The reaction of one equivalent $\text{Co}(\text{NCS})_2$ with four equivalents of urotropine (hexamethylenetetramine) in ethanol leads to the formation of two compounds, namely, bis(ethanol- κO)bis(thiocyanato- κN)bis(urotropine- κN)cobalt(II), $[\text{Co}(\text{NCS})_2(\text{C}_6\text{H}_{12}\text{N}_4)_2(\text{C}_2\text{H}_6\text{O})_2]$ (**1**), and tetrakis(ethanol- κO)bis(thiocyanato- κN)cobalt(II)–urotropine (1/2), $[\text{Co}(\text{NCS})_2(\text{C}_2\text{H}_6\text{O})_4] \cdot 2\text{C}_6\text{H}_{12}\text{N}_4$ (**2**). In **1**, the Co cations are located on centers of inversion and are sixfold coordinated by two terminal N-bonded thiocyanate anions, two ethanol and two urotropine ligands whereas in **2** the cobalt cations occupy position Wyckoff position *c* and are sixfold coordinated by two anionic ligands and four ethanol ligands. Compound **2** contains two additional urotropine solvate molecules per formula unit, which are hydrogen bonded to the complexes. In both compounds, the building blocks are connected via intermolecular O–H···N (**1** and **2**) and C–H···S (**1**) hydrogen bonding to form three-dimensional networks.

1. Chemical context

Thiocyanate anions are versatile ligands that exhibit a variety of coordination modes, leading to rich structural chemistry (Näther *et al.*, 2013). For less chalcophilic metal cations such as Mn^{II} , Fe^{II} , Co^{II} or Ni^{II} , most compounds contain terminal N-bonded thiocyanate anions, whereas for chalcophilic metal cations such as for example Cd^{II} , the μ -1,3-bridging mode is preferred. Therefore, the synthesis of bridging compounds with the former cations is sometimes difficult to achieve, which is a pity, because such compounds are of interest due to their magnetic properties (Mautner *et al.*, 2018; Mekuimemba *et al.*, 2018; Mousavi *et al.*, 2020; Palion-Gazda *et al.*, 2015; Suckert *et al.*, 2016). This is especially the case with cobalt, which frequently exhibits interesting behavior due to its large magnetic anisotropy, so we and others have been studying such compounds for several years (Shi *et al.*, 2006; Jin *et al.*, 2007; Wellm *et al.*, 2020; Prananto *et al.*, 2017). Within this project we are interested for example in the influence of the co-ligand on the magnetic anisotropy and the magnetic behavior of compounds, in which the cations are linked by thiocyanate anions into chains (Böhme *et al.*, 2020; Rams *et al.*, 2020; Ceglarska *et al.*, 2021; Werner *et al.*, 2014, 2015).

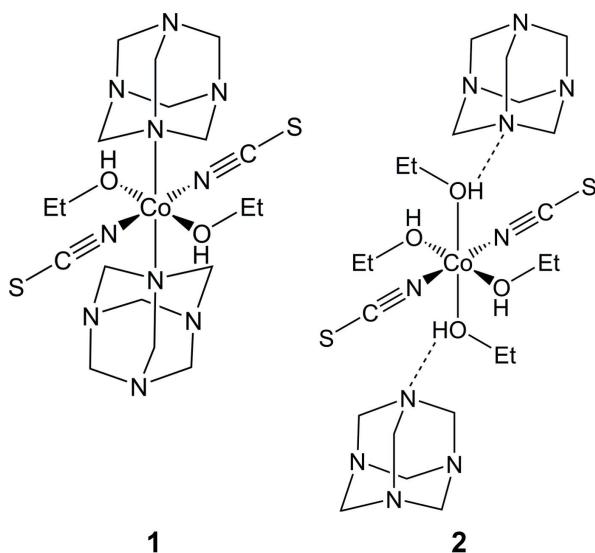

In the course of our systematic work, we became interested in urotropine as a co-ligand. Therefore, we reacted $\text{Co}(\text{NCS})_2$ with urotropine in acetonitrile, which leads to the formation of a compound with the composition $[\text{Co}(\text{NCS})_2(\text{H}_2\text{O})_2(\text{urotropine})_2] \cdot (\text{urotropine})_2(\text{MeCN})_2$ consisting of discrete

OPEN ACCESS

complexes, which are linked by urotropine and acetonitrile solvate molecules into a hydrogen-bonded network (Krebs *et al.*, 2021). In principle, the formation of discrete solvato complexes would be no problem because in several cases such complexes can be transformed by thermal decomposition into the desired compounds with a bridging coordination of the anionic ligands (Näther *et al.*, 2013), but XRPD measurements proved that this crystalline phase was not obtained pure.

