Employing Artificial Intelligence to eCommerceWeb serviceGJCST Classification1.2.1,H.3.5

R. Vadivel¹ Dr. K. Baskaran²

Abstract-In recent years, web services have played a major role in computer applications. Web services are essential, as the design model of applications are dedicated to electronic businesses. This model aims to become one of the major formalisms for the design of distributed and cooperative applications in an open environment (the Internet). A main objective of this paper is application of techniques from the field of artificial intelligence (AI) to the field of web services (WS). Current commercial and research-based efforts are reviewed and positioned within these two fields. Particular attention is given to the application of AI techniques to the important issue of WS composition. Within the range of AI technologies considered, we focus on the work of the Semantic Web and Agent-based communities to provide web services with semantic descriptions and intelligent behavior and reasoning capabilities. Re-composition of web services is also considered and a number of adaptive agent approaches are introduced and implemented in publication domain and one of the areas of work is eCommerce.

Keywords-Web Services, Semantic Web, eCommerce, Artificial intelligence, Publication Domain, Dynamic Web

I. INTRODUCTION

urrently, Web services give place to active research and this is due both to industrial and theoretical factors. On one hand. Web services are essential as the design model of applications dedicated to the electronic business. On the other hand, this model aims to become one of the major formalisms for the design of distributed and cooperative applications in an open environment (the Internet). Research in the field of semantic web / web service (WS) and artificial intelligence (AI) communities are coming together to develop solutions that will take us to the next and more mature generation of the web application. The composition of web services to create a value-chain greater than the sum of the parts is a key part of what can be expected. The fulfilment of the vision of the web as an informationproviding and world-altering provider of servicesis not far away. More futuristic is the notion of serendipitous. In both visions the services and outcomes may be the same.

However, the difference between the two visions is that the first can be achieved through static and manual solutions and the second requires dynamic and automated solutions. While

helpful for the first, the addition of semantic content on the web is essential to enable automatic discovery and

vadivel.rangasamy@gmail.com)

composition of multiple services. It is natural that earlier work in the field of AI will assist in realization of the (artificially) intelligent web. The work on the Web Services Modelling Framework(WSMF) is an example of AI being applied to this field. WSMF offers the combined use of ontology, goal (problem-type) repositories, web service descriptions and mediators to handle interoperability issues. The agent community, which is primarily AI-based, has also been actively conducting WS related research.

Our own distributed agent-based work and the AgentFactory, originates from our earlier AI research intocomplex knowledge based systems and generic task basedconfiguration. On the one hand, our work on planning andautomated configuration offers a way of composing eCommercewebservices. On the other hand, WSs potentially provide uswith components needed to achieve an implementation ofour design. Through the addition of techniques from theSemantic Web community, the benefits of combining ouragent technology with WSs has been mutual.

This paper offers a review of research that overlaps the fields of WS and AI. In the following section we describe web services and the need for semantics to be added. In section B we look at how the Semantic Web communities, within the field of AI, are offering semantics. In section C we present AI-based research to address the discovery of

WSs. In *section* D we consider both commercial and AIbasedtechniques for WS composition. In *section* E, thenotion of re-composition of WS is considered and howadaptive agent technology, including our own, can addressthis problem. We conclude with future directions for therole of AI in the web services field.

II. RELATED WORKS

A. Web Services

Web services are typically application programming interfaces (API) or web APIs that can be accessed over a network, such as the Internet, and executed on a remote system hosting the requested services.

Web services are a new way of connecting business. Web services are platform-neutral and vendor-independent protocols that enable any form of distributed processing to be performed using XML and Web-based technologies.

1) Just-in-time integration

The Web Services architecture describes the principles behind the next generation of e-business architectures, presenting a logical evolution from object-oriented systems to systems of services. Web Services systems promote

About-¹Computer Science, Karpagam University Pollachi Road, Eachanari, Coimbatore, Tamilnadu India 641 024 (e-mail-

About-²Asst. Professor (RD), Dept. of CSE and IT, Govt. College of Technology, Coimbatore – 641 006

significant decoupling and dynamic binding of components: All components in a system are services, in that they encapsulate behavior and publish a messaging API to other collaborating components on the network. Services are marshaled by applications using service discovery for dynamic binding of collaborations. Web Services reflect a new service-oriented architectural approach, based on the notion of building applications by discovering and orchestrating network-available services, or just-in-time integration of applications.

