

Genetic architecture of the white matter connectome of the human brain

Zhiqiang Sha, Ph.D.
Language and Genetics Department,
Max Planck Institute for Psycholinguistics

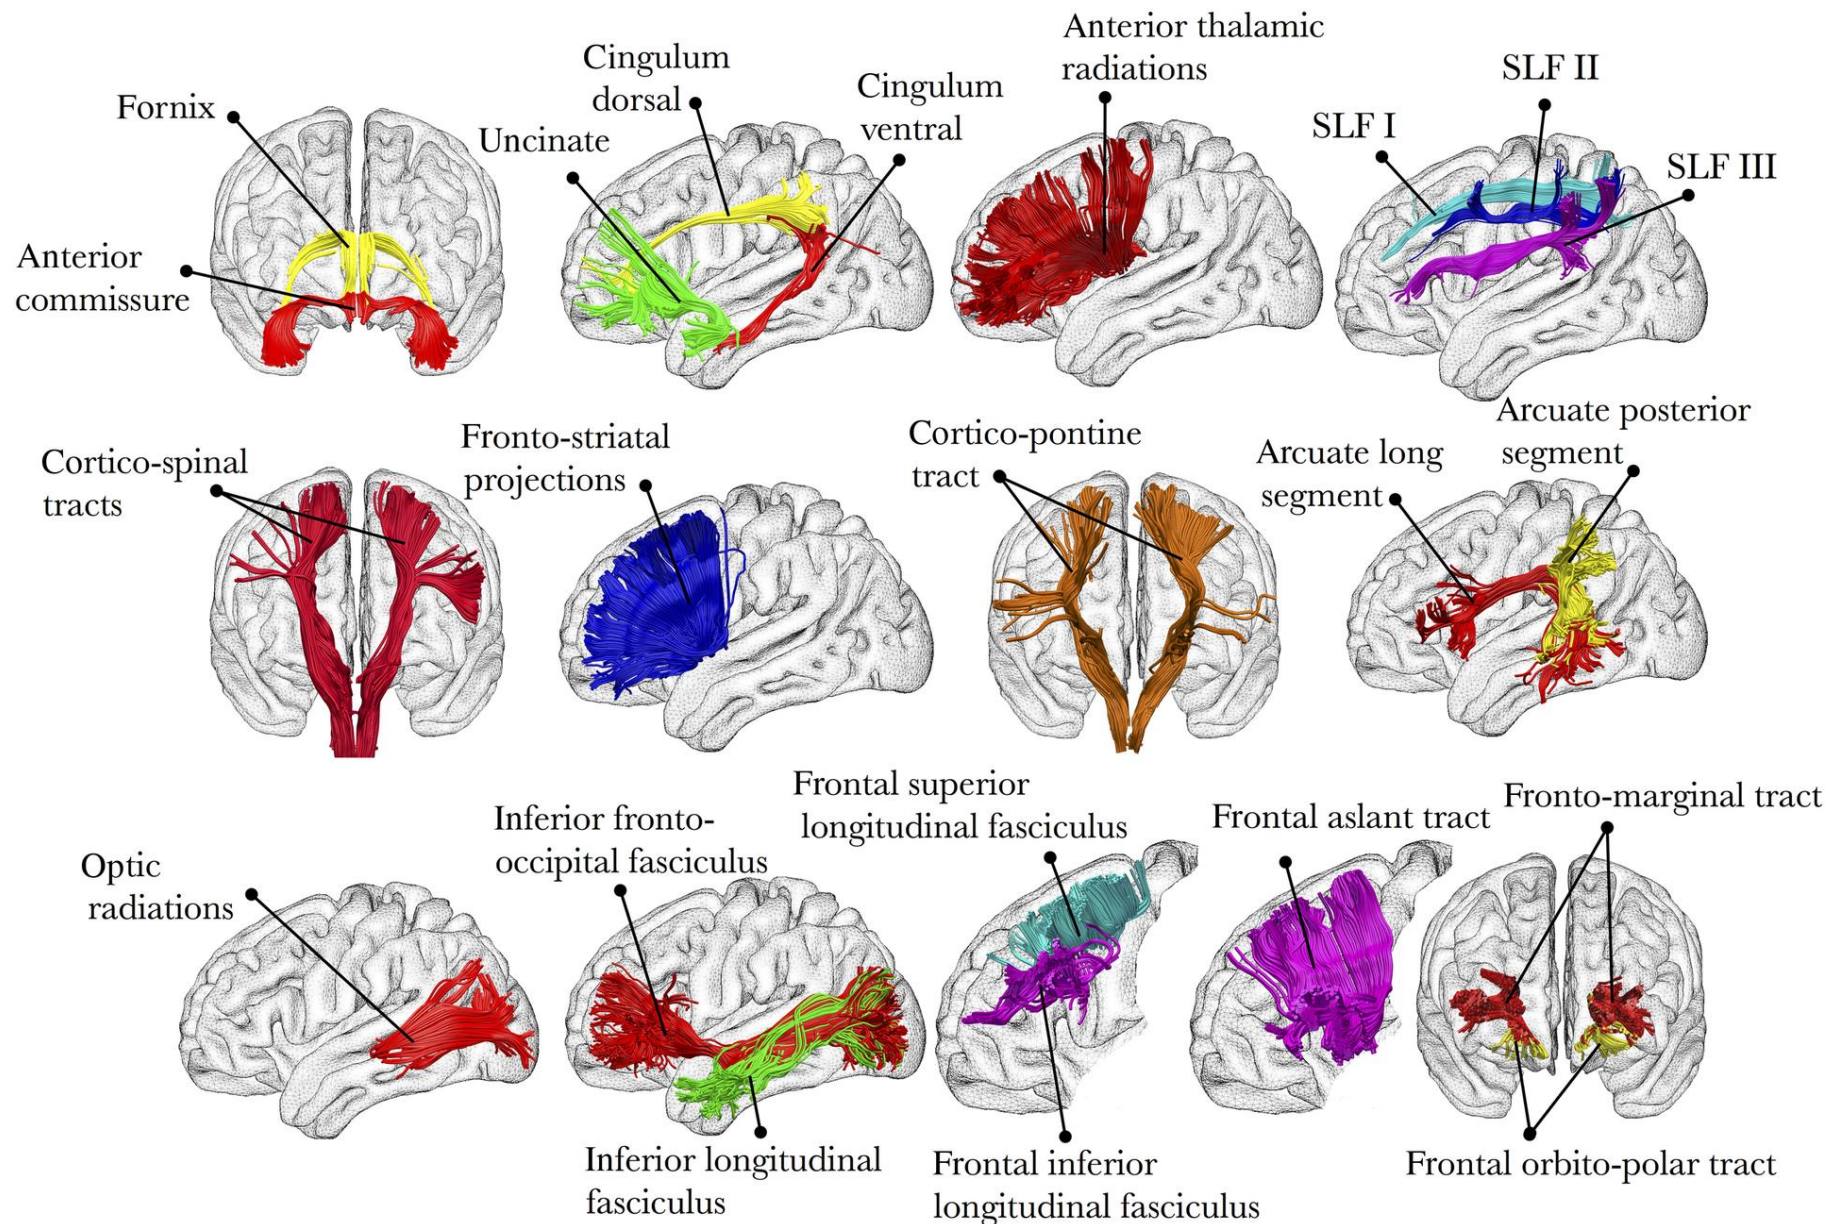

