#### Abstract

Multiobjective DC optimization problems arise naturally, for example, in data classification and cluster analysis playing a crucial role in data mining. In this paper, we propose a new multiobjective double bundle method designed for nonsmooth multiobjective optimization problems having objective and constraint functions which can be presented as a difference of two convex (DC) functions. The method is of the descent type and it generalizes the ideas of the double bundle method for multiobjective and constrained problems. We utilize the special cutting plane model angled for the DC improvement function such that the convex and the concave behaviour of the function is captured. The method is proved to be finitely convergent to a weakly Pareto stationary point under mild assumptions. Finally, we consider some numerical experiments and compare the solutions produced by our method with the method designed for general nonconvex multiobjective problems. This is done in order to validate the usage of the method aimed specially for DC objectives instead of a general nonconvex method.

## 1 Introduction

Multiobjective optimization problems arise naturally in the wide range of practical applications, since the objectives under the scope are usually simultaneously related to various goals. Thus, compromises have to be made in order to obtain a solution being as good as possible for every objective. Real-life applications for multiobjective optimization can be found, for instance, in the fields of economics [34], engineering [31], and mechanics [32], to name but a few. Along with multiobjective nature, many practical applications have nonsmooth (i.e. nondifferentiable) characteristics.

This paper focuses on multiobjective nonsmooth optimization, and the particular interest is in descent methods. The essential feature of a descent method is the ability to obtain a better solution for each objective at every iteration. In the literature, there are some nonsmooth descent methods for convex (see e.g. [4,5,19]) and for nonconvex (see e.g. [27,30,37,42]) multiobjective problems. A descent method can be used either by running it repeatedly from different starting points and, therefore, obtaining an approximation of the set of optimal solutions, or as a component of some interactive method [29,30,33].

A wide subclass of nonconvex functions is formed by the functions having special structure such that they can be decomposed as a difference of two convex functions. These functions are called DC functions. The benefit of the DC functions springs from the ability to utilize the convex analysis and the fact that many functions can be expressed as a DC function. The DC decomposition is not unique, and unfortunately, it might be hard to single out. In practice, the problems with objectives in explicit DC form arise, for instance, in clustering [3], spherical separability problems [10], production-transportation planning [13], wireless sensor network planning [1], and data visualization [6]. All of these are solved as a single-objective problem even if the nature of each problem is multiobjective, and they are mainly transformed into a single-objective problem by adding objectives up. There exists a lot of studies dedicated to the theory of the DC functions (see e.g. $[11,12,41]$ ) and to develop single-objective methods for the DC objectives from the different bases (see e.g. [9,14, 16, 17, 21, 22, 35, 39]). However, the DC functions as the objectives of the multiobjective optimization problem has attracted significantly less attention. In $[8,36,40]$, there are presented optimality conditions for the multiobjective DC optimization problem. Additionally, few proximal point methods in [15] have lately come to light.

The aim of this paper is to bring together two areas of optimization and to design a new descent multiobjective method with DC objectives being able to handle DC constraints. The new multiobjective double bundle method for DC optimization (MDBDC) utilizes the DC structure of the objective and the constraint functions. The method is inspired by the good numerical performance of the single-objective double bundle method for DC optimization (DBDC) [17] and its ability to find global solutions although it is only a local method.

The basic idea of MDBDC is to combine the main features of DBDC with the use of the improvement function $[19,42]$ as, for instance, in the multiobjective proximal bundle method (MPB) $[27,30]$. Along with the sketch of the method, we prove the finite convergence of MDBDC to the weakly Pareto stationary solution under mild assumptions. By the authors' best knowledge, there does not exist any other descent method, specially designed for multiobjective DC optimization, such that weak Pareto stationarity of the solutions can be ensured instead of Pareto criticality. We analyze the numerical performance of MDBDC, and compare the results obtained by MDBDC with the ones obtained by MPB. MPB is used, since it is a method for a problem with general nonconvex objectives having a structure that is
somehow similar to our method. The purpose of this comparison is to motivate the use of the method designed specially for the DC objectives instead of the general nonconvex method.

The remainder of the paper is organized as follows. A brief summary of the relevant material on multiobjective and DC optimization is given in Sect. 2. Section 3 is devoted to derive the new MDBDC method and to prove its convergence. In Sect. 4, we investigate the numerical properties of MDBDC. Finally, in Sect. 5 some concluding remarks are given.

## 2 Preliminaries

We consider a multiobjective DC optimization problem of the form

$$
\begin{equation*}
\min _{\boldsymbol{x} \in X} f_{1}(\boldsymbol{x}), \ldots, f_{k}(\boldsymbol{x}), \tag{1}
\end{equation*}
$$

where $X=\left\{\boldsymbol{x} \in \mathbb{R}^{n} \mid g_{l}(\boldsymbol{x}) \leq 0, l \in L\right\}$ and $L=\{1, \ldots, m\}$. Additionally, the set $I=$ $\{1, \ldots, k\}$ denotes the indices of the objectives. The objectives $f_{i}: \mathbb{R}^{n} \rightarrow \mathbb{R}, i \in I$ and the constraints $g_{l}: \mathbb{R}^{n} \rightarrow \mathbb{R}, l \in L$ are assumed to be DC functions. A function $f$ is a DC function if it can be decomposed as a difference of two convex functions $p: \mathbb{R}^{n} \rightarrow \mathbb{R}$ and $q: \mathbb{R}^{n} \rightarrow \mathbb{R}$ such that $f=p-q$. This is called a DC decomposition of $f$, where $p$ and $q$ are $D C$ components.

The objectives and the constraints of the problem (1) may be nonsmooth. If a DC function is nonsmooth, then at least one of the DC components is nonsmooth. Based on the DC structure, DC functions are locally Lipschitz continuous (LLC) at $\boldsymbol{x} \in \mathbb{R}^{n}$ [12] meaning that there exist a Lipschitz constant $K>0$ and $\varepsilon>0$ such that $\left|f_{i}(\boldsymbol{y})-f_{i}(z)\right| \leq K\|\boldsymbol{y}-z\|$ for all $\boldsymbol{y}, \boldsymbol{z} \in$ $B(\boldsymbol{x} ; \varepsilon)$, where $B(\boldsymbol{x} ; \varepsilon)$ is an open ball with a center $\boldsymbol{x}$ and a radius $\varepsilon$.

Next we briefly recall relevant results from nonsmooth, DC and multiobjective optimization. For more details we refer to [2,7,12,25,29,41]. We begin with two useful properties of DC functions. First, if $f$ is of the form

$$
\begin{equation*}
f(\boldsymbol{x})=\max \left\{f_{j}(\boldsymbol{x}) \mid j \in \mathcal{J}, \mathcal{J} \text { is finite and } f_{j} \text { is a DC function }\right\}, \tag{2}
\end{equation*}
$$

then $f$ is a DC function [12]. Second, for a DC function $f$, there exists the directional derivative $f^{\prime}(\boldsymbol{x} ; \boldsymbol{d})$ at $\boldsymbol{x} \in \mathbb{R}^{n}$ in every direction $\boldsymbol{d} \in \mathbb{R}^{n}$ [12] and

$$
f^{\prime}(\boldsymbol{x} ; \boldsymbol{d})=\lim _{t \downarrow 0} \frac{f(\boldsymbol{x}+t \boldsymbol{d})-f(\boldsymbol{x})}{t} .
$$

Thus, a DC function is said to be directionally differentiable at any $\boldsymbol{x}$.
The subdifferential of a convex function $f$ at the point $\boldsymbol{x} \in \mathbb{R}^{n}$ is the nonempty, convex and compact set

$$
\partial_{c} f(\boldsymbol{x})=\left\{\boldsymbol{\xi} \in \mathbb{R}^{n} \mid f(\boldsymbol{y}) \geq f(\boldsymbol{x})+\boldsymbol{\xi}^{T}(\boldsymbol{y}-\boldsymbol{x}) \text { for all } \boldsymbol{y} \in \mathbb{R}^{n}\right\} .
$$

The element $\boldsymbol{\xi} \in \partial_{c} f(\boldsymbol{x})$ is called a subgradient of $f$ at $\boldsymbol{x}$. Additionally, for a convex function $f$ and all $\boldsymbol{d} \in \mathbb{R}^{n}$ at $\boldsymbol{x}$ (see e.g. [2])

$$
\begin{equation*}
f^{\prime}(\boldsymbol{x} ; \boldsymbol{d})=\max \left\{\boldsymbol{\xi}^{T} \boldsymbol{d} \mid \boldsymbol{\xi} \in \partial_{c} f(\boldsymbol{x})\right\} \tag{3}
\end{equation*}
$$

We give the following two useful subdifferential calculus rules [2] for convex functions. First, if $f$ is the sum of convex functions $f_{j}, j \in \mathcal{J}$ such that $\mathcal{J}$ is finite, or in other words,

$$
\begin{equation*}
f(\boldsymbol{x})=\sum_{j \in \mathcal{J}} f_{j}(\boldsymbol{x}) \text { then } \partial_{c} f(\boldsymbol{x})=\sum_{j \in \mathcal{J}} \partial_{c} f_{j}(\boldsymbol{x}) . \tag{4}
\end{equation*}
$$

Second, we can obtain the subdifferential of $f$ of the form (2) where the involved functions $f_{j}$ are convex with

$$
\begin{equation*}
\partial_{c} f(\boldsymbol{x})=\operatorname{conv}\left\{\partial_{c} f_{j}(\boldsymbol{x}) \mid j \in \mathcal{J}(\boldsymbol{x})\right\}, \tag{5}
\end{equation*}
$$

where conv denotes the convex hull of the set and $\mathcal{J}(\boldsymbol{x})=\left\{j \in \mathcal{J} \mid f_{j}(\boldsymbol{x})=f(\boldsymbol{x})\right\}$.
The generalized subdifferential of a LLC function $f$ at $\boldsymbol{x} \in \mathbb{R}^{n}$ is [7]

$$
\partial f(\boldsymbol{x})=\operatorname{conv}\left\{\lim _{i \rightarrow \infty} \nabla f\left(\boldsymbol{x}_{i}\right) \mid \boldsymbol{x}_{i} \rightarrow \boldsymbol{x} \text { and } \nabla f\left(\boldsymbol{x}_{i}\right) \text { exists }\right\} .
$$

If $f$ is convex, then $\partial f(\boldsymbol{x})$ coincides with $\partial_{c} f(\boldsymbol{x})$.
Next we consider the concept of optimality in constrained multiobjective optimization. The solution $\boldsymbol{x}^{*} \in X$ is a global Pareto optimum for the problem (1) if there does not exist another solution $\boldsymbol{x} \in X$ such that $f_{i}(\boldsymbol{x}) \leq f_{i}\left(\boldsymbol{x}^{*}\right)$ for all $i \in I$ and $f_{j}(\boldsymbol{x})<f_{j}\left(\boldsymbol{x}^{*}\right)$ for at least one $j \in I$. The solution $\boldsymbol{x}^{*} \in X$ is a global weak Pareto optimum for the problem (1), if there does not exist another solution $\boldsymbol{x} \in X$ such that $f_{i}(\boldsymbol{x})<f_{i}\left(\boldsymbol{x}^{*}\right)$ for all $i \in I$. Moreover, $\boldsymbol{x}^{*} \in X$ is a local (weak) Pareto optimum if there exists $\delta>0$ such that $\boldsymbol{x}^{*} \in X$ is a global (weak) Pareto optimum on $X \cap B\left(\boldsymbol{x}^{*} ; \delta\right)$. Based on the above definitions, every Pareto optimum is a weak Pareto optimum.