B. Semantic description of Web Services

WSDL, SOAP and UDDI are seen as steps in the right direction but ones that will fail to achieve the goals of improved automation and interoperability, because they rely on a priori standardizations and require humans in the loop. To support automated reasoning, knowledge representations (such as markup languages) will be needed that express both data and rules for reasoning. The ability to dynamically locate and compose web services based on their semantic description will rely on the richness of the description and the robustness of the matching techniques used. Ontology will be used to enable definition and comprehension of meaningful content. These are the concerns of the Semantic Web community. Additionally, agents will be needed to interpret the content and transform user requests into optimized delivered solutions. The Intelligent Brokering Service for Knowledge-Component Reuse on the WWW (IBROW)4can be seen as a forerunner of the Semantic Web. In IBROW problem solving methods (PSMs) and ontologies were the components being configured, the current focus is on WS configuration. PSMs and ontologies when used together are also capable of delivering services. The most significant work that has been done to describe web services has been conducted by the DAML-S coalition. The matching of service providers and service requesters via semantic descriptions of the services are key goals of this work. DAML-S uses the DAML+OIL specification language (which extends the weak semantics of RDF(S)) to define a number of ontologies that can be specifically used to describe web services. DAML-S is built on the AI-based action metaphor where each service is either an atomic/primitive or composite/complex action. Knowledge preconditions and knowledge effects are handled via the inputs and outputs of the web service. The DAML-S coalitions are providing solutions to work with current WS standards. For example, a DAML-S service grounding definition can be mapped to a WSDL definition of the service. A number of approaches to service discovery and composition hat we discuss in the following sections use or extend the DAML-S web service ontology.

C. Discovering Web Services

Discovery involves locating and/or matchmaking against some selection criteria. An earlier AI system, Lark, which involved annotation of agent capabilities to enable them to be located and brokered, clearly solved a problem similar to the discovery of WS by a middle agent. This work has developed into the DAML-S Matchmaker⁵. To support matchmaking a number of filters may be configured by the user to achieve the desired tradeoff between performance and matching quality. These filters include: word frequency comparison, ontology similarity matching, ontology subsumption matching, and constraint matching.

Offer an alternative to sequential searching when matchmaking an agent with a service request. They point out that finding possible partners via matching of service advertisements with requests is not enough. To support runtime interactions we need smarter behavior to handle components that are not quite what was requested and combining several partial components to meet the original request. The solution to overcome sequential searching is the conversion of the concepts into number intervals and the use inheritance hierarchies to determine subclass and equality relations. A generalized search tree is used to handle partial matches.

The feasibility of matchmaking largely depends on the annotation of web services. AI can also be applied to this problem. A number of markup tools have been developed for document markup and these could be applied to the semantic description of WSs. The SHOE Knowledge Annotator [19] uses ontologies to guide knowledge annotation. To produce RDF-based markup, COHSE or AeroDAMLcan be used. These approaches start with descriptions in DAML+OIL and DAML, respectively. These approaches support automatic conversion of markup languages but do not support information extraction or automatic mark-up. OntoMat does support some form of automated extraction of semantics. OntoMat combines the resource with its DAML-S markup. The MnM approach additionally stores the annotations in a knowledge base. Automated markup in MnM is achieved using techniques from knowledge engineering; machine learning and natural language processing have developed a query language that is used to find services.

The solution to finding services is to first describe the service using the process ontology with the assistance of the MIT Process Handbook. The Handbook is large and allows reuse to assist in ontology definition. Next, the ontology is indexed by breaking it down into its components such as attributes, ports, dependencies, subtasks and exceptions. The requester can form a query in the query language that will use the index to find matches.

Clearly AI is already contributing solutions for locating, matchmaking, querying and annotation of WS to facilitate their discovery. Discovery of web services is an important issue as it is a prerequisite to their use. However, the real value of web services lies in their composition.

D. Composing Web Services

Web service composition can be simply defined as: —Ite problem of composing autonomous services to achieve newfunctionality". WS composition is not just analternative to application development but a means of reducing the application backlog problem because: manyservices are moving online; integration is easier since WSsconform to the HTTP protocol and many independent providers have related services that need to be combined tosatisfy user requirements. The rigidity and lack of intelligence of current solutions has spawned a number of research projects from a number of other research fields.

