Lee , PharmD, PhD; on behalf of the Implementing Genomics in Practice (IGNITE) Network Pharmacogenetics Working Group\*

**BACKGROUND:** Studies have demonstrated increased risk of major atherothrombotic events in *CYP2C19* loss-of-function (LOF) variant carriers versus non-carriers treated with clopidogrel after percutaneous coronary intervention (PCI). We sought to evaluate real-world outcomes with the clinical implementation of *CYP2C19*-guided antiplatelet therapy after PCI.

**METHODS AND RESULTS:** Data from 9 medical centers where genotyping was performed in the setting of PCI were included. Alternative therapy with prasugrel or ticagrelor was recommended for patients with a *CYP2C19* LOF variant. The primary outcome was the composite of major atherothrombotic events (all-cause death, myocardial infarction, ischemic stroke, stent thrombosis, or hospitalization for unstable angina) within 12 months following PCI. Moderate or severe/life-threatening bleeding within 12 months was a secondary outcome. Among 3342 patients, 1032 (31%) were LOF carriers, of whom 571/1032 (55%) were treated with alternative therapy. In LOF carriers, the rate of major atherothrombotic events was lower in patients treated with alternative therapy versus clopidogrel (adjusted HR, 0.56; 95% Cl 0.39–0.82). In those without a LOF allele, no difference was observed (adjusted HR, 1.07; 95% Cl 0.71–1.60). There was no difference in bleeding with alternative therapy versus clopidogrel in either LOF carriers or those without a LOF allele.

**CONCLUSIONS:** Real-world data demonstrate lower atherothrombotic risk in *CYP2C19* LOF carriers treated with alternative therapy versus clopidogrel and similar risk in those without a LOF allele treated with clopidogrel or alternative therapy. These data suggest that PCI patients treated with clopidogrel should undergo genotyping so that *CYP2C19* LOF carriers can be identified and treated with alternative therapy.

Key Words: clopidogrel ■ CYP2C19 ■ pharmacogenetics

ual antiplatelet therapy with clopidogrel, prasugrel, or ticagrelor in combination with aspirin is recommended to reduce the risk of major adverse cardiovascular events (MACE) after percutaneous

coronary intervention (PCI).<sup>1</sup> Clopidogrel is a prodrug dependent on the cytochrome P450 (CYP) 2C19 enzyme for bioactivation to its active metabolite, which inhibits platelet activation. Approximately 30% of

# **CLINICAL PERSPECTIVE**

## What Is New?

- Results in a real-world setting expand the generalizability of recent randomized trials and suggest patients treated with clopidogrel after percutaneous coronary intervention should be genotyped to ensure the absence of *CYP2C19* LOF variants.
- Although alternative P2Y<sub>12</sub> inhibitors are preferred over clopidogrel in the setting of acute coronary syndrome, many patients remain poor candidates for alternative therapy.

# What Are the Clinical Implications?

• Implementation of *CYP2C19* genotyping can help guide which patients derive the greatest clinical benefit from alternative agents and those in whom clopidogrel may be effective and safe.

# Nonstandard Abbreviations and Acronyms

CYP2C19	cytochrome P450 2C19
LOF	loss-of-function
TAILOR-PCI	Tailored Antiplatelet Initiation to Lessen Outcomes due to Decreased Clopidogrel Response After Percutaneous Coronary Intervention

individuals carry a loss-of-function (LOF; defined as the combination of no function and decreased function alleles<sup>2</sup>) variant in *CYP2C19* that results in reduced or absent enzyme activity, and diminished antiplatelet effects in clopidogrel-treated patients.<sup>3</sup> As a consequence, clopidogrel is less effective at preventing adverse cardiovascular events after PCI in LOF allele carriers compared to non-carriers,<sup>4</sup> whereas neither prasugrel nor ticagrelor are affected by *CYP2C19* genotype.<sup>5–7</sup>