In order to give an optimality condition for the constrained multiobjective problem, we define some concepts related to cones of the set $S \subseteq \mathbb{R}^{n}$ [2]. First, a set $S$ is a cone if $\lambda \boldsymbol{x} \in S$ for all $\lambda \geq 0$ and $\boldsymbol{x} \in S$. We denote by ray $S=\{\lambda \boldsymbol{x} \mid \lambda \geq 0, \boldsymbol{x} \in S\}$ and cone $S=$ ray conv $S$. Furthermore, we define a contingent cone at $\boldsymbol{x} \in S$ and a polar cone, respectively,

$$
\begin{aligned}
K_{S}(\boldsymbol{x}) & =\left\{\boldsymbol{d} \in \mathbb{R}^{n} \mid \text { there exist } t_{i} \downarrow 0 \text { and } \boldsymbol{d}_{i} \rightarrow \boldsymbol{d} \text { with } \boldsymbol{x}+t_{i} \boldsymbol{d}_{i} \in S\right\}, \\
S^{\leq} & =\left\{\boldsymbol{d} \in \mathbb{R}^{n} \mid \boldsymbol{x}^{T} \boldsymbol{d} \leq 0, \text { for all } \boldsymbol{x} \in S\right\} .
\end{aligned}
$$

Throughout the paper, we denote by

$$
F(\boldsymbol{x})=\bigcup_{i \in I} \partial f_{i}(\boldsymbol{x}) \text { and } G(\boldsymbol{x})=\bigcup_{l \in L(\boldsymbol{x})} \partial g_{l}(\boldsymbol{x}),
$$

where $L(\boldsymbol{x})=\left\{l \in L \mid g_{l}(\boldsymbol{x})=0\right\}$. In the following, we state a necessary condition for local weak Pareto optimality.

Theorem 1 [26] If $\boldsymbol{x}^{*} \in X$ is a local weak Pareto optimum for the problem (1), and the constraint qualification $G^{\leq}\left(\boldsymbol{x}^{*}\right) \subseteq K_{X}\left(\boldsymbol{x}^{*}\right)$ holds, then

$$
\begin{equation*}
\mathbf{0} \in \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+\operatorname{cl} \text { cone } G\left(\boldsymbol{x}^{*}\right), \tag{6}
\end{equation*}
$$

where cl is a closure of the set.
If the point $\boldsymbol{x}^{*}$ satisfies the condition (6), then it is called weakly Pareto stationary.
The well-known necessary local optimality condition for unconstrained single-objective optimization with a LLC objective $f$ at $\boldsymbol{x}^{*} \in \mathbb{R}^{n}$ is that $\mathbf{0} \in \partial f\left(\boldsymbol{x}^{*}\right)$. The point $\boldsymbol{x}^{*}$ is called Clarke stationary if this condition holds. Moreover, if $f$ is convex, then the condition ensures global optimality. For the unconstrained single-objective DC problem with the objective $f=p-q$, if $\boldsymbol{x}^{*} \in \mathbb{R}^{n}$ is a local optimum, then $\partial q\left(\boldsymbol{x}^{*}\right) \subseteq \partial p\left(\boldsymbol{x}^{*}\right)$ [41]. However, this condition is hard to verify in practice, since we usually do not know, or cannot calculate, the whole subdifferentials of DC components. Therefore, many methods for single-objective DC optimization stop after finding a critical point $\boldsymbol{x}^{\prime} \in \mathbb{R}^{n}$ satisfying [41]

$$
\begin{equation*}
\partial p\left(\boldsymbol{x}^{\prime}\right) \cap \partial q\left(\boldsymbol{x}^{\prime}\right) \neq \emptyset . \tag{7}
\end{equation*}
$$

Whenever $\boldsymbol{x}^{\prime}$ is critical, then $\mathbf{0} \in \partial p\left(\boldsymbol{x}^{\prime}\right)-\partial q\left(\boldsymbol{x}^{\prime}\right)$. However, the subdifferential calculus [7] only implies

$$
\begin{equation*}
\partial f\left(\boldsymbol{x}^{\prime}\right) \subseteq \partial p\left(\boldsymbol{x}^{\prime}\right)-\partial q\left(\boldsymbol{x}^{\prime}\right) \tag{8}
\end{equation*}
$$

where the equality holds if either $p$ or $q$ is differentiable at $\boldsymbol{x}^{\prime}$. Hence, we might end up with a solution such that $\mathbf{0} \in \partial p\left(\boldsymbol{x}^{\prime}\right)-\partial q\left(\boldsymbol{x}^{\prime}\right)$ but $\mathbf{0} \notin \partial f\left(\boldsymbol{x}^{\prime}\right)$. Due to this, $\boldsymbol{x}^{\prime}$ might not be a local optimum or even a saddle point. Therefore, criticality is a weaker condition for a local optimum $\boldsymbol{x}^{*} \in \mathbb{R}^{n}$ than Clarke stationarity $\mathbf{0} \in \partial f\left(\boldsymbol{x}^{*}\right)$, which is often obtained in nonconvex optimization. Nevertheless, Clarke stationarity implies criticality.

This kind of observation can be made in multiobjective optimization as well by comparing weak Pareto stationarity (6) with the multiobjective Pareto criticality condition given in [15]: in the unconstrained case, the solution $\boldsymbol{x}^{\prime} \in \mathbb{R}^{n}$ is called Pareto critical if

$$
\begin{equation*}
\mathbf{0} \in \operatorname{conv}\left\{\partial p_{i}\left(\boldsymbol{x}^{\prime}\right)-\partial q_{i}\left(\boldsymbol{x}^{\prime}\right) \mid i \in I\right\} . \tag{9}
\end{equation*}
$$

Indeed, it is easy to see that a weakly Pareto stationary point $\boldsymbol{x}^{*}$ satisfies

$$
\mathbf{0} \in \operatorname{conv}\left\{\partial f_{i}\left(\boldsymbol{x}^{*}\right) \mid i \in I\right\} \subseteq \operatorname{conv}\left\{\partial p_{i}\left(\boldsymbol{x}^{*}\right)-\partial q_{i}\left(\boldsymbol{x}^{*}\right) \mid i \in I\right\},
$$

by applying (8) to the condition (6). Thus, weak Pareto stationarity implies Pareto criticality.
However, the inverse does not necessarily hold. Consider the unconstrained case of the problem (1) with two objectives having DC components as follows: $p_{1}(x)=\max \{-x, 2 x\}$, $q_{1}(x)=\max \{-2 x, x\}, p_{2}(x)=\max \left\{x^{2}, x\right\}$, and $q_{2}(x)=\max \left\{0.5 x^{2},-x\right\}$, where $x \in \mathbb{R}$. In order to verify the condition (9), we consider the point $x^{\prime}=0$ and check whether the intersection

$$
\lambda \partial p_{1}\left(x^{\prime}\right)+(1-\lambda) \partial p_{2}\left(x^{\prime}\right) \cap \lambda \partial q_{1}\left(x^{\prime}\right)+(1-\lambda) \partial q_{2}\left(x^{\prime}\right)
$$

is an empty set or not. With $\lambda=1$, the intersection is $[-1,2] \cap[-2,1]=[-1,1]$. This set is nonempty, and thus, the point $x^{\prime}$ is Pareto critical. On the other hand, $0 \notin$ $\operatorname{conv}\left\{\partial f_{1}\left(x^{\prime}\right), \partial f_{2}\left(x^{\prime}\right)\right\}=\{1\}$, and thus $x^{\prime}$ is not weakly Pareto stationary.

## 3 Multiobjective double bundle method for DC optimization

In this section, we describe with details the new multiobjective double bundle method (MDBDC) solving multiobjective optimization problems (1) with DC functions as objectives and constraints. The method is of the descent type, since it improves all the objectives simultaneously at every iteration.

The basic idea of MDBDC is to use the same framework as the multiobjective proximal bundle method (MPB) [27,30]. We use the strategy for handling several objectives and constraints which is based on the techniques in [19,27,42]. With this strategy, we transform the constrained multiobjective problem to an unconstrained single-objective one. After that, we employ a new cutting plane model similar to the one used in the proximal bundle method for DC optimization (PBDC) [16]. This model uses explicitly the DC decomposition of the new objective in order to capture both the convex and the concave behaviour of it. Finally, we modify the double bundle method for DC optimization (DBDC) [17] to solve the single-objective problem and to obtain the weakly Pareto stationary solution for the original multiobjective problem (1).

### 3.1 Cutting plane model for DC functions and direction finding

We define the improvement function $H: \mathbb{R}^{n} \times \mathbb{R}^{n} \rightarrow \mathbb{R}[19,42]$ by

$$
\begin{equation*}
H(\boldsymbol{x}, \boldsymbol{y})=\max \left\{f_{i}(\boldsymbol{x})-f_{i}(\boldsymbol{y}), g_{l}(\boldsymbol{x}) \mid i \in I, l \in L\right\} \tag{10}
\end{equation*}
$$

Since $H(\cdot, \boldsymbol{y})$ is a maximum of DC functions, it is a DC function and its DC decomposition can be obtained as in [12]. Let the DC decompositions of $f_{i}$ and $g_{l}$ be $f_{i}=p_{i}-q_{i}$ for all $i \in I$ and $g_{l}=r_{l}-s_{l}$ for all $l \in L$. The functions $f_{i}$ and $g_{l}$ can be rewritten as

$$
\begin{aligned}
& f_{i}(\boldsymbol{x})=p_{i}(\boldsymbol{x})+\sum_{\substack{j \in I \\
j \neq i}} q_{j}(\boldsymbol{x})+\sum_{t \in L} s_{t}(\boldsymbol{x})-\sum_{j \in I} q_{j}(\boldsymbol{x})-\sum_{t \in L} s_{t}(\boldsymbol{x}) \\
& g_{l}(\boldsymbol{x})=r_{l}(\boldsymbol{x})+\sum_{\substack{t \in L \\
t \neq l}} s_{t}(\boldsymbol{x})+\sum_{j \in I} q_{j}(\boldsymbol{x})-\sum_{j \in I} q_{j}(\boldsymbol{x})-\sum_{t \in L} s_{t}(\boldsymbol{x})
\end{aligned}
$$

In order to simplify the notations, we denote

$$
\begin{align*}
A_{i}(\boldsymbol{x}, \boldsymbol{y}) & =p_{i}(\boldsymbol{x})+\sum_{\substack{j \in I \\
j \neq i}} q_{j}(\boldsymbol{x})+\sum_{t \in L} s_{t}(\boldsymbol{x})-f_{i}(\boldsymbol{y}) \text { and } \\
B_{l}(\boldsymbol{x}) & =r_{l}(\boldsymbol{x})+\sum_{\substack{t \in L \\
t \neq l}} s_{t}(\boldsymbol{x})+\sum_{j \in I} q_{j}(\boldsymbol{x}) \tag{11}
\end{align*}
$$

Now the DC decomposition of $H(\cdot, \boldsymbol{y})$ can be written as

$$
H(\boldsymbol{x}, \boldsymbol{y})=H_{1}(\boldsymbol{x}, \boldsymbol{y})-H_{2}(\boldsymbol{x})
$$

where

$$
\begin{align*}
H_{1}(\boldsymbol{x}, \boldsymbol{y}) & =\max \left\{A_{i}(\boldsymbol{x}, \boldsymbol{y}), B_{l}(\boldsymbol{x}) \mid i \in I, l \in L\right\} \text { and } \\
H_{2}(\boldsymbol{x}) & =\sum_{j \in I} q_{j}(\boldsymbol{x})+\sum_{t \in L} s_{t}(\boldsymbol{x}) \tag{12}
\end{align*}
$$

and both $H_{1}(\cdot, \boldsymbol{y})$ and $H_{2}$ are convex with respect to $\boldsymbol{x}$. Throughout the paper, the vector $\boldsymbol{y}$ in (10)-(12) is treated as a constant. Therefore, for instance, $\partial H(\boldsymbol{x}, \boldsymbol{y})$ is calculated with respect to $\boldsymbol{x}$.

The improvement function $H(\cdot, \boldsymbol{y})$ has three elementary properties justifying the use of it.

Theorem $2[27,42]$ The improvement function $H(\cdot, \boldsymbol{y})(10)$ has the following properties:
(i) If $H(\boldsymbol{x}, \boldsymbol{y})<H(\boldsymbol{y}, \boldsymbol{y}), \boldsymbol{x} \in \mathbb{R}^{n}, \boldsymbol{y} \in X$ then $f_{i}(\boldsymbol{x})<f_{i}(\boldsymbol{y})$ for all $i \in I$ and $g_{l}(\boldsymbol{x})<0$ for all $l \in L$.
(ii) If the solution $\boldsymbol{x}^{*} \in X$ is a global weak Pareto optimum of the problem (1), then

$$
\boldsymbol{x}^{*}=\underset{\boldsymbol{x} \in \mathbb{R}^{n}}{\operatorname{argmin}} H\left(\boldsymbol{x}, \boldsymbol{x}^{*}\right)
$$

(iii) If $\mathbf{0} \in \partial H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right)$, then the solution $\boldsymbol{x}^{*} \in X$ of the problem (1) is weakly Pareto stationary.

