-2$  particles.

$$\rho_1^0 \bar{V}_2^\infty = \rho_1^0 RT \kappa_T^0 (1 - C_{12}^\infty) \quad (11)$$

$$(\kappa_T^0)^{-1} = \rho_1^0 RT (1 - C_{11}^0) \quad (12)$$

$$J = \rho_1^0 RT (C_{11}^0 - C_{12}^\infty) \quad (13)$$

As can be seen in Equations 10 and 13,  $J$  represents the difference between solvent - solvent (1-1) and solvent - solute (1-2) interactions, making it possible to evaluate the ideality of the mixture: a value close to zero indicates that these interactions are very similar. The equations above show that, in IDS, the rearrangement of the solvent around the solute, in relation to the structure of the pure solvent, is not determined by the strength of the interaction between the molecules of solvent and solute, but defined by the intermolecular asymmetry. The values of the direct correlation function integrals,  $C_{ij}$ , for  $\text{CO}_2 + \text{CH}_4$  are higher than for  $\text{CO}_2 + \text{CO}$  (Table 4 shows one of them,  $(C_{12})_{\rho_c}$ ). However, the greater asymmetry of the second system causes a more extensive change in the structure of the solvent, as evidenced by higher values of  $(C_{11} - C_{12})$ ; a graphical representation is shown in Fig. S4 (Supporting Information).

$N_{exc}^\infty$  is defined as the excess number of solvent molecules around a solute molecule in the IDS, in relation to the number of solvent molecules around another solvent molecule. This parameter is related to the radial distribution functions for the

interactions solvent - solute (1 - 2) and solvent - solvent (1 - 1) and consequently with the Krichevskii function:

$$N_{exc}^{\infty} = (N_{12} - N_{11}) = 4\pi\rho_1^0 \int_0^{R_{shell}} [g_{12}(r) - g_{11}(r)]r^2 dr = -\kappa_T^0 \left( \frac{\partial P}{\partial x_2} \right)_{T,V}^{\infty} \quad (14)$$

Where  $N_{12}$  represents the number of solvent molecules around a solute molecule and  $N_{11}$  indicates that each solvent molecule is surrounded by a box of  $N_{11}$  solvent molecules. If we consider the sign obtained for the Krichevskii function in our current work, we realise that the exchange of one solvent molecule for another of solute, at constant volume and temperature, causes a decrease in the local density of CO<sub>2</sub> molecules around a molecule of solute in the IDS compared to that of pure CO<sub>2</sub>, and the effect is greater for CO than for CH<sub>4</sub>. A plot of  $N_{exc}^{\infty}$  vs  $\rho_{CO_2}$  is shown in Fig S5 (Supporting Information), and Table 4 lists the minimum values found for the excess coordination number,  $N_{exc}^{\infty}$ , of our systems at 308.15 K.

Moreover, the affinity of solvent molecules for a molecule of solute, or cluster size,  $N_1^{exc}$ , may be calculated from the properties of the pure solvent and from the so-called dimensionless Krichevskii parameter  $A_{Kr}^* = A_{Kr}/\rho_1^0 RT$ ,

$$N_1^{exc} = 4\pi\rho_1^0 \int_0^{R_{shell}} [g_{12}(r) - 1]r^2 dr = \rho_1^0 RT \kappa_T^0 (1 - A_{Kr}^*) \quad (15)$$

Fig. 11 shows the evolution of  $N_1^{exc}$  with the density of pure solvent for our systems: it becomes a divergent function at the solvent critical point,  $N_1^{exc} \rightarrow +\infty$ , and at 308.15 K, the maximum for the CO<sub>2</sub> + CO system is smaller in magnitude than that for CO<sub>2</sub> + CH<sub>4</sub> (Table 4).

Finally, according to Wheeler's Decorated Lattice Model (Wheeler, 1972), the behaviour of a near-critical system can be classified in terms of the solvent-solute interaction energy,  $\varepsilon_{12}$ , when adding a solute molecule to the solvent under isobaric and isothermal conditions: (i) attractive behaviour ( $\varepsilon_{12} \ll 0$ ) which results in a volume contraction and an enrichment of solvent around the solute ( $\bar{V}_2^\infty \rightarrow -\infty$ ,  $N_1^{exc} \rightarrow +\infty$ ); (ii) weakly attractive behaviour ( $\varepsilon_{12} < 0$ ), causing a volume expansion together with an enrichment in solvent ( $\bar{V}_2^\infty \rightarrow +\infty$ ,  $N_1^{exc} \rightarrow +\infty$ ); and (iii) repulsive behaviour ( $\varepsilon_{12} > 0$ ) that leads to a volumetric expansion and a decrease in solvent around the solute ( $\bar{V}_2^\infty \rightarrow +\infty$ ,  $N_1^{exc} \rightarrow -\infty$ ). Debenedetti and Mohamed in 1989 and Lee and Cochran in 1994 established that for IDS in the vicinity of the critical point, mixtures can be classified within the previous regimes depending on the sign of the Krichevskii parameter,  $A_{Kr}$ , the value of the dimensionless parameter,  $A_{Kr}^*$ , and the divergence signs for different properties:  $\bar{V}_2^\infty$ ,  $N_1^\infty$ , and  $N_1^{exc}$ .

For the mixtures included in this study:

$$A_{Kr} > 0; \quad \bar{V}_2^\infty \rightarrow +\infty; \quad N_1^\infty \rightarrow -\infty; \quad 1 > A_{Kr}^* > 0; \quad N_1^{exc} \rightarrow +\infty$$

Therefore we can conclude that both systems, near the solvent critical point, behave as weakly attractive mixtures. There are studies in the literature on the nature of the  $\text{CO}_2 + \text{CH}_4$  system based on Molecular Dynamics Simulation (Baglin et al., 2000; Skarmoutsos and Samios, 2006; Parris, 2010). Skarmoutsos and Samios determined that this system shows repulsive behaviour with a value of the excess coordination number slightly negative,  $N_1^\infty = -0.261$ . However, their calculations were performed under conditions of temperature and pressure away from the critical point:  $T = 323.15$  K and  $P = 9.94$  MPa.

