Social Class and Test Performance

From Stereotype Threat to Symbolic Violence and Vice Versa

■ JEAN-CLAUDE CROIZET AND
MATHIAS MILLET

Each year, the profile report issued by the College Board systematically reveals that Scholastic Assessment Test (SAT) scores are strongly related to parental annual income (College Entrance Examination Board, 2009). The very rich get the best scores, the very poor the lowest. This chapter focuses on the ways in which stereotypes that portray the poor as not intelligent impact test achievement. Compared to other literatures on gender or race, research on stereotype threat associated to social class remains largely underdeveloped, albeit consistent. First, we present research on the attitudes and stereotypes that people hold toward those who are poor. Poor people are the victims of a contemptuous stereotype that portray them as unintelligent and lazy. We then review the work that has studied the impact of such negative stereotypes on both achievement and ability testing. Borrowing from work on intersectionality and social reproduction (Bourdieu & Passeron, 1970), we next advocate for conceptualizing socioeconomic status, not as a personal variable, but more as a social process involving power asymmetry in the social structure. We then propose that stereotype threat is the psychological manifestation of a symbolic violence embedded in evaluative settings. We finally suggest that future research should investigate how ideology (stereotypes), institutional practices (evaluative settings), and behavior (performance) work together to recycle power and privilege into individual differences in intellectual merit.

Keywords: Stereotype threat, socioeconomic status, poverty, intelligence, power, symbolic violence

Rich people are not only rich; they are also more intelligent.¹ Research in psychometrics reveals that on average, people who are better off have higher IQs than do the poor (Sirin, 2005; White, 1982). This is old news. Soon after developing the first intelligence test in 1905, Binet discovered that children from affluent neighborhoods had a superior intelligence than their peers living in the poor suburbs

1 of Paris (Binet, 1911). Since then, this fact has been repeatedly and consistently
2 observed. This is perhaps the only aspect of this literature that is not controversial.

3 The relationship between socioeconomic status (SES) and Scholastic Assess-
4 ment Test (SAT) scores for example is particularly illustrative. For a long time, the
5 College Board has claimed that the SAT measures academic skills and not intelli-
6 gence. Yet, available research indicates that the SAT, in accordance with the spirit of
7 its inventor, still measures “IQ” or intelligence to a large extent (Frey & Detterman,
8 2004). Figure 12.1 plots the 2009 distribution of SAT scores according to parental
9 income (College Entrance Examination Board, 2009). The graph shows a gradual
10 increase of 10–70 points in SAT scores with each extra \$20,000 in parental annual
11 income. This association is strong enough so that a student’s score could actually
12 be guessed based on the car his or her parents drive, something referred to as the
13 “Volvo effect” (Sacks, 1999).

14 Many explanations have been proposed to account for the fact that the poor
15 have, on average, lower IQs than the rich. Some stress that IQ is the cause of social
16 class. According to the hereditarian view incarnated by Herrnstein and Murray’s
17 *Bell Curve* (1994), individual and group differences in IQ are mainly a matter of
18 heredity. Rich kids have higher IQs because they inherit smart genes from smarter
19 parents. Opposed to this view, some advocate that IQ is the consequence rather than
20 the cause of social class. Poor kids have a lower IQ because they grow up in environ-
21 ments characterized by strong material deprivation and substandard schooling,
22 which prevents the normal development of their cognitive abilities (Duncan &
23 Brooks-Gunn, 1999). The opposition of these two camps has focused most of
24 the attention on the debate about the social class gap in intelligence. The vividness

Figure 12.1 The relationship between parental income and SAT score (i.e., the “Volvo effect,” adapted from College Entrance Examination Board, 2009).

1 of the confrontation has nevertheless overshadowed an implicit, but important,
2 agreement of views between the two positions: Test scores measure intelligence.