Background

White matter fiber tracts connecting neurons of different regions

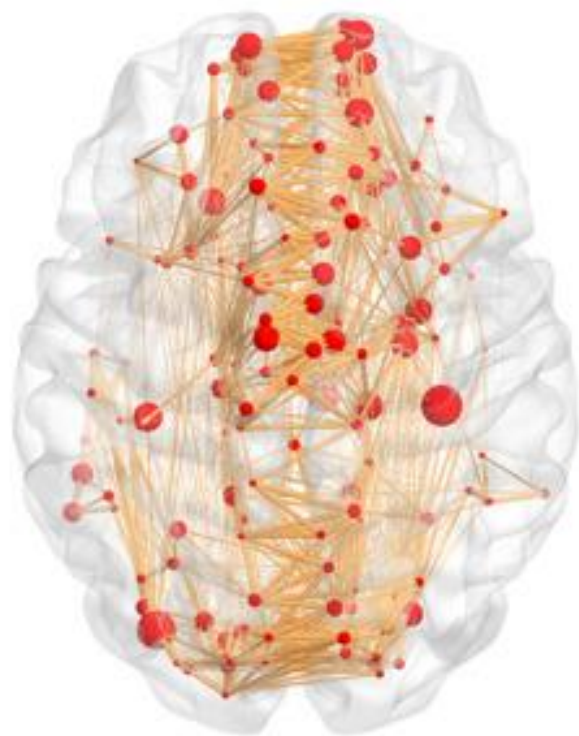

Background

Major fiber tracts connecting cerebral cortex, subcortical regions and cerebellum

