## **Introduction**

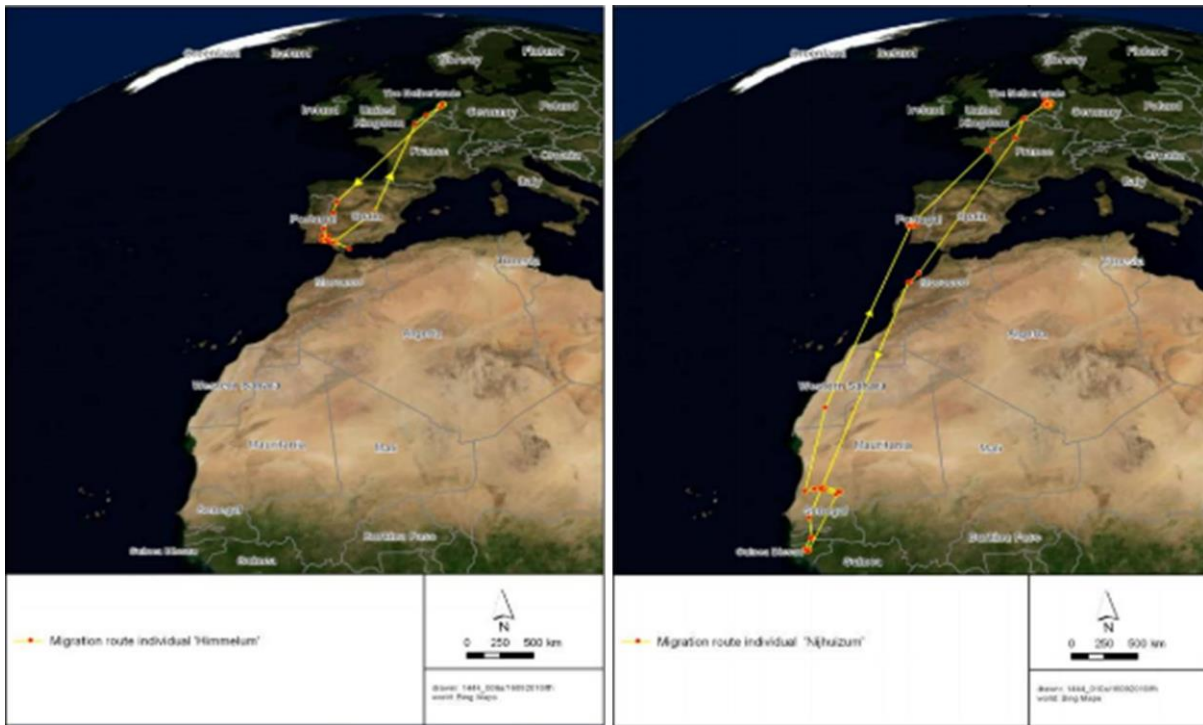

The Black-tailed Godwit (*Limosa limosa*; BTG) is a meadow bird (Verstrael 1987; Thijse 1904). The current Dutch population is estimated at fewer than 40.000 breeding pairs (Kentie et al. 2016) and represents an important part of the total continental BTG population *Limosa limosa limosa*. However, the number of breeding pairs have declined rapidly over the last decades, as compared to the 120.000 pairs in the 1960s (Mulder 1972). This is mainly caused by a change in agricultural land use. Intensification and rationalisation have led to degradation of the breeding habitat, resulting in low reproduction. The population in the Netherlands cannot produce enough chicks for a stable population. (Vickery et al. 2001; Newton 2004; Tscharnke et al. 2005; Teunissen & Soldaat 2006; Roodbergen et al. 2012). After the breeding season godwits migrate to southern Europe (Spain and Portugal) and West-Africa where they stay for wintering (Márquez-Ferrando et al. 2009; Hooijmeijer et al. 2013).

## **Demographic research Southwest Friesland**

To measure the changes in population numbers and the causes, in 2004 the University of Groningen started a long-term research in the south-western part of Friesland, The Netherlands. In 2007 the research area has expanded up to 8400 hectares and since 2012 it increased again with another 1600 hectares (Groen et al. 2012). A colour-marked population of godwits was set up to make them individually recognizable. The knowledge that has been collected with this research has been implemented by policy makers and nature conservation organisations.