Two randomized controlled trials recently examined outcomes after PCI with *CYP2C19* genotypeguided P2Y<sub>12</sub> inhibitor therapy (ie, alternative therapy prescribed to LOF allele carriers and clopidogrel prescribed to those without a LOF allele).<sup>8,9</sup> The POPular-Genetics trial found genotype-guided treatment to be non-inferior to universal use of ticagrelor or prasugrel with regard to net adverse atherothrombotic or major bleeding events while also significantly reducing the risk of bleeding events requiring clinical intervention.<sup>8</sup> In the tailored antiplatelet initiation to lessen outcomes due to decreased clopidogrel response after percutaneous coronary intervention (TAILOR-PCI) trial, the reduction in major atherothrombotic events with use of alternative therapy versus clopidogrel in LOF allele carriers did not reach statistical significance (P=0.06), although there was a significant reduction in the prespecified analysis of cumulative major atherothrombotic events over 12 months and in the post hoc analysis of events at 90 days.9 A recent meta-analysis that included 15 949 genotyped patients from 7 randomized trials, including TAILOR-PCI, reported that treatment with prasugrel or ticagrelor reduced major atherothrombotic events compared to clopidogrel in CYP2C19 LOF allele carriers (relative risk [RR], 0.70; 95% CI 0.59-0.83).10 In contrast, no difference was observed in patients without a LOF allele (RR, 1.0; 95% CI 0.80-1.25) and a significant genotype\*treatment interaction was reported (P=0.013), suggesting that the benefits conferred by using prasugrel or ticagrelor over clopidogrel was primarily evident in LOF allele carriers.

Multiple health care institutions offer clinical CYP2C19 genotyping to assist with antiplatelet selection after PCI.<sup>11,12</sup> On behalf of the NHGRI Implementing Genomics in Practice (IGNITE) Network Pharmacogenetics Working Group, we conducted an initial observational examination of outcomes in 1815 patients from 7 US institutions who received clinical CYP2C19 genotyping at the time of PCI. We reported a lower rate of atherothrombotic events among LOF allele carriers who were treated with prasugrel or ticagrelor versus clopidogrel.<sup>13</sup> We have continued to follow the original patients up to a year and expanded our cohort to 2 additional sites, and 1527 additional patients. Herein, we report outcomes with CYP2C19-quided antiplatelet therapy in our expanded study population of patients who underwent PCI for either an acute coronary syndrome (ACS) or chronic coronary syndrome indication and received clinical CYP2C19 genotyping.

# **METHODS**

Data and analytic codes that support findings from this manuscript are available from the authors upon reasonable request.

# **Study Population**

Nine institutions (University of Florida, Gainesville; University of Florida, Jacksonville; University of North Carolina, Chapel Hill; University of Maryland, Baltimore; University of Alabama, Birmingham; University of Pennsylvania; University of Pittsburgh; University of Illinois, Chicago; and Indiana University) contributed data for 3342 patients. All patients were  $\geq$ 18 years of age, underwent PCI for an ACS (n=2290) or a chronic coronary syndrome (n=1052) indication, were genotyped clinically for CYP2C19, and received a  $P2Y_{12}$  inhibitor (clopidogrel, prasugrel, or ticagrelor). Patients were included regardless of length of follow-up.

The processes for performing genotype-guided therapy across our sites have been previously described.<sup>11</sup> Data collection procedures were approved by the Institutional Review Board at each institution. Depending on the site, subjects gave informed consent or the requirement was waived. Briefly, genotyping was performed in a Clinical Laboratory Improvement Amendments (CLIA)-licensed laboratory at each institution, with results returned via the electronic health record (EHR). All sites genotyped for the CYP2C19\*2 and \*3 LOF alleles, with additional rare LOF alleles detected at 5 of the 9 sites (Table S1). The \*17 (gain-of-function) allele was also detected at all sites. The poor metabolizer (PM, 2 LOF alleles) and intermediate metabolizer (IM, one LOF allele) phenotypes were assigned in accordance with CPIC guidelines.<sup>3</sup> Alternative antiplatelet therapy with prasugrel or ticagrelor was recommended at each site for LOF carriers in the absence of contraindications, whereas no recommendations were made for those without a LOF allele. No treatment alterations were recommended based on the presence of a \*17 allele according to Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines. The ultimate prescribing decision was left to the clinician's discretion.

# **Data Abstraction**

Data were manually abstracted from the EHRs at each site using a common data collection form as previously described<sup>13</sup> but with slight modifications for this study. Data were collected through review of patient encounters, beginning with the hospitalization for the index PCI, defined as the PCI performed in association with *CYP2C19* genotyping, and including subsequent outpatient encounters and hospitalizations. We followed patients until the outcome of interest, discontinuation of any P2Y<sub>12</sub> inhibitor, up to 12 months post-PCI, whichever was the earliest.

