ABSTRACT

In the interfollicular epidermis (IFE), stem cells (KSC) generate transit amplifying (TA) cells that, after symmetric divisions, produce differentiating daughters. Here, we isolated and characterized the highly proliferative interfollicular epidermal basal cell population “early” TA (ETA) cells, based on its capacity to adhere to type IV collagen. Proliferation and colony forming efficiency in ETA cells are lower than in KSC, but higher than in “late” TA (LTA). Stem and differentiation markers confirmed that ETA cell display a unique phenotype. Skin reconstructs derived from ETA cells present different features (epidermal thickness, Ki67 and survivin expression), as compared to skin equivalents generated from either KSC or LTA cells. The low affinity neurotrophin receptor CD271, that regulates the KSC to TA cells transition in human epidermis through an on/off switch control mechanism, is predominantly expressed in ETA cells. Skin equivalents generated from siRNA CD271 ETA cells display a more proliferative and less differentiated phenotype, as compared to mock-derived reconstructs. Consistently, CD271 overexpression in LTA cells generates a more proliferative skin equivalent than mock LTA cells. Finally, CD271 expression declines with ageing and cellular senescence. We conclude that ETA cells represent the first KSC progenitor with exclusive features. CD271 identifies and modulates ETA cells, thus participating in the early differentiation and regenerative capacity of human epidermis.

SIGNIFICANCE STATEMENT

The early events involved in the differentiation process of human epidermis are not fully understood, in part because of the difficulty in discriminating keratinocyte stem cells (KSC) from their progenitors. In this study, we identified an “early” transit amplifying cell (ETA) population with unique and different features, as compared to both KSC and TA cells. ETA cell-derived 3D reconstructs display skin regenerative capacity inferior to KSC, but greater than TA cells. CD271 is exclusively expressed in ETA cells and modulates their functions.

CD271 expressing ETA cells are an essential part of the niche and take part in the early differentiation process of human keratinocytes.

1. INTRODUCTION

Human epidermal homeostasis and maintenance depends on adult stem cells that have an unlimited self-renewal ability and contribute to skin regeneration.¹ The classical model consists of slow-cycling stem cells that divides asymmetrically to give raise to one stem and one transit amplifying (TA) cell. TA cells, after few rounds of division, become differentiated cells.^{2,3} On the other hand, lineage tracing data show that basal layer of the epidermis contains a single equipotent population of progenitor cells that contribute to long-term tissue maintenance by randomly balancing proliferation and differentiation.⁴ More recently, Mascrè and co-workers reestablished the keratinocyte stem (KSC)/progenitor model demonstrating, by quantitative analysis of clonal fate data and proliferation dynamics, the presence of the hierarchy comprising slow-cycling KSC and committed progenitor cells.⁵ Moreover, quiescent KSC proliferate only after TA cells are generated, indicating the latter cells as an active signal within the niche.⁶ In contrast to the quiescence state of KSC, TA cells are highly proliferative and are essential to form new layers during epidermal stratification and in regeneration after injury.⁷ Yet, little is known on the early events occurring during the transition from KSC to more differentiated progenitors. Moreover, distinguishing KSC from TA cells remains a technical challenge, particularly because of the lack of reliable markers.

β_1 -integrin expression and function have been originally used to separate KSC from TA.⁸ β_1 -integrin signaling protects KSC from apoptosis,⁹ and blocking this receptor induces anoikis through caspase-8 activation in human keratinocytes.¹⁰ More specifically, we have shown that β_1B -integrin isoform is responsible for cell death in keratinocytes.¹¹ β_1 -integrin signaling also maintains cell survival and control proliferation and apoptosis of human KSC progenitors.¹²

Neurotrophins are a family of structurally and functionally related proteins that play a critical role in the survival, differentiation and apoptosis in the nervous system.¹³

1
2
3 NT functions are mediated by the low-affinity CD271 (p75^{NTR}) and the tyrosine kinase (Trk)
4 family of receptors.¹⁴ CD271 belongs to the tumor necrosis factor receptor superfamily and
5 shares with the other members the “death domain”.¹⁵ Most skin cells synthesize and release NT
6 and express NT receptors, contributing to a network of autocrine and paracrine activities.¹⁶ In
7 human epidermis, where it acts independently of Trk, CD271 is predominantly expressed in
8 TA cells, mediates apoptosis and differentiation.¹⁷ We have shown recently that CD271 also
9 regulates the transition from KSC to TA cells in human epidermis.¹⁸ When we separated KSC
10 from TA, β_1 -integrin inversely correlated to CD271 silencing or overexpression.¹⁸ Here we
11 report the isolation and characterization of an early TA cell subpopulation (ETA), based on the
12 expression levels of β_1 -integrin and unique functions. We present evidence that CD271
13 identifies ETA and plays a critical role in early differentiation and regeneration of human
14 epidermis.

