32 Abstract.

33 Purpose. To investigate the influence of maturation on match 34 running performance in elite male youth soccer players. Methods. Thirty-seven elite male youth soccer participants from 35 an English professional soccer academy from the U14s, U15s, 36 and U16s age groups were assessed over the course of one 37 38 competitive playing season (2018 - 2019). Relative biological 39 maturity was assessed using percentage of predicted adult height 40 (PPAH). A global positioning system (GPS) device was used between 2 and 30 (mean = 8 ± 5) times on each outfield player. 41 42 The position of each player in each game was defined as 43 defender, midfielder or attacker and spine or lateral. Five match running metrics were collected: total distance covered; high 44 45 speed running distance (HSR); very high-speed running distance 46 (VHSR); maximum speed attained and number of accelerations. **Results.** Relative biological maturity was positively associated 47 48 with all GPS running metrics for U14s. The U15/16s showed 49 variation in the associations amongst the GPS running metrics against maturity status. A multi-level model which allowed 50 slopes to vary was the best model for all parameters for both age 51 52 groups. In the U14 age group, advanced maturation was associated with greater HSR. However, maturation did not 53 54 contribute towards variance in any of the indices of running performance in the U15/16s. In the U15/16 age group, 55 56 significance was observed in the spine / lateral playing positions 57 when undertaking actions that required covering distance at high speeds. *Conclusions*. Maturation appeared to have an impact on 58 59 match running metrics within the U14s cohort. However, within 60 the U15/16s, the influence of maturation on match running 61 metrics appeared to have less of an impact. 62 63 64 65 66 67 68 69 70 71 72 73 74 Keywords: maturation, soccer, running, adolescent, GPS

75 Introduction

The identification and development of talented young soccer
players are the primary aims of professional soccer academies.
Individual differences in maturation have been shown to impact
player selection, fitness, and performance, making it challenging
to identify those players with the most potential to succeed at
adult level¹.

82 Male soccer players who are advanced in maturation have been 83 shown to present greater height, weight, mass-for-stature, and 84 also demonstrate superior performance on tests of speed, strength, power, agility, and endurance^{2,3}. The physical and 85 athletic advantages associated with earlier maturation emerge at 86 87 the onset of puberty and remain relatively stable through mid and 88 late adolescence. Longitudinal data suggests that it is only in 89 early adulthood that these advantages are attenuated or, in some 90 cases, reversed (i.e. over 20 years of age)⁴.

91 Within elite soccer academies, there appears to be a bias towards 92 boys that are advanced in maturity, with this bias becoming more apparent in older age groups⁵. Previous studies of academy 93 94 soccer players reported that approximately 60 - 80% in the U16 and U17 age groups had a skeletal age that was at least one year 95 96 greater than their chronological age^{6,7}. In contrast, there is a 97 systematic exclusion of individuals who are the youngest / least 98 mature in soccer academies², with late maturing individuals 99 more likely to be overlooked or released regardless of the 100 technical, tactical and / or psychological competency^{8,9}.

Buchheit, Mendez-Villanueva, Simpson, Bourdon¹⁰ suggested 101 that biological maturation was positively associated with 102 103 locomotor capacity during competitive play in highly trained 104 youth soccer players (U13 - 18). For example, they highlighted that earlier maturing compared to later maturing boys presented 105 106 significantly higher values for maximum speed, distance 107 covered at high-speed and absolute higher intensity actions 108 during competition. Accordingly, players delayed in maturity 109 may possess a significant athletic disadvantage during 110 competition. This observation may contribute towards the 111 overrepresentation of early maturing in comparison to late 112 maturing boys during the adolescent phase of development ⁹. 113 Note that there are three classifications of maturity status; pre-, 114 circa-, and post-pubescent.

In a second study, Buchheit, Mendez-Villanueva ¹¹ highlighted the influence of maturation on match running metrics and specific tests with running capability over the course of two successive playing seasons. In contrast to the former study¹⁰, only U15s were considered but the results still highlighted that the players who were advanced in their maturity status demonstrated greater peak speeds and distances covered at 122 greater speeds (>16 km·h⁻¹) in a match. However, between the 123 two maturity groups, no differences in total distance covered 124 were identified. Moreover, a moderate to very large (0.5 - 1.0)125 magnitude of correlation between advanced maturity status and 126 match running metrics was identified in midfielders and wingers.