Background

White matter connectivity changes during neurodevelopment and aging

Age(yrs):9-20

Age(yrs):30-40

Age(yrs):50-60

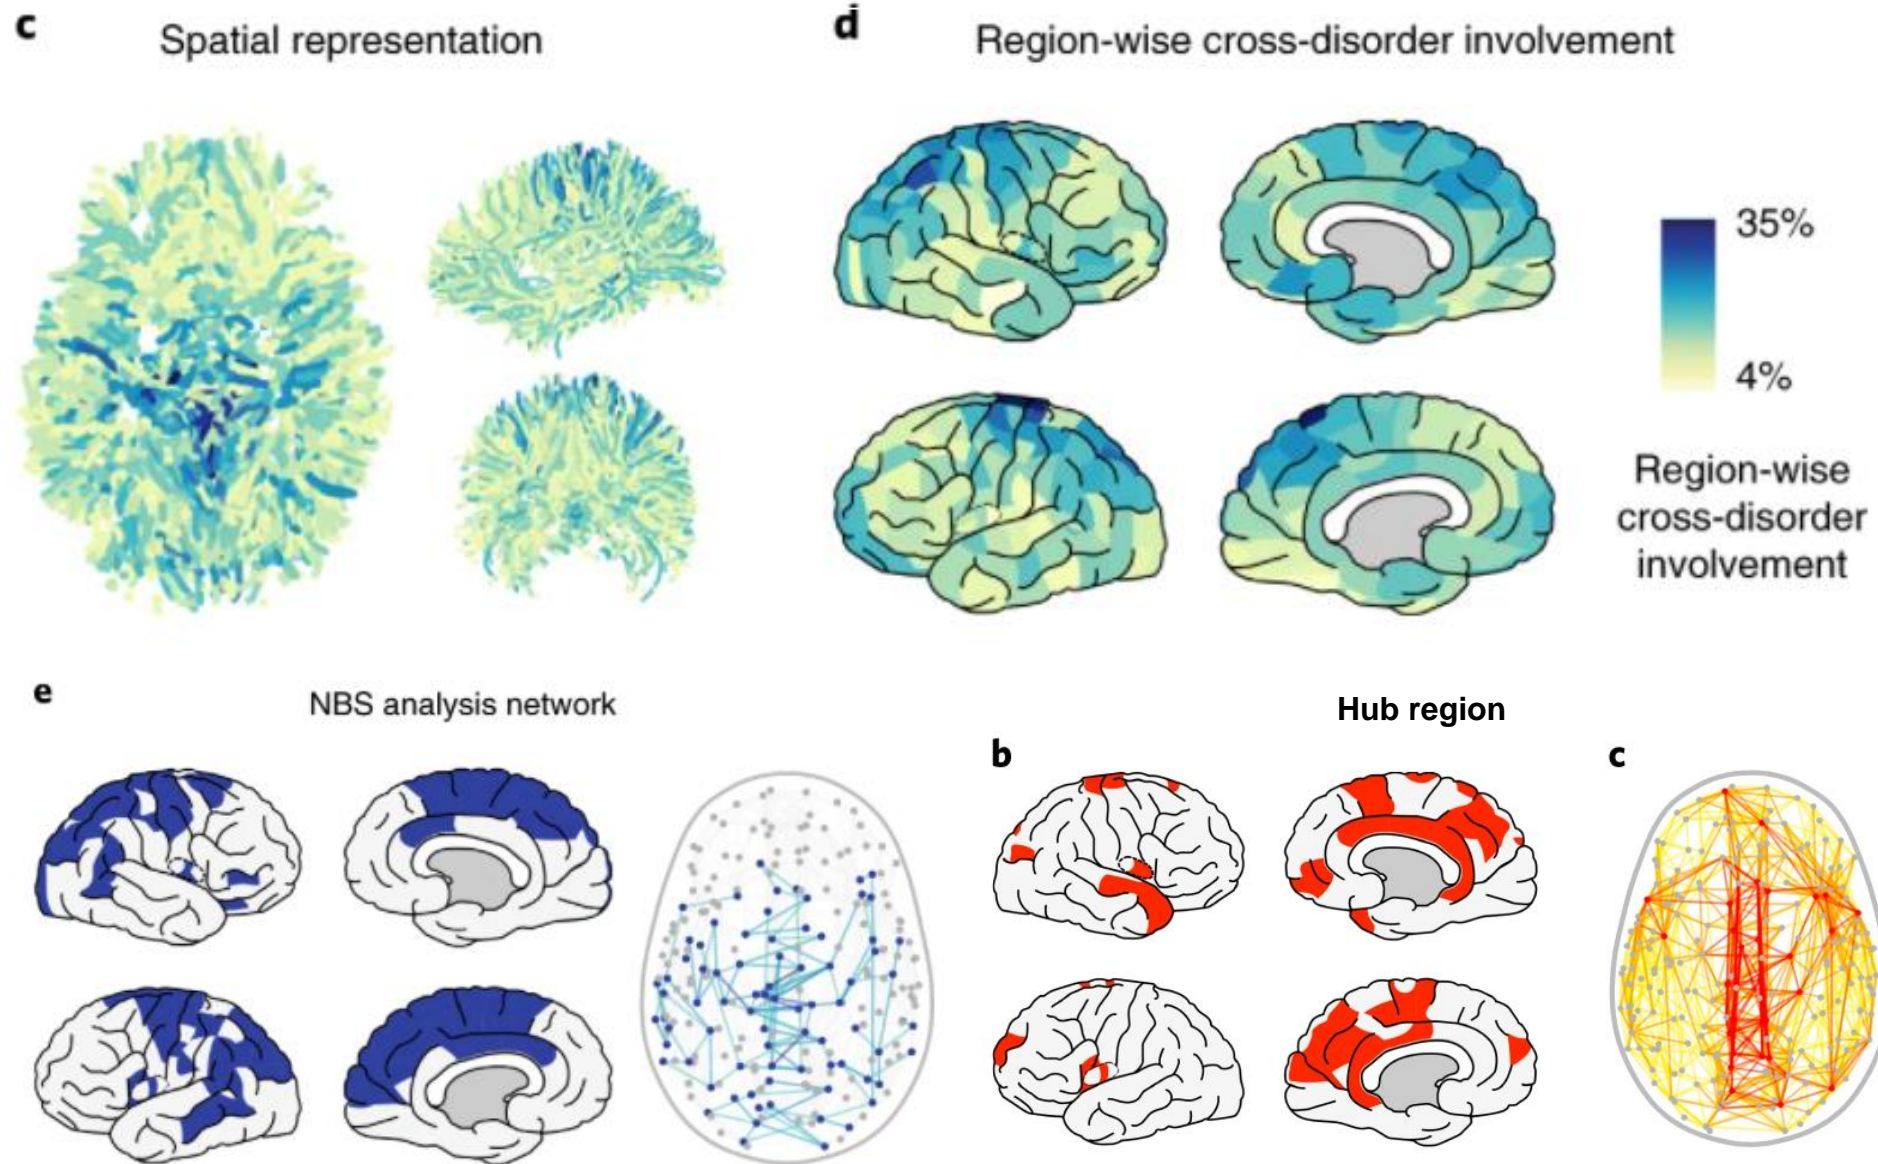

Age(yrs):70-85

Dynamic changes of white matter connectome across lifespan

Background

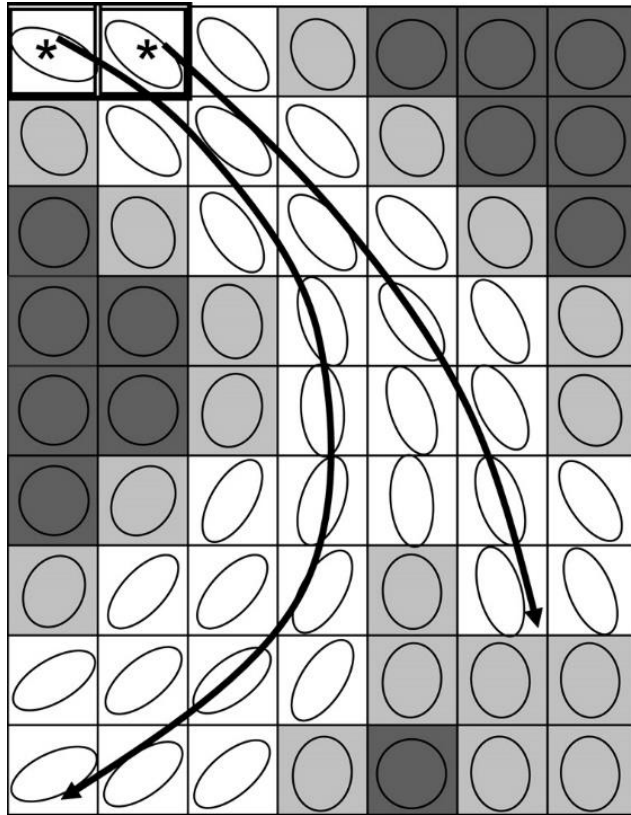

Disrupted white matter connectivity across neuropsychiatric disorders

Background

Tractography technology tracks the white matter tracts in the human brain

DTI is sensitive to **water molecule diffusion** which is constrained to be especially parallel to nerve fibers

Fiber tractography is to reconstruct **fiber tracts** (i.e. **white matter connectivity**) by linking the voxels that have the same orientation, while counting the streamlines between the start point and end point.

Mori et al., 1999, Ann Neurol

Mori et al., 2006, Neuron

Background

UK Biobank (UKB) provides a great opportunity with large sample size to explore genetics of brain structure.

For the genetic information, UKB has collected about 500,000 subjects (ages 40-80 years), including genotypes, exome sequences and whole genome sequences.

For the imaging study, UKB aims to conduct detailed MRI imaging scans of over 100,000 participants in Stockport, Newcastle, Bistol and Reading centers.

Now, they have scanned about 48,000 subjects with brain imaging and genetic information.

The image shows a banner from the UK Biobank website. At the top left is the logo 'biobank^{uk}' with the tagline 'improving the health of future generations'. To the right of the logo is a navigation menu with links: Introduction, About, Further Information, Imaging, Incidental findings, Testimonials, News, Contact us, Directions, and Further documents. The main text of the banner reads 'Improving the health of future generations'. Below this, the number '48,240' is displayed in five separate blue rounded squares. Underneath the number, it says 'Participants scanned so far - help us make it to 100,000!'. The banner also features silhouettes of a tree and people on the left, and a person walking a dog on the right.