Outcomes were identified from provider-reported diagnoses at each encounter or clinical notes in the event of death. One site also called patients to assess for the occurrence of events. Type of antiplatelet therapy was assigned to each patient at the time of each event or at the time of last follow-up in which treatment with a P2Y<sub>12</sub> inhibitor was documented.

# **Study End Points**

The primary outcome was the composite of major atherothrombotic events, defined as the composite of all-cause death or first occurrence of myocardial infarction, ischemic stroke, stent thrombosis, or hospitalization for unstable angina within 12 months following the index PCI, consistent with the TAILOR-PCI trial.<sup>9</sup> Secondary outcomes were major atherothrombotic events within 90 days of the index PCI (consistent with the TAILOR-PCI trial<sup>9</sup>) and clinically significant bleeding events, defined as Global Use of Strategies to Open Occluded Arteries (GUSTO) moderate (requiring blood transfusion but not resulting in hemodynamic compromise) or severe/life-threatening (intracerebral hemorrhage or bleeding resulting in hemodynamic compromise requiring treatment)<sup>14</sup> within 12 months of the index PCI.

# **Statistical Analysis**

Data were curated and aggregated at the University of Florida, Gainesville. The primary analysis compared rates between LOF allele carriers treated with alternative therapy (LOF-alternative group) versus clopidogrel (LOF-clopidogrel group) and between patients without a LOF allele on clopidogrel (non-LOF-clopidogrel group) versus alternative therapy (non-LOF-alternative group). The interaction between LOF allele carrier status and P2Y<sub>12</sub> inhibitor therapy at event or last follow-up was also assessed. Pre-specified subgroup analyses were completed in patients with an ACS indication (ST-segment elevation or non-ST-segment elevation myocardial infarction or unstable angina) for PCI versus those with a non-ACS/elective indication for PCI.

To adjust for differences between groups, we fit logistic regression models to estimate the probability (propensity score) of receiving clopidogrel versus alternative therapy conditional on baseline characteristics (socio-demographics, BMI, smoking status, stent indication, stent type, medical history, and discharge medications). Propensity scores, estimated separately for each comparison (ie, LOF carriers, non-LOF carriers and ACS-specific strata), were then used to generate stabilized inverse probability of treatment weights (SIPTWs).<sup>15</sup> Non-LOF propensity scores were further trimmed to remove non-overlap between treatment groups. We evaluated differences in all covariates between treatment groups before and after weighting using appropriate test for univariate comparisons. We then used Cox proportional hazard models of the weighted comparison groups to estimate hazard ratios for atherothrombotic and bleeding events for LOF carriers and the non-LOF groups. We also present Kaplan Meier Plots using the SIPTW weighted comparison groups. All statistical analyses were performed using R statistical software (version 4.0).<sup>16</sup>

# RESULTS

# **Patient Characteristics**

Patient characteristics are shown in Table 1. Among the 3342 patients, the mean age was 63 years, 32% were

female, 20% were of African ancestry, and 69% had an ACS indication for PCI. A total of 1032 (31%) patients were LOF allele carriers (28% IMs, 3% PMs), of whom 571 (55%) were treated with alternative therapy and 461 (45%) with clopidogrel 75 mg/day (Figure 1); 77% of PMs and 53% of IMs received alternative therapy (Figure S1). Among patients in the LOF group treated with alternative therapy, 337 received prasugrel, 219 received ticagrelor, and 15 received high-dose clopidogrel (Figure 1). Among patients in the non-LOF group (n=2310, 69%), 378 (16%) were treated with alternative therapy and 1932 (84%) with standard-dose clopidogrel.

There were differences in age, sex, medical history, and anticoagulant use between LOF allele carriers prescribed alternative therapy versus clopidogrel (Table 1), pointing to an older population with more comorbidities receiving clopidogrel. These characteristics along with body mass index, stent type, and statin use also differed between non-LOF-alternative and non-LOF-clopidogrel the groups with a similar trend toward older patients with more comorbidities receiving clopidogrel. These imbalances were negligible after propensity score adjustment. All standardized differences were <10% in LOF allele carriers, suggesting adequate covariate balance between groups (Table S2). Among patients in the non-LOF group, the standardized difference between treatments for history of gastrointestinal or intracranial hemorrhage was 10.5%. Adjusting for this variable in the Cox proportional hazard model of the weighted comparison groups did not affect results (Table 2).