## 5.2. *Effect of impurities in the process design*

Given that the technology for natural gas (NG) transport is well developed and that there are vast pipeline networks dedicated to this use, it would seem a possibility to use existing gas pipeline for CO<sub>2</sub> transport. However, the large differences between the behaviour of CH<sub>4</sub> (main component in NG) and that of CO<sub>2</sub> (main compound in CCS), in practice limit this use to transport in gas phase (ElementEnergy 2010, Serpa et al. 2011). Therefore, it may become necessary to design a new pipeline network to transport CO<sub>2</sub> in dense or supercritical phase. Furthermore, the presence of impurities in the anthropogenic CO<sub>2</sub> stream, even in small proportions, can significantly modify the properties of the fluid to be transported, primarily the phase equilibrium, density and viscosity, which strongly affects pipeline hydraulics and many other aspects of pipeline design and operation (Seevam et al., 2008). In order to evaluate these effects the usual parameters related to transport have been used: mass flow,  $m$ , erosional velocity,  $v_E$ , pipeline inner diameter,  $D$ , Reynolds number,  $Re$ , Darcy-Weisbach friction factor,  $f$ , pressure drop per unit length  $\Delta P/L$ , and capacity of the booster stations,  $W$  (Table 5). To calculate them, models based on the law of Bernoulli for incompressible flow, applied to full and turbulent flow in circular shaped pipelines have been used. These models, relatively simple but pragmatic, have been reviewed and accepted by the industrial and engineering community (Vandeginste and Piessens 2008, ElementEnergy 2010). To establish a comparison between the behaviour of the pure CO<sub>2</sub> stream and the stream containing impurities, normalized parameters have been defined,  $X/X_0$ , where  $X$  are the above mentioned parameters for the mixtures and  $X_0$  for pure CO<sub>2</sub>. Table S4 (Supporting Information) shows the equations for normalized parameters, as well as certain conditions that have been kept constant for both

streams in their calculations. In this manner, the deviations from unity of the normalized parameters are due to the different compositions and, therefore, different properties of pure and anthropogenic CO<sub>2</sub> streams.

Conditions of composition ( $x_{\text{CO}_2} \cong 0.97$ ), pressure ( $P = 8.6\text{-}20$  MPa) and temperature ( $T = 304.21$  and  $308.15$  K) used for the calculation are within customary in CCS technology (ElementEnergy 2010, Li et al., 2011). The experimental values of the densities used in the calculation have been taken from this work, from Blanco et al. 2012 and from Velasco et al. 2011. The viscosities have been obtained from REFPROP 9.0 (Lemmon et al. 2010) by using the extended corresponding states (ECS) model developed by Klein et al. (1997).

To obtain the friction factors,  $f$ , and the pressure drops per metre,  $\Delta P/L$ , standard values for pipeline inner diameter,  $D = 0.508$  m, and mass flow,  $m = 317$  kg/s (Serpa et al. 2011), and roughness height of commercial steel,  $e = 4.6 \times 10^{-5}$  m (Vandeginste and Piessens 2008), have been used.

The results are shown in Table S5 (Supporting Information) and in Fig. 11, 12, and S6-S9 (Supporting Information). As can be seen, the differences with respect to the behaviour of pure CO<sub>2</sub> are greater for CO<sub>2</sub>+CO than for CO<sub>2</sub>+CH<sub>4</sub> mixtures, in accordance with the conclusions drawn in section 5.1 (the CO molecule provokes greater structural disruption than CH<sub>4</sub> in their respective mixtures with CO<sub>2</sub>). For both systems, the differences increase with increasing  $T$  and decreasing  $P$ . They became significant at pressures ranged from 8.6 to 10 MPa, but they are smaller than 10% above 15 MPa.

For a transport velocity and a pipeline inner diameter, the mass flow,  $m$ , is lower for mixtures than for pure CO<sub>2</sub> ( $m/m_0 = 0.96 - 0.66$ , Fig. S8, Supporting Information), due to the lower density of the mixtures. Normalized Darcy-Weisbach friction factors,  $f/f_0$ , are as well lower than 1 (0.995 - 0.999, Fig. S9, for the utilized pipeline inner diameter, mass flow and roughness height). The rest of the normalized parameters are greater than 1, which means that the corresponding values for the mixtures parameters are higher than those for pure CO<sub>2</sub>. The higher deviations appear in the mixture CO<sub>2</sub>+CO at 308.15 K and 8.6 MPa, with  $Re/Re_0 = 1.75$  and  $(\Delta P/L)/(\Delta P_0/L) = 1.50$ . Pressure drop per metre is higher for mixtures than for pure CO<sub>2</sub> in all the studied cases, a fact which might require an increase in the number of boosters along the network, especially if transport is carried out at low pressures.

## 6. Conclusions

Density measurements of the {CO<sub>2</sub> (1) + CH<sub>4</sub> (2)} and {CO<sub>2</sub> (1) + CO (2)} systems were carried out under conditions of composition, pressure and temperature of interest in CCS technology:  $x_{\text{CO}_2} \geq 0.97$ ,  $P = 0.1$  to 20 MPa, and  $T = T_c(\text{CO}_2) = 304.21$  K for both systems and at  $T = 308.15$  K for the CO<sub>2</sub> + CO system. All  $P$ - $\rho$ - $T$ - $x_{\text{CO}_2}$  data have been obtained using a vibrating-tube densimeter, and the mean relative standard deviation of density,  $\bar{S}_\rho^r$ , was estimated to be better than 0.13%. Other properties related to experimental data such as isothermal compressibility,  $\kappa_T$ , excess molar volume,  $V_m^E$ , and solute partial molar volume,  $\bar{V}_2$ , in the critical region ( $T = 304.21$  and 308.15 K and  $P = 5 - 10$  MPa) have been calculated as a function of pressure and composition.