Background

Aims of the present study

Here we carried out a brain-wide tractography on 30,810 participants from **UK Biobank**.

- Estimate **heritability** and perform **multivariate GWAS analysis** of the tract measures
- **Functional annotation** of genetic variants that associate with structural connectome
- Assess the association of **regional connectivity** with other clinical traits, including **psychiatric disorders** (schizophrenia, bipolar disorder, autism, attention-deficit hyperactivity disorder), **neurological disorders** (Alzheimer's disease, amyotrophic lateral sclerosis, and epilepsy) and **handedness**.
- Genetic influences on fiber tracts linking **core language regions**.

Methods

Individualized structural network construction

T1-weighted image

Anatomical
parcellation

Node definition

Diffusion-weighted image

Fiber
tractography

Edge definition

White matter structural
connectivity matrix

Methods

Node and edge-level measures per individual

Two types of measurement per individual:

➤ **Edge-level**
Count the number of streamlines linking each pair of regions, while adjusting for the brain size by dividing by the average volume of both regions.

➤ **Node-level**
Degree centrality of each region: Sum the connectivity linking to a given region

Methods

Genetics of structural connectome of the human brain

1. Sample quality control

- Exclude outliers based on **heterozygosity** (PC corrected heterozygosity > 0.19) and **genotype missingness** (missing rate > 0.05).
- Exclude subjects with a **mismatch** of their self-reported and genetically inferred sex.
- Exclude the subjects **without “white British ancestry”**.
- Exclude the subjects with relatedness of **kinship coefficient** > 0.0442.

2. Genetic quality control

- Exclude variants with **minor allele frequencies** < 1%.
- Exclude variants with **INFO** < 0.7.
- Exclude variants with **Hardy-Weinberg equilibrium** $p < 1 \times 10^{-7}$.