## **Migration and wintering sites Black-tailed Godwit**

In 1983-1984 the wintering sites of godwits were explored for the first time. At that moment most godwits were wintering in rice areas along the West-African coast in Senegal, Gambia, Guinea-Bissau and further. Big numbers of godwits also occurred in the inner Niger delta in Mali (Altenburg & van der Kamp 1985), but they probably belonged to the eastern European population. Recently, the wintering behaviour has partly changed with an increasing number of godwits deciding to winter in southern Spain at National Park Doñana. In the 1980s during the first counts, only 4% of the NW-European population used this area as a wintering site but recent estimations suggest a big change with up to 23% of the population wintering in Spain. The most important reason for this is probably the creation of new artificial fishponds and rice fields. It is remarkable that this increase is not driven by climatic changes in the Sahel zone of West-Africa (Márquez-Ferrando et al. 2013). For godwits, staying Iberia can be advantageous because they can skip a 3000 kilometre (v.v.) travel over the Sahara, a potentially dangerous migration route and save their fat stores for the next breeding season.

**Figure 1.** Two migration routes of satellite tagged birds in 2009. The left map shows the route of an Iberian wintering bird. On the right an African wintering bird. Iberian wintering birds save a 6000 km flight and don't need to cross the Sahara twice (Hooijmeijer et al., 2013)..

### Conservation

The change in wintering grounds is remarkable and an important reason why we want to do (demographic) research in West-Africa. We know now that juveniles are more likely to make these kind of shifts than adults (Verhoeven et al., 2017), but not how they develop their individual migration strategy and perhaps thereby change the migration pattern of the species. These changes can also have consequences for the survival rate of both adults and juveniles. Moreover, they can lead to differences in reproductive success, for example due to differences in body condition upon arrival on the breeding grounds. Both are demographic parameters that can rapidly influence population dynamics. A better understanding of these processes is therefore also important from a conservation point of view; the Black-tailed Godwit qualifies since 2006 as “Near Threatened” on the IUCN Red List.

Until now, West-Africa is the only area along the migratory flyway from where we don't receive many observations of colour-marked individuals. Only small numbers of colour-ringed birds have been reported, mainly by birdwatchers and, recently, by local scientists. Unfortunately the numbers of sightings are too small to make demographic comparisons between wintering sites.

### Expeditions West-Africa and Iberia

In November 2014 the University of Groningen, in cooperation with Global Flyway Network and financially supported by Birdlife Netherlands, embarked upon their first expedition to the wintering grounds in West-Africa and since then we visited the area 2-3 times per year. We aim to set up a demographic research project in this area in close cooperation with local scientists, volunteers and conservation organisations. The most important goal of the first missions was to get a good overview of the wintering grounds, resighting conditions, local facilities and knowledge and to make a start with setting up a dataset of individually recognizable godwits that winter in West-Africa. Secondly we made a pilot study of habitat choice and prey choice. At this moment comparable research is done in NP Doñana (Spain), Extremadura (Spain) and the Tejo/Sado estuaries near Lisbon (Portugal). The last two are used as stop-over sites in February. Therefore it is mandatory to continue our

research at all these locations to find links between wintering sites, stop-over sites and breeding sites. Research questions we want to get into in the future with our work in West-Africa, Spain, Portugal and the Netherlands are:

- What is the overall difference in adult mortality between birds wintering in West-Africa and Iberia? And where along the flyway do these differences occur?
- Can birds change their wintering strategy during their life? And is this age-dependent?
- Does reproductive success determine where birds winter?
- Has the wintering strategy consequences for their migration and breeding phenology? And are there consequences for their reproductive success?

### **Habitat study**

Anthropogenic alteration of natural wetlands is having a major impact worldwide with consequences (both negative and positive) for migratory species such as continental black-tailed godwits. The majority of continental black-tailed godwits breed in grassland meadows situated in north-west and Eastern Europe (March – July) after which they migrate southwards for the non-breeding period (mid July – February), finding forage resources within wetlands and agricultural rice fields. On their migratory route black-tailed godwits pass through France and either stage or spend the non-breeding period in southern Spain and Portugal. Many will make the Saharan crossing to overwintering sites in West Africa, namely; the Senegal Delta and coastal region of Senegal, The Gambia, Guinea-Bissau, Guinea, Sierra Leone and central Mali.