The volumetric behaviour has been compared to literature data and it has been modelled with three Equations of State. The deviations obtained have been: Peng-Robinson,  $MRD_\rho \leq 3.5\%$ ; rescaled PC-SAFT,  $MRD_\rho \leq 2.8\%$ ; and GERG,  $MRD_\rho \leq 1.0\%$ . Thus the three EoS have been validated, for these binary systems, under CCS technology conditions.

Using the Krichevskii Function concept and the Kirkwood-Buff Theory, we have carried out a theoretical study of the interactions between  $\text{CO}_2$  and CO, or  $\text{CO}_2$  and  $\text{CH}_4$  molecules. To this end we have calculated: (i) the Krichevskii function,  $J$ , and the Krichevskii parameter,  $A_{Kr}$ , which reflect the change experimented by the pressure when replacing a molecule of solvent by another of solute in infinitely dilute solutions, IDS, at constant  $T$  and  $V$ ; (ii) the partial molar volume of the solute at infinite dilution,  $\bar{V}_2^\infty$ ; (iii) the direct correlation function integrals,  $C_{ij}$ ; (iv) the excess coordination number,  $N_{exc}^\infty$ ; and (v) the affinity of the solvent per solute molecule, or cluster size,  $N_1^{exc}$ . From the sign of the Krichevskii parameter,  $A_{Kr}$ , its dimensionless counterpart,  $A_{Kr}^*$ , and the divergence signs for different structural properties in the systems studied ( $A_{Kr} > 0$ ;  $\bar{V}_2^\infty \rightarrow +\infty$ ;  $N_{exc}^\infty \rightarrow -\infty$ ;  $1 > A_{Kr}^* > 0$ ;  $N_1^{exc} \rightarrow +\infty$ ), we can conclude that these mixtures exhibit weakly attractive behaviour.

We have proven that the presence of impurities in  $\text{CO}_2$ , even in small proportions, modifies the properties of mixtures. This results, in turn, in a modification of the parameters related to the design and operation in the process of fluid transport, depending on the nature of the mixture, the pressure and the temperature, and must be taken into account in the planning of CCS facilities. In this paper we have quantified the effect of small amounts of  $\text{CH}_4$  and CO in  $\text{CO}_2$  transport through various normalized

parameters (related to their corresponding values when the fluid to be transported is pure CO<sub>2</sub>). The parameters studied were: pipeline inner diameter,  $D$ , erosional velocity,  $v_E$ , transport velocity,  $v$ , Reynolds number,  $Re$ , booster capacity,  $W$ , mass flow,  $m$ , Darcy-Weisbach friction factor,  $f$ , and pressure drop,  $\Delta P$ . Differences with respect to pure CO<sub>2</sub> increase with increasing temperature and decreasing pressure, becoming important (up to 75% in some cases) for 8.6 MPa <  $P$  < 10 MPa (working operating pressures in transport), and converge to smaller values (less than 10%) for  $P$  > 15 MPa.

We have observed, in all the properties studied in this work (volumetric, structural and operational for CCS technology), that the presence of CO as an impurity in anthropogenic CO<sub>2</sub> produces a greater disruption in relation to pure CO<sub>2</sub> than that of CH<sub>4</sub>.

### Appendix A.

#### Relation between period, $\tau$ , and density, $\rho$ .

$$\rho(P, T) = \left( \frac{M_0}{V_i(P, T)} \right) \left[ \left( \frac{K(P, T)}{K_0(T)} \right) \left( \frac{\tau^2(P, T)}{\tau_0^2(T)} \right) - 1 \right] \quad (A1)$$

$$\rho(P, T) = \rho_{ref}(P, T) \frac{\left( \frac{K(P, T)}{K_0(T)} \right) (\tau^2(P, T) - \tau_0^2(T))}{\left( \frac{K(P, T)}{K_0(T)} \right) (\tau_{ref}^2(P, T) - \tau_0^2(T))} \quad (A2)$$

Where

$\rho(P, T)$  is the density of the inner fluid to be determined at pressure  $P$  and temperature  $T$

$\rho_{ref}(P, T)$  is the density of the reference fluid at pressure  $P$  and temperature  $T$

$M_0$  is the mass of the vibrating tube under vacuum

$V_i(P, T)$  is the internal volume of the vibrating tube at pressure  $P$  and temperature  $T$

$K(P, T)$  is the transversal stiffness of the vibrating tube at pressure  $P$  and temperature  $T$

$K_0(T)$  is the transversal stiffness under vacuum of the vibrating tube at temperature  $T$

$\tau(P, T)$  is the period of the vibrating tube with inner fluid to be determined at pressure  $P$  and temperature  $T$

$\tau_{ref}(P, T)$  is the period of the vibrating tube with reference fluid at pressure  $P$  and temperature  $T$

$\tau_0(T)$  is the period under vacuum of the vibrating tube at temperature  $T$

### Uncertainty, $U(y)$

The expanded ( $k=2$ ) uncertainty in the density,  $\rho$ , excess molar volumes,  $V_m^E$ , and solute molar partial volumes,  $\bar{V}_2$ , have been calculated by the rules of error propagation law (JCGM 100, 2008):

$$U(y) = k u_c(y) = k \left[ \sum_{i=1}^N \left( \frac{\partial f}{\partial x_i} \right)^2 u^2(x_i) \right]^{\frac{1}{2}} \quad (\text{A3})$$

Where

$k$  is the coverage factor

$u_c(y)$  is the combined standard uncertainty of the estimated  $y$

$x_i$  represent the input variables

$(\partial f / \partial x_i)$  is the sensitivity coefficient of the input variable  $x_i$