3. Brain measures

Automated Anatomic Labeling atlas

- Node level (degree)
- Edge level (connectivity)

We finally included 30,810 participants

	Male	Female
Participants	14,636	16,174
Age	64.56 ± 7.59	63.20 ± 7.34

Methods

SNP heritability and multivariate GWAS analysis

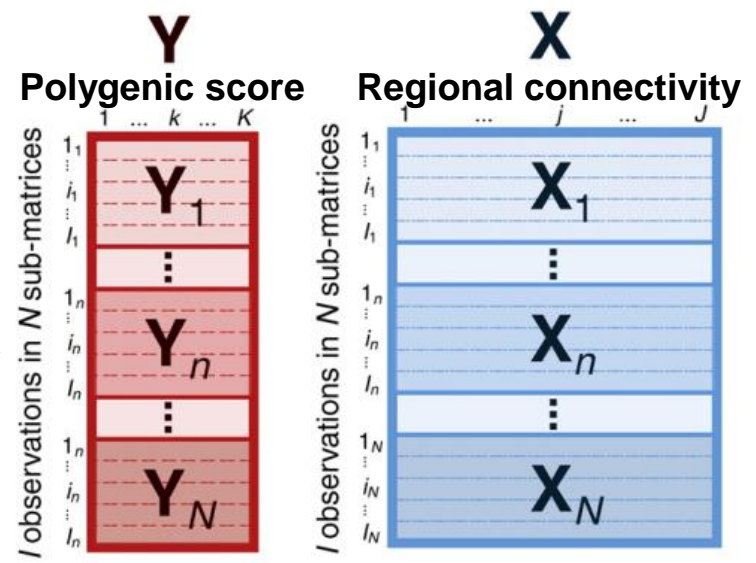

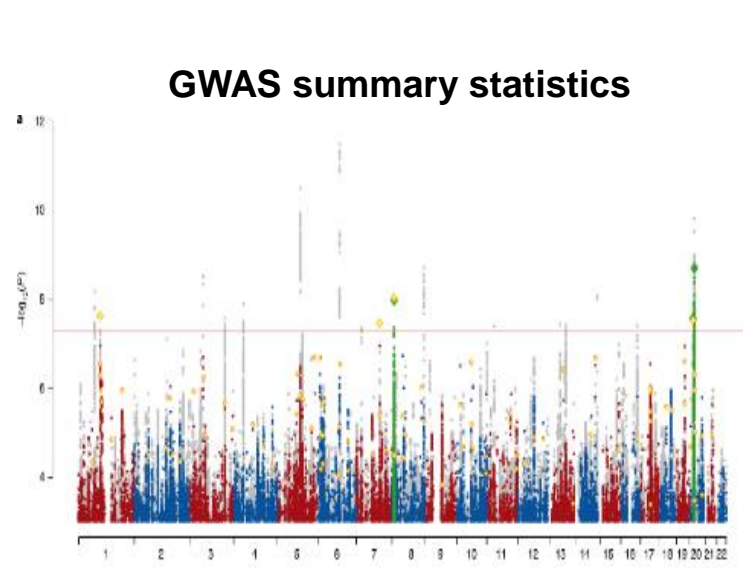

- 1. SNP heritability:** Estimate the proportion of variance in a phenotype explained by all SNPs using GCTA.
 - (1) Remove cryptic relatedness (cutoff: 0.025).
 - (2) Construct genetic relationship matrix.
 - (3) Calculate genome-based restricted maximum likelihood (GREML).

- 2. Multivariate GWAS** (separately for node- and edge-level metrics):
 - (1) For each significantly heritable trait, test **univariate association** with additive genetic model for each SNP.
 - (2) Separately for each SNP, test its univariate association with each brain measure, convert the P values to z scores, then use **Mahalanobis distance** to compute a single multivariate association X^2 (null distribution obtained through permutation; MOSTest software).
 - (3) Identify **brain traits** that make the greatest contributions to overall multivariate association by calculating the mean of unsigned z-scores across lead SNPs.

- 3. Covariates used in the GWAS analysis:** age, nonlinear age, 10 genetic principle components, assessment center, genotype measurement batch and sex.

Methods

Associations of regional connectivity with different polygenic scores

Canonical correlation model

$$u_1 = a_{11}x_1 + a_{12}x_2 + \dots + a_{1j}x_j$$
$$u_2 = a_{21}x_1 + a_{22}x_2 + \dots + a_{2j}x_j$$
$$\vdots$$
$$u_N = a_{N1}x_1 + a_{N2}x_2 + \dots + a_{Nj}x_j$$

3) Cognitive annotations

2) Co-activation map

1) Region with high loadings (|r|>0.2)