Proof (i) The claim follows immediately from the definition of $H(\cdot, \boldsymbol{y})$.
(ii) Assume that $\boldsymbol{x}^{*} \in X$ is a global weak Pareto optimum of the problem (1) and thus, $g_{l}\left(\boldsymbol{x}^{*}\right) \leq 0$ for all $l \in L$. Hence, $H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right)=0$. Suppose then, that $\boldsymbol{x}^{*} \neq$ $\operatorname{argmin}_{\boldsymbol{x} \in \mathbb{R}^{n}} H\left(\boldsymbol{x}, \boldsymbol{x}^{*}\right)$. Now there exists $\boldsymbol{y}^{*} \in \mathbb{R}^{n}$ such that $H\left(\boldsymbol{y}^{*}, \boldsymbol{x}^{*}\right)<H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right)=0$. Based on (i), $f_{i}\left(\boldsymbol{y}^{*}\right)<f_{i}\left(\boldsymbol{x}^{*}\right)$ for all $i \in I$ and $g_{l}\left(\boldsymbol{y}^{*}\right)<0$ for all $l \in L$ meaning that $\boldsymbol{y}^{*} \in X$ contradicts the assumption of global weak Pareto optimality of $\boldsymbol{x}^{*}$.
(iii) By Theorem 3.23 in [2] and Lemma 2.10 in [25], we obtain

$$
\begin{aligned}
\mathbf{0} \in \partial H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right) & \subseteq \operatorname{conv}\left\{F\left(\boldsymbol{x}^{*}\right) \cup G\left(\boldsymbol{x}^{*}\right)\right\} \\
& \subseteq \operatorname{conv}\left\{\operatorname{conv} F\left(\boldsymbol{x}^{*}\right) \cup \operatorname{conv} G\left(\boldsymbol{x}^{*}\right)\right\} \\
& =\left\{\lambda \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+(1-\lambda) \operatorname{conv} G\left(\boldsymbol{x}^{*}\right) \mid \lambda \in[0,1]\right\} .
\end{aligned}
$$

Thus, there exists $\lambda^{*} \in[0,1]$ such that $\mathbf{0} \in \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+\mathrm{cl}$ cone $G\left(\boldsymbol{x}^{*}\right)$. Indeed, if $\lambda^{*} \in$ $(0,1]$, then

$$
\begin{aligned}
\mathbf{0} & \in \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+\frac{1-\lambda^{*}}{\lambda^{*}} \operatorname{conv} G\left(\boldsymbol{x}^{*}\right) \\
& \subseteq \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+\operatorname{ray} \operatorname{conv} G\left(\boldsymbol{x}^{*}\right) \\
& \subseteq \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+\operatorname{cl} \operatorname{cone} G\left(\boldsymbol{x}^{*}\right) .
\end{aligned}
$$

On the other hand, if $\lambda^{*}=0$, we observe

$$
\mathbf{0} \subseteq \operatorname{conv} G\left(\boldsymbol{x}^{*}\right) \subseteq \operatorname{cone} G\left(\boldsymbol{x}^{*}\right) \subseteq \operatorname{conv} F\left(\boldsymbol{x}^{*}\right)+\mathrm{cl} \text { cone } G\left(\boldsymbol{x}^{*}\right)
$$

Thus, $\boldsymbol{x}^{*}$ satisfies the condition (6) implying weak Pareto stationarity of $\boldsymbol{x}^{*}$.
In the following, the index $h$ relates to the $h$-th iteration and the current iteration point is denoted by $\boldsymbol{x}_{h} \in \mathbb{R}^{n}$. We assume that, at each auxiliary point $\boldsymbol{y}_{j} \in \mathbb{R}^{n}$ from the previous iterations, we can evaluate $p_{i}\left(\boldsymbol{y}_{j}\right), q_{i}\left(\boldsymbol{y}_{j}\right), r_{l}\left(\boldsymbol{y}_{j}\right)$, and $s_{l}\left(\boldsymbol{y}_{j}\right)$ and arbitrary $\boldsymbol{\xi}_{p, i}\left(\boldsymbol{y}_{j}\right) \in \partial p_{i}\left(\boldsymbol{y}_{j}\right)$, $\boldsymbol{\xi}_{q, i}\left(\boldsymbol{y}_{j}\right) \in \partial q_{i}\left(\boldsymbol{y}_{j}\right), \boldsymbol{\xi}_{r, l}\left(\boldsymbol{y}_{j}\right) \in \partial r_{l}\left(\boldsymbol{y}_{j}\right)$, and $\boldsymbol{\xi}_{s, l}\left(\boldsymbol{y}_{j}\right) \in \partial s_{l}\left(\boldsymbol{y}_{j}\right)$ for all $i \in I$ and $l \in L$. From these, $A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right), B_{l}\left(\boldsymbol{y}_{j}\right), H_{1}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)$, and $H_{2}\left(\boldsymbol{y}_{j}\right)$ can be composed by using (11) and (12). Due to the convexity, their subgradients $\boldsymbol{a}_{i}, \boldsymbol{b}_{l}, \boldsymbol{h}_{1}$, and $\boldsymbol{h}_{2}$, respectively, are obtained by using the subdifferential calculus rules (4) and (5).

We collect information from the previous iterations into separate bundles. The bundles corresponding to $A_{i}\left(\cdot, \boldsymbol{x}_{h}\right)$ and $B_{l}$ are

$$
\begin{align*}
\mathcal{B}_{A, i}^{h} & =\left\{\left(\boldsymbol{y}_{j}, A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right), \boldsymbol{a}_{i, j}\right) \mid j \in J_{1}^{h}\right\} \quad \text { and } \\
\mathcal{B}_{B, l}^{h} & =\left\{\left(\boldsymbol{y}_{j}, B_{l}\left(\boldsymbol{y}_{j}\right), \boldsymbol{b}_{l, j}\right) \mid j \in J_{1}^{h}\right\} \tag{13}
\end{align*}
$$

for all $i \in I, l \in L$, where $\boldsymbol{a}_{i, j} \in \partial A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)$ and $\boldsymbol{b}_{l, j} \in \partial B_{l}\left(\boldsymbol{y}_{j}\right)$ are the subgradients and $J_{1}^{h}$ is the set of indices. Moreover, we define bundles

$$
\mathcal{B}_{A}^{h}=\bigcup_{i \in I} \mathcal{B}_{A, i}^{h}, \quad \mathcal{B}_{B}^{h}=\bigcup_{l \in L} \mathcal{B}_{B, l}^{h}, \quad \text { and } \quad \mathcal{B}_{1}^{h}=\mathcal{B}_{A}^{h} \bigcup \mathcal{B}_{B}^{h} .
$$

For every $j \in J_{1}^{h}$, we have one element in $\mathcal{B}_{1}^{h}$ related to $\left(\boldsymbol{y}_{j}, H_{1}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right), \boldsymbol{h}_{1, j}\right)$, where $\boldsymbol{h}_{1, j} \in \partial H_{1}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)$. The bundle related to $H_{2}$ is

$$
\begin{equation*}
\mathcal{B}_{2}^{h}=\left\{\left(\boldsymbol{y}_{j}, H_{2}\left(\boldsymbol{y}_{j}\right), \boldsymbol{h}_{2, j}\right) \mid j \in J_{2}^{h}\right\}, \tag{14}
\end{equation*}
$$

where $\boldsymbol{h}_{2, j} \in \partial H_{2}\left(\boldsymbol{y}_{j}\right)$ and $J_{2}^{h}$ is the set of indices. Note that the only restriction for the bundles $\mathcal{B}_{1}^{h}$ and $\mathcal{B}_{2}^{h}$ is that they must contain the triplets related to the current iteration point $x_{h}$.

In the spirit of Theorem 2, we derive a method producing solutions $\boldsymbol{x}^{*} \in X$ such that $\mathbf{0} \in \partial H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right)$. First, our aim is to find a search direction $\boldsymbol{d}^{h} \in \mathbb{R}^{n}$ by solving the problem

$$
\begin{equation*}
\min _{\boldsymbol{d} \in \mathbb{R}^{n}} H\left(\boldsymbol{x}_{h}+\boldsymbol{d}, \boldsymbol{x}_{h}\right) . \tag{15}
\end{equation*}
$$

In order to approximate the problem (15), we utilize the cutting plane model which is based on the one presented in [16]. With this new model, we can take into account both the convex and the concave behaviour of $H\left(\cdot, \boldsymbol{x}_{h}\right)$ by linearizing its DC components separately.

The convex DC components of $H\left(\cdot, \boldsymbol{x}_{h}\right)$ can be linearized by using the classical cutting plane model $[20,28,38]$. We linearize all the components $A_{i}\left(\cdot, \boldsymbol{x}_{h}\right)$ and $B_{l}$ of the first DC component $H_{1}\left(\cdot, \boldsymbol{x}_{h}\right)$ :

$$
\begin{aligned}
& \hat{A}_{i}^{h}(\boldsymbol{x})=\max _{j \in J_{1}^{h}}\left\{A_{i}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)+\boldsymbol{a}_{i, j}^{T}\left(\boldsymbol{x}-\boldsymbol{x}_{h}\right)-\alpha_{i, j}^{A}\right\} \text { and } \\
& \hat{B}_{l}^{h}(\boldsymbol{x})=\max _{j \in J_{1}^{h}}\left\{B_{l}\left(\boldsymbol{x}_{h}\right)+\boldsymbol{b}_{l, j}^{T}\left(\boldsymbol{x}-\boldsymbol{x}_{h}\right)-\alpha_{l, j}^{B}\right\},
\end{aligned}
$$

where $\boldsymbol{a}_{i, j} \in \partial A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)$ and $\boldsymbol{b}_{l, j} \in \partial B_{l}\left(\boldsymbol{y}_{j}\right)$ for $j \in J_{1}^{h}$. The linearization errors evaluated at $x_{h}$ for all $j \in J_{1}^{h}$ are

$$
\begin{aligned}
& \alpha_{i, j}^{A}=\alpha_{i}^{A}\left(\boldsymbol{x}_{h}, \boldsymbol{y}_{j}\right)=A_{i}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)-A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)-\boldsymbol{a}_{i, j}^{T}\left(\boldsymbol{x}_{h}-\boldsymbol{y}_{j}\right) \text { for all } i \in I \\
& \alpha_{l, j}^{B}=\alpha_{l}^{B}\left(\boldsymbol{x}_{h}, \boldsymbol{y}_{j}\right)=B_{l}\left(\boldsymbol{x}_{h}\right)-B_{l}\left(\boldsymbol{y}_{j}\right)-\boldsymbol{b}_{l, j}^{T}\left(\boldsymbol{x}_{h}-\boldsymbol{y}_{j}\right) \text { for all } l \in L .
\end{aligned}
$$

Additionally, for each $j \in J_{1}^{h}$ we denote by $\alpha_{1, j}^{H}$ the linearization error associated with the triplet $\left(\boldsymbol{y}_{j}, H_{1}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right), \boldsymbol{h}_{1, j}\right) \in \mathcal{B}_{1}^{h}$. Thus, the linearization of the first DC component $H_{1}\left(\cdot, \boldsymbol{x}_{h}\right)$ is

$$
\begin{equation*}
\hat{H}_{1}^{h}(\boldsymbol{x})=\max \left\{\hat{A}_{i}^{h}(\boldsymbol{x}), \hat{B}_{l}^{h}(\boldsymbol{x}) \mid i \in I, l \in L\right\} . \tag{16}
\end{equation*}
$$