The work by has arisen from experience in the distributed systems and networking fields. They havedeveloped the Infrastructure for Composability at Runtimeof Internet Services (ICARIS). They have extended WSDLto develop the Web Services Offerings Language (WSOL). They offer flexibility and adaptability but their approach isvery alternative. Instead of trying to solve the problem ofhow to find services dynamically and combine them, theyfocus on the situation where providers and requestors arealready matched but will at times either make changes totheir services or requests. A service is seen to havenumerous offerings. The functionality will be the same butthe constraints will differ such as authorization rights andQoS. They suggest that a limited number of classes ofservices be offered and described. Then using WSOL they are able to specialize the classes into offerings. Theirsolution offers dynamic switching between offerings. Froma commercial point of view the notion of offerings makessense as customers probably prefer to do business with companies they already know and businesses want tomaintain their existing client base.

The work at Hewlett Packard laboratories on eFlowis similar in that dynamiccomposition involves automaticadaptation of the configuration at runtime according to therequests of the individual customer. The approach is drivenby the view that composition adds value but to staycompetitive, composition needs to be dynamic as services offered need to adapt to stay competitive. Their goal is toallow dynamic change in service processes with no orminimal human intervention. While they take a businessprocess perspective they point out that web services are less static, predictable or repetitive compared to -raditional"business processes. Similar to most current commercial solutions, dynamic composition is made possible due to theuse of a central repository that has clients and providersalready attached to it.

The notion of generic solutions that are customized according to user constraints is a recurring theme in much of the literature. Also look at composition as theselection of possible services based on user specified criteria. They offer a centralized, pipes and filtersarchitecture with two main components: a composer (userinterface) and an inference engine (IE) component (whichincludes a knowledge base of known services). Theinference engine is an OWL reasoner and includes axiomsto find all relevant entailments, such as the inheritancerelation between two classes which may not

have beenmade explicit. The user identifies some criteria that theservice must satisfy. The matchmaker (IE) selects servicesthat might be suitable based on those criteria and thecomposer shows them to the user. Suitable services forcomposition are ones whose output can be an input to aselected service. While execution of WS may be performedautomatically, the actual task of composition is performedby a human using the services suggested by the system.

Model-based reasoning is a common techniqueemployed in AI approaches. In SWORD entity relationshipmodelling of services is performed by -baseservice modellers" to produce a --worldmodel". Afterbuilding a world model for each service, a compositionmodel is developed that models each service as an action.An expert system is used to automatically determine if the composite service can be created with existing services and if so aplan of execution is generated.

In summary, a number of solutions are offered to provide webservice composition. The approaches described in this sectionshow that composition can be assisted through the use of classdefinitions, inheritance hierarchies and model and rule-basedreasoning. In many cases, decision making is left to humans. Theonly automated composition offered is in limited situations wherea central repository is used and the requestor and provider are partof the same system. However, the web is distributed in nature.Intelligent reasoning and collaboration between services is neededto handle this complexity. Agents are capable of both.

E. Agents and Web Services

The autonomous and reasoning capabilities of agents make them well suited for handling cross-organizational decision making. For example, agents can be used to (re)negotiate contracts which would then require: determination of which processes are needed to fulfil the contract; creation of new business processes; and adaptation of existing business processes. Two main agent-oriented approaches exist: use wrappers to make WS behave like agents and; using agents to orchestrate WS.

1) Adding Behaviour to WS via Agents Wrappers

WS are componential, independent, software applications similar to agents. However, agents are also reactive, social and capable of reasoning. If we wish web services to work together, we need to give them social and reasoning capabilities. This can be achieved by wrapping a service in an agent. In the work of, a composition language is used to create an agent wrapper which allows services to collaborate. The created agent has first-order reasoning abilities that have been derived from the DAML-S description of the service. This then allows one agent wrapped service to know what other agent-wrapped services are capable of doing and whether they can assist in the service/agent meeting its goals. Also offer an agent-based wrapper approach to web services. They have developed a tool for creating wrappers so that web sources can be queried in a similar manner to databases. They then use an interactive, hierarchical constraint propagation system to perform integration. As in, the end user interacts via a GUI to manage the orchestration. The Racing project6 offers amediator architecture also using agent wrappers that are structured into a hierarchy. A number of different agent wrappers are supported: user, query translation, query planning, resource wrapper, ontology, matchmaking, and cloning and coordination agents. The use of agent wrappers is a way of allowing multi-agent system technology to be applied to web services