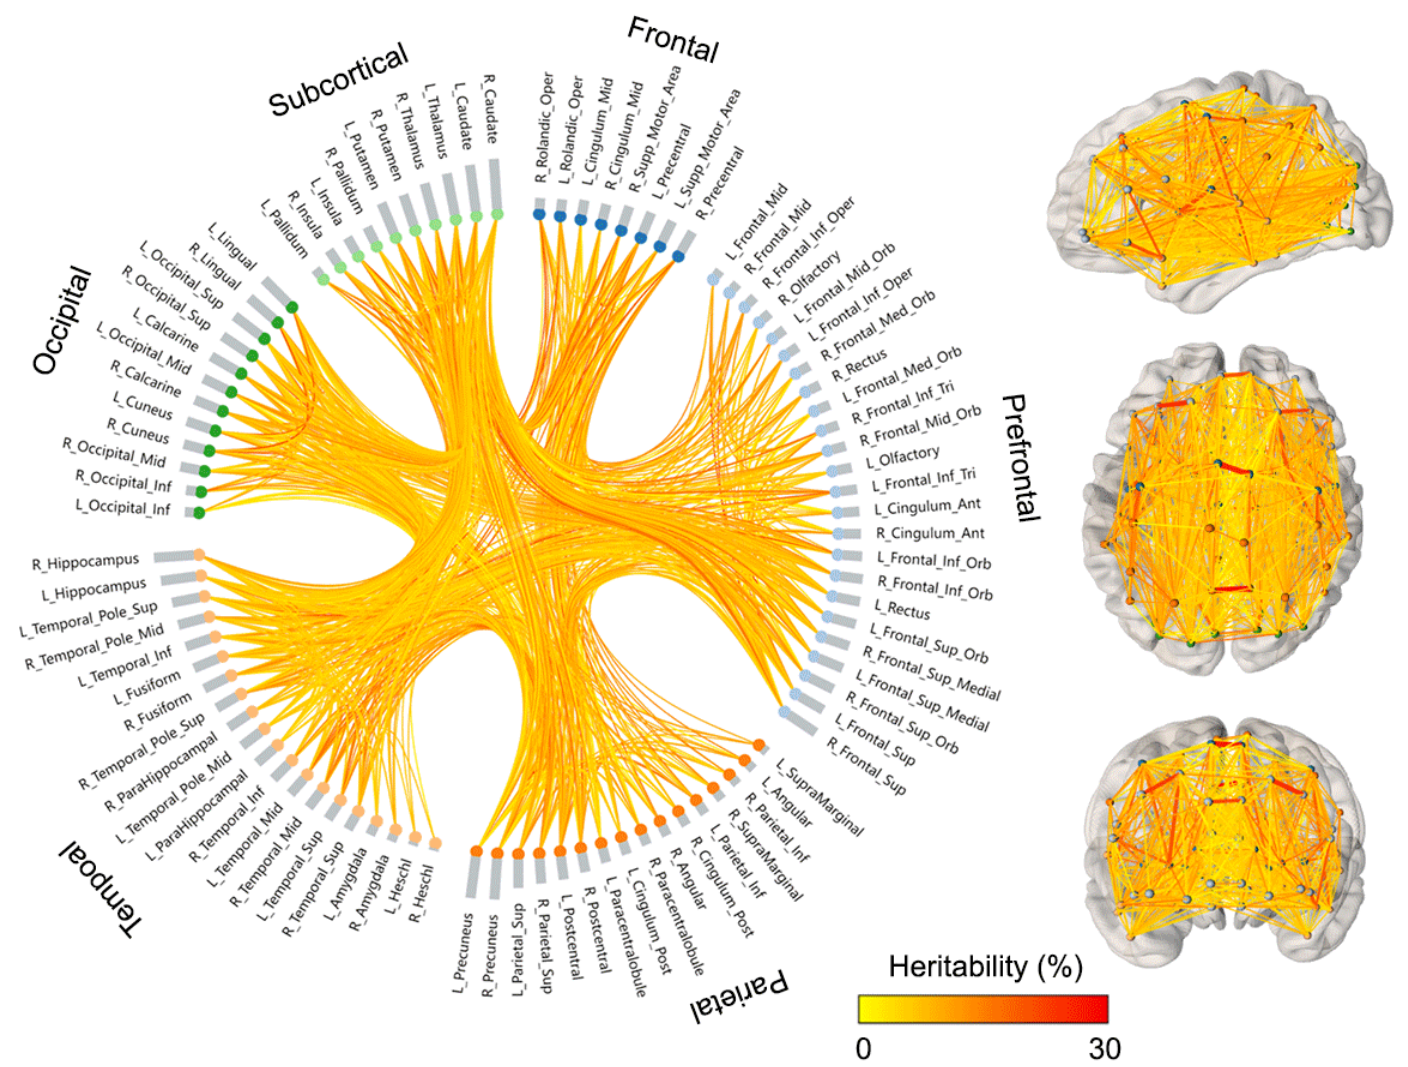

Results

SNP heritability analysis

Heritability of node-level measures

Heritability of edge-level measures

851 edge-level measures showed significantly heritable after Bonferroni correction