Similarly, we can linearize the second DC component $H_{2}$ by

$$
\begin{equation*}
\hat{H}_{2}^{h}(\boldsymbol{x})=\max _{j \in J_{2}^{h}}\left\{H_{2}\left(\boldsymbol{x}_{h}\right)+\boldsymbol{h}_{2, j}^{T}\left(\boldsymbol{x}-\boldsymbol{x}_{h}\right)-\alpha_{2, j}^{H}\right\}, \tag{17}
\end{equation*}
$$

where $\boldsymbol{h}_{2, j} \in \partial H_{2}\left(\boldsymbol{y}_{j}\right)$ for $j \in J_{2}^{h}$ and the linearization error evaluated at $\boldsymbol{x}_{h}$ for all $j \in J_{2}^{h}$ is

$$
\alpha_{2, j}^{H}=\alpha_{2}^{H}\left(\boldsymbol{x}_{h}, \boldsymbol{y}_{j}\right)=H_{2}\left(\boldsymbol{x}_{h}\right)-H_{2}\left(\boldsymbol{y}_{j}\right)-\boldsymbol{h}_{2, j}^{T}\left(\boldsymbol{x}_{h}-\boldsymbol{y}_{j}\right) .
$$

Furthermore, all the linearization errors are nonnegative [20].
Finally, we approximate $H\left(\cdot, x_{h}\right)$ by combining the convex cutting plane models of its DC components. Thus, we obtain the following piecewise linear, nonconvex DC approximation of $H\left(\cdot, x_{h}\right)$ :

$$
\hat{H}^{h}(\boldsymbol{x})=\hat{H}_{1}^{h}(\boldsymbol{x})-\hat{H}_{2}^{h}(\boldsymbol{x}) .
$$

The problem (15) is now estimated with the nonsmooth nonconvex DC problem

$$
\begin{equation*}
\min _{\boldsymbol{d} \in \mathbb{R}^{n}} P^{h}(\boldsymbol{d})=\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)-\hat{H}_{2}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)+\frac{1}{2 t}\|\boldsymbol{d}\|^{2}, \tag{18}
\end{equation*}
$$

where $t>0$ is a proximity parameter used widely at bundle methods while the convex stabilizing term $\frac{1}{2 t}\|\boldsymbol{d}\|^{2}$ keeps the approximation local enough and ensures the existence of the search direction. The search direction obtained as a solution of the problem (18) is denoted by $\boldsymbol{d}_{t}^{h}$.

We give the following properties making it legitimate to apply the new cutting plane model $\hat{H}^{h}$.

Lemma 1 The following properties hold:
(i) $\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right) \leq H_{1}\left(\boldsymbol{x}_{h}+\boldsymbol{d}, \boldsymbol{x}_{h}\right)$ and $\hat{H}_{2}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right) \leq H_{2}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)$.
(ii) For any $t>0$, we have $\hat{H}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}_{t}^{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq-\frac{1}{2 t}\left\|\boldsymbol{d}_{t}^{h}\right\|^{2} \leq 0$.

Proof (i) These follow immediately from the definition of the cutting plane model.
(ii) For the feasible solution $\boldsymbol{d}^{\prime}=\mathbf{0}$ of (18), $\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\mathbf{0}\right) \leq H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)$ and

$$
\hat{H}_{2}^{h}\left(\boldsymbol{x}_{h}+\mathbf{0}\right)=\max _{j \in J_{2}^{h}}\left\{H_{2}\left(\boldsymbol{x}_{h}\right)-\alpha_{2, j}^{H}\right\}=H_{2}\left(\boldsymbol{x}_{h}\right),
$$

since $\boldsymbol{x}_{h}$ is included in $\mathcal{B}_{2}^{h}$ implying that there exists at least one $j \in J_{2}^{h}$ such that $\alpha_{2, j}^{H}=0$. Thus,

$$
\begin{aligned}
\hat{H}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}^{\prime}\right)+\frac{1}{2 t}\left\|\boldsymbol{d}^{\prime}\right\|^{2} & =\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\mathbf{0}\right)-\hat{H}_{2}^{h}\left(\boldsymbol{x}_{h}+\mathbf{0}\right) \\
& \leq H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)-H_{2}\left(\boldsymbol{x}_{h}\right)=H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)
\end{aligned}
$$

and for the global solution $\boldsymbol{d}_{t}^{h}$ of the problem (18), we obtain

$$
\hat{H}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}_{t}^{h}\right)+\frac{1}{2 t}\left\|\boldsymbol{d}_{t}^{h}\right\|^{2} \leq \hat{H}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}^{\prime}\right)+\frac{1}{2 t}\left\|\boldsymbol{d}^{\prime}\right\|^{2} \leq H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) .
$$

The solution $\boldsymbol{d}_{t}^{h}$ of the problem (18) can be shown to be always bounded.
Lemma 2 For any proximity parameter $t>0$, it holds that

$$
\left\|\boldsymbol{d}_{t}^{h}\right\| \leq 2 t\left(\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right\|+\left\|\boldsymbol{h}_{2, \max }\right\|\right)
$$

where $\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right) \in \partial H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)$ and $\left\|\boldsymbol{h}_{2, \max }\right\|=\max _{j \in J_{2}^{h}}\left\{\left\|\boldsymbol{h}_{2, j}\right\|\right\}$.
Proof Our proof begins with the following observation which is based on (17):

$$
\begin{equation*}
\hat{H}_{2}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right) \leq H_{2}\left(\boldsymbol{x}_{h}\right)+\max _{j \in J_{2}^{h}}\left\{\boldsymbol{h}_{2, j}^{T} \boldsymbol{d}\right\} \leq H_{2}\left(\boldsymbol{x}_{h}\right)+\left\|\boldsymbol{h}_{2, \max }\right\|\|\boldsymbol{d}\| . \tag{19}
\end{equation*}
$$

Now the triplet $\left(\boldsymbol{x}_{h}, H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right), \boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right)$, where $\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right) \in \partial H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)$, belongs to $\mathcal{B}_{1}^{h}$, and from (16) it follows that for all $\boldsymbol{d} \in \mathbb{R}^{n}$

$$
\begin{equation*}
\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right) \geq H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)+\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)^{T} \boldsymbol{d}-\alpha_{1}^{H}=H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)+\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)^{T} \boldsymbol{d}, \tag{20}
\end{equation*}
$$

where $\alpha_{1}^{H}$, equalling to zero, is the linearization error associated to the triplet $\left(\boldsymbol{x}_{h}, H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right.$, $\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)$ ).

We establish the claim by combining (19), (20) and Lemma 1 (ii). Thus,

$$
-\frac{1}{2 t}\left\|\boldsymbol{d}_{t}^{h}\right\|^{2} \geq \hat{H}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}_{t}^{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \geq-\left(\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right\|+\left\|\boldsymbol{h}_{2, \max }\right\|\right)\left\|\boldsymbol{d}_{t}^{h}\right\| \text {. }
$$

In order to solve globally the direction finding problem (18), we notice that the DC components of $P^{h}$ are $\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)+\frac{1}{2 t}\|\boldsymbol{d}\|^{2}$ and $\hat{H}_{2}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)$. Furthermore, the second DC component $\hat{H}_{2}^{h}$ is polyhedral convex meaning that $\hat{H}_{2}^{h}$ is of the form $\max \left\{\boldsymbol{u}_{k}^{T} \boldsymbol{x}-v_{k} \mid k \in \mathcal{K}\right\}$, where $\boldsymbol{u}_{k} \in \mathbb{R}^{n}$, $v_{k} \in \mathbb{R}$, and $\mathcal{K}$ is finite. Thus, we employ the solution approach presented in $[21,22,35]$ to obtain the global solution of the problem (18).

We can reformulate the objective function $P^{h}$ of the problem (18) by recalling (17) in the form

$$
P^{h}(\boldsymbol{d})=\min _{j \in J_{2}^{h}}\left\{P_{j}^{h}(\boldsymbol{d})=\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)-H_{2}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{h}_{2, j}^{T} \boldsymbol{d}+\alpha_{2, j}^{H}+\frac{1}{2 t}\|\boldsymbol{d}\|^{2}\right\} .
$$

Therefore, we obtain

$$
\min _{\boldsymbol{d} \in \mathbb{R}^{n}} \min _{j \in J_{2}^{h}}\left\{P_{j}^{h}(\boldsymbol{d})\right\}=\min _{j \in J_{2}^{h^{W}}} \min _{\boldsymbol{d} \in \mathbb{R}^{n}}\left\{P_{j}^{h}(\boldsymbol{d})\right\},
$$

and for this reason, the order of the minimization can be changed in the problem (18). Thus, due to the size of the bundle $\mathcal{B}_{2}^{h}$, we solve $\left|J_{2}^{h}\right|$ convex, nonsmooth subproblems

$$
\begin{equation*}
\min _{\boldsymbol{d} \in \mathbb{R}^{n}} P_{j}^{h}(\boldsymbol{d})=\hat{H}_{1}^{h}\left(\boldsymbol{x}_{h}+\boldsymbol{d}\right)-H_{2}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{h}_{2, j}^{T} \boldsymbol{d}+\alpha_{2, j}^{H}+\frac{1}{2 t}\|\boldsymbol{d}\|^{2}, \tag{21}
\end{equation*}
$$

where $j \in J_{2}^{h}$ and the solution of the subproblem $j \in J_{2}^{h}$ is denoted by $\boldsymbol{d}_{t}^{h}(j)$. Moreover, the overall global solution $\boldsymbol{d}_{t}^{h}$ of the problem (18) is $\boldsymbol{d}_{t}^{h}=\boldsymbol{d}_{t}^{h}\left(j^{*}\right)$, where the index $j^{*}=$ $\operatorname{argmin}\left\{P_{j}^{h}\left(\boldsymbol{d}_{t}^{h}(j)\right) \mid j \in J_{2}^{h}\right\}$. In practice, the size of $\mathcal{B}_{2}^{h}$ can be freely chosen such that $\left|J_{2}^{h}\right| \geq 1$, and thus, we can control the amount of computation. The solution process can be eased by rewriting (21) as a smooth problem and solving its dual.

### 3.2 Guaranteeing weak Pareto stationarity

In order to avoid the bad behaviour of Pareto critical points discussed in Sect. 2, we ensure approximate weak Pareto stationarity in MDBDC. By Theorem 2 (iii), $\boldsymbol{x}^{*} \in \mathbb{R}^{n}$ is weakly Pareto stationary, if $\boldsymbol{x}^{*}$ is Clarke stationary for $H\left(\cdot, \boldsymbol{x}^{*}\right)$. Thus, it is sufficient to consider the single-objective DC problem (15). Since we use only the DC structure of this problem, a natural approach would be to verify the criticality condition (7). However, Clarke stationarity is harder to obtain, and to achieve this, we apply the escaping procedure presented in [17]. The beauty of this procedure lies in its ability to ensure that $\boldsymbol{\xi}_{1}-\xi_{2}$ such that $\boldsymbol{\xi}_{1} \in \partial p(\boldsymbol{x})$, $\xi_{2} \in \partial q(\boldsymbol{x})$ belongs to the subdifferential of $f=p-q$ at $\boldsymbol{x} \in \mathbb{R}^{n}$. Moreover, if a point is not Clarke stationary, then the procedure generates a descent direction.

