**Abstract** A miniaturized dual-band antenna array using a negative index metamaterial is presented for WiMAX, LTE, and WLAN applications. This left-handed metamaterial plane is located behind the antenna array, and its unit cell is a combination of split-ring resonator, square electric ring resonator, and rectangular electrical coupled resonator. This enables the achievement of a metamaterial structure exhibiting both negative permittivity and permeability, which results in antenna size miniaturization, efficiency, and gain enhancement. Moreover, the proposed metamaterial antenna has realized dual-band operating frequencies compared to a single frequency for normal antenna. The measured reflection coefficient ( $S_{11}$ ) shows a 50.25% bandwidth in the lower band (from 2.119 to 3.058 GHz) and 4.27% in the upper band (from 5.058 to 5.276 GHz). Radiation efficiency obtained in the lower and upper band are >95 and 80%, respectively.

## 1 Introduction

In the last few years, there has been a significant interest in using metamaterial structures to realize the new electromagnetic properties that may not be readily obtainable in nature [1, 2]. An example of this is metamaterial structures that produces a negative refractive index (NRI) with negative permittivity and permeability properties that are known as double-negative metamaterial (DNM) [3]. They are widely investigated due to their potential applications in various fields such as wireless technology and microwaves. These novel engineered materials are first introduced by Veselago [4] and verified experimentally after several decades [5].

Metamaterial promises a new class of antennas due to their effectiveness in improving antennas' performance and size miniaturization [6–8]. Meanwhile, patch antennas are chosen in this work as they feature advantageous physical and electromagnetic properties such as low profile, low cost, small size, reasonable gain, and good radiation patterns [9]. However, conventional patch antennas suffer from narrow bandwidths, low gains and efficiencies, and large sizes at low frequencies. Therefore, numerous types of metamaterials structures such as SRR, SERR, capacitance-loaded strip (CLS), spiral resonators (SR) and periodic array structures are proposed to enable improvement of their physical and electrical features [10–12]. To date, different metamaterial structures have been investigated for antenna miniaturization, improving gain and efficiency and enabling multi-band operation [13]. For instance, SRRs unit cells structures are generally employed as loading structure placed along an antenna to reduce the resonant frequency of an antenna [10, 14, 15].

This paper presents a miniaturized dual-band antenna array using a novel combination of DNG metamaterial unit

cell for WiMAX, LTE, and WLAN applications. The proposed left-handed metamaterial unit cell located on the reverse of the antenna substrate combines the SRR, SERR, and rectangular ELC resonator. This structure exhibits negative refractive index (NRI) and negative permittivity and permeability, which results in a compact, dual-band antenna array ( $0.17\lambda \times 0.36\lambda \times 0.004\lambda$ ) with more than 95% of radiation efficiency.