Results

Multivariate GWAS analysis

Multivariate GWAS of node-level measures

**154 lead SNPs in
128 genomic loci**

Multivariate GWAS of edge-level measures

**231 lead SNPs in
181 genomic loci**

Results

Brain regions contributing to the multivariate associations

Regions driving significant associations

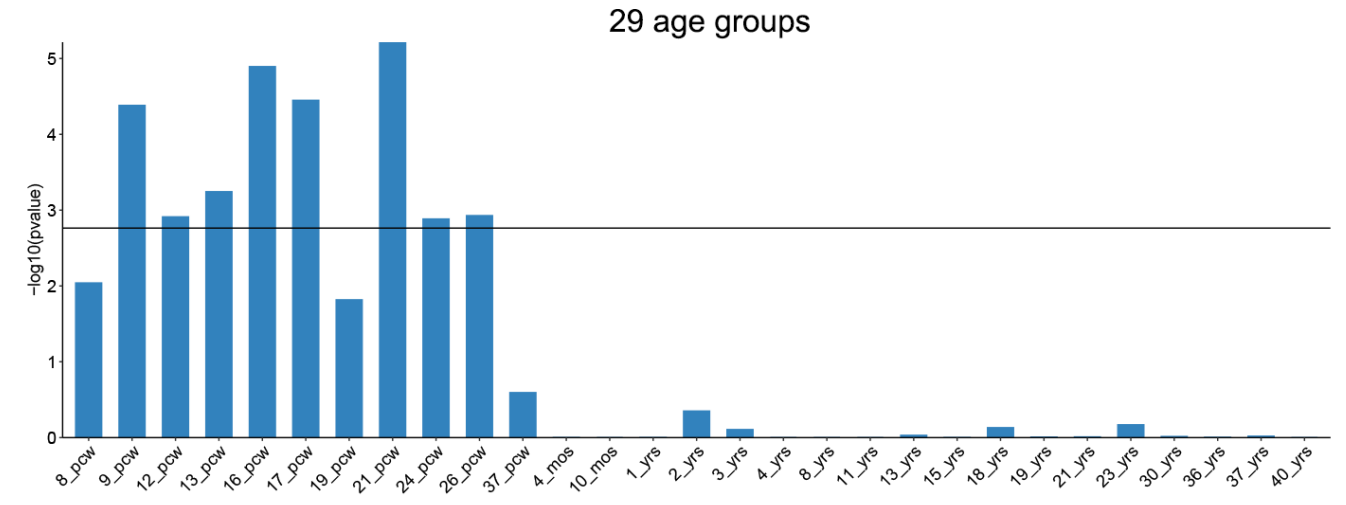

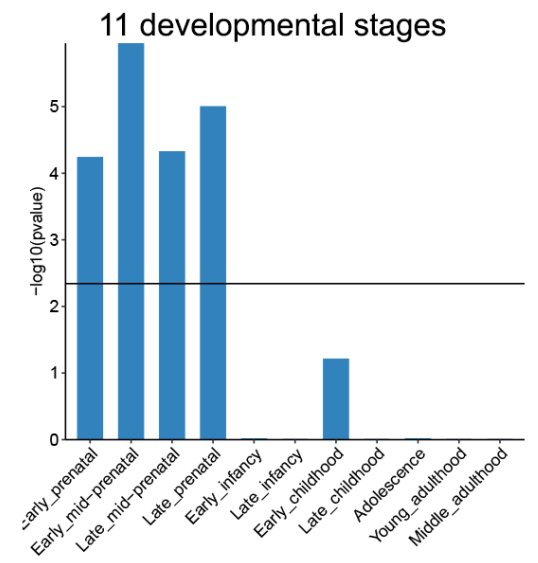

Connectivity driving significant associations

Increased polygenic risk for schizophrenia, bipolar disorder, autism associated with generally **reduced** connectivity of cortical regions, **increased** subcortical connectivity

Results

Multivariate association of regional connectivity with polygenic scores

- **Increased polygenic risk** for Alzheimer's disease, amyotrophic lateral sclerosis associated with generally **increased connectivity of cortical regions**
 - Plasticity > compensatory changes?
 - Individuals expressing their polygenic risk might participate less?

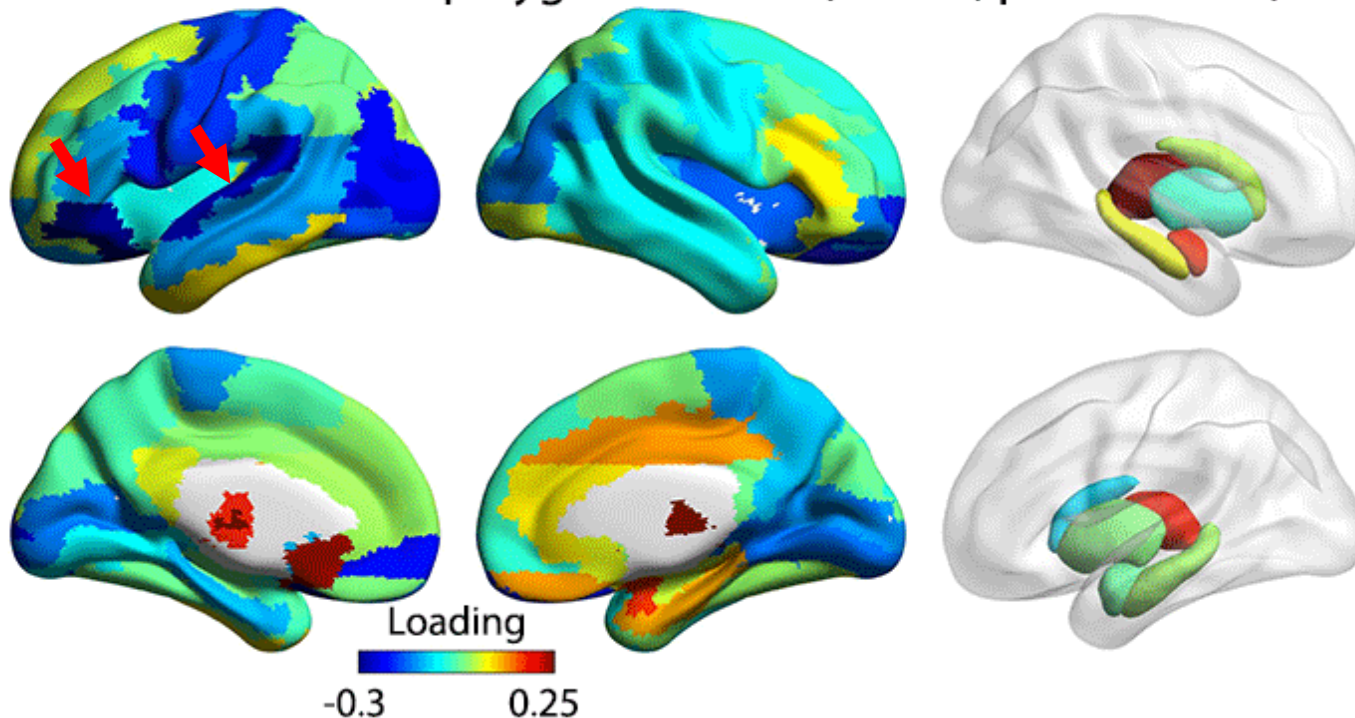

Results

Multivariate association of regional connectivity with handedness polygenic score