We describe here only the most essential parts of this procedure, and all the results presented regarding this procedure are valid for any DC function even if we give them here for $H(\cdot, \boldsymbol{y})=H_{1}(\cdot, \boldsymbol{y})-H_{2}$. For more details we refer to [17]. The escaping procedure needs one mild assumption holding in nearly all practical applications:

A1 : The subdifferentials $\partial H_{1}(\boldsymbol{x}, \boldsymbol{y})$ and $\partial H_{2}(\boldsymbol{x})$ are polytopes for each $\boldsymbol{x} \in \mathbb{R}^{n}$.
Recall that the directional derivative of a convex function can be written like (3). Now we denote the directional derivatives of $H_{1}(\boldsymbol{x}, \boldsymbol{y})$ and $H_{2}(\boldsymbol{x})$ with respect to $\boldsymbol{x} \in \mathbb{R}^{n}$ in the direction $\boldsymbol{d} \in \mathbb{R}^{n}$ by

$$
\begin{aligned}
& H_{1}^{\prime}(\boldsymbol{x} ; \boldsymbol{d})=\max \left\{\boldsymbol{w}^{T} \boldsymbol{d} \mid \boldsymbol{w} \in \partial H_{1}(\boldsymbol{x}, \boldsymbol{y})\right\} \text { and } \\
& H_{2}^{\prime}(\boldsymbol{x} ; \boldsymbol{d})=\max \left\{\boldsymbol{w}^{T} \boldsymbol{d} \mid \boldsymbol{w} \in \partial H_{2}(\boldsymbol{x})\right\} .
\end{aligned}
$$

For any $\boldsymbol{d} \in \mathbb{R}^{n}, \boldsymbol{d} \neq \mathbf{0}$, we define the sets

$$
\begin{aligned}
\sigma_{1}(\boldsymbol{x}, \boldsymbol{y} ; \boldsymbol{d}) & =\left\{\boldsymbol{\xi} \in \partial H_{1}(\boldsymbol{x}, \boldsymbol{y}) \mid \boldsymbol{\xi}^{T} \boldsymbol{d}=H_{1}^{\prime}(\boldsymbol{x} ; \boldsymbol{d})\right\} \text { and } \\
\sigma_{2}(\boldsymbol{x} ; \boldsymbol{d}) & =\left\{\boldsymbol{\xi} \in \partial H_{2}(\boldsymbol{x}) \mid \boldsymbol{\xi}^{T} \boldsymbol{d}=H_{2}^{\prime}(\boldsymbol{x} ; \boldsymbol{d})\right\} .
\end{aligned}
$$

Furthermore, let $T_{D C}$ be a set of full measure at the point $\boldsymbol{x} \in \mathbb{R}^{n}$ such that $\sigma_{1}(\boldsymbol{x}, \boldsymbol{y} ; \boldsymbol{d})$ and $\sigma_{2}(\boldsymbol{x} ; \boldsymbol{d})$ are singletons for any $\boldsymbol{d} \in T_{D C}$.

Theorem 3 [17] Let $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^{n}, \boldsymbol{d} \in T_{D C}, \sigma_{1}(\boldsymbol{x}, \boldsymbol{y} ; \boldsymbol{d})=\left\{\boldsymbol{\xi}_{1}\right\}$ and $\sigma_{2}(\boldsymbol{x} ; \boldsymbol{d})=\left\{\xi_{2}\right\}$. Then $\xi_{1}-\xi_{2} \in \partial H(\boldsymbol{x}, \boldsymbol{y})$.

Based on this result, in order to compute $\boldsymbol{\xi} \in \partial H(\boldsymbol{x}, \boldsymbol{y})$ utilizing the DC components, we need to find for any $\boldsymbol{d} \in \mathbb{R}^{n}$ a direction $\overline{\boldsymbol{d}} \in T_{D C}$ such that $\|\boldsymbol{d}-\overline{\boldsymbol{d}}\|<\delta$ for any sufficiently small $\delta \in(0,1)$.

The escaping procedure bases on the following result:
Theorem 4 [17] Let $\boldsymbol{x} \in \mathbb{R}^{n}, \boldsymbol{d} \in \mathbb{R}^{n}$ be any direction such that $\boldsymbol{d} \neq \mathbf{0}$ and the assumption A1 be valid. Then for a given $\boldsymbol{v} \in V$, where $V=\left\{\boldsymbol{v} \in \mathbb{R}^{n}\left|\boldsymbol{v}=\left(v_{1}, \ldots, v_{n}\right),\left|v_{i}\right|=1, i=\right.\right.$ $1, \ldots, n\}$, there exists $\alpha_{0} \in(0,1]$ such that for all $\alpha \in\left(0, \alpha_{0}\right]$ :
(i) $\overline{\boldsymbol{d}}(\alpha)=\boldsymbol{d}+\mathbf{e}^{n}(\alpha) \in T_{D C}$, where $\mathbf{e}^{n}(\alpha)=\left(\alpha v_{1}, \alpha^{2} v_{2}, \ldots, \alpha^{n} v_{n}\right)$.
(ii) $\sigma_{1}(\boldsymbol{x}, \boldsymbol{y} ; \overline{\boldsymbol{d}}(\alpha)) \subset \sigma_{1}(\boldsymbol{x}, \boldsymbol{y} ; \boldsymbol{d}) \subseteq \partial H_{1}(\boldsymbol{x}, \boldsymbol{y})$ and $\sigma_{2}(\boldsymbol{x} ; \overline{\boldsymbol{d}}(\alpha)) \subset \sigma_{2}(\boldsymbol{x} ; \boldsymbol{d}) \subseteq \partial H_{2}(\boldsymbol{x})$ for all $\boldsymbol{y} \in \mathbb{R}^{n}$.
(iii) $\xi_{1}-\xi_{2} \in \partial H(\boldsymbol{x}, \boldsymbol{y})$ for $\xi_{1} \in \sigma_{1}(\boldsymbol{x}, \boldsymbol{y} ; \overline{\boldsymbol{d}}(\alpha)), \xi_{2} \in \sigma_{2}(\boldsymbol{x} ; \overline{\boldsymbol{d}}(\alpha))$, and all $\boldsymbol{y} \in \mathbb{R}^{n}$.

In order to estimate the subdifferential $\partial H(\boldsymbol{x}, \boldsymbol{y})$, we briefly introduce the Goldstein $\varepsilon$ subdifferential for the improvement function $H(\cdot, \boldsymbol{y})$ [28]:

$$
\partial_{\varepsilon}^{G} H(\boldsymbol{x}, \boldsymbol{y})=\operatorname{cl} \operatorname{conv}\{\partial H(\boldsymbol{z}, \boldsymbol{y}) \mid \boldsymbol{z} \in B(\boldsymbol{x} ; \varepsilon)\} .
$$

Thus $\partial H(\boldsymbol{x}, \boldsymbol{y}) \subseteq \partial_{\varepsilon}^{G} H(\boldsymbol{x}, \boldsymbol{y})$ for each $\varepsilon \geq 0$ and the smaller the parameter $\varepsilon$ is, the better estimate we get. In Algorithm $1, D_{1}=\left\{\boldsymbol{d} \in \mathbb{R}^{n} \mid\|\boldsymbol{d}\|=1\right\}$ is a unit sphere in $\mathbb{R}^{n}$ and the set $U_{j}$ is an approximation of $\partial_{\varepsilon}^{G} H(\boldsymbol{x}, \boldsymbol{y})$ such that $U_{j} \subset \partial_{\varepsilon}^{G} H(\boldsymbol{x}, \boldsymbol{y})$ for all iterations $j \geq 0$.

### 3.3 Algorithm

In this section, we combine the above presented subsections and give a detailed description of MDBDC. In order to guarantee the convergence of MDBDC, we suppose that A1 is satisfied along with the following assumption for the level set at the starting point $\boldsymbol{x}_{0} \in X$ :

A2 : The level set $\mathcal{F}_{0}=\left\{\boldsymbol{x} \in X \mid f_{i}(\boldsymbol{x}) \leq f_{i}\left(\boldsymbol{x}_{0}\right)\right.$, for all $\left.i \in I\right\}$ is compact.
To simplify the presentation, we divide MDBDC into four algorithms. Algorithm 2 gives the outline of the whole method while Algorithm 3 describes the main iteration of MDBDC being the heart of the method by producing new iteration points. Additionally, we use Algorithm 1 presented in Sect. 3.2 to ensure weak Pareto stationarity and the scaling procedure Algorithm 4 described later in this section. The scaling procedure is applied in order to avoid numerical difficulties.

The proximity parameter $t$ is updated in two places: during the execution of the main iteration and between two main iterations. In the latter case, the updating procedure in Step 2 of Algorithm 2 is inspired by the weighting update method given in [20], and $t$ may either increase or decrease. In Step 5 of Algorithm 3, $t$ may only decrease.

```
Algorithm 1 Escaping procedure
Data: The point \(\boldsymbol{x} \in \mathbb{R}^{n}\) under consideration, the descent parameter \(m_{1} \in(0,1)\), the stopping tolerance \(\delta \in(0,1)\), and the proximity measure \(\varepsilon>0\).
Step 0. (Initialization) Select the direction \(\boldsymbol{d}_{0} \in D_{1}\) and find \(\overline{\boldsymbol{d}}_{0}(\alpha) \in T_{D C}\) at \(\boldsymbol{x}\) using \(\boldsymbol{d}_{0}\). Compute \(\xi_{1} \in \sigma_{1}\left(\boldsymbol{x}, \boldsymbol{x} ; \overline{\boldsymbol{d}}_{0}(\alpha)\right)\) and \(\xi_{2} \in \sigma_{2}\left(\boldsymbol{x} ; \overline{\boldsymbol{d}}_{0}(\alpha)\right)\). Set \(U_{0}=\left\{\boldsymbol{\xi}_{1}-\xi_{2}\right\}, \tilde{\boldsymbol{x}}=\boldsymbol{x}\) and \(j=0\).
```

Step 1. (Clarke stationarity) Find $\overline{\boldsymbol{u}}_{j}$ as the solution of the problem

$$
\min _{\boldsymbol{u} \in U_{j}} \frac{1}{2}\|\boldsymbol{u}\|^{2}
$$

If $\left\|\overline{\boldsymbol{u}}_{j}\right\| \leq \delta$, then approximate Clarke stationarity is obtained and EXIT with $\boldsymbol{x}^{+}=\boldsymbol{x}$.
Step 2. (Search direction) Compute the search direction $\boldsymbol{d}_{j+1}=-\overline{\boldsymbol{u}}_{j} /\left\|\overline{\boldsymbol{u}}_{j}\right\|$.
Step 3. (New subgradient) Find $\overline{\boldsymbol{d}}_{j+1}(\alpha) \in T_{D C}$ at $\tilde{\boldsymbol{x}}$ using $\boldsymbol{d}_{j+1}$. Compute $\boldsymbol{\xi}_{1} \in \sigma_{1}\left(\tilde{\boldsymbol{x}}, \tilde{\boldsymbol{x}} ; \overline{\boldsymbol{d}}_{j+1}(\alpha)\right)$ and $\xi_{2} \in \sigma_{2}\left(\tilde{\boldsymbol{x}} ; \overline{\boldsymbol{d}}_{j+1}(\alpha)\right)$. Set $\bar{\xi}_{j+1}=\boldsymbol{\xi}_{1}-\xi_{2}$. If $\boldsymbol{x} \neq \tilde{\boldsymbol{x}}$, then go to Step 5.
Step 4. (Descent test) If $\left(\overline{\boldsymbol{\xi}}_{j+1}\right)^{T} \boldsymbol{d}_{j+1} \leq-m_{1}\left\|\overline{\boldsymbol{u}}_{j}\right\|$, then go to Step 6.
Step 5. (Update) Set $U_{j+1}=\operatorname{conv}\left\{U_{j} \bigcup\left\{\bar{\xi}_{j+1}\right\}\right\}, \tilde{\boldsymbol{x}}=\boldsymbol{x}$ and $j=j+1$. Go to Step 1 .
Step 6. (Step-length) Calculate

$$
\beta^{*}=\arg \max \left\{\beta>0 \mid H\left(\boldsymbol{x}+\beta \boldsymbol{d}_{j+1}, \boldsymbol{x}\right)-H(\boldsymbol{x}, \boldsymbol{x}) \leq-m_{1} \beta\left\|\bar{u}_{j}\right\|\right\}
$$

If $\beta^{*}>\varepsilon$, then $\boldsymbol{x}^{+}=\boldsymbol{x}+\beta^{*} \boldsymbol{d}_{j+1}$, and EXIT. Otherwise, $\tilde{\boldsymbol{x}}=\boldsymbol{x}+\beta^{*} \boldsymbol{d}_{j+1}$ and go to Step 3.

```
Algorithm 2 Multiobjective double bundle method for DC optimization (MDBDC)
Data: The stopping tolerance \(\delta \in(0,1)\), the proximity measure \(\varepsilon>0\), the enlargement parameter \(\theta>0\), the quality measure \(\eta \geq 0\), the decrease parameters \(r, c_{1}, c_{2}, c_{3} \in(0,1)\), the increase parameter \(R>1\), the descent parameters \(m_{1}, m_{2} \in(0,1)\) and \(m_{3} \in\left(m_{2}, 1\right)\), and the threshold \(\tau_{\max }>0\).
```