3 In opposition to this postulate, some researchers have argued that test scores are
4 not a valid reflection of individual endowment in intelligence (Davis & Havighurst,
5 1948). Thus, the relationship between social class and IQ may be more informative
6 of the property of the test itself rather than of the attributes of the test takers. For
7 example, test items can be biased in their content, and being able to identify the
8 Milo's Venus statue (e.g., The Kaufman Assessment Battery for Children K-ABC,
9 Kaufman & Kaufman, 1983) is more indicative of a child's familiarity with the white
10 upper middle-class culture than of her intelligence. According to this approach,
11 IQ would predict important outcomes not because it identifies cognitive ability but
12 more simply because it measures acculturation with white middle-class values,
13 which are fundamental to succeed in a white middle-class society. Removing con-
14 tent bias should not only offer a more valid measure of competency, it could
15 also eliminate the gap between the rich and the poor (Eells, Davis, Havighurst,
16 Herrich & Tyler, 1951). Adding to the skepticism about the significance of the
17 class gap in test scores, some research has proposed that the gap could reflect the
18 situational impact of social stereotypes that target people from low socioeconomic
19 backgrounds.

20 Testing situations are explicitly designed to be "neutral." Their function is to
21 locate variations in performance only at the individual level. They apparently consti-
22 tute a perfect implementation of Kelley's (1967) covariation principle for disposi-
23 tional attribution: sameness of circumstances—the test situation is the same for all
24 takers, and sameness of stimuli—the test is the same for all and is not biased against
25 certain groups. Literature on stereotype threat, however, reveals a different picture.
26 Indeed, a standard testing situation is saturated with undermining and enhancing
27 ideologies (Adams, Biernat, Branscombe, Crandall, & Wrightsman, 2008) that
28 selectively affect the performance of the poor and the rich and contribute to the test
29 score gap. In this chapter, our goal is to review this literature. We will first present the
30 research that documents the existence of social class stereotypes. Second, we will
31 review the evidence of stereotype threat effects related to social class. We will finally
32 discuss several theoretical issues for future research.

33 ■ STEREOTYPES ABOUT SOCIAL CLASS

34 Although research on attitudes, prejudice, and stereotypes constitute by far the most
35 productive area of social psychology, psychologists have shown surprisingly little
36 interest in the attitudes and stereotypes toward the poor. Yet, social class is a funda-
37 mental determinant of any individual's life course, and poverty is a pervasive problem
38 in many industrialized countries. In 2008, in the United States, for example, 39.8 mil-
39 lion people lived below the federal poverty level (13.2% of the population). Despite
40 this situation, and the fact that poverty has been at the heart of the political debate for
41 decades (welfare, health care, education, etc.; see Bullock, 1995), the literature on
42 prejudice and discrimination against the poor remains marginal (Lott, 2002).

1 When it is taken into account, class is often just an additional variable in the study
 2 of prejudice and discrimination that target other groups (Spencer & Castano, 2007).
 3 Until recently, most of the research on the perception of social class had focused
 4 almost exclusively on the kind of attributions people make to explain why some are
 5 poor (Bullock, 1995; Kluegel & Smith, 1986). Findings consistently reveal that the
 6 American Dream is still alive: Individuals believe that social status is earned and that
 7 people are responsible for their social standing in society. Research on the attitudes
 8 toward the poor is scarce, but available evidence indicates that people expect those
 9 who are poor to have lower intellectual ability (Baron, Albright, & Malloy, 1995;
 10 Darley & Gross; 1983; Désert, Préaut, & Jung, 2009; Miller, McLaughlin, Haddon,
 11 & Chansky 1968; Régner, Huguet, & Monteil, 2002). It is only recently that schol-
 12 ars have systematically investigated the attitudes that young white Americans hold
 13 about social class (Cozarelli, Wilkinson, & Tagler, 2001). These researchers showed
 14 stereotypes about the poor were largely negative; people from low SES groups were
 15 portrayed as being unintelligent, uneducated, unmotivated, and irresponsible. Out
 16 of the 39 personality traits used to describe the groups, 38 yielded significant differ-
 17 ences unfavorable to the working class. This fact has been captured by research on
 18 the stereotype content model, which has demonstrated that the poor form one of
 19 the few social groups targeted by a clearly negative (i.e., nonambivalent) stereotype
 20 (Fiske, Cuddy, Glick, & Xu, 2002). They are disliked and disrespected, and this
 21 attitude is widely spread across cultures (Fiske et al., 2002), even among educated
 22 liberals (Brantlinger, 2003). In other words, the poor are the victims of a “contemp-
 23 tuous” prejudice (see Fiske et al., 2002) that portrays them as unintelligent and lazy.

