1989 Fiscal Year Final Research Report Summary

Basic research on neurotransmitter mapping for establishing objective nuclear medicine imaging of dementia

Research Project

Project/Area Number

63440040

Research Category

Grant-in-Aid for General Scientific Research (A)

Allocation Type

Single-year Grants

Research Field

Radiation science

Research Institution

Kanazawa University

Principal Investigator

HISADA Kinichi Kanazawa University, School of medicine, Professor, 医学部, 教授 (50019882)

Co-Investigator(Kenkyū-buntansha)

MATSUDA Hiroshi Kanazawa University, School of Medicine, Assistant, 医学部, 助手 (90173848)

SHIBA Kazuhiro Kanazawa University, Radioisotope Center, Assistant, アイソトープ総合センター, 助手 (40143929)

AMANO Ryōhei Kanazawa University, School of Allied Medical Professions, Associate professor, 医療技術短期大学部, 助教授 (30111769)

MORI Hirofumi Kanazawa University, Radioisotope Center, Associate Professor, アイソトープ総合センター, 助教授 (90019604)

Project Period (FY)

1988 – 1989

Keywords

dementia / neurotransmitter / autoradiography / neuroreceptor / acetylcholine / radioligand / nuclear medicine imaging / Alzheimers disease

Research Abstract

A fundamental study was performed on the nuclear medicine imaging of cholinergic innervation in the brain. A cholinergic denervation model was experimentally prepared by producing an ibotenic acid lesion in unilateral basal forebrain in the rat, which is reported to be one of animal models of Alzheimer's disease. To assess the passive avoidance performance in terms of acquisition of new responses and long term retention, a step-through apparatus with high precision was newly developed. Acquisition latencies showed no significant differences between models and sham-controls. However,

models revealed statistically significant shorter retention latencies than sham-controls. Histochemical investigation disclosed neuronal cell loss, gliosis, and diminished acetylcholine esterase (AchE) staining in a ventral region of globus pallidus, substantia innominata, and internal capsule in the basal forebrain lesion. Furthermore decreased AchE staining was observed in the frontal, parietal, and temporo-lateral projection cortices ipsilateral to the lesion in models. Quantitative determination of chorine acetyltransferase (CAT) and AchE in parietal cortices showed statistically significant 46% and 40% decrease on an average, respectively, in the ipsilateral side compared to the contralateral side. These results suggest that this animal model is approved as an appropriate experimental model of Alzheimer's disease. Quantitative determination of acetylcholine in parietal cortices revealed statistically significant 31% decrease on an average in the ipsilateral side relative to the contralateral side to the lesion. In-vitro receptor autoradiography showed no significant differences in total, M₁, and M₂ muscarinic acetylcholine receptors between the ipsilateral and contralateral cortices to the lesion. Simultaneous sapping of presynaptic cholinergic innervation using ³H-2-(4-phenylpiperidino)cyclohexanol (AH5183) demonstrated significant 14% decrease of AH5183 binding on an average in the ipsilateral relative to the contralateral fronto-parieto-temporal cortices to the lesion. These results suggest that AH5183 is a promising ligand for mapping cholinergic innervation. The ¹²³I or ^{99m}Tc labelling of AH5183 is to be expected in view of application to a SPECT study.▲ Less