Step 0. (Initialization) Select $\boldsymbol{x}_{0} \in X$ and execute Algorithm 4 for scaling. Compute $\boldsymbol{a}_{i} \in \partial A_{i}\left(\boldsymbol{x}_{0}, \boldsymbol{x}_{0}\right)$ for all $i \in I, \boldsymbol{b}_{l} \in \partial B_{l}\left(\boldsymbol{x}_{0}\right)$ for all $l \in L$, and $\boldsymbol{h}_{2} \in \partial H_{2}\left(\boldsymbol{x}_{0}\right)$. Initialize $\mathcal{B}_{1}^{0}$ and $\mathcal{B}_{2}^{0}$ by setting $J_{1}^{0}=$ $J_{2}^{0}=\{1\}$ and $\mathcal{B}_{A, i}^{0}=\left\{\left(\boldsymbol{a}_{i}, 0\right)\right\}$ for all $i \in I, \mathcal{B}_{B, l}^{0}=\left\{\left(\boldsymbol{b}_{l}, 0\right)\right\}$ for all $l \in L$, and $\mathcal{B}_{2}^{0}=\left\{\left(\boldsymbol{h}_{2}, 0\right)\right\}$. Set $t=t_{\min }=t_{\text {max }}=0$. Initialize the counters $h=0$ and $\tau=0$.
Step 1. (Main iteration) Find a new iteration point $\boldsymbol{x}_{h+1}$ by executing Algorithm 3. If $\boldsymbol{x}_{h+1}=\boldsymbol{x}_{h}$, then Clarke stationarity is achieved, and STOP with $x^{*}=x_{h}$ as the final solution.
Step 2. (Parameter update) Initialize $\tilde{t}=t$.
(a) If $H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq m_{3}\left(\hat{H}^{h}\left(\boldsymbol{x}_{h+1}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right)$ and $\tau>0$, set

$$
\tilde{t}=0.5 t \frac{\hat{H}^{h}\left(\boldsymbol{x}_{h+1}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)}{\hat{H}^{h}\left(\boldsymbol{x}_{h+1}\right)-H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right)}
$$

and go to Step 2(c).
(b) If $\tau>3$, then set $\tilde{t}=2 t$.
(c) Set $t^{+}=\max \left\{\min \left\{\tilde{t}, 10 t, t_{\max }\right\}, t_{\min }\right\}$ and $\tau=\max \{1, \tau+1\}$. If $t \neq t^{+}$, then update $t=t^{+}$and $\tau=1$.

Step 3. (Bundle update) Select the bundles $J_{1}^{h+1} \subseteq J_{1}^{h}$ and $J_{2}^{h+1} \subseteq J_{2}^{h}$. Update the linearization errors using (22) for all the elements in $\mathcal{B}_{1}^{h+1}$ and $\mathcal{B}_{2}^{h+1}$. Compute $\boldsymbol{a}_{i} \in \partial A_{i}\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h+1}\right)$ for all $i \in I$, $\boldsymbol{b}_{l} \in \partial B_{l}\left(\boldsymbol{x}_{h+1}\right)$ for all $l \in L$, and $\boldsymbol{h}_{2} \in \partial H_{2}\left(\boldsymbol{x}_{h+1}\right)$. Insert $\left(\boldsymbol{a}_{i}, 0\right)$ and $\left(\boldsymbol{b}_{l}, 0\right)$ into $\mathcal{B}_{1}^{h+1}$ for all $i \in I, l \in L$, and $\left(\boldsymbol{h}_{2}, 0\right)$ into $\mathcal{B}_{2}^{h+1}$. Select an index $j$ corresponding to these insertions and add $j$ into $J_{1}^{h+1}$ and $J_{2}^{h+1}$. Set $h=h+1$ and go to Step 1 .

We begin by discussing about Algorithm 2. First we notice that the linearization errors can be updated by using the following formulas for all $i \in I$ and $l \in L$

$$
\begin{align*}
\alpha_{i}^{A}\left(\boldsymbol{x}_{h+1}, \boldsymbol{y}_{j}\right) & =\alpha_{i}^{A}\left(\boldsymbol{x}_{h}, \boldsymbol{y}_{j}\right)+\tilde{A}_{i}\left(\boldsymbol{x}_{h+1}\right)-\tilde{A}_{i}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{a}_{i, j}^{T}\left(\boldsymbol{x}_{h+1}-\boldsymbol{x}_{h}\right) \\
\alpha_{l}^{B}\left(\boldsymbol{x}_{h+1}, \boldsymbol{y}_{j}\right) & =\alpha_{l}^{B}\left(\boldsymbol{x}_{h}, \boldsymbol{y}_{j}\right)+B_{l}\left(\boldsymbol{x}_{h+1}\right)-B_{l}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{b}_{l, j}^{T}\left(\boldsymbol{x}_{h+1}-\boldsymbol{x}_{h}\right) \\
\alpha_{2}^{H}\left(\boldsymbol{x}_{h+1}, \boldsymbol{y}_{j}\right) & =\alpha_{2}^{H}\left(\boldsymbol{x}_{h}, \boldsymbol{y}_{j}\right)+H_{2}\left(\boldsymbol{x}_{h+1}\right)-H_{2}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{h}_{2, j}^{T}\left(\boldsymbol{x}_{h+1}-\boldsymbol{x}_{h}\right), \tag{22}
\end{align*}
$$

where $\tilde{A}_{i}(\boldsymbol{x})=A_{i}(\boldsymbol{x}, \boldsymbol{x})+f_{i}(\boldsymbol{x})$. Thus, we store only elements $(\boldsymbol{\xi}, \alpha)$ in $\mathcal{B}_{1}^{h}$ and $\mathcal{B}_{2}^{h}$, where $\xi$ is a subgradient and $\alpha$ is the corresponding linearization error instead of the triplets in (13) and (14).

In the beginning of Step 3, the bundles $\mathcal{B}_{1}^{h+1}$ and $\mathcal{B}_{2}^{h+1}$ can be freely chosen, and it is possible to reset either the bundle $\mathcal{B}_{1}^{h+1}$ or $\mathcal{B}_{2}^{h+1}$ or even both. However, both of these bundles must contain at least one element in Step 1. This is guaranteed, since at the end of Step 3, we add elements corresponding to the new iteration point $\boldsymbol{x}_{h+1}$ into both bundles.

```
Algorithm 3 Main iteration for MDBDC
Data: The stopping tolerance \(\delta \in(0,1)\), the enlargement parameter \(\theta>0\), the quality measure \(\eta \geq 0\), the
decrease parameters \(r, c_{1}, c_{2}, c_{3} \in(0,1)\), the increase parameter \(R>1\), the descent parameter \(m_{2} \in(0,1)\),
the threshold \(\tau_{\text {max }}>0\), and the subgradients \(\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right) \in \partial H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\) and \(\boldsymbol{h}_{2}\left(\boldsymbol{x}_{h}\right) \in \partial H_{2}\left(\boldsymbol{x}_{h}\right)\).
```

Step 0. (Initialization) Set $\boldsymbol{d}_{t}=\mathbf{0}$. Calculate $j^{*}=\operatorname{argmax}_{j \in J_{2}}\left\{\left\|\boldsymbol{h}_{2, j}\right\|\right\}$ and set $\boldsymbol{h}_{2, \max }=\boldsymbol{h}_{2, j^{*}}$,

$$
\begin{equation*}
t_{\min }=r \cdot \frac{\theta}{2\left(\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right\|+\left\|\boldsymbol{h}_{2, \max }\right\|\right)}, \tag{23}
\end{equation*}
$$

and $t_{\text {max }}=R t_{\text {min }}$. If $t \notin\left[t_{\min }, t_{\text {max }}\right]$, then select $t \in\left[t_{\text {min }}, t_{\text {max }}\right]$.
Step 1. (Criticality) If $\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{h}_{2}\left(\boldsymbol{x}_{h}\right)\right\|<\delta$, then go to Step 3.
Step 2. (Search direction) Calculate the search direction $\boldsymbol{d}_{t}$ as a solution of (18).
Step 3. (Clarke stationarity) If $\left\|\boldsymbol{d}_{t}\right\|<\delta$ or $\hat{H}\left(\boldsymbol{x}_{h}+\boldsymbol{d}_{t}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)>-\eta$, then execute Algorithm 1 for the point $\boldsymbol{x}_{h}$. Set $\boldsymbol{x}_{h+1}=\boldsymbol{x}^{+}$and $\tau=0$, and EXIT.
Step 4. (Descent test) Set $\boldsymbol{y}=\boldsymbol{x}_{h}+\boldsymbol{d}_{t}$. If

$$
\begin{equation*}
H\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq m_{2}\left(\hat{H}(\boldsymbol{y})-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right), \tag{24}
\end{equation*}
$$

then set $\boldsymbol{x}_{h+1}=\boldsymbol{y}$ and EXIT.
Step 5. (Bundle update) Compute $\boldsymbol{a}_{i} \in \partial A_{i}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)$ and $\alpha_{i}^{A}\left(\boldsymbol{x}_{h}, \boldsymbol{y}\right)$ for all $i \in I, \boldsymbol{b}_{l} \in \partial B_{l}(\boldsymbol{y})$ and $\alpha_{l}^{B}\left(\boldsymbol{x}_{h}, \boldsymbol{y}\right)$ for all $l \in L$, and $\boldsymbol{h}_{2} \in \partial H_{2}(\boldsymbol{y})$ and $\alpha_{2}^{H}\left(\boldsymbol{x}_{h}, \boldsymbol{y}\right)$.
(a) If $\boldsymbol{y} \notin \mathcal{F}_{0}$ and $\left\|\boldsymbol{d}_{t}\right\|>\theta$, then set $t=t-c_{1}\left(t-t_{\min }\right)$ and $\tau=0$. Go to Step 2.
(b) If $\tau \geq-\tau_{\max }$, then $t=t-c_{2}\left(t-t_{\min }\right)$. Otherwise, $t=t-c_{3}\left(t-t_{\min }\right)$. Set $\tau=$ $\min \{-1, \tau-1\}$. Insert $\left(\boldsymbol{a}_{i}, \alpha_{i}^{A}\left(\boldsymbol{x}_{h}, \boldsymbol{y}\right)\right)$ and $\left(\boldsymbol{b}_{l}, \alpha_{l}^{B}\left(\boldsymbol{x}_{h}, \boldsymbol{y}\right)\right)$ into $\mathcal{B}_{1}$ for all $i \in I, l \in L$, and $\left(\boldsymbol{h}_{2}, \alpha_{2}^{H}\left(\boldsymbol{x}_{h}, \boldsymbol{y}\right)\right)$ into $\mathcal{B}_{2}$. Select a suitable index $j$ corresponding to these insertions and add $j$ into $J_{1}$ and $J_{2}$.

Step 6. (Parameter update) If $\left\|\boldsymbol{h}_{2}\right\|>\left\|\boldsymbol{h}_{2, \max }\right\|$, then set $\boldsymbol{h}_{2, \max }=\boldsymbol{h}_{2}$ and update $t_{\min }$ using (23). Go to Step 2.

Next we discuss about the main iteration of MDBDC in Algorithm 3. Since the current iteration point $\boldsymbol{x}_{h}$ does not change during the execution of Algorithm 3, we omit the index $h$, expect for $\boldsymbol{x}_{h}$, to simplify the algorithm. The execution of Algorithm 3 either yields a new iteration point or ensures Clarke stationarity of our current solution.

In practice, the sizes of the bundles are limited. The size of $\mathcal{B}_{1}$ has to be large enough to contain space for elements related to both $\mathcal{B}_{A}$ and $\mathcal{B}_{B}$ meaning that $\left|J_{1}\right| \geq k+m$. On
the other hand, we can control the number of subproblems solved in Step 2 being the most time-consuming part of Algorithm 3. The only restriction is that $\left(\boldsymbol{h}_{2}\left(\boldsymbol{x}_{h}\right), 0\right)$ must be included into $\mathcal{B}_{2}$, and therefore, $\left|J_{2}\right| \geq 1$.