24 ■ STEREOTYPE THREAT AND SOCIAL CLASS

25 Since the classic research of Steele and Aronson (1995), an important literature has
 26 yielded support for the hypothesis that, in standard testing situations, stereotypes of
 27 intellectual inferiority can affect intellectual achievement. Once again, although the
 28 number of studies examining how social stereotypes undermine performance has
 29 skyrocketed, research on stereotype threat and social class is largely underdeveloped.

30 The first study revealing stereotype threat effect related to social class was con-
 31 ducted in France. Croizet and Claire (1998) asked undergraduates to take a difficult
 32 test adapted from the verbal section of the Graduate Record Examination (GRE).
 33 Class was determined by parental occupation and education. Students were selected
 34 as low SES if their parents never finished high school and were unskilled workers.
 35 Students of high SES had parents who had college degrees and held professional
 36 occupations. Because there were some concerns about the possibility that the
 37 stereotype may not be salient enough, the researchers asked half of the participants
 38 before they took the test to indicate the level of their parents’ education. Surprisingly,
 39 this salience manipulation had absolutely no impact on intellectual achievement.
 40 When participants were informed that the test was a measure of their cognitive
 41 ability, students from low socioeconomic backgrounds performed lower than their
 42 high SES peers. Yet, when the test was introduced as a simple laboratory exercise,

1 nondiagnostic of ability, the low SES students performed as well as the others.
2 Interestingly and congruent with the literature on stereotype threat, high SES
3 benefitted from the diagnostic condition (i.e., a lift effect, see Croizet & Claire,
4 1998; Croizet & Dutrévis, 2004, 2010; Walton & Cohen, 2003).

5 Surprisingly, some doubts were raised about the generality of this finding. The
6 argument coined even at the editorial stage was that the social class stereotype threat
7 effect was a “French” effect because of the classist structure of the French society.
8 The implicit assumption was that this finding would not be observed in the United
9 States, where stereotypes about social class are less prevalent. It took several years
10 for this issue to be settled. Harrison, Stevens, Monty, and Coakley (2006) had white
11 and non-white college students take difficult math and verbal tests (SAT).
12 Participants were from lower (\$39,000 and under per year), middle (\$40,000—
13 \$79,999 per year), or upper classes (over \$75,000 per year). For one half of the par-
14 ticipants, the test was framed to minimize stereotype threat: A study of the cognitive
15 processes underlying performance. The other participants were informed that they
16 were about to take a valid measure of math and verbal abilities to investigate the
17 reasons for the underachievement of the poor in college. Consistent with previous
18 research, this study demonstrated a stereotype threat effect related to social class on
19 both verbal and math performance. Students of lower income performed worse on
20 the task when it was presented as a valid test of their abilities than they did when it
21 was characterized in a nonthreatening way. Whereas middle-class college students
22 were unaffected by the manipulation, those from upper-class backgrounds per-
23 formed better under the diagnostic condition than they did under the nondiagnos-
24 tic. Almost at the same time, B. Spencer and Casteno (2007) confirmed both
25 stereotype threat and stereotype lift related to class with another American sample.
26 Importantly and contrary to Croizet and Claire’s initial finding, these researchers
27 showed that the mere salience of SES was enough to disrupt performance among
28 the poor when the task was nondiagnostic, suggesting that there might be some cul-
29 tural differences about the situational prevalence of class stereotypes in educational
30 contexts.