In further work, we used ethanol as a solvent leading to the formation of two different crystals in the same batch that were characterized by single-crystal X-ray diffraction. The crystals in this batch were crushed and investigated by XRPD. Comparison of the experimental pattern with that calculated for **1** and **2** reveal that only **1** can be detected together with at least one additional and unknown crystalline phase. The reason for this observation is unclear, but it might be that **2** is unstable and transforms into a new phase on grinding.

2. Structural commentary

The asymmetric unit of **1**, $\text{Co}(\text{NCS})_2(\text{urotropine})_2(\text{EtOH})_2$, consists of one crystallographically independent Co cation, located on a center of inversion, as well as one thiocyanate anion, one urotropine ligand and one ethanol molecule occupying general positions (Fig. 1). In **2**, $[\text{Co}(\text{NCS})_2](\text{EtOH})_4 \cdot (\text{urotropine})_2$, the asymmetric unit contains one cobalt cation on position of site symmetry 222 (Wyckoff position *c*), one thiocyanate anion that is located on a twofold rotation axis and one urotropine molecule on an inversion axis (Fig. 2). The Co–N distance to the thiocyanate anions in **1** is slightly shorter than in **2**, whereas the Co–O bond length to the ethanol ligand is longer (compare Tables 1 and 2). The former can be traced back to the fact that in **2** the Co cation is exclusively coordinated by ethanol, whereas in **1** this cation is additionally coordinated by a urotropine ligand, which is a stronger donor than ethanol, transferring additional charge to the Co center. This leads to a strengthening of the Co–N thiocyanate bond and therefore this bond length is shorter. This is also supported by previous investigations when discrete complexes with an N_6 (four N atoms of N-donor co-

ligands) or N_4O_2 (two N-donor co-ligands and two e.g. water molecules) coordination were compared. For N_4O_2 coordination, the CN stretching vibration of the thiocyanate anions is significantly shifted to higher values, which indicates that the C–N bond becomes stronger, leading to a weakening of the

Co—N bond (Böhme *et al.*, 2020). The angles around the Co cations deviate from the ideal octahedral values, which shows that the octahedra are slightly distorted (see supporting information). The octahedron in **2** is more distorted than in **1**, which is obvious from the octahedral angle variance (1.8138 for **1** and 8.1624 for **2**) and the mean octahedral quadratic elongation (1.0062 for **1** and 1.0023 for **2**) calculated by the method of Robinson *et al.* (1971).

3. Supramolecular features

In the crystal structures of both compounds, intermolecular hydrogen bonding is observed (Tables 3 and 4). In **1**, the

discrete complexes are linked *via* intermolecular $\text{O}-\text{H}\cdots\text{N}$ hydrogen bonding between the hydroxyl H atoms of one complex and the N atoms of neighboring complexes into chains extending in the *a*-axis direction (Fig. 3 and Table 3). These chains are further linked into a three-dimensional network by $\text{C}-\text{H}\cdots\text{S}$ hydrogen bonding between the thiocyanate S atoms and each one H atom of urotropine ligands (Fig. 4). There are additional $\text{C}-\text{H}\cdots\text{N}$ and $\text{C}-\text{H}\cdots\text{O}$ contacts but from the distances and angles it is indicated that these are very weak interactions (Table 3).

Computer programs: *CrysAlis PRO* (Rigaku OD, 2021), *SHELXT2014/5* (Sheldrick, 2015a), *SHELXL2016/6* (Sheldrick, 2015b), *DIAMOND* (Brandenburg & Putz, 1999) and *publCIF* (Westrip, 2010).

In the crystal structure of **2**, each complex is linked to neighboring complexes *via* intermolecular O—H···N hydrogen bonds between the four O—H hydrogen atoms of one complex and the N atoms of the urotropine molecules of four neighboring complexes to form a three-dimensional network (Fig. 5 and Table 4). From the H···N distance and the O—H···N angle it is obvious that this corresponds to a strong interaction. In contrast to **1**, no C—H···S hydrogen bonding is observed and the additional C—H···N contact represents a weak interaction (Table 4).