2. MATERIALS AND METHODS

2.1 Cell culture

35
36
37
38 Human keratinocytes were obtained from neonatal foreskin or from normal human adult
39 epidermal keratinocytes (NHEK) isolated from female skin. All samples were collected with a
40 written informed consent of patients, according to the Declaration of Helsinki after approval of
41 the Modena Medical Ethical Committee (Prot. 184/10). Fresh keratinocytes were separated in
42 subpopulations on the basis of their ability to adhere to type IV collagen 100 $\mu\text{g/ml}$ (Sigma, St.
43 Louis, MO, USA), as described in Figure 1A modifying Tiberio et al⁹. Keratinocytes were
44 analyzed immediately after the separation or cultured in Keratinocyte Serum-Free Medium
45 Epilife (MEPI500CA, Life Technologies, Carlsbad, CA, USA) supplemented with HKGS (Life

9

10 **2.2 MTT assay**

11
12 Freshly isolated keratinocyte subpopulations were seeded in a 96-well tissue culture plate (5000
13
14 cells/well), and MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, Sigma)
15
16 assay was performed up to 196 hrs after plating. The results are normalized on 24 hrs values of
17
18 MTT positive cells.
19
20
21
22

23 **2.3 Colony forming efficiency (CFE) assay**

24
25 Freshly isolated keratinocyte subpopulations were plated at a density of 100 cells/dish in a
26
27 6well-plate on mitomycin C-treated 3T3 cells ($2.4 \times 10^4/\text{cm}^2$) and cultivated in DMEM and
28
29 Ham's F12 media¹⁸. Fourteen days later, dishes were fixed and colored with 4%
30
31 formaldehyde/1% Rhodamine B. Colonies that contained more than 10 cells were counted and
32
33 CFE was calculated. The colony number was expressed as a percentage of the number cells
34
35 plated. Colonies were further analyzed according to their diameter.
36
37
38
39
40
41

42 **2.4 Long Term assay**

43
44 Freshly isolated keratinocyte subpopulations were plated at the density of 1000 cells/cm² in
45
46 keratinocyte serum-free medium. At the 80% confluence, cells were serially passaged at the
47
48 same density (1000 cells/cm²) until the growth capacity of the cells was exhausted. Total cell
49
50 number of cells obtained at each passage was calculated. In addition, Population Doubling
51
52 capacity was calculated as follow $PD = 3.322 * \log_{10} \left(\frac{N_{\text{cellsPn}}}{N_{\text{cellsP1}}} \right)$
53

12
13

14 **2.6 siRNA transfection of ETA cells**

15
16 ETA keratinocytes were grown at sub confluency. Cells were then transfected with 50nM
17
18 CD271 or scrambled siRNA (Dharmacon Inc, Lafayette, CO, USA), as previously described¹⁸.
19
20 After 48 hrs cells were used for western blotting (WB) or for skin equivalent setting up.
21
22
23
24
25

26 **2.7 Infection of LTA cells**

27
28 LTA cells were transduced by infection with viral supernatant generated by CD271-LNSN
29
30 packaging cells or by LNSN packaging cells (kindly provided from F Mavilio) in medium for
31
32 keratinocytes in the presence of polybrene (8 µg/ml)¹⁷. 48 hrs after infection, cells were lysed
33
34 for WB analysis or used for skin equivalent setting up.