127 Additionally, two studies have investigated match running metrics after grouping players by playing position^{10,12}. Measures 128 of match running metrics in youth soccer players, in particular 129 130 high-speed running (HSR), were shown to be associated with 131 playing position within youth soccer players aged between 12.2 – 14.0 years¹⁰. More recently, Lovell, Fransen, Ryan, 132 Massard, Cross, Eggers, Duffield ¹² examined the influence of 133 134 maturity timing and the interaction with playing position upon 135 match running metrics amongst U15 soccer players. This study 136 showed that maturity timing was influential across all playing 137 positions i.e. for each position, later maturing players covered 138 greater distances. Therefore, it is important to consider position 139 when assessing relationships between maturity and match 140 running metrics.

141 The focus of the present study was to investigate the variation in 142 match running metrics caused by differences in maturity status. Unlike previous studies¹⁰⁻¹², which have relied on either the Mirwald maturity offset¹³ or maturity ratio¹⁴ for determining 143 144 145 maturity status, this study uses percentage of predicted adult 146 height (PPAH) at the time of observation., The method assumes 147 that among youth of the same chronological age, a youth that is 148 relatively closer to their predicted mature height is biologically 149 older (i.e. more advanced in maturity at the time of observation) 150 than a youth that is relatively further removed from their 151 predicted adult height than expected for age ⁴. It has previously 152 been shown that maturity does influence elements of match 153 running metrics, and there may also be a further interaction with playing position^{11,12}. However, a limitation of these studies is 154 that they used match running metrics collected from either half 155 games¹¹ or shortened-match tournament games¹², and so may not 156 157 be directly relatable to a typical full match. This is a gap in understanding that will also be addressed here. 158

159 Therefore, the current study aimed to investigate the influence of 160 maturity (determined by PPAH) and playing position on match 161 running metrics for participants covering the full range of 162 maturity categories. Full game data will be considered; this will 163 ensure that tactical and fatigue effects are accounted for, 164 particularly due to the demands of different positions. By 165 analysing a cohort of participants that cover three age groups, 166 and displaying position specific results, this study will reveal the 167 different demands placed on players as they move between age 168 groups and assess the influence of playing position in each age 169 group.

170 Methods

Prior to the study commencing, ethical approval was obtained
from the Ethics Committee of Faculty of Science & Engineering,
at Manchester Metropolitan University. Parents / guardians of
the participants were notified of the aim of the study, research
procedures, requirements, benefits, and risks and provided
written informed consent. The participants also provided assent.

177 Participants

Thirty-seven elite male youth soccer players (born between 2001 178 179 and 2005) from an English professional soccer academy $(15.1 \pm 1.4 \text{ years, height } 172.5 \pm 9.4 \text{ cm, weight } 61.2 \pm 11.0 \text{ kg})$ 180 181 participating in the U14s, U15s, and U16s age groups were assessed over the course of one competitive playing season 182 183 (2018 - 2019). Throughout the course of the season, 184 anthropometric variables (heights and masses) for each 185 participant were collected every two months and each player 186 competed in between two and 30 full matches (mean = 8 ± 5 187 matches), resulting in 274 player files. All participants were 188 outfield players.

189 Methodology

190 The U14s consisted of 21 participants. As a number of players 191 from the U15s are frequently asked to 'play up' in U16s, these 192 two groups were combined to make a single U15/16s group, 193 totalling 16 participants. The analyses for the U14s and U15/16s 194 samples were conducted separately as each sample included 195 players at different stages of maturation. For example, all of the 196 players in U15/16s were in the later stages of post-peak height 197 velocity (PHV); in contrast, the U14s included players that were pre-, circa-, and post-PHV. Players from the U14s participated 198 199 in approximately 8 hours of combined soccer specific training 200 sessions per week, players in U15/16s undertook approximately 201 10 hours of combined specific training sessions per week, shown 202 in Table 1.