### 2 Antenna design geometry

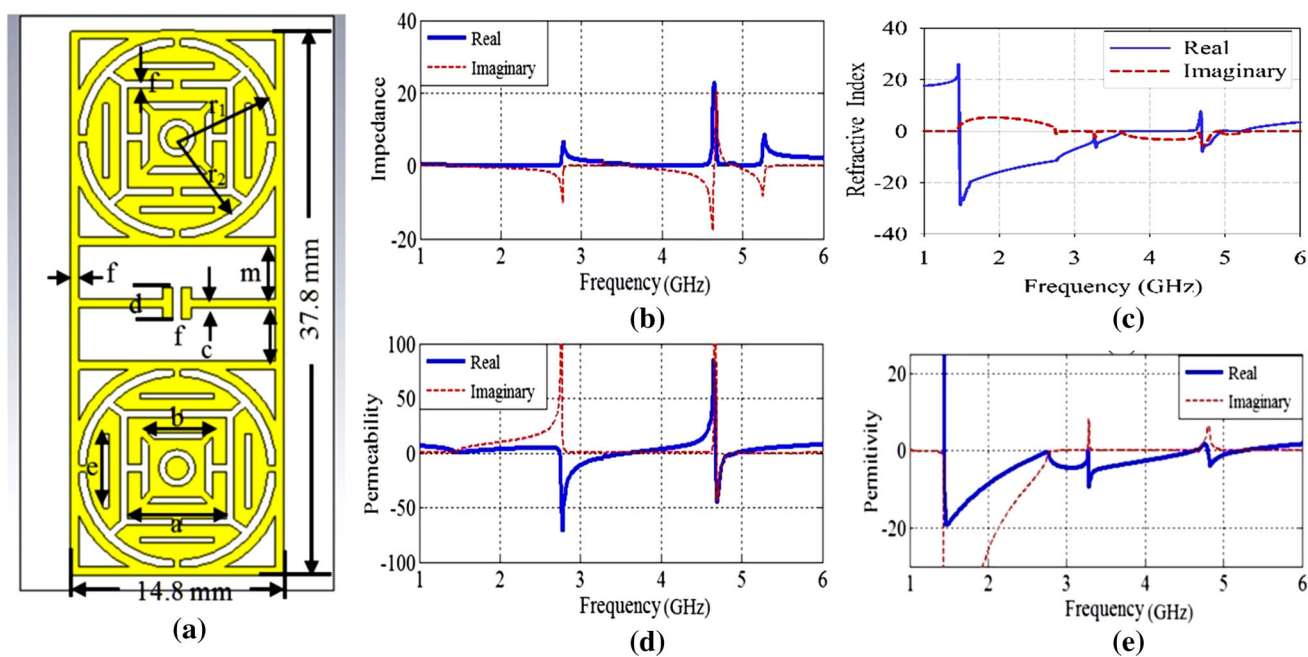

Figure 1a shows the front view of the combined unit cell structure. It combines the SRR and SERR which are both magnetic resonant structures. The perpendicular magnetic field produced by those cells generates negative permeability. Meanwhile, the rectangular ELC resonator is located between the above mentioned cells and is used to generate negative permittivity. The dimensions of the proposed unit cells are illustrated in Table 1. Figure 1b–e illustrates the real and imaginary values of impedance,

refractive index, permeability, and permittivity. The result indicated that the proposed structure features a negative refractive index from 1.5 to 3.6 GHz.

Figure 2a, b illustrates the simulated geometry of the proposed antenna. It is an array containing 10 elements; each rectangular element is dimensioned at  $4 \times 4 \text{ mm}^2$ . The antenna is fed using a combination of both series and corporate feed techniques. It is designed on a 0.51-mm-thick RT/duroid<sup>®</sup>5880 substrate. The metamaterial unit cells and ground plane are located on the rear side of the antenna. The dimensions of the proposed antenna array are listed in Table 1.

### 3 Experimental results and discussion

Figure 3 shows the fabricated 10-element array prototype. Its reflection coefficients ( $S_{11}$ ) are then measured in an anechoic chamber using an Agilent E8051C network analyzer and compared with simulations in Fig. 4. It covers two bands which fulfill the WLAN, LTE, and WiMAX

operating bands. The simulated and measured reflection coefficient  $S_{11}$  is below  $-10$  dB for both operating bands. The measured results indicated an increase in the bandwidth for the first band from 40.08% (simulated) to 50.25% (measured) and the second band bandwidth slightly increased to 4.27%. This is due to the fabrication accuracy issues of the small unit cells.

Figure 5 illustrates the gain, radiation, and total efficiencies of the proposed antenna. It can be seen that the maximum gain of the proposed antenna in the first band is 2.8 dB and is increased to 3.48 dB in the second band.

Conversely, the radiation and total efficiencies in the first band varies between 88 and 98.5% while for the second band these parameters have been reduced to 88 and 79%, correspondingly. Radiation patterns shown in Figs. 6 and 7

indicate an omnidirectional behavior in the first band (at 2.4 GHz) while a bi-directional in the second band (at 5.1 GHz). Furthermore, the degradation in total efficiency in the second band is due to the fact the small antenna showed high losses at higher frequency and thus reducing its total efficiency [16–18].

An overview of such antennas published in literature is given in Table 2. It can be observed that the antenna proposed in this work results in a significant size miniaturization while maintaining high efficiency in comparison to the state of the art.

## 4 Conclusions

A miniaturized dual-band antenna array using DNG metamaterials is presented. A novel combination of left-handed metamaterial SRR, SERR, rectangular electrical coupled (ELC) resonator unit cells is proposed. The features of negative permittivity, permeability and refractive index (NRI) are validated numerically from the proposed unit cells structure. They are then placed on the reverse side of an antenna array. The measured reflection coefficient ( $S_{11}$ ) shows a 50.25% of bandwidth in the first band (from 2.119 to 3.058 GHz) and 4.27% (from 5.058 to 5.276 GHz) in the second band. Radiation efficiencies obtained from this structure are >95% (in the first band) and 80% in the second band.