31 Research has also documented the psychological cost of stereotype threat beyond
32 performance disruption. Indeed, lower -income participants exposed to stereotype
33 threat report higher test anxiety, lower confidence in their ability to perform, and
34 lower identification with academic domains (Harrison et al., 2006; Spencer &
35 Castano, 2007). The literature has also established the generalizability of the phe-
36 nomenon across several tasks: From verbal, math, and English GRE-like tasks (e.g.,
37 Croizet & Claire, 1998; Harrison et al., 2006) to psychometric tests (Croizet &
38 Dutrévis, 2004; Désert & al., 2009). Probably one of the most disturbing findings
39 concerning stereotype threat related to social class is the fact that it affects perfor-
40 mance on nonverbal IQ tests that were specially developed to limit language bias in
41 psychometric assessment. Raven’s progressive matrices test (Raven, Raven, & Court,
42 1988), for example, is often considered as one of the purest measures of intelligence
43 (i.e., “g,” see Herrnstein & Murray, 1994, p. 273; Snow, Kyllonen & Marshalek,

1 1984). Yet, research has demonstrated that achievement on such tests is sensitive to
 2 stereotype threat that targets the poor (Croizet & Dutr vis, 2004). For example,
 3 D sert et al. (2009) showed that children from a low socioeconomic background
 4 performed worse on Raven’s test when it was introduced using the standard instruc-
 5 tions rather than when it was described as a game. Importantly, this finding was
 6 observed among children who were only 6 years old and replicated among 7- to
 7 9-year-old students, suggesting that stereotype threat can affect achievement and
 8 therefore students’ life very early on.

9 ■ INTERSECTIONALITY AND STEREOTYPE THREAT

10 Even though research has cleverly demonstrated that even dominant groups can
 11 experience stereotype threat, social settings are framed in a way that most of the
 12 groups experiencing this predicament are from the bottom of the social hierarchy:
 13 blacks, Latinos, the poor, women. Those are the groups targeted by a stereotype of
 14 lower intelligence (Fiske et al., 2002). So far, the existence of stereotype threat has
 15 been established by focusing on separate identities defined in terms of race, gender,
 16 or class. But this approach is limiting because it ignores the fact that individuals
 17 usually belong to several categories that overlap and depend on one another.

18 The concept of *intersectionality*, initially developed by feminist and critical race
 19 theorists (e.g., Crenshaw, 1993), explicitly refers to the reality that groups hold mul-
 20 tiple statuses in society. Although theoretically neglected, intersectionality may
 21 explain certain findings in the stereotype threat literature, like the fact that the debil-
 22 itating effect of stereotype threat occurs for only certain combinations of identities.
 23 For example, in one study, stereotype threat disrupted women’s math performance
 24 but only for Mexican American females not white women, something referred to as
 25 the “double minority effect” (Gonzales, Blanton, & Williams, 2002). In the same
 26 vein, Andreoletti and Lachman (2004) investigated how age stereotypes that depict
 27 the elderly as having poor memory affects recall performance. Their results showed
 28 that older participants (aged 60 or higher) performed less well when a memory test
 29 was characterized as revealing age differences (stereotype condition) than when it
 30 was described as a test showing no age difference (counter stereotype condition) or
 31 when no reference to the stereotype was made (standard condition). Interestingly,
 32 the elderly with higher education (more than a 4-year college degree) were the
 33 only ones showing this standard stereotype threat effect. Participants with low
 34 education showed memory deficit in both the stereotype and the counterstereo-
 35 type conditions as compared to the standard condition. The authors’ conclusion
 36 was that “education may be a more important factor than age with regard to suscep-
 37 tibility and resilience to memory aging stereotypes” (Andreoletti & Lachman,
 38 2004, p. 145).