4. Database survey

The Cambridge structure Database (CSD version 5.42, last update November 2020; Groom *et al.*, 2016) already contains some structures of transition-metal thiocyanate coordination compounds with urotropine as a co-ligand. This includes a mixed complex with the composition [Co(NCS)₂(C₆H₁₂N₄)(CH₃OH)₂(H₂O)], in which the cobalt cations are coordinated by water, ethanol, urotropine and N-bonded thiocyanate anions (Refcode: POFGAT; Shang *et al.*, 2008). It also contains two compounds with the composition [Co(NCS)₂(H₂O)₄]·2C₆H₁₂N₄ (Refcode: XILXOG; Li *et al.*, 2007) and [Co(NCS)₂(C₆H₁₂N₄)₂(H₂O)₂][Co(NCS)₂(H₂O)₄]·2H₂O (Refcode: MOTNIS; Liu *et al.*, 2002; MOTNIS01; Zhang

et al., 1999; MOTNIS02; Chakraborty *et al.*, 2006; MOTNIS03; Lu *et al.*, 2010), that also form discrete complexes with terminal N-bonded thiocyanate anions. The structure of these compounds is somehow related to that in **1** and **2** with the major difference being that the ethanol is replaced by water. Discrete complexes have also been reported with other transition-metal thiocyanates including, for example, nickel (Refcode: XILROA; Bai *et al.*, 2007; XILROA01; Lu *et al.*, 2010) and zinc (Refcode: SIMXIY; Kruszynski & Swiatkowski, 2018), but none of them contains ethanol as a co-ligand. The latter structure with the composition [Zn(NCS)₂(urotropine)₂·(H₂O)₂]·[Zn(NCS)₂(H₂O)₄]·2H₂O contains two different complexes, one of them similar to **1** and the second similar to **2** with the difference that the EtOH is exchanged by water.

Finally, it is noted that with cadmium and mercury a crystal structure with urotropine is reported in which the Cd cations are linked by pairs of thiocyanate anions into chains, which are further linked by the urotropine ligand (Refcode: DOZZOI; Bai *et al.*, 2009 and DIJSIY; Mak & Wu, 1985). The formation of such a compound can be traced back to the fact that cadmium and mercury are much more chalcophilic than cobalt. There is one additional structure with cadmium similar to that mentioned above. In this structure, the cadmium cations are linked by pairs of thiocyanate anions into chains that are either connected by two EtOH molecules or urotro-

pine ligands, which connect neighboring chains (FEWZOY; Barszcz et al., 2013).

5. Synthesis and crystallization

Synthesis Co(NCS)₂ and urotropine were purchased from Merck. All chemicals were used without further purification.

Single crystals of **1** and **2** were obtained by reacting 0.15 mmol of Co(NCS)₂ (26.3 mg) with 0.6 mmol of urotropine (84.1 mg) in 1 mL of ethanol after one day.

Experimental details

The data collection for single crystal structure analysis was performed using a Rigaku XtaLAB Synergy Dualflex kappa-diffractometer equipped with HyPix hybrid photon counting HPC detector, using Cu-K α radiation from a PhotonJet micro-focus X-ray source.

The PXRD measurements were performed with Cu K α_1 radiation ($\lambda = 1.540598 \text{ \AA}$) using a Stoe Transmission Powder Diffraction System (STADI P) equipped with a MYTHEN 1K detector and a Johansson-type Ge(111) monochromator.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 5. All non-hydrogen atoms were refined anisotropically. The C—H hydrogen atoms were positioned with idealized geometry (methyl H atoms allowed to rotate but not to tip) and were refined isotropically with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ (1.5 for methyl H atoms). The O—H hydrogen atoms were located in the difference map and were refined with restraints for the O—H distance (DFIX) and varying isotropic displacement parameters. The crystal of **1** was twinned by non-merohedry and therefore, a twin refinement using data in HKLF-5 format was performed where all equivalents were merged [BASF parameter = 0.309 (1)].

Detector resolution: 10.0000 pixels mm⁻¹
 ω scans

Absorption correction: multi-scan
(CrysAlisPro; Rigaku OD, 2021)

$$T_{\min} = 0.586, T_{\max} = 1.000$$

4731 measured reflections

4731 independent reflections

4504 reflections with $I > 2\sigma(I)$

$$\theta_{\max} = 80.3^\circ, \theta_{\min} = 5.0^\circ$$

$$h = -9 \rightarrow 9$$

$$k = -14 \rightarrow 14$$

$$l = -16 \rightarrow 17$$

Refinement

Refinement on F^2

Least-squares matrix: full

$$R[F^2 > 2\sigma(F^2)] = 0.044$$

$$wR(F^2) = 0.124$$

$$S = 1.06$$

4731 reflections

157 parameters

1 restraint

Primary atom site location: dual

Hydrogen site location: mixed

H atoms treated by a mixture of independent
and constrained refinement

$$w = 1/[\sigma^2(F_o^2) + (0.0719P)^2 + 0.7955P]$$

where $P = (F_o^2 + 2F_c^2)/3$

$$(\Delta/\sigma)_{\max} < 0.001$$

$$\Delta\rho_{\max} = 0.63 \text{ e \AA}^{-3}$$

$$\Delta\rho_{\min} = -0.43 \text{ e \AA}^{-3}$$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refined as a 2-component twin.

(Parsons *et al.*, 2013)
Absolute structure parameter: 0.0070 (19)

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