# **Clinical Outcomes**

The median follow-up after PCI was 6.3 months (interquartile range: 1.0-11.0 months), during which 353 patients (10.6%) had a major atherothrombotic event (event rate 21 per 100 patient-years). For the primary analysis (Table 2 and Figure 2A), the rate of major atherothrombotic events was lower among LOF allele carriers receiving alternative therapy versus clopidogrel (17.1 versus 34.4 per 100 patient-years, unadjusted HR, 0.50; 95% CI: 0.35–0.72; P<0.001) and remained lower after propensity score adjustment (adjusted HR, 0.56; 95% CI: 0.39-0.82; P=0.002). In contrast, major atherothrombotic event rates in patients without a LOF allele did not significantly differ between the alternative therapy and clopidogrel-treated groups (18.1 versus 19.9 per 100 patient-years, respectively; adjusted HR, 1.08; 95% Cl, 0.72-1.62; P=0.715; Table 2) (P=0.030 for interaction between LOF carrier status and P2Y<sub>12</sub> inhibitor therapy at event or last follow-up). Consistent with previous reports,<sup>3</sup> clopidogrel-treated patients with a LOF allele had a higher rate of atherothrombotic events compared with clopidogrel-treated patients without a LOF allele (34.4 versus 19.9 per 100 patientyears, HR, 1.67; 95% Cl, 1.27-2.19; P<0.001).

The difference in risk of major atherothrombotic events between the LOF-alternative and LOF-clopidogrel groups was more pronounced at 90 days (18.9 versus 52.5 per 100 patient-years, adjusted HR, 0.40; 95% CI 0.23–0.71; P=0.002), while no difference was observed at 90 days between non-LOF treatment groups (adjusted HR, 1.09; 95% CI 0.64–1.86; P=0.752). In addition, *CYP2C19* IMs receiving alternative therapy had lower major atherothrombotic event rates when compared with IMs receiving clopidogrel (16.0 versus 35.1 per 100 patient-years, HR, 0.46; 95% CI, 0.31–0.68; P<0.001).

The majority of atherothrombotic events (280 of 353 total events, 79%) occurred in patients presenting with an ACS at the time of PCI (Table 3 and Figure 2B). Among ACS patients, the rate of atherothrombotic events was lower in the LOF-alternative group (17.8 per 100 patient-years) compared to the LOF-clopidogrel group (46.3 per 100 patient-years; adjusted HR, 0.49; 95% CI 0.32-0.76, P=0.001). However, rates were similar in the non-LOF-alternative and non-LOF-clopidogrel groups (19.6 and 23.8 per 100 patient-years, respectively; adjusted HR, 1.05; 95% CI 0.67-1.66, P=0.834). Atherothrombotic event rates were lower overall in patients without an ACS indication for PCI, ranging from 12.5 to 15.2 per 100 person-years, and did not differ between the alternative therapy and clopidogrel groups in either LOF carriers or non-LOF patients (Table 3 and Figure 2C).

A clinically significant bleeding event occurred in 124 (3.7%) patients (Table 2 and Figure 3). Bleeding rates were similar in the LOF-alternative and LOF-clopidogrel groups (7.9 and 7.1 per 100 patient-years, respectively; adjusted HR, 1.15; 95% CI 0.60–2.20; P=0.685), and in the non-LOF-alternative and non-LOF-clopidogrel groups (7.4 and 6.8 per 100 patient-years, respectively; adjusted HR, 1.30; 95% CI 0.71–2.38; P=0.397).