39

40 **2.8 SA-β-Gal Staining**

41
42 We used the SA-β-Gal staining kit (Sigma-Aldrich) to determine the replicative senescence
43
44 according to Itahana et al.¹⁹. This β-galactosidase activity at pH 6.0 is present only in senescent
45
46 cells. In presence of β-galactosidase, the X-Gal substrate (5-bromo-4-chloro-3-indolyl-β-D-
47
48 galactopyranoside) is hydrolyzed and changes its color in blue due to the formation of 5-bromo-
49
50 4-chloro-3-indol. The cells were incubated in 1×fixation buffer for 6 minutes at room
51
52 temperature, washed twice with 1×PBS and incubated overnight with staining solution at 37 °C
53
54 without CO₂. Results were presented as percentage of blue positive cells.
55
56
57
58
59
60

2.9 Western blotting analysis (WB)

Freshly isolated keratinocyte populations were harvested for CD271 in lysis buffer pH 7.5 (150mM NaCl, 15mMMgCl, 1mM EGTA, 50mM Hepes, 10% Glicerol, 1% Triton), or for β 1-integrin in RIPA buffer. WB was performed as previously described⁹. Membranes were first incubated in blocking buffer and then overnight at 4°C with primary antibodies: mouse anti-human CD271, clone ME20.4 (Upstate, Lake Placid, NY, USA), mouse anti-human β 1 integrin, clone 12G10 (Abcam Cambridge, UK), mouse anti-human β -actin, clone AC-15 (Sigma). Then membranes were incubated with anti-mouse peroxidase-conjugated secondary antibodies (Biorad, Hercules, CA). Membranes were developed in Clarity Max ECL substrate (BioRad) and images captured with ChemiDoc Imaging System (Biorad). The band intensity was quantitatively determined using Fiji-ImageJ software (Wayne Rasband, National Institute of Mental Health, Bethesda, MD, USA), and protein levels' intensity was normalized to β -actin expression.

2.10 Automated Capillary Electrophoresis Western Analysis

Normal Human Epidermal Keratinocytes were lysed in whole cell extraction buffer (25mM Tris HCL buffer pH 7.5; 0.25 M saccharose 0.2 mM MgSO₄; 20 mM EDTA; 0.4 % Triton X-100; 2 mM DTT; 5 μ g/ml leupeptin; 0,4 mM PMSF). CD271 protein levels were determined by capillary electrophoresis immunoassay by following the WES user guide from ProteinSimple and after determination of primary antibody dilution. Cell extracts samples (1,92 μ g of protein/lane) were mixed with a 5 \times Master Mix (DTT, fluorescence labeled maker, SDS) and then heated at 70 °C for 10 min. The samples, the biotin labeled protein ladder (12 kDa, 40 kDa, 66 kDa, 116 kDa, 180 kDa and 230 kDa), blocking reagent, CD271 Receptor antibody at a dilution of 1:100 (NBP2-19669, Novus Biologicals Europe), HRP-conjugated secondary antibody, luminol S/peroxide, and separation and stacking matrices were also dispensed to

1
2
3 designated wells plate. After plate loading, the electrophoresis and immunodetection steps took
4
5 place in the capillary system (ProteinSimple WES, Santa Clare, CA, USA) and were fully
6
7 automated with instrument default settings. Peak areas were determined using Compass
8
9 software (Protein Simple) and normalized to β -actin (loading control) (NB600-532, Novus
10
11 Biologicals Europe).
12
13
14
15
16

17 **2.11 Immunofluorescence (IF)**

18
19 Freshly isolated keratinocyte subpopulations were fixed in 4% buffered PFA and cytospun onto
20
21 glass slides. Cells were permeabilized with TritonX100 0,1%, stained for K10 (clone EP1607Y,
22
23 Epitomics, Burlingame, CA, USA), K15 (EPR1614Y, Epitomics), and Involucrin (clone I9018,
24
25 Sigma) and then labeled with Alexa Fluor secondary antibodies, Alexa Fluor 546 and 488-
26
27 conjugated goat IgGs (Invitrogen). Then slides were stained with 1 μ g/ml Dapi (Sigma).
28
29 Immunofluorescence on skin equivalent slides was performed as in IHC methods except for the
30
31 different primary antibodies: K10, K15 and survivin (Novus Biologicals, Littleton, CO, USA)
32
33 and the secondary antibodies Alexa Fluor 546 and 488-conjugated goat IgGs (Invitrogen).
34
35 Micrographs were taken on a Confocal Scanning Laser Microscopy (Leica TCS4D) (Leica,
36
37 Exton, PA, USA). Quantification of immunofluorescence staining was performed by analyzing
38
39 six representative fields for each staining sample, using ImageJ software. Scoring was made by
40
41 means of positive cell counting.
42
43
44
45
46
47
48