Due to the DC decomposition of the improvement function, one objective may dominate the others and hide their effect if the magnitudes of objective function values differ a lot. To avoid this, MDBDC contains a scaling procedure presented in Algorithm 4. With this procedure, we obtain modified objective functions maintaining the same optima as the original objectives.

```
Algorithm 4 Scaling procedure
    Step 1. Calculate \(i^{*}=\operatorname{argmin}\left\{\left|f_{i}\left(x_{0}\right)\right| \mid i \in I\right\}\).
    Step 2. For each \(i \in I\), search the value \(\kappa_{i}\) such that \(10^{\kappa_{i}-1} \leq\left|f_{i}\left(\boldsymbol{x}_{0}\right)\right| \leq 10^{\kappa_{i}}\). If \(\kappa_{i}<0\), then \(\kappa_{i}=0\).
    Step 3. For each \(i \in I\), set \(v_{i}=\kappa_{i} *-\kappa_{i}\). If \(v_{i} \leq-2\), then \(v_{i}=v_{i}+1\). Set \(\omega_{i}=10^{v_{i}}\) and \(f_{i}=\omega_{i} f_{i}\)
            being the scaled objective function.
```

### 3.4 Convergence

We devote this section to prove the convergence of MDBDC. This convergence analysis is divided as follows: Lemmas 4 and 5 are auxiliary results and Lemmas 3 and 6 are summarized by saying that there does not exists any infinite cycle in Algorithm 3. Finally, in Theorem 5 we state that MDBDC stops after a finite number of iterations and Theorem 6 considers weak Pareto stationarity of the solution. Throughout the convergence analysis, we assume that $\mathbf{A 1}$ and $\mathbf{A 2}$ are valid. Additionally, for $\theta>0$ we define $\mathcal{F}_{\theta}=\left\{\boldsymbol{x} \in \mathbb{R}^{n} \mid d\left(\boldsymbol{x}, \mathcal{F}_{0}\right) \leq \theta\right\}$, where $d\left(\boldsymbol{x}, \mathcal{F}_{0}\right)=\inf \left\{\|\boldsymbol{x}-\boldsymbol{z}\| \mid \boldsymbol{z} \in \mathcal{F}_{0}\right\}$.

We begin recalling Theorem 4.9 in [17] asserting a finite upper bound for the number of iterations of Algorithm 1.

Lemma 3 [17] Let the assumption $\mathbf{A 1}$ be valid and the level set $\mathcal{F}=\left\{z \in \mathbb{R}^{n} \mid H(z, \boldsymbol{x}) \leq\right.$ $H(\boldsymbol{x}, \boldsymbol{x})\}$ be compact for $\boldsymbol{x} \in \mathbb{R}^{n}$. Algorithm 1 terminates after at most

$$
\left\lceil\frac{\ln \left(\frac{\delta^{2}}{K^{2}}\right)}{\ln \left(1-\frac{\left(1-m_{1}\right)^{2} \delta^{2}}{8 K^{2}}\right)}\right\rceil
$$

iterations, where $\lceil\cdot\rceil$ is a ceiling of the number, $m_{1} \in(0,1)$, and $K>\delta>0$ is the Lipschitz constant of $H(\cdot, \boldsymbol{y})$ at the point $\boldsymbol{x} \in \mathbb{R}^{n}$, when $\boldsymbol{y}=\boldsymbol{x}$.

The following auxiliary result is proved similarly to Lemma 3 in [16].
Lemma 4 If the condition (24) in Step 4 of Algorithm 3 is not satisfied, then

$$
\boldsymbol{\xi}_{1}^{T} \boldsymbol{d}_{t}-\alpha_{1}>m_{2}\left(\hat{H}_{1}(\boldsymbol{y})-H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right)+\left(1-m_{2}\right)\left(\hat{H}_{2}(\boldsymbol{y})-H_{2}\left(\boldsymbol{x}_{h}\right)\right),
$$

where $\boldsymbol{y}=\boldsymbol{x}_{h}+\boldsymbol{d}_{t}, \xi_{1} \in \partial H_{1}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)$ and $\alpha_{1}=H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)-H_{1}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)+\boldsymbol{\xi}_{1}^{T} \boldsymbol{d}_{t}$.
Proof If (24) does not hold, then by Lemma 1 (i)

$$
H_{1}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)-H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)>m_{2}\left(\hat{H}(\boldsymbol{y})-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right)+\hat{H}_{2}(\boldsymbol{y})-H_{2}\left(\boldsymbol{x}_{h}\right),
$$

when we use the DC decomposition of $H\left(\cdot, \boldsymbol{x}_{h}\right)$. We obtain the result by noticing that $H_{1}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)-H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)=\boldsymbol{\xi}_{1}^{T} \boldsymbol{d}_{t}-\alpha_{1}$, when $\xi_{1} \in \partial H_{1}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)$ and $\alpha_{1}=H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)-$ $H_{1}\left(\boldsymbol{y}, \boldsymbol{x}_{h}\right)+\boldsymbol{\xi}_{1}^{T} \boldsymbol{d}_{t}$.

Before stating the finite convergence of Algorithm 3, we collect some crucial observations.
Lemma 5 Let the assumption A2 be valid. During each execution of Algorithm 3
(i) $\boldsymbol{x}_{h} \in \mathcal{F}_{\theta}$ and $\boldsymbol{y}_{j} \in \mathcal{F}_{\theta}$ for all $j \in J_{1} \cup J_{2}$.
(ii) there exists $C>0$ such that $\left\|\boldsymbol{x}_{h}-\boldsymbol{y}_{j}\right\|<C$ for every $\boldsymbol{y}_{j} \in \mathcal{B}_{1} \cup \mathcal{B}_{2}$.
(iii) $\boldsymbol{a}_{i, j} \in \partial A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)$ and $\boldsymbol{b}_{l, j} \in B_{l}\left(\boldsymbol{y}_{j}\right)$ and $\alpha_{i, j}^{A}$ and $\alpha_{l, j}^{B}$ for all $i \in I, l \in L$, and $j \in J_{1}$ are bounded.
(iv) $\boldsymbol{h}_{2, j} \in \partial H_{2}\left(\boldsymbol{y}_{j}\right)$ and $\alpha_{2, j}^{H}$ for all $j \in J_{2}$ are bounded.
(v) $t_{\min }$ is bounded from below with a positive threshold and $t_{\max }$ is bounded from above.

Proof (i) The points $\boldsymbol{y}_{j}$ on $\mathcal{B}_{1}$ and $\mathcal{B}_{2}$ are ensured to belong to $\mathcal{F}_{\theta}$ by Step 5 of Algorithm 3. In addition, $\boldsymbol{x}_{h}$ is on $\mathcal{F}_{\theta}$, since each iteration point decreases the value of the objectives.
(ii) The set $\mathcal{F}_{\theta}$ is compact by $\mathbf{A 2}$, and together with (i), this implies the claim.
(iii) Every $A_{i}\left(\cdot, \boldsymbol{x}_{h}\right)$ and $B_{l}$ for all $i \in I$ and $l \in L$ are LLC. Thus, there exists a Lipschitz constant for each of these functions on $\mathcal{F}_{\theta}$. Fix $K_{1}>0$ overestimating these constants. Now $\left\|\boldsymbol{a}_{i, j}\right\| \leq K_{1}$ and $\left\|\boldsymbol{b}_{l, j}\right\| \leq K_{1}$ for all $i \in I, l \in L$ and $j \in J_{1}$ by (i). Combining (ii) with the above observations,

$$
\begin{aligned}
\left|\alpha_{i, j}^{A}\right| & \leq\left|A_{i}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)-A_{i}\left(\boldsymbol{y}_{j}, \boldsymbol{x}_{h}\right)\right|+\left\|\boldsymbol{a}_{i, j}\right\|\left\|\boldsymbol{x}_{h}-\boldsymbol{y}_{j}\right\| \\
& \leq K_{1}\left\|\boldsymbol{x}_{h}-\boldsymbol{y}_{j}\right\|+K_{1} C \leq 2 K_{1} C
\end{aligned}
$$

for all $i \in I$ and $j \in J_{1}$. Similarly, we can show that $\left|\alpha_{l, j}^{B}\right| \leq 2 K_{1} C$ for every $l \in L$ and $j \in J_{1}$.
(iv) The proof is similar to (iii), since $H_{2}$ is LLC with a Lipschitz constant $K_{2}>0$ on $\mathcal{F}_{\theta}$.
(v) From (iii) and (iv) we can derive that $t_{\min } \geq \bar{t}_{\min }=\frac{r \theta}{2\left(K_{1}+K_{2}\right)}>0$ yielding the positive lower bound for $t_{\min }$. If the condition in Step 1 of Algorithm 3 is not satisfied, then

$$
\delta \leq\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)-\boldsymbol{h}_{2}\left(\boldsymbol{x}_{h}\right)\right\| \leq\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right\|+\left\|\boldsymbol{h}_{2}\left(\boldsymbol{x}_{h}\right)\right\| \leq\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right\|+\left\|\boldsymbol{h}_{2, \max }\right\| .
$$

The upper bound for $t_{\text {max }}$ is obtained, since

$$
\begin{equation*}
t_{\max } \leq \bar{t}_{\max }=\frac{R r \theta}{2 \delta}<\infty \tag{25}
\end{equation*}
$$

Next we are in a position to show the same kind of a result as Lemma 5 in [16] guaranteeing that we do not have an infinite loop in Algorithm 3.

Lemma 6 Let the assumption A2 be valid. For any $\delta \in(0,1)$, Algorithm 3 cannot pass infinitely through the sequence of Steps from 2 to 6.

Proof Suppose that Steps from 2 to 6 are executed infinitely. We index by $i \in \mathcal{I}$ the quantities related to the $i$-th passage. Now $\left\|\boldsymbol{d}_{t}^{i}\right\| \geq \delta$ for each $i \in \mathcal{I}$, since Algorithm 1 cannot be entered.

Assume that Step 5(a) is passed infinitely. In Step 5, the proximity parameter $t$ decreases at each pass and converges to $t_{\min }$, since $t_{\min }$ is monotonically decreasing and by Lemma 5 (v), it is bounded from below. In addition, $t_{\min }$ is always smaller than the threshold

$$
\rho=\frac{\theta}{2\left(\left\|\boldsymbol{h}_{1}\left(\boldsymbol{x}_{h}\right)\right\|+\left\|\boldsymbol{h}_{2, \max }^{i}\right\|\right)},
$$

and therefore, after a finite number of passes $t<\rho$. This yields a contradiction, since $\left\|\boldsymbol{d}_{t}^{i}\right\| \leq \theta$ by Lemma 2 and Step 5(a) can no longer be executed.