Concentrating our efforts in Senegal, we used remote sensing products (Modis EVI 16 day time series) and 3.5 years of good quality locations of black-tailed godwits (equipped with PTT satellite tags) to generate a spatially and temporally explicit habitat prediction model using MaxEnt modelling. We found that during the non-breeding period black-tailed godwits show a preference for stable habitats within a relatively low productivity range (EVI value 0.1-0.2), which are associated with open wetlands, low vegetation cover and shallow surface water. However, remote sensing data is difficult to interpret without accurate ground-truthing information. Additionally, godwits spend much of their time foraging either on the mudflats of saline mangrove wetlands or in wet rice fields, however little is known of the nature of the prey items at different times of the year. In this study we aimed to conduct a survey categorizing and describing habitats, measuring environmental variables such as water salinity and soil penetration pressure, feeding efficiency of the godwits and carefully searching the substrate to establish the identity of godwit prey items.

Between 27 August and 6 September 2018 we visited the most important areas in the Casamance in South Senegal to record resightings of individual birds and describe godwit habitat. In this report we present a daily overview of our findings with photos, locations we visited, numbers present and the first conclusions and recommendations.

## Daily reports

Map of the areas visited during the expedition, and showing the location of the famous Amalia!

### 29 August 2018

Today we travelled from The Netherlands to Senegal. We spent the night at hotel Begue Pokai in Toubab Dialaw at 40 min drive from the fancy new airport. Our guide Idrissa Ndiaye was already in the Casamance for 3 days to explore good sites for us to visit.

### 30 August 2018

An early start we left Dakar at 06h30, caught a flight to Ziguinchor at 09h00. Idrissa and driver Marcel were there to greet us. We headed straight to the field despite the pouring rain. We skipped the Colobane rice fields because of heavy rains. We continued along the road to Cap Skirring and found 190 godwits at the Niambalang mudflats east of Oussouye and managed to read 9 ring combinations. Godwits were roosting on the mudflats and foraging in the mud of a flooded and ploughed rice field. The field did not contain any rice seedlings only mud walls and raised mud in rows for where the rice would soon be planted.

The rain ensured that the water was about 30cm deep. Probing holes created by the foraging godwits could clearly be seen, with the highest intensity in the mud closest to the water. The penetrometer set up on the softest possible measure barely registered any resistance. The water in 3 different paddies had an exceptionally high pH around 9.5 and 10, salinity was very low 500 – 800  $\mu\text{S}$ , and soil moisture was high 37 – 45% volume, measured with the Thetaprobe. We collected some mud samples with the 100 cm<sup>3</sup> pf ring for further chemical and nutrient measures. We also captured 14 new survey sites by identifying the land use, and capturing representative photos of the area. We continued along this road and took the turnoff to Miomp where one of the transmitter birds had been located. Due to the bad condition of the road we could not get close enough to the exact site and decided to continue to the Cabrousse rice fields. Maintenance of the dikes, ploughing and

planting were in full swing and a lot of people were working in the field. No godwits were found here and they were not seen recently either.

It kept on raining (>70 mm today!) and on the way back to Bignona we stopped at the Colobane rice fields. But it was already getting too dark and most birds had probably already left to the roost. We only read 1 codeflag.

View from the plane of the rice fields adjacent to Ziguinchor, it's the rainy season! The soil is waterlogged and the rice paddies are filled with water.

Godwits foraging on earthworms on the ploughed rice paddies.

### **31 August 2018**

The day started dry but as soon as we had reached the Baila mudflats it had started raining again. We scanned the mudflats but found no birds; perhaps the water level was too high for them to forage? We continued to the Dianki rice fields. On the way there we passed through several smaller rice field complexes but no godwits were encountered. In Dianki we spent the rest of the day scanning every corner of the rice fields but found no more than 100 individuals. A lot of people were in the field preparing the paddies or planting the rice. Almost all birds that we found, were foraging in recently ploughed parcels. We took several soil samples but did not find any obvious prey items. From the probing holes we could see that they were searching for food in the flanks of the small dikes, perhaps looking for spilled grains from the previous harvest that become available in the mud from the paddies that is used to reinforce the dikes? We also found 3 cm long earthworms in the fresh dikes; that could also be what they are looking for.