$u^2(x_i)$  is the variance of  $x_i$

### Relative Mean Standard Deviation, $\bar{S}_x^r$ , and Mean Relative Deviation, $MRD_x$

The relative mean standard deviation is calculated:

$$\bar{S}_x^r = \frac{100}{N} \sum_{j=1}^N ({}_j S_x^r) \quad (\text{A4})$$

Where  ${}_j S_x^r$  is the relative standard deviation by point:

$${}_j S_x^r = \frac{{}_j S_x}{\frac{1}{n} \sum_{i=1}^n x_i^{\text{exp}}} \quad (\text{A5})$$

and  ${}_j S_x$  is the standard deviation by point:

$${}_j S_x = \sqrt{\frac{n \sum_{i=1}^n (x_i^{\text{exp}})^2 - (\sum_{i=1}^n x_i^{\text{exp}})^2}{n(n-1)}} \quad (\text{A6})$$

The relative mean deviation is calculated:

$$MRD_x = \frac{100}{N} \sum_{i=1}^N \left| \frac{x_i^{\text{exp}} - x_i^*}{x_i^{\text{exp}}} \right| \quad (\text{A7})$$

Where  $x_i^{\text{exp}}$  are experimental data

$x_i^*$  are bibliographic or calculated values

$N$  is the number of points

$n$  is the number of analysis for given  $T$  and  $P$

**Table 4.**

Comparison between the values obtained for the  $\text{CO}_2 + \text{CH}_4$  and  $\text{CO}_2 + \text{CO}$  systems for several structural parameters and properties: Krichevskii parameter,  $A_{Kr}$ ; reduced Krichevskii parameter,  $A_{Kr}^*$ ; maximum value of the partial molar volume of solute at infinite dilution at  $T = 308.15$  K,  $(\bar{V}_2^\infty)_{max}$ ; minimum value of the excess solvent number at  $T = 308.15$  K,  $(N_{exc}^\infty)_{min}$ ; cluster size at  $T = 308.15$  K,  $(N_1^{exc})_{max}$ , and direct correlation function integrals,  $C_{ij}$  at  $\rho = \rho_c(\text{CO}_2)$  and  $T = 308.15$  K.

Parameter/Property	$T / \text{K}$	System	
		$\text{CO}_2 + \text{CH}_4$	$\text{CO}_2 + \text{CO}$
$A_{Kr} / \text{MPa}$	304.21	$20.383 \pm 0.004$	$26.418 \pm 0.005$
$A_{Kr}^*$	304.21	0.76	0.98
$(\bar{V}_2^\infty)_{max} / \text{cm}^3 \cdot \text{mol}^{-1}$	308.15	3300	3950
$(N_{exc}^\infty)_{min}$	308.15	-33	-38
$(N_1^{exc})_{max}$	308.15	11	3
$10^{-3}(C_{12})_{\rho_c} / \text{cm}^3 \cdot \text{mol}^{-1}$	308.15	0.020	0.006
$10^{-3}(C_{11} - C_{12})_{\rho_c} / \text{cm}^3 \cdot \text{mol}^{-1}$	308.15	0.072	0.085

**Table 5.**

Equation overview for the calculation of several parameters in pipeline design and operation (ElementEnergy 2010).

Parameter	Formula	Symbols
Mass flow	$m = \rho \times v \times A$	$m$ = mass flow (kg/s); $\rho$ = fluid density (kg/m <sup>3</sup> ); $v$ = fluid velocity (m/s); $A$ = pipeline inner section (m <sup>2</sup> ).
Pipeline inner diameter sizing	$D = \left( \frac{4 \times m}{v \times \pi \times \rho} \right)^{1/2}$	$D$ = inner diameter (m); $m$ = mass flow (kg/s); $v$ = fluid velocity (m/s); $\rho$ = fluid density (kg/m <sup>3</sup> ).
Erosional velocity	$v_E = \frac{C}{\sqrt{\rho}}$	$v_E$ = erosional velocity (m/s); $C$ = empirical constant; $\rho$ = fluid density (kg/m <sup>3</sup> ).
Reynolds number	$Re = \frac{\rho \times v \times D}{\mu}$	$Re$ = Reynolds number; $\rho$ = fluid density (kg/m <sup>3</sup> ); $v$ = fluid velocity (m/s); $D$ = inner diameter (m); $\mu$ = fluid viscosity (Pa.s).
Capacity of the booster stations	$W = \frac{m}{\rho} \times \frac{(P_{out} - P_{in})}{\eta_{booster}}$	$W$ = capacity of the booster station (MW); $m$ = mass flow (kg/s); $\rho$ = fluid density (kg/m <sup>3</sup> ); $P_{out}$ = booster outlet pressure (MPa); $P_{in}$ = booster inlet pressure (MPa); $\eta_{booster}$ = booster efficiency.
Darcy-Weisbach friction factor	$f = \frac{1.325}{\left[ \ln \left[ \frac{e}{3.7 \times D} + \frac{5.74}{Re^{0.9}} \right] \right]^2}$	$f$ = Darcy-Weisbach friction factor; $e$ = roughness height (m); $D$ = inner diameter (m); $Re$ = Reynolds number.
Pressure drop per metre	$\frac{\Delta P}{L} = \frac{8 \times f \times m^2}{\rho \times \pi^2 \times D^5}$	$(\Delta P/L)$ = pressure drop per metre (Pa/m); $m$ = mass flow (kg/s); $\rho$ = fluid density (kg/m <sup>3</sup> ); $f$ = Darcy-Weisbach friction factor; $D$ = inner diameter (m).

**Influence of methane and carbon monoxide in the volumetric behavior of the anthropogenic CO<sub>2</sub>. Experimental data and modelling in the critical region.**

**Table S4.**

Normalized parameters,  $X/X_0$ , in pipeline design and operation. Symbols are the same that in Table 5. Symbols without subscript refer to the mixture, and subscript “0” indicates pure CO<sub>2</sub>.