# DISCUSSION

To date, this is the largest real-world investigation of clinical outcomes from clinical implementation of *CYP2C19* testing to guide antiplatelet therapy prescribing for patients undergoing PCI. We demonstrate the feasibility of a genotype-guided strategy across multiple institutions, as evidenced by frequent use of prasugrel or ticagrelor in *CYP2C19* LOF allele carriers. We also observed lower atherothrombotic event rates in LOF allele carriers treated with alternative therapy compared with clopidogrel, particularly among patients with an ACS indication for PCI. In contrast, no difference in atherothrombotic event risk was observed in those without a LOF allele treated with clopidogrel compared to alternative therapy. There were also no significant differences in bleeding event rates between

All patients (n=3342)         LOF-alternative (n=571)           63±12         60±11           1075 (32)         60±11           1075 (32)         158 (28)           2448 (73)         117 (21)           235 (7)         413 (72)           235 (7)         413 (72)           235 (7)         41 (7)           30±6         30±7           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           30±6         117 (21)           305 (89)         143 (72)           939 (28)         143 (25)           939 (28)         143 (25)           938 (28)         143 (25)           1         156 (35)           1         161 (28)           1         163 (85)           1         163 (85)           1         163 (85)           1         160 (33)           1         160 (33)           1         163 (85) <th>LOF-alternative (n=571) 60±11 158(28) 413(72) 117(21)</th> <th>Standardized differences for comparison of LOF-clopidogrel 0.336 0.157 0.088 0.088 0.054 0.027 0.027 0.027</th> <th>Non-LOF-alternative (n=378)           60±10           99 (26)           29 (26)           237 (76)           62 (16)           29 (8)           29 (8)           31±6           114 (30)           106 (28)           106 (28)</th> <th>Non-LOF- clopidogrel           (n=1932)           64±12           657 (34)           371 (19)           371 (19)           128 (7)           30±6           539 (28)           321 (17)           527 (27)</th> <th>Standardized differences for comparison of non-LOF alternative vs non-LOF-clopidogrel 0.349 0.171 0.08 0.08 0.14 0.05 0.05 0.05</th>	LOF-alternative (n=571) 60±11 158(28) 413(72) 117(21)	Standardized differences for comparison of LOF-clopidogrel 0.336 0.157 0.088 0.088 0.054 0.027 0.027 0.027	Non-LOF-alternative (n=378)           60±10           99 (26)           29 (26)           237 (76)           62 (16)           29 (8)           29 (8)           31±6           114 (30)           106 (28)           106 (28)	Non-LOF- clopidogrel           (n=1932)           64±12           657 (34)           371 (19)           371 (19)           128 (7)           30±6           539 (28)           321 (17)           527 (27)	Standardized differences for comparison of non-LOF alternative vs non-LOF-clopidogrel 0.349 0.171 0.08 0.08 0.14 0.05 0.05 0.05

### Figure 1. Study population by CYP2C19 group and antiplatelet therapy.

A total of 22/461 (5%) of patients in the LOF-clopidogrel group were *CYP2C19* PMs. A total of 76/571 (13%) of patients in the LOF-alternative group were *CYP2C19* PMs. APT indicates antiplatelet therapy; LOF, loss-of-functio; and PCI, percutaneous coronary intervention. \*Alternative therapy in patients with 1 or 2 LOF alleles consisted of prasugrel (n=337), ticagrelor (n=219), or high-dose clopidogrel (150 mg/day, n=4; 225 mg/day, n=11). <sup>†</sup>Alternative therapy in the non-LOF group consisted of prasugrel (n=231), ticagrelor (n=146), or high-dose clopidogrel (150 mg/day, n=1). <sup>#</sup>P<0.001 for use of alternative therapy in the non-LOF group compared with the LOF group.

clopidogrel and alternative therapy regardless of LOF carrier status. These findings validate results from prior nonrandomized studies, small randomized trials, and meta-analyses demonstrating that a genotype-guided strategy, with use of prasugrel or ticagrelor in *CYP2C19* LOF allele carriers, lowers atherothrombotic event risk compared with conventional treatment

strategies without significantly increasing major bleeding risk.<sup>10,17-24</sup>

Our findings also extend those from recent large randomized clinical trials to a real-world clinical setting, providing further evidence of the safety and effectiveness of *CYP2C19* genotype-guided antiplatelet therapy following PCI. The TAILOR-PCI trial was conducted in

 Table 2.
 Primary and Secondary Outcomes by CYP2C19 and Antiplatelet Therapy

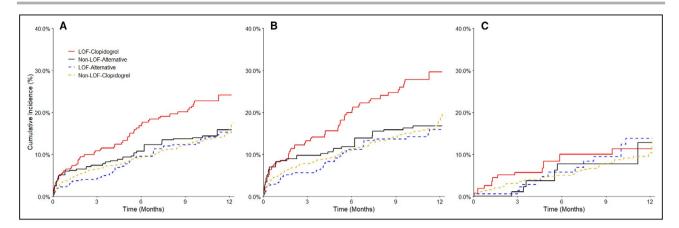

GIB indicates gastrointestinal bleed; HR, hazard ratio; ICH, intracerebral brain hemorrhage; LOF, loss-of function; and PCI, percutaneous coronary intervention.