49 **2.12 Immunohistochemistry (IHC)**

50
51 Paraffin-embedded biopsies (4 μ m) of normal human skin and skin reconstructs were stained
52
53 for protein analysis by immunohistochemistry as previously described²⁰. Sections were stained
54
55 with hematoxylin and eosin (H&E) or stained for Ki67 (clone MIB-1, Dako, Glostrup,
56
57 Denmark) with 3,3'-diaminobenzidine (DAB) as cromogen, according to ultraView Universal
58
59
60

1
2
3 DAB detection kit instructions (Ventana, Oro Valley, AZ, USA). The epidermal thickness was
4
5 quantitatively determined using ImageJ software (Wayne Rasband). The number of suprabasal
6
7 and basal positive nuclei for Ki67 was counted and expressed as number of positive nuclei/basal
8
9 cell. This was performed on at least 3 different sections and the results were reported as a mean.
10
11
12
13

14 **2.13 RNA extraction, reverse transcription and real-time qPCR**

15
16 Total RNA from cultured cells was extracted using a NucleoSpin RNA kit (740709; Macherey
17
18 Nagel, Düren, Germany). Reverse transcription was performed on 500 ng of total RNA using
19
20 a High Capacity cDNA Reverse Transcription Kit (4368813, Applied Biosystems). Real-time
21
22 qPCR was achieved with the 7900HT Fast Real-Time PCR System with 96 Well Block Module
23
24 (Applied Biosystems). The mRNA expression of 3 target genes was analyzed using predesigned
25
26 and optimized inventoried assays (Applied Biosystems) according to the manufacturer's
27
28 instructions. The following assays were used: (Hs00606991_m1) Ki67 marker of proliferation;
29
30 (Hs00923894_m1) P16 and (Hs01121172_m1) P21 markers of cyclin dependent kinase
31
32 inhibitor; and to normalize gene expression, β -2-microglobulin (B2M) (Hs99999907_m1) was
33
34 used as housekeeping gene.
35
36
37
38
39
40
41

42 **2.14 Statistical analysis**

43
44 Results are presented as means \pm SEM, obtained from at least three different experiments. Prism
45
46 Software (Graph Pad Software V9.0) was used to perform statistical analysis. A two-tailed
47
48 unpaired Student's t-test was used for statistical comparisons between two groups, while
49
50 ordinary one-way ANOVA followed by Tukey's multiple comparisons was used for more than
51
52 two groups, as indicated in figure legends. A value of $P < 0.05$ or less was assumed to indicate
53
54 a statistically significant difference in the compared parameters.
55
56

3. RESULTS

3.1 Isolation and characterization of early TA (ETA) cells from human keratinocytes

Human interfollicular stem cells (IFSC) were first identified by isolation from skin and by culturing them in vitro. Three clonal types from single keratinocyte were characterized for their different multiplication capacity, namely holoclones with the highest proliferation rate, meroclones characterized by a lower growth potential and the non-growing paraclones.²¹ Jones and Watt first reported high expression of β_1 -integrin as a marker for human IFSC. This method is based on the different capacity of keratinocytes to adhere to the β_1 -integrin ligand type IV collagen and allows the isolation of KSC and TA cells.⁸ The method has been widely used and improved over the years, by enriching subpopulations with different genes.²² To better identify keratinocyte subpopulations, we have modified this method by reducing the time of adherence to type IV collagen and characterizing the cells (Fig 1A). Keratinocytes adhering for five minutes (KSC 5'), express higher amounts of β_1 -integrin (Fig. 1A) and display a superior colony forming efficiency (CFE), as compared to the cells adhering in twenty minutes (KSC 20') (Fig 1B, C). Moreover, colonies are strikingly more numerous in the fast-adhering cells (KSC 5'), with the number of large colonies being higher than in keratinocytes adhering in 20 minutes (KSC 20') (Fig 1B, C). Figure 1D shows the high number of colonies in all the dimensional range analyzed, in particular 3-4 mm diameter, in rapidly adhering cells (KSC 5'). Our approach also allows the isolation of two different TA populations, the early TA (ETA) and the late TA (LTA) cells, as shown by CFE and the dimension of colonies. In detail, CFE in ETA is statistically higher than in LTA cells that are isolated after overnight adhesion (Fig 1B). Consistently, both small and large colonies are more numerous in ETA than in LTA cells (Fig 1D).