39 Here, we argue that these findings point to the necessity to consider intersection-
 40 ality. Cumulative lack of power and control may make one more sensitive to the
 41 undermining effect of stereotypes in the same way that accumulation of power may

1 make one more sensitive to the enhancing effect of stereotypes. Therefore, one could
2 predict that some African Americans may experience stereotype threat related to
3 race at a lower level of situational threat when they also happen to be poor
4 and female.

5 The intersectionality framework has a lot to offer at this level because it questions
6 the implicit but often powerful understanding of identity as a simple demographic
7 individual attribute. It forces theoretical refinement of the predicament associated
8 to social identities (American Psychological Association, Task Force on
9 Socioeconomic Status, 2007). Cole (2009) recently proposed that a systemic con-
10 sideration of intersectionality would lead researchers to do three things: question
11 the definition of their categories (e.g., who are the elderly in the sample, what gender,
12 what race, what class?); examine the role played by inequality (i.e., power and
13 resources asymmetry); and identify the commonalities between groups (e.g., most
14 groups experiencing stereotype threat have lower status and are excluded from the
15 educational system, whereas those experiencing stereotype lift are the beneficiaries
16 of it). In other words, this approach advocates conceptualizing identity not as
17 a personal variable but more as a social process involving groups' position in the
18 social structure.

19 A study carried out by a group of sociologists yielded evidence suggesting that
20 such a shift may have heuristic value. Lovaglia, Lukas, Houser, Thye, and Markowsky
21 (1998) experimentally assigned participants to either a low- or high-status position.
22 Status was randomly determined by left- or right-handedness, which was predicted
23 to be positively or negatively related to the ability required for an upcoming task.
24 This relationship was further justified by a biological rationale invoking the right or
25 left parts of the brain. Participants were informed that they would also later be
26 assigned to different occupations and pay level, based on their status and aptitude
27 score (i.e., supervisors \$17 per hour; analysts \$8; menials \$4.5). Assignment rules
28 were clearly favorable for high-achieving high-status individuals and unfavorable for
29 low-achieving low-status individuals. Participants then took the Raven Progressive
30 Matrices test. Results from three studies revealed that participants' scores were influ-
31 enced by their status. Participants who had a higher status (i.e., expectation of higher
32 ability and advantaged by the system) obtained a higher IQ (e.g., 120, Experiment
33 2) than did those who were randomly assigned to a low status (i.e., who had a repu-
34 tation of low ability and disadvantaged by the system; IQ = 112). In other words,
35 Lovaglia et al. (1998) revealed that creating a social hierarchy with different status
36 and privilege was enough to induce stereotype threat effects on IQ scores.

37 The reasons why stereotype threat effects are limited to or magnified by certain
38 combinations of identities (e.g., ethnicity and gender, age and class) therefore
39 deserves further attention. The answer is unlikely to involve the inclusion of more
40 demographic variables. Rather, research on intersectionality proposes a shift in our
41 understanding of the concept of social categories and identities. Instead of inform-
42 ing about the individuals within the groups, social categories define the structural
43 relations that shape individual, social, and institutional practices (Cole, 2009;
44 Markus & Moya, 2010; Zuberi & Bonilla Silva, 2008).

Policy Box

The persistence of the achievement gap between the rich and the poor constitutes one of the biggest challenges for a democratic society committed to equal opportunity. Education serves the important function of selecting individuals based on their sole merit, but research on stereotype threat and social class suggests that the implementation of equality in educational settings is problematic. Testing situations are usually considered to be neutral, but they are actually differently experienced by the rich and the poor. They contribute substantially to the class gap in test scores. Test scores should therefore be considered less an indicator of individual cognitive potential but more as the by-product of educational and social situations. One positive consequence of this finding is that the power of educational situations on performance is more important than usually thought. Research shows that subtle situational changes, notably minimizing the belief that level of achievement reflects intellectual value, generate positive educational outcomes in terms of performance, motivation, and sense of belonging. Because immediate situations are under the control of teachers, such interventions are easy to implement. On the more negative side, this literature questions our commitment to meritocracy because test scores systematically measure something other than individual merit. Therefore, using them to determine who gets ahead in education becomes problematic. Finally, research points out that the process driving these effects is beyond the level of the classroom or the school. Although this should in no way be a reason for inaction, we should also avoid “educationalizing” social problems, looking to the classroom for the key to an issue that is deeply rooted in the wider society.