203 ****INSERT TABLE 1 NEAR HERE****

204

205 Measurement and Estimate of Maturity

Biological maturity status for each player was estimated and expressed as a 'z-score' relative to their group mean and standard deviation; these were specific to their age group, calculated based on the most recent three years of anthropometric data collected within the academy. <u>Anthropometric measures were</u> <u>taken at two-month intervals during the respective seasons.</u> The approach was the same as the method in¹⁵, however, specific

- 213 sample means and standard deviations were used as they differed
- from the population data, demonstrated in Table 2.
- 215 ******INSERT TABLE 2 NEAR HERE******

216 Matches were performed on outdoor natural grass fields 217 $(85 \times 64 \text{ m}^2 \text{ (U14s)} \text{ and } 105 \times 68 \text{ m}^2 \text{ (U15/16s)})$, with 11 players 218 per side. Playing time was 2×40 -minute halves. Participants were assigned an outfield playing position (defender, midfielder 219 220 or attacker and also whether they were a spine [central] or lateral 221 [wide] player) in each game. Playing positions were defender 222 (n=14), midfielder (n=15) or attacker (n=8); and spine (n=20)223 or lateral (n=17) for both groups (U14s and U15/16s combined). 224 Tactically, all teams played in a 4-3-3 formation, as shown in 225 Figure 1. GPS metrics for each fixture were aligned to the nearest 226 anthropometric data collection point.

227 ******INSERT FIGURE 1 NEAR HERE******

228 <u>Match Running Metrics</u>

All outfield players wore their own individual GPS device for
every match (10-Hz, Viper Units; STATSports, Newry, Ireland).
The GPS device sampled at 10-Hz with an integrated
accelerometer with a sampling rate of 100-Hz.

233 It has previously been highlighted that there can be high 234 variability in match-to-match running metrics (e.g. HSR can vary by 15 - 29%)¹⁶. Therefore, data obtained was taken only for 235 players who performed in at least two complete matches. 236 Following each match, data were downloaded to a computer and 237 238 analysed using STATSports software package (Viper Version 239 1.2, 2012). Five match running metrics were collected, the 240 details of these metrics are shown in Table 3.

241 ******INSERT TABLE 3 NEAR HERE******

Only data where participants played for at least 80 minutes of a
match were used. To allow all data to be compared on the same
basis, all metrics (except for maximum speed) were divided by
the total playing time of that player (e.g. 80 + minutes) in each
match and then multiplied by 80 to give these metrics on a per
80-minute basis only.

248 Statistical Analysis

249 Descriptive statistics were calculated for growth and maturation 250 characteristics and GPS metrics, with normality indicated 251 through Kolmogorov-Smirnov and Shapiro-Wilk tests. 252 Multilevel modelling using maximal likelihood estimation, 253 examined predictive associations between biological maturity 254 status, position (defender, midfielder or attacker), spine or lateral 255 position and the GPS metrics amongst the U14s and U15/16s age 256 groups. Correlation plots were created using Microsoft Excel 257 (2010 Excel, Microsoft Corporation, USA), all other analysis 258 was carried out using IBM SPSS 24 (SPSS Inc., Chicago, USA) 259 software, with the level of significance set at p < 0.05.

260 A series of linear multilevel models were generated to examine 261 the predictive associations of biological maturation. Playing 262 position was also included in the statistical models as a 263 categorical variable in order to disambiguate their effects from 264 those of maturation. In accordance with processes described and recommended by Field 17, a stepwise approach was used 265 266 whereby additional predictors were subsequently added to the 267 model. The baseline model included with only the dependent 268 variable (GPS metrics), was initially tested (Model 1). Following 269 evaluations of Model 1, Model 2 introduced a random intercept 270 to account for participants model that took into account 271 participants and repeated measures across matches was 272 evaluated (Model 2). During Model 3, Thirdly, the slopes describing the relationship between biological maturation and 273 274 the match running metrics were allowed to vary; maturation, 275 playing position and spine / lateral were introduced remained as 276 fixed factors (Model 3). A final model where slopes were 277 allowed to vary for the position and the spine / lateral positions 278 was tested (Model 4). Any modifications to the models beyond 279 Model 3 were only accepted if they significantly improved the 280 model fit. Model fit was evaluated using the Akaike Information 281 Criterion (AIC)¹⁸.