1
2
3 To further characterize subpopulations, keratinocytes were freshly isolated and analyzed by
4 immunofluorescence. K15, that identifies proliferating cells, is highly expressed in KSC 5',
5 while it declines in ETA to further decrease in LTA and disappear in post-mitotic (PM) cells.
6
7 K10 is nearly absent in KSC, slightly increases in ETA, while is abundantly expressed in LTA
8 and PM cells. Involucrin, a late differentiation marker, is greatly expressed in LTA and PM
9 cells, while it is significantly lower in ETA cells. These results show that KSC 5' (from now
10 on indicated as only KSC) transit to an early progeny before committing to a more complete
11 differentiation.

23 **3.2 ETA cells display unique proliferative and regenerative features.**

24 β_1 -integrin stimulates keratinocyte proliferation in healthy and diseased skin.^{23,24,25} β_1 -integrin
25 is also associated with long term growth potential in human epidermis.^{26,27} We analyzed cell
26 proliferation in keratinocyte subpopulations separated using the integrin-based adhesion
27 capacity, as described. The number of viable cells reflecting proliferation by MTT assay is
28 lower in ETA cells than in KSC. On the other hand, ETA cells display a higher proliferation
29 rate than LTA cells (Fig. 2A). Consistently, long term growth is the highest in KSC and
30 statistically declines in ETA cells that, in turn, grow to a greater rate as compared to LTA cells
31 (Fig. 2B). The estimation of population doubling (PD) levels shows similar ranges for ETA and
32 LTA cells, except for passage 3, where ETA cells display a significantly higher PD rate than
33 LTA cells (Fig 2C). This demonstrates that an early KSC daughter exists with an intermediate
34 growth potential.
35
36

40
41
42
43
44
45
46
47
48
49

50
51 We have previously shown that TA cells are capable of generating three-dimensional (3D) skin
52 equivalents (SE).¹⁸ To better characterize the function of ETA cells, we created 3D skin
53 reconstructs from KSC, ETA and LTA cells. 6 days after seeding, epidermal thickness in SE
54 derived from ETA cells tends to be reduced, as compared to SE generated from KSC. However,
55
56
57
58
59
60

1
2
3 epidermis in SE derived from ETA is thicker than in LTA SE. At 12 days after seeding, the
4
5 difference becomes more relevant (Fig. 2D). At 6 days after seeding, cells are still in their
6
7 replicative status, as confirmed by the same rate of Ki-67 positive cells, while Ki-67 positive
8
9 cells decrease at the later timepoints in ETA and LTA SE. However, ETA cells preserve a
10
11 statistically significant higher proliferative status compared to LTA cells also at 12 days after
12
13 seeding in the SE (Fig. 2E). Proliferation and differentiation markers were used to better
14
15 characterize SE from the three keratinocyte subpopulations, using healthy human skin as a
16
17 control. Survivin, that was originally shown to identify KSC,²⁸ is more expressed in SE derived
18
19 from these cells than in SE from ETA. ETA SE express a higher number of survivin positive
20
21 cells than LTA SE. Similarly, K15 expression is comparable among KSC and ETA SE and
22
23 greater in ETA SE than in LTA SE. On the other hand, involucrin is more expressed in LTA
24
25 and ETA SE than in SE derived from KSC (Fig. 2F). Taken together, these results show that
26
27 ETA cells contribute to epidermal regeneration to a better extent than LTA cells.
28
29
30
31
32
33
34

3.3 Silencing of CD271 in ETA cells generates a more proliferative SE

35
36
37 CD271 is randomly expressed in the basal layer of human epidermis, while no staining is
38
39 detected in the suprabasal layers. More specifically, CD271 is predominantly expressed in TA
40
41 cells, both at the mRNA and protein level with little expression in KSC.¹⁷ Moreover, CD271
42
43 acts as a mediator of KSC to early progeny transition.¹⁸ We reasoned that CD271 could identify
44
45 the early progenitor cell (ETA) described here and might play an important role in the
46
47 immediate differentiation process. To this purpose, we first evaluated the expression of CD271
48
49 in the three keratinocyte subpopulations, separated as described. CD271 protein levels are
50
51 markedly expressed in ETA, while they are nearly undetectable in KSC and LTA cells (Fig.
52
53 3A). To better understand the role of CD271 in ETA, we silenced the receptor in these cells
54
55 which were in turn used to generate SEs (Fig. 3B). The skin reconstructs were then compared
56
57
58
59
60