\*Data are presented as the number of patients in each group who experienced the event over 12 months of follow-up after the index PCI.

<sup>†</sup>The event rate was calculated as the number of events per 100 patient-years of follow-up.

<sup>‡</sup>The hazard ratio was adjusted with stabilized inverse probability weights derived from exposure propensity scores.

<sup>§</sup>The HR after adjusting for history of GIB or ICH: adjusted HR 1.08; 95% CI, 0.72–1.62; P=0.726.

**Figure 2.** Major atherothrombotic events with clinical implementation of *CYP2C19*-guided antiplatelet therapy after PCI. **A**, All patients. **B**, Patients with an ACS indication for PCI. **C**, Patients with a non-ACS/elective indication for PCI. ACS indicates acute coronary syndrome; LOF, loss-of-function; and PCI, percutaneous coronary intervention. Weighted data are shown for patients with a *CYP2C19* loss-of-function (LOF) allele treated with clopidogrel (LOF-clopidogrel) or alternative therapy (LOF-alternative) and for patients without a LOF allele treated with clopidogrel (non-LOF-clopidogrel) or alternative therapy (non-LOF-alternative). Note that patients were standardized to 2 different populations based on LOF allele status.

patients with either an ACS or chronic coronary syndrome indication for PCI and compared the efficacy of ticagrelor versus clopidogrel in the subset of patients with a LOF allele. While the reduction in major atherothrombotic events between groups at 12 months did not reach statistical significance (HR, 0.66; 95% CI 0.43–1.02, P=0.06), post hoc analysis showed a significant reduction in events at 90 days (HR, 0.21; 95% CI 0.08–0.54, P=0.001).<sup>9</sup> We similarly observed lower atherothrombotic event rates in LOF allele carriers treated with alternative therapy versus clopidogrel at 90 days (adjusted HR, 0.40; 95% CI 0.23–0.71, P=0.002), and unlike TAILOR-PCI, the difference was also evident at 12 months (adjusted HR, 0.56; 95% CI 0.39–0.82, P=0.003). The observed effect sizes in our study were similar to TAILOR-PCI. Additionally, there was no difference in clinically significant bleeding events between LOF carriers treated with alternative therapy compared to clopidogrel in either our real-world study (HR, 1.15; 95% CI 0.60–2.21) or TAILOR-PCI (HR, 1.22; 95% CI 0.60–2.51).<sup>9</sup>

Most atherothrombotic events in our study population occurred in those presenting with an ACS indication for PCI, and subgroup analyses were in line with previous analyses suggesting that the strongest associations between *CYP2C19* LOF allele status and clopidogrel treatment outcomes occur in ACS patients.<sup>25,26</sup> It is worth noting that, we were likely underpowered to confidently determine whether treatment of LOF allele carriers with prasugrel or ticagrelor significantly

 Table 3.
 Major Atherothrombotic Events in acute coronary syndrome and Chronic Coronary Syndrome (Non-ACS)

 Subgroups by CYP2C19 and Antiplatelet Therapy

ACS indicates acute coronary syndrome; and LOF, loss-of-function.

\*Data are presented as the number (%) of patients in each group who experienced the event over 12 months of follow-up after the index PCI.

<sup>†</sup>The event rate was calculated as the number of events per 100 patient-years of follow-up.

<sup>‡</sup>The HR was adjusted with inverse probability weights derived from exposure propensity scores.

# Figure 3. Clinically significant bleeding events with clinical implementation of *CYP2C19*-guided antiplatelet therapy after PCI.