Regarding colour rings we did not have a very fruitful day. We checked at least 86 individuals but found only 1 bird of our scheme and 2 of the Spanish scheme.

In the Dianki rice field complex there is a huge dike, installed by international funding. The dike separates the rice paddies from a mangrove wetland. The recent heavy rains have filled all the existing rice paddies and the large water buffer area. The sluice gate in the dike was open allowing the excess rainwater to flow from the water buffer area into the mangrove wetland. Salinity measured in the water buffer areas and rice paddies in preparation for planting was really low 20 – 200  $\mu$ S, in the mangrove wetland it was higher around 3.4 mS. The highest salinity was encountered in the abandoned salinized rice on the outside of the big dike 6.9 mS. pH in the different habitats ranged from 9.5 to 6.0 and the heavily flooded soils were soft measuring between 0.1 to 8.2 on the lowest combination of spring and cone. We collected a further 16 habitat description points noting the current season differences from our previous visit in Nov/Dec 2016.

Dianki rice fields water buffer area, filled with water and reeds.

### **01 September 2018**

Good dry weather initially with no cloud cover, but later around 12 pm reached 100% cloud cover. A cool coastal breeze kept the temperature low, ~25 °C. A long walk today through the rice fields of Fintiok, Koubanao and Hatioune and adjacent mangrove wetlands, however quite informative in

terms of godwit foraging behaviour. We observed a group of godwits foraging both in the rice paddies, those which had been used as seedling nurseries – freshly harvested for replanting, and those that were ploughed and ready for planting, as well as in the extremely salty mangrove wetland adjacent to the rice fields (about 160 birds). The heavy rains ensured that all rice paddies and abandoned paddies were filled with fresh rainwater between 20 and 50 cm deep. Tussocks of grass were placed on the existing paddy walls for additional strengthening. These will dry later in the year and form part of the paddy wall maintenance. However at this moment these overturned tussocks were extremely interesting to godwits who were actively probing into these upside down tussocks, both the exposed tussocks and as far as we know the tussocks that were under the water. We carefully investigated a few of these paddies that were used for foraging and found many ~3cm red earthworms. The feeding efficiency showed quite a high success rate of between 18 and 25 food items per minute. Salinity measured in the fresh water rice paddies was really low at 440  $\mu$ S, and penetration pressure was almost zero in the water logged clay.

In the adjacent mangrove wetland we measured hyper saline conditions of 44.3 mS, as well as penetration pressure of almost zero. The godwits were mainly foraging in shallow pools of ~15cm deep, or in shallow creeks. Feeding efficiency was quite high between 18 and 33 prey items per minute. We investigated the mud where they had been foraging and managed to find only one chironomid. We sampled the general area twice and sieved out the sample in the pools of water but were unable to find any more chironomids nor any other suitable candidate food items. This was strange given the high intake rates of the godwits. Nonetheless we took a full set of environmental measures and a representative soil sample in both the rice paddies and the mangrove wetland. We added a further 11 sites to our habitat description sample set.

Many people were working in the rice fields like in the fields we visited the previous days. Fintiok and also Koubanao still have the most well maintained fields; in Hatioune >75% had been abandoned and the dikes were not well maintained. We heard many times from local farmers that godwits come to the rice fields mainly in the early morning to forage. Later when the fields become full of people, most of them seem to move to the mangrove wetlands (tannes). Here they continue foraging or spend time roosting. We also heard from many farmers that the godwits caused serious damage by trampling the freshly planted seedlings. We did not see any birds in these kind of fields however. In total we saw about 200 individuals between 10:00 and 18:30; 75 in the rice fields and the rest in the tannes. It was a productive day colour-ringwise: we read 9 combinations, 7 were from our own scheme. 4 of them had been seen here in previous years.

At the edge of the mangrove wetland and Fintiok rice paddies looking towards the approaching storm.