1
2
3 to SE derived from KSC and from scrambled ETA cells (Fig. 3C). Epidermis is statistically
4
5 thicker in CD271siRNA SE than in scramble ETA SE (Fig. 3D). Ki-67 positive cells are more
6
7 numerous in CD271siRNA SE than in scramble ETA SE. Moreover, survivin is significantly
8
9 less expressed in both ETA SE and in CD271siRNA SE than in KSC SE. Survivin positive
10
11 nuclei, that have been shown to be more expressed in KSC,²⁶ statistically decline in either
12
13 scramble or CD271siRNA ETA SE. Similarly, K15 staining intensity is higher in CD271siRNA
14
15 ETA SE than in scramble ETA SE. On the other hand, involucrin is significantly more
16
17 expressed in scramble ETA SE than in CD271siRNA ETA SE (Fig. 3E). These results indicate
18
19 that CD271 identifies ETA cells and is important for keratinocyte homeostasis and epidermal
20
21 differentiation.
22
23
24
25
26
27

28 **3.4 Overexpression of CD271 in LTA cells generates a less differentiated SE**

29
30 We have previously shown that CD271 positive TA cells are early differentiated keratinocytes
31
32 that display a high proliferative potential.¹⁸ To further clarify the role of CD271 in
33
34 keratinocytes, we retrovirally infected freshly isolated LTA cells to induce an upregulation of
35
36 CD271 (Fig.4A) and then we generated skin reconstructs from infected LTA cells, from mock
37
38 LTA and from ETA cells (Fig. 4A). Epidermal thickness is superior in SE created from CD271
39
40 overexpressing LTA cells than in reconstructs from mock LTA and similar to that observed in
41
42 SE from ETA cells (Fig. 4B). Ki-67 staining shows that positive cells are more abundant in SE
43
44 from CD271 infected LTA than in mock LTA SE. Survivin expression is significantly higher
45
46 in SE from CD271 infected LTA cells than in the mock counterpart. Similarly, K15 expression
47
48 is significantly higher in SE from infected LTA than in mock LTA SE. Finally, staining
49
50 intensity of involucrin is stronger in SE from mock LTA than in SE from CD271 overexpressing
51
52 LTA (Fig.4D). These results suggest that CD271 can revert LTA cells to a less differentiated
53
54 and more proliferative phenotype.
55

3.5 CD271 decreases with ageing and cellular senescence

A number of genes are implicated in the senescence and ageing of human skin.²⁹ Little is known however on CD271 expression during skin ageing.³⁰ We have measured CD271 protein levels in keratinocytes from donors of different ages (Fig. 5A). CD271 tends to substantially decrease in middle-aged (mean age = 45.6 ± 2.2) persons, and it is statistically reduced in aged (mean age = 62.0 ± 3.5) people as compared to young (mean age = 29.3 ± 3.2) donors (Fig. 5B). Replicative-induced senescence in human keratinocytes is characterized from passage 4 to 9 by a significant increase of the gene expression of p16INK4a, a cell cycle check point and a reliable marker of cellular ageing,³¹ and of p21, a cyclin-dependent kinase inhibitor that acts as an effector of chronic senescence³² (Fig. 5C). By contrast, Ki-67 gene expression significantly decreased during the same replication passage (Fig. 5D). Furthermore, senescence-associated β -galactosidase (SA-B-Gal) activity in human keratinocytes was not detectable at passage 4, while it became significantly elevated at passage 9 (Fig. 5E). CD271 protein was strongly expressed in normal (passage 4) keratinocytes, while it dramatically decreased in replicative-induced senescent keratinocytes at passage 13 (Fig. 5F). Results in Fig 5G indicate that reduction in CD271 protein level is statistically significant. These results suggest that reduced CD271 is a prerequisite for senescence in human keratinocytes.

4. DISCUSSION

Interfollicular epidermis (IFE) is renewed by KSC and their progenitors in the basal layer within a local microenvironment known as niche. Niche components regulate the fate of KSC and their commitment to differentiation. Because KSC play a critical role in the maintenance and regeneration of epidermis, it is of paramount importance to dissect the events associated with their early differentiation. Investigations in the field have mostly focused on hair follicle (HF)