Weighted data are shown for patients with a *CYP2C19* LOF allele treated with clopidogrel (LOF-clopidogrel) or alternative therapy (LOF-alternative) and patients without a LOF allele treated with either clopidogrel (non-LOF-clopidogrel) or alternative therapy (non-LOF-alternative). Note that patients were standardized to 2 different populations based on LOF allele status. The number of patients in each group was slightly different than for the atherothrombotic end point as patients were stratified based on antiplatelet therapy prescribed at the time of the bleeding event or last follow-up. LOF indicates loss-of-function; and PCI, percutaneous coronary intervention.

lowers atherothrombotic event risk compared to clopidogrel in patients without an ACS indication for PCI due to the relatively small subgroup sample size and lower event rates. This is evidenced by the differences in the major atherothrombotic events rates between LOF allele carriers receiving clopidogrel for ACS and stable CAD (46.3 versus 14.3 event per 100 patientyears). Also, given our pragmatic study design and high frequency of alternative therapy use in CYP2C19 PMs, the overwhelming majority of LOF allele carriers prescribed clopidogrel in our study population were CYP2C19 IMs. Thus, while we observed no difference in atherothrombotic event risk across groups in elective PCI patients, we cannot rule out a higher risk of atherothrombotic events in PMs prescribed clopidogrel. Given the lower magnitude of clinical benefit in elective PCI, a cost-effectiveness analysis of genotype-guided antiplatelet therapy in ACS relative to non-ACS patients is warranted.

The POPular Genetics trial focused on patients undergoing PCI following ST-segment elevation MI and demonstrated that a genotype-guided approach, with *CYP2C19* LOF allele carriers treated with ticagrelor or prasugrel and non-LOF patients treated with clopidogrel, was non-inferior to universal ticagrelor or prasugrel use for risk of developing major cardiovascular or bleeding events after primary PCI.<sup>8</sup> Consistent with these results and a recent meta-analysis,<sup>10</sup> we observed no significant difference in atherothrombotic event rates in patients without a LOF allele treated with clopidogrel compared to those treated with prasugrel or ticagrelor. Notably, there remained no significant difference in event rate when focusing on patients with an ACS indication for PCI. Together, these data suggest that in patients without a LOF allele, clopidogrel is similarly effective as prasugrel or ticagrelor. The POPular Genetics trial also reported lower bleeding rates with genotype-guided therapy compared with alternative therapy, which we did not observe in our study. Lower bleeding rates in the POPular Genetics trial were driven by a reduction of minor bleeding, defined as bleeding requiring clinical intervention. Minor bleeding is more difficult to detect from electronic health records, and was not comprehensively captured in our study.27

The 2020 European Society of Cardiology guidelines for the management of ACS considers CYP2C19guided antiplatelet therapy an alternative to 12 months of dual antiplatelet therapy with prasugrel or ticagrelor based on results from POPular Genetics.<sup>8,28</sup> These recommendations are consistent with those from expert consensus on the use of genetic testing in patients undergoing PCI.<sup>29,30</sup> Our real-world data support these recommendations, and demonstrate the safety and effectiveness of using CYP2C19 testing to guide an antiplatelet therapy after an ACS. Given the emergence of important questions regarding the relative clinical effectiveness of prasugrel versus ticagrelor in ACS patients,<sup>31</sup> it is important to point out that alternative therapy in both TAILOR-PCI and POPular Genetics was comprised almost exclusively ticagrelor (prasugrel was not used in TAILOR-PCI, and was only used in ≈2% of patients in POPular Genetics).9,32 Thus, our real-world data in which either prasugrel or ticagrelor was used as alternative therapy add to the body of evidence on outcomes with genotype-guided antiplatelet therapy after PCI, and specifically suggest that treatment of LOF carriers with either ticagrelor or prasugrel is associated with improved outcomes.