## **02 September 2018**

The day started with an hour long rain shower, but by the time we were ready to head into the field the rain had stopped. Cloud cover was between 80 – 100% the rest of the day. The air temperature ranged from about 25 – 30°C. We met with some local master students from the university in Dakar that are doing a master on herons, Pape Cissao and Maryam, and together we explored the shores of the mangrove wetland near Tobor. We found several groups of godwits adding up to about 250 individuals and most of them were actively foraging in shallow water. Ideal situation for reading colour rings but unfortunately the ring density was low with only 2 birds from our own scheme. This time plenty of success in sampling the mud for prey items. The mud was filled with chironomids which was also shown by the high intake rates of 30 – 44 prey items per minute. Salinity measured 11.5 mS and penetration pressure was higher than yesterday's measures ranging between 3 and 6, in the thick compacted clay. Abandoned rice fields flanked the mangrove wetland, they looked like they have not been active for years as they were fully invaded by local wetland reed species.

After lunch we explored the Colobane rice fields next to Ziguinchor, there were about 600 godwits in different groups that mixed and split up again. The birds were very relaxed around people and could be approached up to 40 meters. That was necessary if you wanted to read the colour rings because they were extremely stained and covered with a film of clay that made the rings almost impossible to read from a distance; we had experienced that in previous years at this site as well. Nevertheless we ended the afternoon with 27 resightings including many from other schemes and even a Finnish bird. Similar to yesterday the godwits were found in a recently ploughed rice field ready for planting. The water was deep ~50cm however the godwits were perched on the mud ridges probing for food items in the overturned grass and rice tussocks. Salinity was very low at 408  $\mu$ S and penetration pressure was zero in the water logged clay of the mud ridges. We sampled the mud that was actively probed by the godwits 3 times with a sieve however, were unsuccessful in obtaining any suitable prey items from the mud. Again, a bit strange as the godwits who were actively foraging were finding between 16 and 32 prey items per minute. We asked one of the ladies who was planting rice seedlings in one of the fields if she had seen many worms while they were ploughing, she said a few weeks back when there was less water in the paddies the fields were full of worms.

The shores of the mangrove wetland at Tobor.

### **03 September 2018**

Another rainy start to the day, but after about an hour downpour the rain eased up. Cloud cover ranged from 90 -100%, and there were a few showers of rain on and off the whole day. The temperature ranged from 25 – 30 °C. We headed North East to a small protected area, Roneraie de Diognere which is situated in a bend of the Soungrougrou tributary of the Casamance River. A German transmitter bird called Melto, had been spending time in a large shallow wetland central to the protected area. We first had to cross the Soungrougrou River via ferry which took some time. We navigated to the nearest village – to the protected area - to ask the Chief permission to visit the area. They very enthusiastically received us and were very curious about our work. The Chief's son joined us to help us navigate along the correct tracks to the edge of the river. From here we walked along the river bank until we reached the protected area. The Chief's son was impressed about the walking conditions, the waterlogged clay was a bit slippery and he apparently doesn't get to walk in these conditions very often. We passed by some rice fields adjacent to the lake, the women recognized the chiefs son and were animatedly surprised to see him. He was curious about our work though and asked many questions. We reached the very salty shallow lake but unfortunately did not have enough time to fully explore the whole area which would have taken more than a full day. Nonetheless we took some environmental measures as this was a rare opportunity to describe a remote environment visited by a satellite tagged godwit. The lake water was hyper saline at 52.7 mS and a soil penetration pressure ranging from 6.8 to 7.4. After this the Chief's son could not bear to walk back along the muddy shore and suggested we take a "short cut" back to the track through the rice fields. This proved to be quite amusing as he was not sure of the way and had to ask the ladies working in the fields for direction because he had to admit that he had not been there for 20 years (the ladies were delighted). We were treated to a view of a large flock of flying pelicans, and ultimately we were successful in finding Marcel driving along the track back to the village. The making for the story of the year, we think, paying a relatively random visit to this remote village of very friendly people. On the way back to the ferry we stopped shortly to explore the shores of the Soungrougou River, but alas still no godwits. We added 12 sites to our wetlands habitat descriptions.