Normalized parameter		Conditions	Formula
normalized inner diameter	$\frac{D}{D_0}$	given mas flow given velocity	$\frac{D}{D_0} = \left(\frac{\rho_0}{\rho}\right)^{0.5}$
normalized erosional velocity	$\frac{v_E}{v_{E_0}}$	assuming the same C (Table 5)	$\frac{v_E}{v_{E_0}} = \left(\frac{\rho_0}{\rho}\right)^{0.5}$
normalized velocity	$\frac{v}{v_0}$	given mas flow given pipeline inner diameter	$\frac{v}{v_0} = \frac{\rho_0}{\rho}$
normalized Reynolds number	$\frac{Re}{Re_0}$	given mas flow given pipeline inner diameter	$\frac{Re}{Re_0} = \frac{\rho \times \mu_0}{\rho_0 \times \mu}$
normalized booster capacity	$\frac{W}{W_0}$	given mas flow given booster configuration	$\frac{W}{W_0} = \frac{\rho_0}{\rho}$
normalized mass flow	$\frac{m}{m_0}$	given pipeline inner diameter given velocity	$\frac{m}{m_0} = \frac{\rho}{\rho_0}$
normalized Darcy-Weisbach friction factor	$\frac{f}{f_0}$	$m = 317 \text{ kg/s} = 10 \text{ Mt/year}$ $D = 0.508 \text{ m} = 20 \text{ inch}$ $e = 4.6 \times 10^{-5} \text{ m} = 0.00015 \text{ ft}$	$\frac{f}{f_0} = \frac{\left[ \ln \left( \frac{e}{3.7 \times D} + \frac{5.74}{Re^{0.9}} \right) \right]^2}{\left[ \ln \left( \frac{e}{3.7 \times D} + \frac{5.74}{Re_0^{0.9}} \right) \right]^2}$
normalized pressure drop per metre	$\frac{\Delta P/L}{(\Delta P/L)_0}$	$m = 317 \text{ kg/s} = 10 \text{ Mt/year}$ $D = 0.508 \text{ m} = 20 \text{ inch}$ $e = 0.00015 \text{ ft}$	$\frac{\Delta P/L}{(\Delta P/L)_0} = \frac{f \times \rho_0}{f_0 \times \rho}$

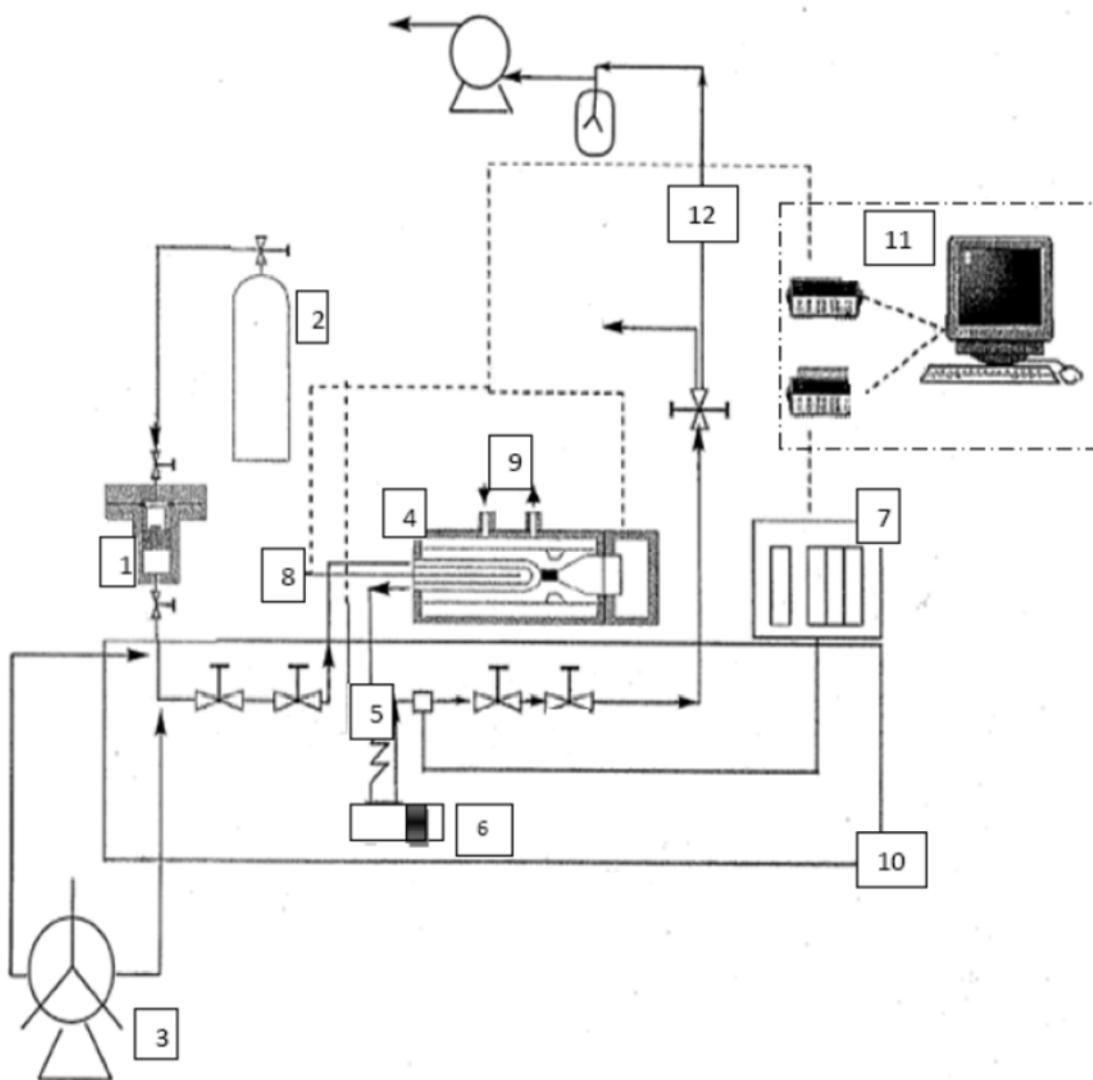

**Table S5.** Normalized parameters for the transport of CO<sub>2</sub> + CH<sub>4</sub> or CO<sub>2</sub> + CO mixtures ( $x_{\text{CO}_2} \cong 0.97$ ), for selected pressures and  $T = 304.21$  and 308.15 K.

