Dear Sir:

In their article, Messrs. Mason and Connelly ${ }^{1}$ have described and

[^0]illustrated the use of four selfchecking digit techniques. These techniques are useful in detecting various types of coding errors generated when numbers are transcribed from one document to another. For each technique, they also evaluated, by simulation, the conditional probability that a single transposition error would be uncovered given that such an error has occurred. In particular, in Table 1, they list the conditional probability of a Mod 11-Geometric technique uncovering a single transposition error as .90 . The conditional probability should have been listed as 1.00 since the Mod 11-Geometric technique can detect all single transposition errors. The proof is as
follows: Let the number to be checked be N , a positive integer of any magnitude. That is
$$
\mathrm{N}=\mathrm{x}_{\mathrm{m}} \ldots \mathrm{x}_{\mathrm{i}+1} \mathrm{x}_{\mathrm{i}} \ldots \mathrm{x}_{3} \mathrm{x}_{2} \mathrm{x}_{1}
$$
base 10 , where m is the number of digits in N , and $\mathrm{x}_{\mathrm{i}}$ is the value of the digit in the $\mathrm{i}^{\text {th }}$ position. Let $\mathrm{N}^{\prime}$ represent N after a single transposition error has occurred. That is,
$$
\mathrm{N}^{\prime}=\mathrm{x}_{\mathrm{m}} \ldots \mathrm{x}_{\mathrm{i}} \mathrm{x}_{\mathrm{i}+1} \ldots \mathrm{x}_{3} \mathrm{x}_{2} \mathrm{x}_{1}
$$

The check digit for N is the complement of the remainder developed when

$$
\begin{aligned}
& 2 \mathrm{x}_{1}+2^{2} \mathrm{x}_{2}+\ldots 2^{i} \mathrm{x}_{\mathrm{i}}+2^{\mathrm{i}+1} \mathrm{x}_{\mathrm{i}+1}+ \\
& \ldots+2^{m} \mathrm{x}_{\mathrm{m}}
\end{aligned}
$$

is divided by 11. The check digit for $\mathbf{N}^{\prime}$ is the complement of the remainder developed when
$2 x_{1}+2^{2} x_{2}+\ldots+2^{i^{-1} x_{1-1}}+$ $2^{i} \mathrm{X}_{\mathrm{i}+1}+2^{i+1} \mathrm{X}_{\mathrm{i}}+\ldots 2^{\mathrm{m}} \mathrm{X}_{\mathrm{m}}$
is divided by 11. However, if $\mathrm{x}_{\mathrm{i}}$ does not equal $x_{i+1}$, the difference between these two dividends (say D1), when divided by 11, will always have a remainder whose magnitude is greater than zero. Therefore, the check digit for $\mathrm{N}^{\prime}$ will not equal the check digit for N , and the single transposition error will always be detected. We can show that D1, when divided by 11 , will have a remainder whose magnitude is always greater than zero by the following:

$$
\begin{aligned}
& 2 \mathrm{x}_{1}+2^{2} \mathrm{x}_{2}+\ldots+2^{i} \mathrm{x}_{\mathrm{i}}+1 \\
& 2^{i+1} \mathrm{x}_{\mathrm{i}+1}+\ldots 2^{\mathrm{m}_{\mathrm{x}}}
\end{aligned}
$$

minus

$$
\begin{aligned}
& 2 \mathrm{x}_{1}+2^{2} \mathrm{x}_{2}+\ldots+2^{\mathrm{i} \mathrm{x}_{\mathrm{i}+1}}+ \\
& 2^{i+1} \mathrm{x}_{1}+\ldots 2^{\mathrm{m}_{\mathrm{x}_{\mathrm{m}}}}
\end{aligned}
$$

equals

$$
2^{i} x_{i}-2^{i} x_{i+1}+
$$

$$
2^{i+1} x_{i+1}-2^{i+1} x_{i}
$$

which equals

$$
2^{i}\left(x_{i+1}-x_{i}\right) .
$$

Now since $x_{i+1}$ and $x_{i}$ are positive integers, $x_{i+1}-x_{i}$ must be an integer and lie between - 9 and +9 . Therefore, 11 can never be a factor of $2^{i}\left(x_{i+1}-x_{i}\right)$. It is only when $x_{i+1}=x_{j}$ that $N$ and $N^{\prime}$ will have the same check digits. But if this were true, then $\mathrm{N}^{\prime}$ equals N , and there would be no single transposition error.

## Critics are correct

Dear Sir:
Thank you for the copy of the Roy and Caron letter.

Their equations are correct. Due to an error in programing, the conditional reliability of the Mod 11Geometric method was listed as 90 per cent when instead it should have been reported as 100 per cent. Our revised Table 1 is shown below.
Although we do agree to the modification of Table 1 for the computational error as noted by Messrs. Roy and Caron, we must point out that our conclusions remain virtually unchanged. The one modification to our conclusions is as follows: "The ability to detect errors is greatest in the Mod 11-Geometric method. In all categories the Mod 11-Geometric method detected coding errors as well or better than the Mod 10 methods and the Mod 11-Arithmetic method. There is an extremely small probability that these results were due to chance (less than one in a thousand)."

John O. Mason, Jr.
University of Alabama

TABLE 1-Revised
RELIABILITY FACTORS ASSOCIATED WITH SELF-CHECKING DIGIT METHODS (ROUNDED to the nearest per cent)

|  | SINGLE TRANSCRIPTION | SINGLE <br> TRANSPOSITION | DOUBLE TRANSPOSITION | RANDOM SCRAMBLE | SUBSTITUTION of Valid, but INCORRECT NUMBER |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Mod 10 Simple Sum | 100\% | 0\% | 0\% | 90\% | 0\% |
| Mod 10 Alternate | 94\% | $90 \%$ | 90\% | 90\% | 0\% |
| Mod 11 Arithmetic | 100\% | $90 \%$ | 90\% | 90\% | 0\% |
| Mod 11 Geometric | 100\% | $100 \%$ | 90\% | 90\% | 0\% |