The saline shallow lake within the Roneraie de Diognere protected area.

#### **04 September 2018**

Our last full field day, started off dry and cloudy 80-100% clouds. Rain showers occurred intermittently throughout the day, and the temperature was quite a bit higher than our previous days ranging from 30 – 35 °C. We explored Djifangor mudflats near Niaguis, a small mangrove protected area east of Ziguinchor. An amazing place with a great diversity of bird species including a super rare sighting of an African Skimmer and 2 Whitebacked Nightheron. A group of 86 godwits were present foraging in the shallow water so we took some environmental measures and a colour ring density sample. Salinity was quite high at 37 mS, and soil penetrability relatively low between 1.4 and 2. This was followed by an exploration of a rice complex near Agnack on the outskirts of Ziguinchor, salinity was really low 215  $\mu$ S and soil penetration pressure was zero in the waterlogged mud. We found a large group of at least 200 godwits resting and preening in a ploughed rice field, a second smaller group were foraging. In this group we found 6 individuals of our own scheme. Like in most rice fields, the birds were extremely easy to approach up to 50 m. We investigated the mud in their rice paddy really well to try to determine what the godwits were eating. At first it looked like it would be unsuccessful, but then after carefully breaking apart a clump of mud around a godwit probing hole we noticed really tiny earthworms ~0.5mm in diameter and about 3 cm long. These tiny earthworms were so delicate that they easily disintegrated when we tried to collect them. Sieving didn't yield anything as they were completely destroyed in the sieving process. So it seems earthworms are the key to the rice fields story at this time of the year.

We revisited Niambalang mudflats and found a flock of 500-600 godwits foraging in shallow water of the salty mangrove wetland just next to the road: easy peasy ringreading and in no time we had another 6 ring combinations. Birds were already moving out probably due to the incoming flood. Some of them were found back in a 2 hectare island in the middle of the mudflat a little further down the road, where someone apparently desperately tried to maintain some rice culture. But it will be a matter of time before this rice field will be abandoned. It was completely impossible to read rings here because the dikes were so high that you could barely see the birds' heads.

Most of the godwits had flown to the same paddy and adjacent mangrove mudflats as on the 30<sup>th</sup> where they were resting, preening and foraging. However, the ploughed field was now freshly planted with rice seedlings. Perhaps the ploughed field with overturned grass tussocks as well as the

fresh rains flooding the paddies create the perfect probing environment for godwits. It seemed today that the addition of the rice seedlings did not deter the godwits from returning to this rice paddy and any trampling of the seedlings may occur accidentally. We managed to get a few extra resightings in this group before we returned to Bignona.

Godwits foraging in the saline shallow lake in the Djifangor mudflats.

Godwits resting and preening in a ploughed rice paddy, in the rice fields of Agnack.

## 05 September 2018

On our final day in the Casamance we said goodbye to Toussaint and Bojang of Auberge Kayanior and headed immediately for the floodplains of Tobor. It was low tide and at first we did not find any birds but we discovered them finally in the large gully close to bridge behind Tobor. Most birds were just resting or preening and only about 60 of the 350 birds that were present were foraging. Despite the good ring reading conditions we only found 1 ringed bird. We picked up a Little Swift that apparently had fallen in the water at the bridge and fortunately it flew away perfectly after its wings had become dry again. We hurried to the Colobane rice fields near Ziguinchor, eager to read more rings on our final morning. We found a group of 700 birds more or less at the same location as earlier this week. Ring reading was good and from a close distance we identified 14 different individuals that were partly seen earlier this week.

To get rid of the mud we could take a shower at the house of Idrissa's nephew, repack our suitcases and after lunch with the team Casamance 2018, Marcel dropped us off at Ziguinchor airport to take the 16:15 flight to Dakar. From there we took the 23:55 flight to Amsterdam and arrived there in the morning of the 6<sup>th</sup>.

Project Little Swift rescue!