1 ■ FROM STEREOTYPE THREAT TO SYMBOLIC 2 VIOLENCE

3 The move from the person to the situation has been a signature of stereotype threat
4 research from the very discovery of the phenomenon. Early on, stereotype threat
5 was defined as a “threat in the air,” something in the situation, not within the indi-
6 vidual (Steele, 1997). According to the initial formulation of the theory, stereotype
7 threat is not a motivational trait of stigmatized individuals; it is a predicament
8 brought into the testing situation by the stereotype. It can be alleviated with subtle
9 situational changes, like altering the presentation of a test. Groups that usually enjoy
10 high status can also experience stereotype threat whenever they are placed in a situ-
11 ation that puts their ability into question (e.g., see Aronson et al. 1999; Leyens,
12 Désert, Croizet, & Darcis, 2000). Yet, such situations are far less frequent in the real
13 world than those encountered by disadvantaged groups.

14 Indeed, in a given society, situations are not randomly arranged and distributed
15 in space. They are organized across institutions. They are nested with ideology,
16 shaped by history and culture, and enacted daily through institutional practices. In
17 other words, they constitute “intentional worlds” (Adams, 2010; Shweder, 1990).
18 Research has revealed that ideologies that depict certain groups as inferior consti-
19 tute a crucial element of individuals’ reality in testing situations. But evaluative situ-
20 ations by themselves should not be considered as just a “neutral” environment

1 permeable to negative stereotypes. Testing situations should also be conceptualized
2 as a social process, historically and culturally situated, that actively contributes to
3 group domination (Croizet, 2010). Research on stereotype threat and stereotype lift
4 has consistently demonstrated that evaluative situations reproduce the status quo.
5 People from high-status groups outperform, while those from low-status groups
6 underperform. We believe that this commonality has been overlooked and should
7 be investigated further (see Cole, 2009). Understanding how situations shape indi-
8 vidual construal of reality and performance is essential, but decrypting the social
9 logic of inequality embedded and enacted in evaluative situations appears now
10 unavoidable.

11 Long-term relations of domination that define class, race, and gender relations
12 are characterized by two important features (Jackman, 1994). They rely heavily on
13 symbolic domination, and they are institutionalized. As pointed out by Max Weber
14 (1914/1978), power relations are also symbolic relations. Throughout history, dom-
15 inant groups have sought to justify their power by manufacturing ideologies that
16 depict them as superior and entitled to control the dominated groups (Zelditch,
17 2001). Some authors argued that the notions of “aptitude” and “intelligence” have
18 served to rationalize the domination of the haves over the have-nots (Bisseret, 1974;
19 Bourdieu & Passeron, 1964). For example, the meaning of aptitude evolved during
20 the 19th century from an unstable predisposition totally dependent on the environ-
21 ment to an immutable and inherited trait (Bisseret, 1974). At that time, the French
22 bourgeoisie, who had accessed power after the revolution, was in need of justifica-
23 tion for its power over the working class that it had earlier mobilized to overthrow
24 the monarchy in the name of freedom, equality, and brotherhood. It was also an era
25 in which slavery and colonialism had to be made compatible with democracies
26 founded on the idea of equality of men. It is at that time that the concept of intelli-
27 gence made its appearance to justify the superiority of rich white men (Carson,
28 2007). Group stereotypes have also played a crucial role in system justification
29 (Jost & Banaji, 2004; Tajfel, 1981). We argue that the idea of intelligence as a stable
30 and individually owned characteristic was also manufactured for that purpose
31 (Croizet, 2010).