$P(\text{MPa})$	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
	$\frac{D}{D_0}$	$\frac{v_E}{v_{E_0}}$	$\frac{v}{v_0}$	$\frac{Re}{Re_0}$	$\frac{W}{W_0}$	$\frac{m}{m_0}$	$\frac{f}{f_0}$	$\frac{\Delta P/L}{(\Delta P/L)_0}$

<sup>(1)</sup>(pipeline inner diameter for mixture transportation) / (pipeline inner diameter for pure CO<sub>2</sub> transportation), for a given mass flow and velocity.

- (<sup>2</sup>) (erosional velocity for mixture transportation) / (erosional velocity for pure CO<sub>2</sub> transportation), assuming the same C (Table 5).
- (<sup>3</sup>) (velocity for mixture transportation) / (velocity for pure CO<sub>2</sub> transportation), for a given mass flow and pipeline inner diameter.
- (<sup>4</sup>) (Reynolds number for mixture transportation) / (Reynolds number for pure CO<sub>2</sub> transportation), for a given mass flow and pipeline inner diameter.
- (<sup>5</sup>) (booster capacity for mixture recompression) / (booster capacity for pure CO<sub>2</sub> recompression), for a given mass flow and booster configuration.
- (<sup>6</sup>) (mass flow for mixture transportation) / (mass flow for pure CO<sub>2</sub> transportation), for a given pipeline inner diameter and velocity.
- (<sup>7</sup>) (Darcy-Weisbach friction factor for mixture transportation) / (Darcy-Weisbach friction factor for pure CO<sub>2</sub> transportation), for a mass flow of 317 kg/s (10 Mt/year), a pipeline inner diameter of 0.508 m (20 inch) and a roughness height of  $4.6 \times 10^{-5}$  m (0.00015 ft).
- (<sup>8</sup>) (pressure drop per metre for mixture transportation) / (pressure drop per metre for pure CO<sub>2</sub> transportation), for a mass flow of 317 kg/s (10 Mt/year), a pipeline inner diameter of 0.508 m (20 inch) and a roughness height of  $4.6 \times 10^{-5}$  m (0.00015 ft).

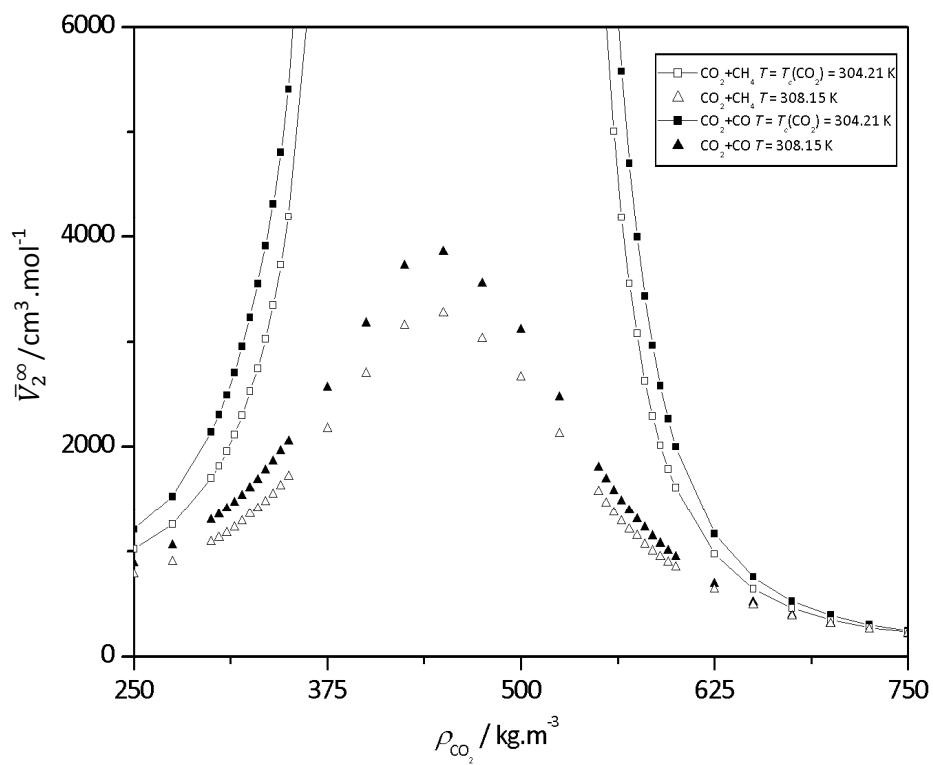

**Fig. S1.** Experimental setup to measure volumetric properties of fluids: (1) loading cell, (2) nitrogen, (3) manual pump, (4) densimeter, (5) vibrating tube output, (6) rupture disk, (7) thermoregulated pressure transducers, (8) platinum temperature probe, (9) externally connected liquid thermoregulated bath, (10) liquid bath, (11) evaluation unit and data acquisition, (12) evacuation and vacuum line.