The real-world nature of our data allowed for evaluation of higher-risk patients than those included in other clinical trials. For example,  $\approx$ 40% of our study population had diabetes, 80% had hypertension, 30% had chronic kidney disease, 25% had history of myocardial infarction, and 10% were treated with an oral anticoagulant. In TAILOR-PCI and POPular Genetics, respectively,  $\approx$ 28% and 12% had diabetes, 62% and 40% had hypertension, 10% and 10% had chronic kidney disease, 15% and 8% had history of myocardial infarction, and 0% (excluded) and 4% were treated with an oral

anticoagulant. This likely contributed to higher atherothrombotic and bleeding event rates in our real-world study population than reported in the randomized clinical trials of CYP2C19 genotype-guided antiplatelet therapy. Importantly, the results from our study, together with the TAILOR-PCI and POPular Genetics randomized trials and recent meta-analyses,<sup>8-10,24</sup> provide compelling data supporting the effectiveness of a genotype-guided strategy. We also observed higher atherothrombotic event rates in clopidogrel-treated patients with a LOF allele compared with those without a LOF allele, as has been reported in multiple studies.<sup>33–37</sup> In addition, prior studies have demonstrated that the increased function CYP2C19\*17 allele does not impact atherothrombotic or bleeding outcomes in clopidogreltreated patients without a LOF allele.<sup>32,38</sup> Collectively, these data lend additional evidence supporting current CPIC guideline recommendations that recommend the use of prasugrel or ticagrelor in patients found to carry a CYP2C19 LOF allele (both IMs and PMs)<sup>3</sup> and also suggest that clopidogrel should not be prescribed following PCI in the absence of CYP2C19 genotyping to reduce the risk of adverse clinical consequences of clopidogrel use in LOF allele carriers.

# **Study Limitations**

We recognize several limitations of our study. The realworld nature of our study meant that prescribers could choose to follow the genotype recommendations or not. Together with the non-randomized design, this resulted in imbalances between groups, which could potentially confound results. While balance was achieved across comparison groups after weighting, we cannot rule out residual confounding around the selection of antiplatelet therapy, especially since we did observe some channeling of clopidogrel toward older more multi-morbid patients with conceivably higher risk for atherothrombotic events. The minor differences in HRs before and after adjustment might alleviate some of these concerns. Another limitation was that there was not a control group who did not receive genetic testing, thus this study cannot evaluate the effectiveness of genetic testing against a genotype agnostic treatment approach. Further, outcomes were determined based on EHR data, without event adjudication and variable length of follow-up. As such, clinical events that were treated in other health systems and deaths may have been missed. Our focus on clinically actionable bleeding (GUSTO moderate or severe/life-threatening bleeding) yielded a low number of bleeding events, which limited power to detect differences between drugphenotype groups. Finally, while there is interest in prasugrel versus ticagrelor treatment outcomes,<sup>31</sup> and it would be of interest to evaluate outcomes by LOF carrier status across clopidogrel, prasugrel, ticagrelor treated patients, the numbers in the subgroups are too small in our study to compare outcomes with appropriate propensity score matching. Future studies in larger populations are needed to evaluate effectiveness and safety of using prasugrel versus ticagrelor in a realworld setting of genotype-guided antiplatelet therapy after PCI.

# CONCLUSIONS

In summary, our prospective, real-world outcomes data expand the generalizability of what has been reported in recent prospective randomized controlled trials and demonstrate the clinical effectiveness of incorporating CYP2C19 genotyping into antiplatelet therapy prescribing decisions after PCI. Furthermore, these data suggest patients with ACS undergoing PCI especially benefit from a genotype-guided strategy and support multiple recent economic analyses demonstrating that CYP2C19-guided antiplatelet therapy is a cost-effective strategy for ACS patients undergoing PCI.<sup>39,40</sup> Although the use of prasugrel and ticagrelor has been increasing in the post-ACS/PCI setting in recent years, a significant portion of patients remain poor candidates for these alternative antiplatelet agents due to higher bleeding risk, lower tolerability, difficulty with adherence and access, as well as higher copay costs compared with clopidogrel.<sup>41</sup> The cumulative data suggest that when clopidogrel is prescribed as part of dual antiplatelet therapy post-PCI in ACS, CYP2C19 genotype should be assessed to avoid clopidogrel use in patients carrying a LOF allele due to the increased risk of major atherothrombotic events.

Values are mean  $\pm$  SD or n (%). \* Weighted absolute standardized differences were calculated using stabilized inverse probability of treatment weighting.

Figure S1. Antiplatelet therapy in poor metabolizers (PMs), intermediate metabolizers (IMs), and patients without a loss-of-function allele.

APT, antiplatelet therapy; IM, intermediate metabolizer; LOF, loss-of-function; PM, poor metabolizer.