32 Yet, domination would not be efficient without some degree of institutionaliza-
33 tion. Institutionalization of domination relieves group members who enjoy high
34 status for having to act individually to benefit from their privilege. Bourdieu
35 and Passeron (1970) proposed that education is an institution that actively contrib-
36 utes to reproduction of the social class structure of society. First, it achieves this
37 function by negating the cultural arbitrariness of educational material and practices
38 that favor certain groups of students (i.e., a group culture is imposed as the only
39 legitimate culture); second, it locates performance not as the outcome of social
40 inequalities and power differentials but as the product of individual differences
41 in talent and merit. Through these two processes, education perpetrates a form
42 of *symbolic violence* that locates the cause of failure of lower-class students on their
43 personal limitations and the success of the upper middle class, not on privilege
44 and power, but on their individual superiority (Bourdieu & Passeron, 1970).

1 We propose that an important function of evaluative situations is to perpetrate this
2 symbolic violence.

3 Research on stereotype threat has brought ample evidence documenting the psy-
4 chological impact of this symbolic violence (Schmader, Johns, & Forbes, 2008). In
5 standard testing situations, low-status group members face symbolic disqualifica-
6 tion (Millet & Thin, 2004); they struggle with a suspicion of intellectual inadequacy
7 that creates an imbalance among their self-concept, their group identity, and the
8 intellectual domain. This disqualification triggers emotions, drains cognitive
9 resources, and disrupts performance (Johns, Inzlicht, & Schmader, 2008).

10 Like intersectionality, the notion of symbolic violence suggests that stereotype
11 threat and lift phenomena related to social class can be conceptualized as the behav-
12 ioral outcome of power dynamics embedded in the exam situation. Under the cover
13 of explicit equality of treatment (i.e., sameness of exam and time), test situations
14 allow the confrontation of social and structural inequality in a confined environ-
15 ment that “essentializes” or transforms privilege and power into individual merit
16 and talent (Croizet & Guinier, 2010). By perpetrating this symbolic violence on
17 a daily basis, tests and exams play a key role in legitimating and reproducing the
18 current social order. Such issues have a long history in sociology. Stereotype threat
19 research suggests that they are opened to sociopsychological scrutiny as well.

20 ■ CONCLUSION

21 In 1911, Alfred Binet was confronted with the fact that the poor scored lower than
22 the rich on his test. After a careful analysis of the available evidence, he concluded
23 that the superiority of the young “bourgeois” was likely due to the language spoken
24 in wealthy families, which, according to him, advantaged them on the test. Almost a
25 century later, the question of why people from low socioeconomic backgrounds
26 underachieve on intellectual tests remains a hotly debated issue. Some recent
27 research scrutinizes prefrontal regions of the brain (Kishiyama, Boyce, Jiminez,
28 Perry, & Knight, 2009), brain size (Rushton & Ankney, 2009), or genes (Posthuma
29 & de Geus, 2006) to identify the cause of lower intelligence. The literature on ste-
30 reotype threat suggests that part of the answer may reside not within the individual
31 but outside, in the testing situation and in a pervasive cultural ideology that portrays
32 the poor as intellectually inadequate. In this chapter, we have documented this
33 evidence. We have argued that research on stereotype threat and social class would
34 benefit from questioning the so-called neutrality of testing situations a step further.
35 Borrowing from work on intersectionality and social reproduction, we have
36 advocated for conceptualizing SES, not as an individual attribute, but as a social
37 process involving power relations in a social hierarchy. According to this approach,
38 evaluative settings contribute to group domination by perpetrating symbolic vio-
39 lence that organizes the disqualification of low SES people’s sense of self-worth.
40 Stereotype threat research has widely documented how suspicions of inferiority
41 and superiority affect test performance. Still more effort is required to understand
42 how ideology (stereotypes), institutional practices (evaluative settings), and behavior

1 (performance) work together to transform power and privilege into individual
2 differences in intellectual merit.

3 ■ ENDNOTE

4 1. Throughout this text, the word “intelligence” refers to psychometric intelligence.