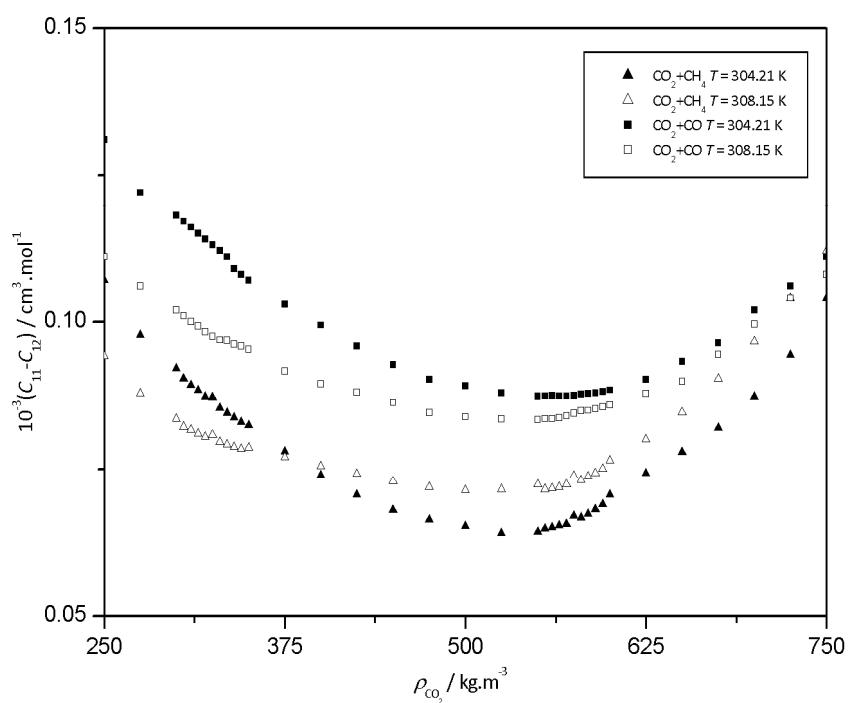

**Fig. S2.** Comparison between  $\bar{V}_2 - P$  literature data and calculated in this work for  $\{\text{CO}_2(1) + \text{CH}_4(2)\}$  system at  $T = 308.15\text{ K}$  and  $x_{\text{CO}_2} \cong 0.996$  mole fraction.

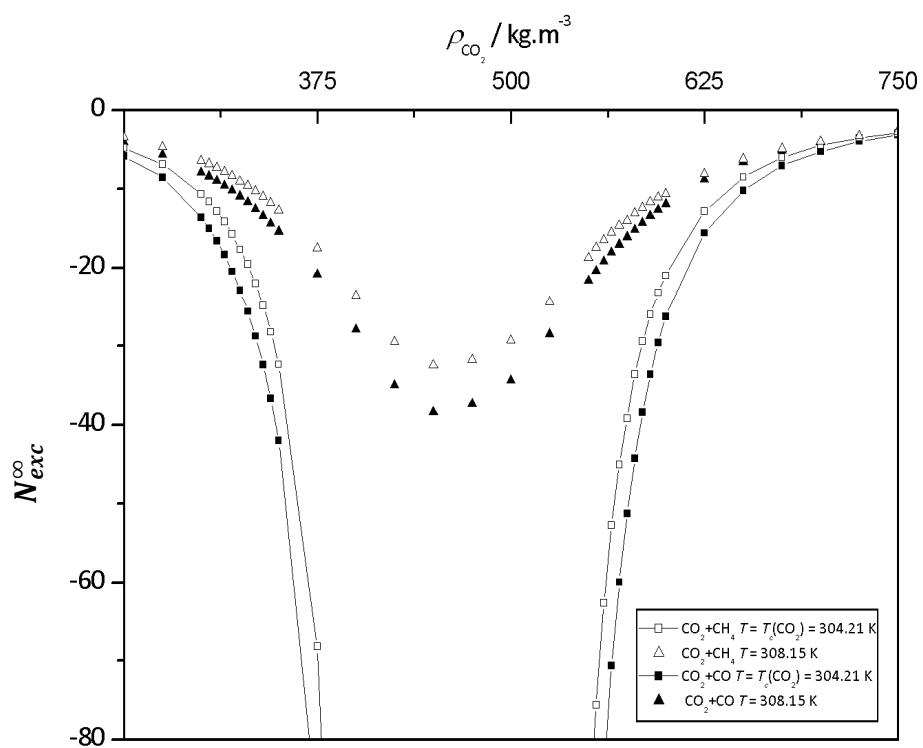

**Fig. S3.** Solute partial molar volume at infinite dilution,  $\bar{V}_2^\infty$ , versus density of the pure solvent,  $\rho_{\text{CO}_2}$ , for the  $\{\text{CO}_2(1) + \text{CH}_4(2)\}$  and  $\{\text{CO}_2(1) + \text{CO}(2)\}$  systems at  $T = 304.21\text{ K}$  and  $T = 308.15\text{ K}$ .

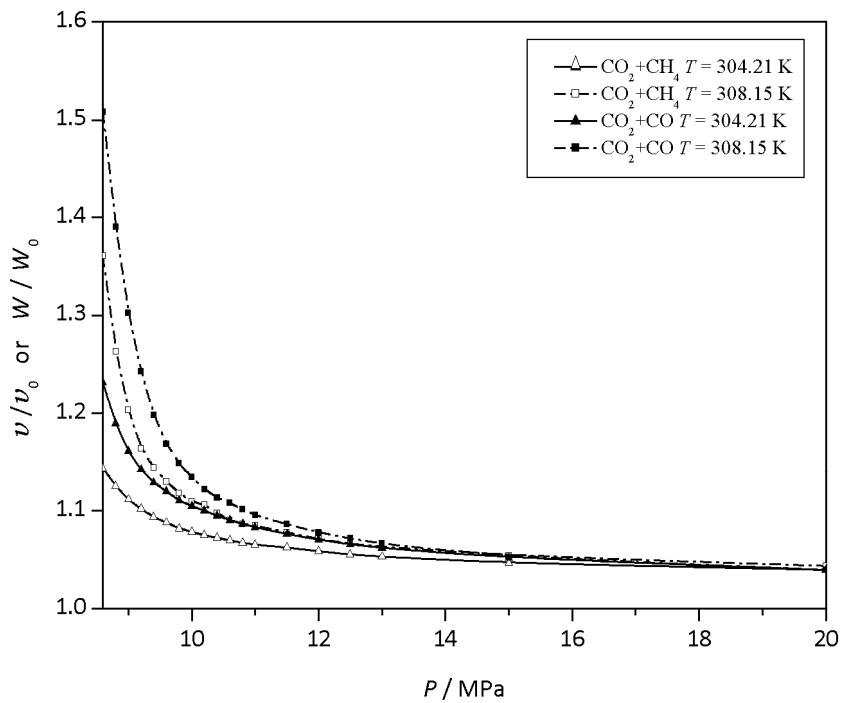

**Fig. S4.** Direct correlation function integrals differences for solvent-solvent (1-1) and solvent-solute (1-2) pair interactions, ( $C_{11} - C_{12}$ ), versus density of the pure solvent,  $\rho_{\text{CO}_2}$ , at  $T = 304.21$  and  $308.15$  K.