2) Composing Web Services using Agents

The work of combines ideas from the Semantic Web, Knowledge Representation and Agent communities to allow WSs to be composed. Their goal is to -onstruct reusable, high-level generic procedures, and to archive them in shareable (DAML-S) generic-procedures ontologies so that multiple users can access them". In the approach, WSs and user constraints are marked up in DAML-S. A generic task procedure is selected by the user and given to the DAML(-S) enabled agent, who customizes the procedure according to the user specific constraints. The generic procedures are written in an extended version of ConGolog, a situation calculus agent programming language, and executed using a Prolog inference engine. Others provide agent-oriented languages for web service description. Propose an Agent Service Description Language (ASDL) and Agent Service Composition Language (ASCL). ASDL is an extension to WSDL and captures external behaviour via a finite state machine. Their work is based on the argument that composition requires more than description of the data, but also requires a strong representation of actions and processes. A number of approaches are focused on the design of agent systems with web services as the components have developed WARP (Workflow Automation through Agent-based Reflective Processes) that uses the XML and WSDL standards. The goal is automatic configuration and management of low-level services (components). The software engineering development process that has been developed is semi-automatic involving multiple software agents and a human workflow designer. They support visualization of the process based on activity diagrams in UML.

3) (Re-)composition and Adaptable Agents

The ability of agents to adapt according to changes in system requirements and the environment is important to enable dynamic and reactive behaviour.

Agents may be adapted in a number of different ways. The knowledge and facts that an agent uses may be adapted for example the agent may use a client profile that changes according to the clients activities (e.g. this type of adaptation typically involves machine learning, e.g. An agent may also adapt its interface according to the platform on which it is being used (e.g.[brand]. A third type of adaptation, and the type of adaptation we are concerned with, is adaptation of the agent's functionality. There is limited work in this area. Semi-automatic agent creation tools such as AGENTBUILDER, D'AGENTS/ AGENT/TCL, ZEUS and PARADE could possibly be extended to support agent adaptation.

Following the use of compositionality in the major softwareengineering paradigms (e.g. functional programming. object-orientedprogramming, componentbased programming and the Factory design pattern, we have developed an AgentFactory. The approach is based on the use of components, thegeneral agent model (GAM) and the DESIRE formal knowledge levelmodelling and specification frameworkfor multi-agentsystems. Our agent (re)structuring approach allows an agentto automatically adapt by reusing existing components. Ourapproach is a combination of process-oriented and objectoriented approaches by treating processes as the 'active' parts of our agent, which are our agent components and classes as the 'passive' part f our agent, which are the data types used in the agent components. We are currently exploring whether DAML-Sdescriptions of web services are adequate for automated configuration of web services by the Agent Factory.the Agent Factory andbased on the notion of design patterns, assists human designers infunctional design, and the configuration of software componentsto fulfil the conceptual design specified by the designers, depending on the agent platform that is to be used. Our approachdoes more: it automates the creation and redesign of both theconceptual and operational design based on the requirements onfunction, behavior and state of an agent. Our use of web services s components is a further distinguishing feature.

While not currently working in the WS area, the Adapt agent approach, bring together adaptive workflow and agentresearch. They consider how agents can be used to collaborate toperform a workflow and make workflow more intelligent andhow workflow can be used to organize a set of agents andcoordinate interaction between people and agents.

The reuse of knowledge has also been a widely researchedtopic and the creation of libraries of problem solving methodsand generic task modelsoffer a similar idea to the functional components in our agent factory. The IBROW project, mentionedearlier, has even more in common with our approach by semi automaticallyconfiguring intelligent problem solvers usingproblem solving methods as building blocks. They use mappingsto act as glue between the components which are modelled asCORBA objects. Unlike our approach, their architecture is restricted to specific languages and architectures, they onlysupport semi-automation and they do not distinguish betweenconceptual and implementation level designs.

III. EXPERIMENTAL RESULTS

In this section we evaluate the performance of the proposed artificial intelligence to eCommerce web service agent. We have created common web service application to integrate the all web and windows application who want to integrate eCommerce application to their application. Refer Fig 1 - 4 work flow of AI based eCommerce web service.