## Summary

We are looking back on a very successful expedition. The rainy season gave us some free showers but the conditions were generally great to do field work. There was a good cloud cover on most of the days and with a bit of wind and rain, the weather was really just fine. Road conditions were no worse than in other years and we could reach any site that we wanted to go to. Thanks to Idrissa, Marcel and Issa Sylla, logistics were perfectly arranged. The heavy rains filled all the rice paddies which completely waterlogged the soil and created a soft muddy bottom, very different from our previous visit in Nov/Dec 2016 when all the water was drained out of the rice paddies and the clay was baked as hard as concrete.

We found a good number of birds this year; about 2150 if you would simply add up the maximum numbers encountered at each site. But we know that godwits exchange a lot between sites and several birds were seen at multiple locations within this week. And scrolling through their life histories it became quite clear that individual birds frequent the same sites over the years. We

scored 89 resightings of our own scheme and 21 from other ringing schemes in 8 days of fieldwork; these 89 resightings represented 72 individuals. More than 99% of the birds were in full winter plumage and with an average fat-score of 3,5 (n=43; API scale 1-5), they were in excellent condition and ready for a consecutive flight to Guinea Bissau or even further.

Foraging individuals were mostly found in two kinds of habitats: either in more or less saline mudflats or in recently ploughed rice fields. In the first habitat they apparently were foraging on Chironomids but in the latter they seemed to be after different kinds of worms. We found two kinds of worms: 3 cm long and 2 mm thick ones that looked like small earthworms and 3 cm long and 0.5 mm thick ones. The first ones were found in the drier parts of the ploughed fields, either in the small dikes or in clumps of mud that were just above the water level. The thin worms seemed to be much more confined to the parts of the rice fields that were fully covered with water. This is unlike the rice fields in Iberia; godwits in West Africa don't seem to forage on spilled rice from the previous harvest, despite the fact that they are present at exactly the same period of the rice cultivation cycle. In the samples we explored, we did not find any rice kernels, which is also very different from the situation in Iberia. So we learned that the presence of foraging godwits indicated the presence of worms in the freshly ploughed (or freshly seeded) rice paddies or the presence of Chironomids in the more saline mangrove wetlands.

We collected 78 new habitat descriptions with the current wet season conditions, as well as 8 sets of mud samples (in sets of 3) for further analysis for chemical residues, organic matter content and texture analysis. Our samples ranged from the rice fields and mangrove wetlands neighbouring Ziguinchor city, to really remotely located sites, therefore we expect some differences in chemical residues. Additionally we managed to get a good sample of the chironomids and the larger earthworms, but we were not so successful in collecting the small earthworms (just 2!).

A striking observation was the almost complete absence of shelled benthos in the mangrove mudflats and rice fields. We could walk through most of these habitats without shoes (since the sticky mud often sucked our shoes off our feet). This is likely caused by the overexploitation of people gathering these species from the mud for food, as we passed many very large piles of stacked empty shells on the side of the road. These shells are incorporated into cement used for building. On the other hand rice fields and mangrove wetlands near human settlements contained quite a lot of rubbish, e.g. plastic and glass bottles, broken glass, bits of broken concrete (with mangrove benthos shells incorporated into the concrete).

Like in previous years, we heard stories about damage caused by godwits but that differed a lot from site to site. It is clear that godwits were attracted to ploughed rice fields but they kept visiting these fields after the rice seedlings have been planted. We were told that in the Casamance it is not possible to sow rice directly in the paddies because the early arriving godwits would eat the rice. No farmers seem to try that anymore so we cannot confirm that godwits would indeed eat rice in July/ August when the rains arrive. Nowadays the main damage will be caused by trampling freshly planted and not yet established rice seedlings. A solution could be to plough many rice fields at the same time so that the godwits would be diluted over many fields. What we witnessed this week is that there were only a few paddies in each rice field complex that were recently ploughed in the past two weeks and that a lot of godwits were found in just a few paddies which might indeed cause damage. The limiting factor here is that the preparation of the fields has to be done completely manually: there simply is not enough man/ woman(!)-power to achieve this. We did not witness anyone chasing godwits from freshly planted fields and hunting does not seem to be an issue either. People just seem to live the fact that they are there.

This expedition was funded by Birdlife Netherlands, University of Groningen, the Spinoza premium (NWO) to TP and supported by Global Flyway Network.

Greetings from Team Casamance 2018, Idrissa, Jos, Ruth and Marcel.