1
2
3 stem cells and/or in the mouse model.³³ Although IFE KSC are expected to exert a more
4
5 important task in skin homeostasis, little is known on the initial events associated with KSC
6
7 exiting the niche, particularly in human skin. In the present study, we describe an early KSC
8
9 progenitor isolated by its integrin levels and adhesion to type IV collagen with unique
10
11 proliferative potential and capable of regenerating human epidermis. While previous studies
12
13 have shown the enrichment for β_1 -integrin in KSC after twenty-minute adhesion to type IV
14
15 collagen,^{22,34} we demonstrate that these cells represent an early TA subpopulation (ETA), as
16
17 opposed to keratinocytes adhering in five minutes that are the actual KSC. Consequently, TA
18
19 cells isolated after overnight adhesion in the original studies,³⁵ display the features of more
20
21 differentiated keratinocytes (LTA). Other markers have been used to distinguish KSC from
22
23 their progenitors,^{36,37,38} although the isolation of TA cells remains elusive. It would be
24
25 interesting to re-evaluate the markers and functions of the keratinocyte subpopulations using
26
27 our modified culture system.
28
29
30
31
32

33 ETA cells described here appear to display a similar behavior to keratinocytes expressing high
34
35 levels of phosphorylated p63 (pp63). Indeed, Suzuki and Senoo have shown that human KSC
36
37 initial differentiation is accompanied by pp63, rapid decrease of β_1 -integrin expression and
38
39 reduced proliferative potential.³⁹ In the mouse system, two distinct interfollicular KSC
40
41 populations with different rates of proliferation, differentiation and upward transport have been
42
43 described.⁴⁰ We might infer that the short-lived early progenitors expressing medium integrin
44
45 levels characterized by Sada and co-workers correspond to the ETA cells presented in the
46
47 current paper. It should be noted that two TA subpopulations with different features exist in
48
49 HFKSC⁴¹ and in epithelial tissue other than epidermis.⁴²
50
51
52
53

54 A complex NT network has been shown to perform diverse functions in human skin.⁴³
55
56 Keratinocytes release NT that, in turn, exert autocrine activities through the high-affinity
57
58 receptors Trks and CD271.⁴⁴ We have previously shown that KSC express the highest levels of
59
60

1
2
3 nerve growth factor⁴⁵ that acts as a mitogen and a survival factor for the neighbor cells.⁴⁶ We
4
5 have also provided evidence that CD271 mediates apoptosis in human keratinocytes.¹⁷ This
6
7 suggests that a NT network can definitely take part in the KSC and progenitor niche and regulate
8
9 epidermal homeostasis.⁴⁷ In particular, we propose that CD271 expressed in ETA cells is a
10
11 critical mediator of the niche. Indeed, CD271 overexpression induces the switch of KSC to TA
12
13 cells, and CD271 silencing reverts TA cells to a KSC phenotype.¹⁸ Moreover, CD271 reverts
14
15 LTA cell-generated SE into a less differentiated phenotype, while silencing of CD271 renders
16
17 ETA cell-generated SE more similar to KSC skin reconstructs. This feedback loop between
18
19 KSC, ETA and LTA cells reminds of the interdependency concept proposed by Hsu and co-
20
21 workers, where TA cells expressing Sonic Hedgehog are critical components of the niche and
22
23 regulate KSC fate.⁴⁸ In agreement with this concept, we envisage that ETA cells expressing
24
25 CD271 serve as an active signal for KSC differentiation and epidermal regeneration.

26
27
28
29
30 CD271 also appears to delay senescence in bulk keratinocytes, thus contributing to the
31
32 maintenance of epidermal homeostasis. While the precise mechanism of action remains to be
33
34 elucidated, the anti-oxidant selenium was shown to protect keratinocyte senescence through
35
36 cell adhesion mediated by β_1 -integrin binding to type IV collagen and by reducing p16INK4a
37
38 gene.⁴⁹ Moreover, in human keratinocytes, CD271 down-modulates NF- κ B¹⁷ that is normally
39
40 correlated with cell senescence through the activation of senescence-associated secretory
41
42 phenotype (SASP).⁵⁰

43
44
45
46
47 Psoriasis is a T helper type17-mediated inflammatory disease, keratinocytes being essential and
48
49 possibly early players in the pathogenesis.⁵¹ β_1 -integrin is aberrantly expressed in the suprabasal
50
51 epidermal layers in psoriasis, while ectopic expression of β_1 -integrin recapitulates a
52
53 psoriasiform phenotype in different animal models,^{52,24} indicating that integrin signaling plays
54
55 a key role in psoriasis. Little is known on the correlation between integrin and CD271.⁵³ We
56
57 recently showed that psoriatic TA cells lack CD271 and are resistant to apoptosis, while re-
58
59
60