A. Application Overview

The Order Management System (eCommerce) has been written to provide a common means to create simple orders and process credit card transactions. The first version works only with PayPal's PayFlowProw service but can be updated to work with other online merchant services (e.g. Authorize). When the need to use an alternative provide comes up we'll code the core library accordingly. Any changes here will not affect the way you use the service.

1) Not a User Management System

The system doesn't offer any user management capabilities like sign in. It assumes the calling application knows who the user is let's it take care of any user authentication required. When you're coding your shopping carts you need primary means of identification and is required before you can process any payments.

2) Typical Lifecycle / Process Flow

It's important to understand how the Order Management System (OMS) works so you can make use of the methods in the most efficient way.

The first thing you'll need to do is to create a Processing Session in the OMS. This is done by calling the **GetSessionForKnownUser()** method and passing in the email address of the current user. The OMS will create a session and a shopping cart for the user. It's recommended that you store the ID of the session in your application cookie or in your database so it can be reused. It's not efficient to create a session every time!

To retrieve the shopping cart you simply call the **GetShoppingCart()** method. To add an item to the shopping cart simply call the **AddItemToShoppingCart()** method passing in a properly constructed ShoppingCartItem object. To remove an item from the shopping cart simply call the **RemoveItemFromShoppingCart()** method passing in the item to remove. You can also empty the shopping cart by calling the **EmptyShoppingCart()** method.

3) Ready to Checkout

Once you've populated the shopping cart, authenticated your user you're ready to process the transaction and turn the Shopping Cart into an Order. To do this you must create a **PaymentProcessingKey**. Think of this is a temporary key allowing you to make a credit card transaction. To create one you call the **GeneratePaymentProcessingKet()** method passing in the session. It will configure it with the session and the associated shopping cart ready for processing.

4) Payment Information Page

This page is the one responsible for taking the credit card information and processing the payment through the online payment gateway (e.g. PayFlowPro). The Order summary is displayed at the top of the page so the user can make sure they're purchasing the correct item(s). The next section prompts for the credit card information including the CVV2 security code location on the credit card. to handle all of this. The Order Management System simply provides the relevant methods to create Processing Sessions, Shopping Carts etc you just need to implement them.

The Order Management System does keep track of "users" (customers) through the use of an email address. This is the

The last section prompts the user for the billing address that's associated with the credit card they're using. If the user is purchasing physical goods they should also populate a shipping address. If the order consists of only electronic items the shipping address can be left blank.

5) Processing the Payment

Once the user is happy that all the information has been entered correctly they should click the "Purchase Now" button to initiate the payment transaction. Processing payments is actually using a two step process:

1. The first step is to authorize the payment. The reason we do this is to basically test to see if the payment information is correct and that the payment card will accept the new payment being attempted without actually taking the funds. The reason we do this is to make sure the transaction will succeed. If this step fails we send the user back to the payment information page and display them the error. It basically means that we'll never process an order unless the payment succeeds.

2. The second step is to then retrieve the actual funds allocated during the first authorization step. At this point we're 99.9% confident that the transaction will succeed because the authorization was successful.

After a successful transaction the system performs some cleanup routines and processes the order:

- 1. Updates the status of the order to Complete
- 2. Constructs an invoice and sends this to the user
- 3. Constructs a notification email and sends this to the
- person setup in the installation configuration

4. Calls the Call-back page defined int the installation configuration. This page is located on calling application and is generally responsible for firing any triggers based on the products that were just purchased. For example it might need to perform an upgrade of a profile or add a new feature.

Once all this is complete the user is sent to the Order Confirmation Page where a summary of the order is presented.

IV. CONCLUSION

The work of the Semantic Web community to provide semantic description of web services will play a key role in enabling agents to automatically compose web services. In this eCommerce application has implemented in embedded windows and web applications with cross-platforms and it's successfully interoperability of applications. A standard communication between the agents is clearly defined and very less amount of data loss.

Existing agent platforms may need to be adapted to handle the specific requirements of web services. But in this system with no trouble to adaptable all kind of computer applications and tested in real world applications. The RETSINA functional architecture includes four basic types of agents: interface, task, information and middle agents who communicate via a special agent communication language. Each of these agents includes four reusable modules: communication and coordination, planning, scheduling and monitoring. The middle agent plays a critical role in matching providers with requesters and is offered as a solution to the heterogeneous nature of agents over the web.

In future work will continue on artificial intelligence to natural language technology research will assist discovery of web services and agents will play an important role in using web services to satisfy user requests.