- Polygenic influence on handedness associated with connectivity of **language-related regions**
 - Consistent with findings based on anatomical asymmetry of the cerebral cortex (Sha et al. PNAS 2021)
 - Developmental and evolutionary links between left-hemispheric specializations for handedness and language

Multivariate association of regional connectivities with left-handedness polygenic scores ($r=0.07$, $p=1.74 \times 10^{-31}$)

Functional terms

Results White matter connectivity linking left-hemispheric language regions

Results

Language-related tracts and closest genes to lead SNPs

- Connectivity between the pars opercularis and pars triangularis cortex
- Connectivity between the middle temporal and superior temporal cortex
- Connectivity between the pars opercularis and middle temporal cortex
- Connectivity between the pars opercularis and superior temporal cortex
- Connectivity between the pars triangularis and middle temporal cortex
- Connectivity between the pars triangularis and superior temporal cortex

C Closest genes to lead SNPs associated with core language network fiber tracts

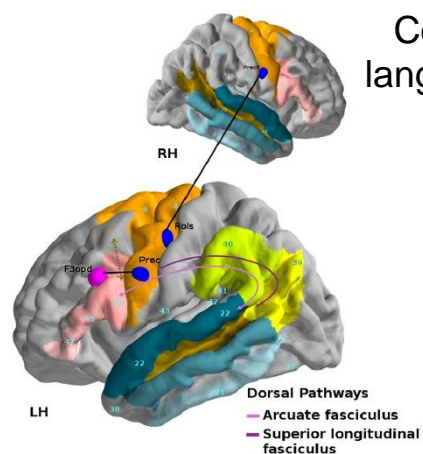

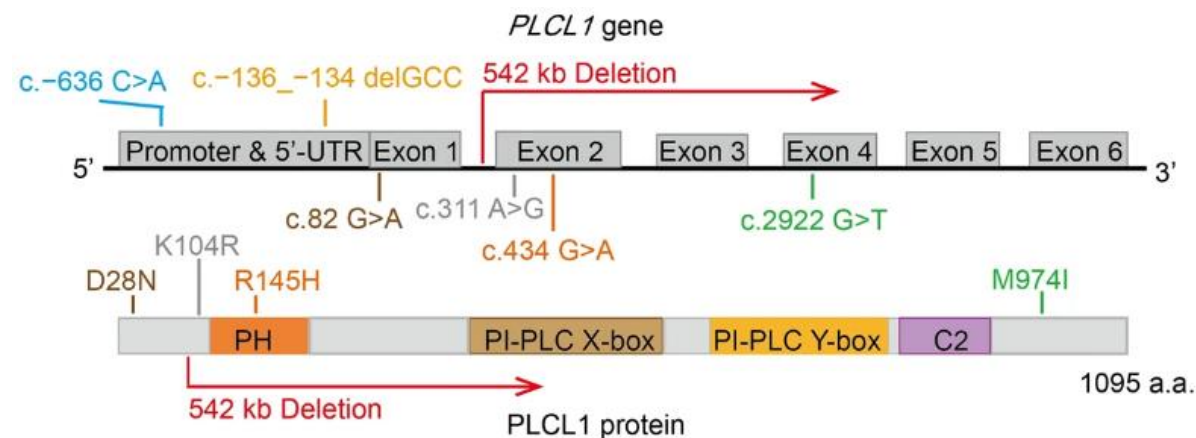

Results

Language-related tracts and closest genes to lead SNPs

rs12636275 is an intron of ***EPHA3***,
regulating **axon projection maps**
and **language-related connectivity**

rs7580864 is an intron of ***PLCL1***,
associated with **autism** and
GABA signaling pathway

Connectivity between
language-related regions

Discussion

Neural differentiation is important for the white matter network formation.

Axon pruning might shape the precise white matter connectivity.

SEMA3A is the top gene in the gene-based association analysis

Conclusions I

- Inter-individual variation in adult white matter connectivity is especially influenced by genes that are:
 - active in the prenatal developing brain
 - upregulated in stem cells, astrocytes, microglia, neurons of prenatal brain
 - involved in neurodevelopmental processes including neural migration, neural projection guidance and axon development
- Roles of glial cells in neurodevelopment are not well understood
 - Astrocytes can express positional guidance cues, e.g. SEMA3A, required for neuronal circuit formation (mediating attraction or repulsion of the growth cone at the axonal tip)
 - Embryonic microglia associate with developing axons and can affect nerve bundle formation

Conclusions II

- Polygenic scores for various psychiatric and neurological disorders showed significant associations with white matter connectivity
 - Each implicating distinct sets of brain regions with trait-relevant functional profiles
- Polygenic risk for disorders likely to manifest:
 - partly through affecting the development of large-scale structural brain networks
 - particularly during prenatal brain development.