Maturity remained fixed throughout all models as this was
treated as a continuous variable. The number of matches in which
participants competed were entered as the repeated factor in the
models.

286 **Results**

287 Descriptive statistics for chronological age, biological maturation and GPS match running metrics are segregated by 288 289 age group (U14s and U15/16s) are reported in Table 4. 290 Participants in the older age groups (U15/16s) were on average 291 12.0 cm taller, (7%), 16.1 kg heavier (24%) and were more 292 advanced in maturation (5.6%) than players in the U14s cohort. 293 Likewise, per 80 minutes, the U15/16s participants presented 294 greater match running metrics; on average they displayed greater 295 total distance in competitive matches, 484 m-(5.5%), HSR, 296 185 m (34.0%), VHSR, 49 m (52.0%), were quicker, 1.9 km · h⁻¹ 297 (6.4%) and typically made 14(24.6%) more accelerations than 298 the U14s. Note that this could be a factor of the different pitch 299 sizes. Match running metrics segregated by playing position are 300 displayed in Table 5.

- 301 ****INSERT TABLE 4 NEAR HERE****
- 302 ******INSERT TABLE 5 NEAR HERE******

On average, midfielders typically covered greater total distance,
however, attackers covered greater distances at higher speeds
(HSR and VHSR), and also achieved the greatest maximum
speed and number of accelerations. There was also a split
between the spine and lateral participants, when it came to HSR
and VHSR, lateral participants appeared to complete more of
these types of actions.

Correlation plots (1-tailed) of relative biological maturity and match running metrics are presented in Figure 2 (U14s) and Figure 3 (U15/16s) where each completed 80 minute match for every participant was plotted. Relative biological maturity was positively associated with all of the GPS metrics for U14s (though with low correlation values), but this was not the case for all of the GPS metrics for the U15/16s.

317 ******INSERT FIGURE 2 NEAR HERE******

318 ******INSERT FIGURE 3 NEAR HERE******

319 Multilevel models were generated to examine the predictive 320 associations of biological maturation and playing position upon 321 match running metrics. Parameters associated with the best 322 fitting model are presented in Table 6 for U14s and Table 7 for U15/16s. Coefficients (β) , standard errors (SE), significance 323 values (p) and confidence associated with each of the final 324 models (95% CI) are presented in Table 6 and Table 7, 325 326 respectively. In both of the tables, attackers and lateral positions 327 are the respective base against which the other positions are 328 compared.

329 ******INSERT TABLE 6 NEAR HERE******

330 ****INSERT TABLE 7 NEAR HERE****

For all of the indices of match running metrics in the U14s and
U15/16s cohorts, Model 3 provided the best fit. That is, Model 4,
which allowed the slopes to vary randomly for position and
spine / lateral, did not result in improvements in model fit.

335 Discussion

336 The purpose of the present study was to investigate the influence 337 of biological maturity and playing position associated variations 338 on match running metrics amongst elite youth male soccer 339 players from U14 – U16 age groups. Significant effects on HSR 340 were seen from maturity when studied across the range of 341 maturity classifications (i.e. U14s age group), but not when only 342 considering individuals of a single maturity classification (i.e. 343 U15/16s age group).

The findings of the current study (shown in Table 4) are in line
with previous research in youth soccer whereby older age groups
displayed higher total distances, greater HSR and VHSR
distances, and were also quicker than the younger age groups¹⁹.
These results reflect the superior physical and athletic attributes

of the older participants and the greater physical demandsassociated with competing in older age groups.