1
2
3 expression of CD271 renders these cells susceptible to cell death.¹⁷ Moreover, SE derived from
4
5 CD271 depleted TA cells display a psoriasiform phenotype.¹⁸ Consistently, the present study
6
7 demonstrates that in SE generated from ETA cells silenced for CD271, epidermis is thicker and
8
9 proliferative markers are highly expressed, as compared to mock SE from ETA. Given that
10
11 expansion of the TA cell compartment is a distinct feature of psoriasis,⁵⁴ we speculate that the
12
13 very early progenitor ETA is the psoriatic keratinocyte subpopulation carrying the intrinsic
14
15 defect in the disease. This should open the way to further investigation on the alteration of the
16
17 keratinocyte subpopulations in psoriasis.
18
19

20
21 In conclusion, we have identified and characterize an early TA cell as the initial KSC daughter
22
23 exiting the niche and starting the differentiation process. We also confirm that CD271 plays a
24
25 critical role in the niche and, because of its critical functions in keratinocyte differentiation,
26
27 apoptosis and senescence, regulates epidermal homeostasis.

25 subpopulations were cultured up to 196h after seeding and MTT assay was performed at
26 different times. (B) Long term assay was performed on freshly isolated keratinocyte
27 subpopulations, as described in Materials & Methods. (C) The extent of proliferation of ETA
28 and LTA cells left in a culture was estimated by calculation of the Population Doubling. (D)
29 Reconstructed skin equivalent (SE) models generated from freshly isolated KSC, ETA and
30 LTA cells. After 6 or 12 days from keratinocyte seeding, skin equivalents were paraffin-
31 embedded and sections were stained with H&E. Bar = 100 µm. Epidermal thickness was
32 measured by Fiji-ImageJ software. (E) Immunohistochemical staining of Ki67 was evaluated
33 as percentage of positive cells, as described in Materials & Methods. Bar = 100 µm. (F) Sections
34 of healthy skin and skin equivalents obtained from KSC, ETA and LTA cells, were stained with
35 anti-survivin, anti-K15, and anti-involucrin antibodies by IF. Bar = 100 µm. Stained areas were
36 evaluated by image pixel count using Fiji-ImageJ. Data are represented as mean±SEM.
37 Ordinary one-way ANOVA followed by Tukey's multiple comparisons are represented.
38 Comparisons with KSC5', unless differently indicated, are shown. ns: $p > 0.05$; * $0.01 < p <$
39 0.05 ; ** $p < 0.01$; *** $p < 0.001$; **** $p < 0.0001$.

12 **Figure 5. CD271 expression in aging and replicative senescence.** (A) CD271 expression in
13 NHEK from young ($n = 6$; mean age = 29.3 ± 3.2), middle-age ($n = 5$; mean age = 45.6 ± 2.2)
14 and aged donors ($n = 4$; mean age = 62.0 ± 3.5) were detected by capillary Western blotting
15 and results shown as gel-like image view or pseudo-gel image. (B) CD271 signals were
16 normalized to the β -actin signal and statistical significance was calculated using Kruskal-Wallis
17 followed by Dunn's post hoc test ($p = 0.0036$). (C) (D) P16, P21, Ki67 gene expression were
18 analyzed in normal ($n = 4$ passages or P4) and replicative-induced senescent ($n = 9$ passages or
19 P9) human epidermal keratinocytes (HEK). Gene expression was quantified by RT-qPCR and
20 normalized with $\beta 2M$ expression. (E) Microscopical analysis of NHEK stained with the
21 chromogenic substrate (X-Gal) for senescence-associated β -Galactosidase (SA- β -Gal) activity
22 determination and quantification as % of SA- β -Gal positive cells by image analysis,
23 representative pictures are reported on the right. Statistical significance was calculated using
24 Student's t-test ($p < 0.0001$). (F) CD271 expression signal strength in normal ($n = 4$ passages
25 or P4) and in replicative-induced senescent ($n = 13$ passages or P13) human epidermal
26 keratinocytes (HEK) was analyzed by capillary Western blotting. (G) Results are presented as
27 means and standard deviations of independent samples of triplicate cell cultures in three
28 experiments. CD271 signals were normalized using the β -Actin signals. Statistical significances
29 were calculated using Mann-Whitney's test ($p=0.0003$).