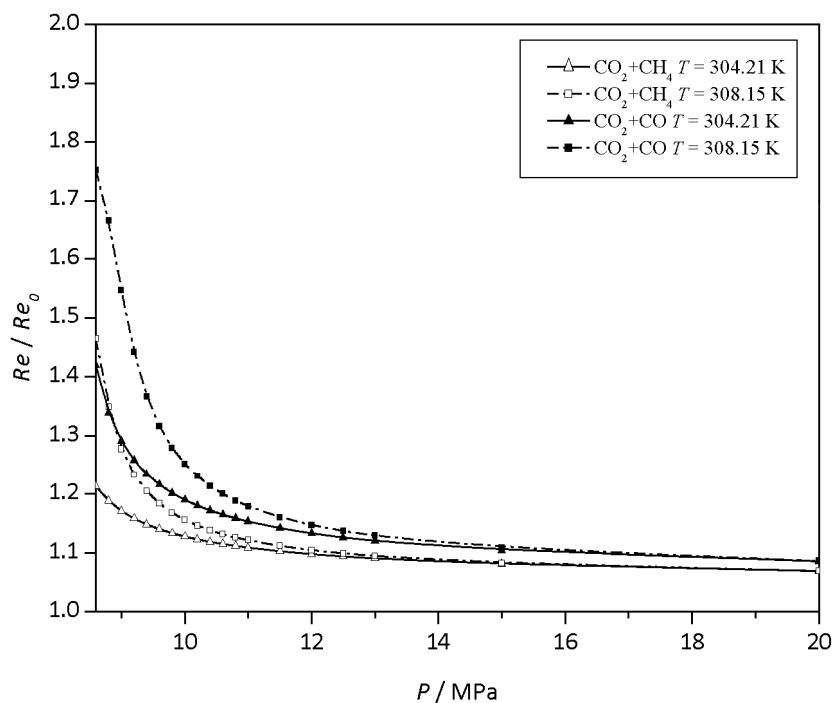

**Fig. S5.** Excess coordination number,  $N_{exc}^\infty$ , versus density of the pure solvent,  $\rho_{\text{CO}_2}$ , for the  $\{\text{CO}_2(1) + \text{CH}_4(2)\}$  and  $\{\text{CO}_2(1) + \text{CO}(2)\}$  systems at  $T = 304.21$  K and  $T = 308.15$  K.

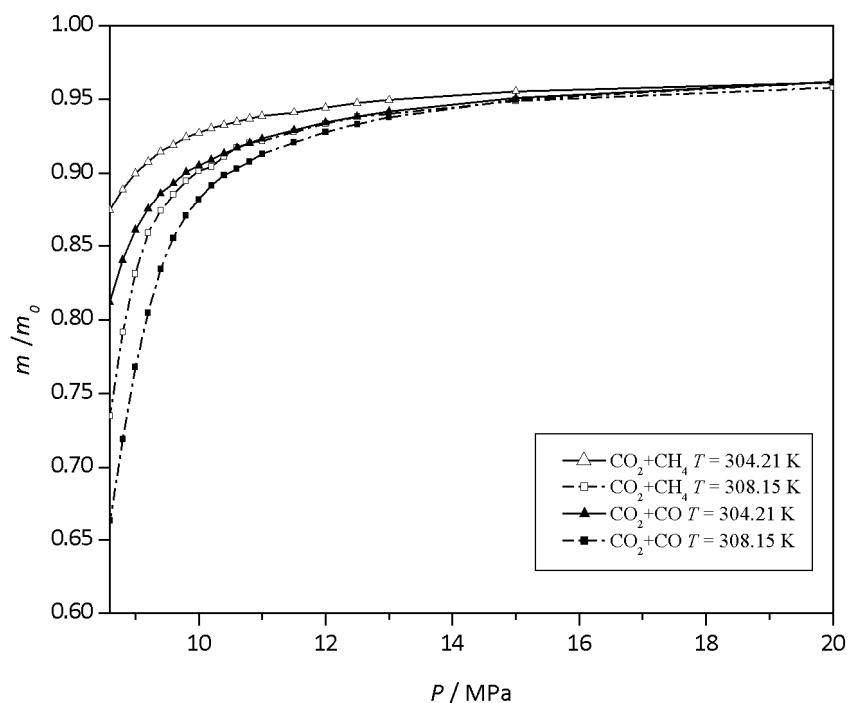

**Fig. S6.** Comparison of normalized transport velocity,  $v/v_0$ , (for a given mass flow and pipeline inner diameter) or normalized booster capacity for fluid recompression,  $W/W_0$ , (for a given mass flow and booster configuration) for mixtures  $\text{CO}_2 + \text{CH}_4$  or + CO with  $x_{\text{CO}_2} \cong 0.97$ .

**Fig. S7.** Comparison of normalized Reynolds number,  $Re/Re_0$ , (for a given mass flow and pipeline inner diameter) for mixtures  $\text{CO}_2 + \text{CH}_4$  or + CO with  $x_{\text{CO}_2} \cong 0.97$ .

**Fig. S8** Comparison of normalized mass flow,  $m/m_0$ , (for a given pipeline inner diameter and transport velocity) for mixtures  $\text{CO}_2 + \text{CH}_4$  or + CO with  $x_{\text{CO}_2} \cong 0.97$ .

**Fig. S9.** Comparison of normalized Darcy-Weisbach friction factor,  $f/f_0$ , for a mass flow of 317 kg/s (10 Mt/year), a pipeline inner diameter of 0.508 m (20 inch) and a roughness height of  $4.6 \times 10^{-5} \text{ m}$  (0.00015 ft) for mixtures  $\text{CO}_2 + \text{CH}_4$  or + CO with  $x_{\text{CO}_2} \cong 0.97$ .