351 The correlations and associated scatterplots between maturation 352 and match running metrics were of particular interest (Figure 2 353 and Figure 3). Across the competitive season, there appears to 354 be a positive association between relative maturation status and 355 the majority of the GPS metrics in the U14s (Figure 2). While 356 some of the highest maximum speeds were distributed across the 357 maturity range, participants that were more advanced in maturity 358 typically covered greater distances at high speed, were quicker 359 and made more accelerations. It is likely that this association exists due to the repeated dominance of the most mature players 360 361 across games. That is, the same athletic advantages afforded to 362 early maturing boys on tests of speed²⁰ seem to exist in match conditions also. Similar findings have been observed in 363 Australian Rules Football players, with more mature players 364 365 demonstrating superior performance on match running metrics than their less mature counterparts²¹. However, this association 366 was not as apparent amongst the U15/16s, whereby there was 367 368 lower R^2 between maturity status and match running metrics 369 (Figure 3). This may be a reflection of the fact that there is a 370 much greater variation in maturity status amongst the U14 371 participants (86.4 – 96.6%, pre-, circa-, post-PHV) than the U15/16s (93.0 - 99.6%, mostly post-PHV). Many of the 372 373 individuals in the U15/16s are much closer to reaching the 374 mature state, reflected by much less variation in maturity. As 375 individuals approach the point of reaching the mature state, 376 differences in maturity become less. Another consideration is 377 that on moving from the U14s to U15s age group, progression 378 and retention decisions are made. If, as shown here, less mature 379 players perform less well than their more mature counterparts, 380 then they are more likely to be released and hence not present in 381 the older age groups, which will also contribute to the smaller 382 range of maturity seen in U15/16s.

383 Within the multi-level regression models for the U14s, maturity 384 only had a significant effect on HSR. The rest of the match 385 running metrics were not impacted by maturity (Table 6). This may suggest that much of what was observed amongst the 386 387 correlation scatter plots (Figure 2) could have been down to the 388 most and least mature players repeatedly over or under 389 performing on the match running metrics across the season (i.e. 390 effect of nesting). Consistent with the correlational analyses, 391 maturation was found to be unrelated to GPS metrics in the 392 models conducted for the U15/U16s (Table 7). The lack of 393 association between maturation and match running metrics may 394 be due to a number of factors. Firstly, variation in maturation 395 within these age groups was more limited with less disparity 396 between the most and least mature players within the U15/16s 397 age group. Further, all of the players within the U15/U16s were

well beyond the mean percentage of adult stature associated with
PHV (91%). Maximum gains in speed and lean muscle mass
tend to fall just before and after predicted age at PHV,
respectively²².

402 Similar findings were observed by Buchheit, Mendez-403 Villanueva, Simpson, Bourdon¹⁰ in games involving players 404 aged 12.2 - 14 years where older and / or more mature players 405 consistently outperformed their younger more immature 406 counterparts, covering greater distances at higher speeds. This 407 could suggest that maturation may impact positively on match 408 running metrics, in particular, those that require an action 409 performed at high speeds. In turn, this may translate to more 410 playing opportunities in matches and the possibility of competing at a higher standard. Rampinini, Impellizzeri, 411 412 Castagna, Coutts, Wisløff²³ highlighted this in the Italian 413 Serie – A elite adult male league. It was identified that better 414 players typically covered more high speed distance with the ball. 415 The selection bias, whereby older and / or more mature players are selected into soccer academies², but also national teams^{24,25} 416 417 could be somewhat described by the aforementioned data. 418 Amongst the U15/16s, the multi-level models (Table 7) were 419 consistent with correlations; maturation had no significant 420 effect. However, significance was observed in the spine / lateral 421 playing positions when undertaking actions that required 422 covering distance at high speeds.

423 The influence of playing position has a well-established effect 424 on youth soccer match running performance¹⁰, an effect that surpasses other factors such as chronological age¹⁰ and physical 425 fitness²⁶. Therefore, the influence of position was analysed 426 427 within the current study to help interpret the effect of maturity 428 on match running metrics. The present study identified 429 positional differences in match running metrics, in particular 430 amongst the U14s, with attackers and lateral players performing 431 more total distance, HSR, VHSR, and accelerations (Table 5).

432 In the U14s age group, defenders demonstrated the lowest total 433 distance covered in a match, lowest distance covered at very high 434 speed and lowest number of accelerations, with similar findings 435 being reported by¹⁰. Midfielders produced the lowest amount of 436 HSR and lowest maximum speeds, contrasting results reported in²⁷, who showed that midfield players ran the most amount of 437 438 HSR during a match. Bradley, Sheldon, Wooster, Olsen, Boanas, 439 Krustrup ²⁸ reported that central midfielders produced highest 440 total distances, this may be due to the positional role of these 441 players, whereby they often link the defence with attack, and are 442 commonly involved in both phases of play, however, in the 443 current study, this was not the case. The differences between the 444 results of the present study and those of Dellal, Chamari, Wong, Ahmaidi, Keller, Barros, Bisciotti, Carling ^{27,}Bradley, Sheldon, 445 446 Wooster, Olsen, Boanas, Krustrup²⁸ could be due to the

447 differences in demand of the tactical roles of the lateral players 448 between the teams analysed in the respective studies. In the 449 U15/16s age group, attackers performed the least amount of total 450 distance covered in a game, with midfield players again covering 451 the most, and similar findings were reported by¹². Central 452 defenders and midfielders operate in highly congested areas of 453 the pitch, therefore, the opportunity to achieve high speeds 454 unopposed can prove somewhat challenging²⁹, potentially 455 explaining the fact that they do not achieve the same distances 456 covered at HSR as attacking players (Table 7), which is 457 consistent with previous research³⁰.

458 The positional differences in accelerations has been reported by 459 Ingebrigtsen, Dalen, Hjelde, Drust, Wisløff³¹ whereby a higher frequency of accelerations seemed to occur in lateral players 460 461 compared to central players. The results of the current study 462 indicate similar findings where lateral players in both age groups experienced on average more accelerations throughout a match 463 464 (Table 5). This may be due to the frequent requirement of wide 465 positions to achieve high speeds, with rapid acceleration 466 necessary to reach this.

467 Due to these differences in playing positions, a one-boot fits all 468 training approach would be unreasonable. Amongst the various 469 playing positions, each one requires a bespoke emphasis on the physical components³². For example, according to Bangsbo, 470 471 Mohr, Krustrup³³, central (spine) defenders undergo the least 472 amount of physical demand in a competitive match (as found in 473 the current study). This in turn equates to a greater emphasis on 474 volume of tactical and technical training, something which is 475 important for the position. Moreover, relative maturity must be 476 accounted for when comparing match running metrics of two 477 players playing in similar positions.

478 The two age groups have a difference in their weekly training 479 programme (Table 1). This was not expected to have a large 480 impact on the results of this study, mainly because the two age groups were treated separately. The additional hours dedicated 481 482 to training in the U15/16 age group may contribute to the lack of 483 relationship between performance and maturity. Likewise, the 484 two age groups play on pitches of different dimensions. Again, 485 this is expected to have minimal impact on the results due to the 486 approach of analysing the age groups separately. Future research 487 in this area could consider these as additional factors in the 488 modelling, especially if they could be varied within an age group 489 or age groups are considered together. Although data were 490 collected on a routine basis within the academy, a limitation of 491 the present study was that it was not always possible to have an 492 equal distribution of measurements across participants. For 493 example, some participants had two measurements, whereas 494 others had up to 30 measurements. This was an unavoidable 495 outcome of the study design (where a minimum playing time was

496 set), but this did restrict the number of points taken for some
497 players which was undesirable. Having a more even distribution
498 of matches represented across individuals might reduce repeated
499 measure effects whereby the same individuals
500 over / underperform in matches.

501 **Practical Applications**

502 Within an age group, using GPS metrics as part of player 503 assessment should be done with caution. Maturity status and 504 positions (playing and spine / lateral) have an influence on 505 outputs affecting direct comparisons.

As the older age group was seen to outperform the younger age
group and particularly high-speed actions scored low within the
U14s, it is advisable to use age, maturity and position specific
bands for all of the match running metrics.

510 **Conclusions**

511 The results of this study are of particular interest to practitioners involved in the development of youth elite soccer players. There 512 is a suggestion that maturation does have an impact on match 513 running metrics within the U14s, however much of the variance 514 may be attributable to individuals under / over performing 515 516 consistently in matches. Furthermore, within the U15/16s, the 517 influence of maturation on match running metrics appeared to 518 have less of an impact. From a practical perspective, such as bio-banding which has previously been used to address factors 519 of growth and maturation^{1,9}, this concept may be better suited 520 towards individuals between the ages of 11 - 14 years, where 521 those factors are going to be more important / influential. 522