Due to Lemma 2, the parameter selection rule $t \in\left[t_{\min }, t_{\max }\right]$, and Lemma 5 (iii)-(v), the sequence $\left\{\boldsymbol{d}_{t}^{i}\right\}_{i \in \mathcal{I}}$ is bounded. Thus, there exists a convergent subsequence $\left\{\boldsymbol{d}_{t}^{i}\right\}_{i \in \mathcal{I}^{\prime} \subseteq \mathcal{I}}$. Additionally, by combining Lemma 5 (iii) and (iv), the sequences $\left\{\hat{H}_{1}\left(\boldsymbol{y}^{i}\right)\right\}_{i \in \mathcal{I}^{\prime} \subseteq \mathcal{I}}$ and $\left\{\hat{H}_{2}\left(\boldsymbol{y}^{i}\right)\right\}_{i \in \mathcal{I}^{\prime} \subseteq \mathcal{I}}$ are bounded. Hence, these sequences have the convergent subsequences for $i \in \mathcal{I}^{\prime \prime} \subseteq \mathcal{I}^{\prime}$ and their limits are denoted by $\hat{H}_{1}^{*}$ and $\hat{H}_{2}^{*}$, respectively. From Lemma 1 (ii) and $\left\|\boldsymbol{d}_{t}^{i}\right\| \geq \delta$, we obtain for all $i \in \mathcal{I}$

$$
\begin{equation*}
\hat{H}_{1}\left(\boldsymbol{y}^{i}\right)-\hat{H}_{2}\left(\boldsymbol{y}^{i}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq-\frac{1}{2 t_{i}}\left\|\boldsymbol{d}_{t}^{i}\right\|^{2} \leq-\frac{\delta^{2}}{2 t_{i}}<0 . \tag{26}
\end{equation*}
$$

Let $t^{*}=\lim _{i \rightarrow \infty} t_{i}$. Now $t^{*}>0$ exists, since the sequence $\left\{t_{i}\right\}_{i \in \mathcal{I}}$ is nonincreasing and bounded from below with a positive threshold by Lemma 5 (v), and $t \in\left[t_{\min }, t_{\max }\right]$. Finally, passing to the limit in (26) yields

$$
\begin{equation*}
\hat{H}_{1}^{*}-\hat{H}_{2}^{*}-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq-\frac{\delta^{2}}{2 t^{*}}<0 \tag{27}
\end{equation*}
$$

To obtain a contradiction, we consider two successive indices $v$ and $w$ in $\mathcal{I}^{\prime \prime}$ and let $\alpha_{1, v}=H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)-H_{1}\left(\boldsymbol{y}^{v}, \boldsymbol{x}_{h}\right)+\boldsymbol{\xi}_{i, v}^{T} \boldsymbol{d}_{t}^{v}$, where $\boldsymbol{\xi}_{i, v} \in \partial H_{1}\left(\boldsymbol{y}^{v}, \boldsymbol{x}_{h}\right)$. Now Lemma 4 gives

$$
\boldsymbol{\xi}_{1, v}^{T} \boldsymbol{d}_{t}^{v}-\alpha_{1, v}>m_{2}\left(\hat{H}_{1}\left(\boldsymbol{y}^{v}\right)-H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right)+\left(1-m_{2}\right)\left(\hat{H}_{2}\left(\boldsymbol{y}^{v}\right)-H_{2}\left(\boldsymbol{x}_{h}\right)\right)
$$

and by the definition of $\hat{H}_{1}$, we get $\hat{H}_{1}\left(\boldsymbol{y}^{w}\right)-H_{1}\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \geq \boldsymbol{\xi}_{1, v}^{T} \boldsymbol{d}_{t}^{w}-\alpha_{i, v}$. By combining these two inequalities, we conclude

$$
\boldsymbol{\xi}_{1, v}^{T}\left(\boldsymbol{d}_{t}^{v}-\boldsymbol{d}_{t}^{w}\right)>m_{2} \hat{H}_{1}\left(\boldsymbol{y}^{v}\right)-\hat{H}_{1}\left(\boldsymbol{y}^{w}\right)+\left(1-m_{2}\right)\left(\hat{H}_{2}\left(\boldsymbol{y}^{v}\right)+H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right) .
$$

A passage to the limit yields $\left(m_{2}-1\right)\left(\hat{H}_{1}^{*}-\hat{H}_{2}^{*}-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right)<0$, but since $m_{2} \in(0,1)$, the property (27) cannot hold.

Summarizing, we have now considered all the possibilities where the infinite cycle may happen in Algorithm 3. We have thus led to the following theorem stating the finite convergence of MDBDC.

Theorem 5 Let the assumptions $\mathbf{A 1}$ and $\mathbf{A 2}$ be valid. For any $\delta \in(0,1)$ and $\varepsilon>0$, the execution of Algorithm 2 stops after a finite number of iterations at the point $\boldsymbol{x}^{*}$ satisfying the approximate Clarke stationary condition $\left\|\boldsymbol{\xi}^{*}\right\| \leq \delta$, where $\boldsymbol{\xi}^{*} \in \partial_{\varepsilon}^{G} H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right)$.

Proof The execution of Algorithm 2 can stop only if the Clarke stationary point $\boldsymbol{x}^{*}$ is found in Step 1. This means that the stopping condition is satisfied in Step 1 of Algorithm 1. Assume, that Algorithm 2 is executed infinitely and this stopping condition is not satisfied.

By Lemmas 3 and 6, the new iteration point $\boldsymbol{x}_{h+1}$ is obtained after a finite number of iterations in Step 3 or 4 of Algorithm 3. If the new iteration point $\boldsymbol{x}_{h+1}$ is found in Step 3, then we have found a direction with a sufficient descent and a step length $\beta^{*}>\varepsilon$ such that

$$
H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)<-m_{1} \varepsilon \delta<0 .
$$

Otherwise, the new iteration point $\boldsymbol{x}_{h+1}$ is found in Step 4 of Algorithm 3 and

$$
H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq m_{2}\left(\hat{H}\left(\boldsymbol{x}_{h}+\boldsymbol{d}_{t}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)\right) .
$$

Therefore, from (25) and (26), we can deduce that

$$
H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq-\frac{m_{2} \delta^{2}}{2 \bar{t}_{\max }}<0
$$

Thus, after each iteration $H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right)-H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right) \leq-\sigma<0$, where

$$
\sigma=\min \left\{m_{1} \varepsilon \delta, \frac{m_{2} \delta^{2}}{2 \bar{t}_{\max }}\right\}>0
$$

By recalling the definition of $H\left(\cdot, \boldsymbol{x}_{h}\right)$ in (10), $H\left(\boldsymbol{x}_{h}, \boldsymbol{x}_{h}\right)=0$. Thus, we obtain $H\left(\boldsymbol{x}_{h+1}, \boldsymbol{x}_{h}\right) \leq-\sigma$, and especially,

$$
f_{i}\left(\boldsymbol{x}_{h+1}\right)-f_{i}\left(\boldsymbol{x}_{h}\right)<-\sigma<0 \text { for all } i \in I .
$$

After the $h$-th iteration,

$$
f_{i}\left(\boldsymbol{x}_{h}\right)-f_{i}\left(\boldsymbol{x}_{0}\right) \leq-h \sigma \text { for all } i \in I
$$

and passing to the limit $h \rightarrow \infty$ yields

$$
\lim _{h \rightarrow \infty} f_{i}\left(\boldsymbol{x}_{h}\right)-f_{i}\left(\boldsymbol{x}_{0}\right) \leq-\infty \text { for all } i \in I
$$

This yields a contradiction, since based on the assumption A2 and Lipschitz continuity, every $f_{i}, i \in I$ must be bounded from below.

Finally, we guarantee weak Pareto stationarity of the solution with a similar result than Theorem 7 in [27].

Theorem 6 Let $f_{i}$ and $g_{l}$ be DC functions for all $i \in I$ and $l \in L$. Suppose that the assumptions A1 and A2 are valid. Then, MDBDC stops after a finite number of iterations with the solution $\boldsymbol{x}^{*}$ being a weakly Pareto stationary point for the problem (1).

Proof Consider a single-objective unconstrained minimization problem with an improvement function $H(\cdot, \boldsymbol{x})$ as its objective. According to Theorem 5, after a finite number of iterations, MDBDC finds a solution $\boldsymbol{x}^{*} \in \mathbb{R}^{n}$ such that it is a Clarke stationary point for $H\left(\cdot, \boldsymbol{x}^{*}\right)$ yielding $\mathbf{0} \in \partial H\left(\boldsymbol{x}^{*}, \boldsymbol{x}^{*}\right)$. Thus, by Theorem 2 (iii) the solution $\boldsymbol{x}^{*}$ is weakly Pareto stationary for the problem (1).

## 4 Numerical experiments

In this section, we study the behaviour of MDBDC. We have collected some academic singleobjective DC problems and combined those to obtain multiobjective DC problems. The problems obtained are solved with MDBDC and MPB $[27,30]$. The aim of these numerical tests is, on the one hand, to verify the usability of MDBDC in practice, and on the other hand, to justify the use of the DC method instead of the general nonconvex method.

The implementation of MPB is done with Fortran 77 and it is described in [24]. MDBDC is implemented with Fortran 95 and both implementations utilize the quadratic solver by Lukšan described in [23]. Additionally, MPB applies an aggregation strategy [18,19]. The implementation of MDBDC used can be downloaded from http://napsu.karmitsa.fi/mdbdc/. The tests are performed under Linux Ubuntu system and $£ 95$ is used as a compiler. We remark that in Step 6 of Algorithm 1 we update $\tilde{\boldsymbol{x}}$ if the step-length $\beta^{*}<\varepsilon$. However, in practice, the implementation of MDBDC stops at this point and the final solution is $\tilde{\boldsymbol{x}}$.

The input parameters for MDBDC are chosen as follows: the stopping tolerance $\delta=10^{-5}$, the proximity measure $\varepsilon=10^{-4}$, the enlargement parameter $\theta=5 \cdot 10^{-5}$ the quality measure and the decrease parameters

$$
\begin{aligned}
& \eta=\left\{\begin{array}{ll}
0, & \text { if } n \leq 100 \\
10^{-5}, & \text { if } 100<n \leq 200, \quad r= \begin{cases}0.75, & \text { if } n<10 \\
10^{-4}, & \text { if } n>200 \\
\frac{n}{n+5}, & \text { if } 10 \leq n \leq 300, \\
0.99, & \text { if } n>300\end{cases} \\
c= \begin{cases}0.4, & \text { if } n<25 \\
0.25, & \text { if } 25 \leq n<100 \\
0.1, & \text { if } 100 \leq n<200 \\
0.01, & \text { if } 200 \leq n<300 \\
0.001, & \text { if } n \geq 300\end{cases}
\end{array} . \begin{array}{l}
\end{array}\right]
\end{aligned}
$$

$c_{1}=0.5, c_{2}=\min \{0.5, c \cdot(k-1)\}$ and $c_{3}=0.1$, the increase parameter $R=10^{10}$, the descent parameters $m_{1}=m_{2}=0.01$ and $m_{3}=0.1$, and the threshold $\tau_{\max }=50$. The maximum size for the bundle $\mathcal{B}_{1}$ is selected to be $\min \{(n+5) \cdot(k+m), 1000\}$ and for the bundle $\mathcal{B}_{2}$ it is 3 . The size of $U_{j}$ in Algorithm 1 is $2(n+5)$. Note that MDBDC is quite sensitive for the parameter selection, and by specifying the parameters for the problem, the execution times of MDBDC may improve a lot. The parameters selected for MPB are default values [24].

The objective functions of the test problems are described in Table 1. The constraint functions of the form $g=r-s \leq 0$ are

$$
\begin{aligned}
& \mathbf{C 1}: r(\boldsymbol{x})=\max \left\{\left(x_{1}+1.5\right)^{2}+\left(x_{1}-1\right)^{2}+x_{2}^{2}+\left(x_{2}-1\right)^{2}-5,0\right\}, \\
& s(\boldsymbol{x})=\left(x_{1}-1\right)^{2}+\left(x_{2}-1\right)^{2}-1 \\
& \mathbf{C 2}: r(\boldsymbol{x})=0, \\
& s(\boldsymbol{x})=\max \left\{x_{1}^{2}+x_{2}^{2}+x_{3}^{2}+x_{4}^{2}-10, x_{1}+x_{2}+x_{3}+x_{4}-5.5\right\} \\
& \text { C3 : } \quad r(\boldsymbol{x})=0.5 n, \\
& s(\boldsymbol{x})=\sum_{i=1}^{n}\left(\boldsymbol{x}_{i}+(-1)^{i+1} \cdot 0.5\right)^{2}
\end{aligned}
$$

Note that $\mathbf{C 1}$ is a DC constraint and both $\mathbf{C} 2$ and $\mathbf{C 3}$ are concave. Finally, unconstrained test problems for two and three objectives are described in Tables 2 and 3 respectively, and constrained test problems are given in Table 4.

The results of the tests performed are reported in Tables 5, 6 and 7. In these tables, the first column describes the problem solved and $n$ is the dimension of the problem. In order

to compare the methods, we have given the number of function calls $n_{f}$, the number of subgradient evaluations $n_{\xi}$ and the CPU time. Since for MPB $n_{f}=n_{\xi}$, only $n_{\xi}$ is reported in addition to the CPU time. In practice, $n_{f}$ and $n_{\xi}$ tell the number of function values and subgradients evaluated for each objective and constraint. Lastly, the column $f\left(\boldsymbol{x}^{*}\right)=$ ( $f_{1}\left(\boldsymbol{x}^{*}\right), \ldots, f_{k}\left(\boldsymbol{x}^{*}\right)$ ) describes the solution obtained.

Two example executions of MDBDC are illustrated in Fig. 1. In these figures, dashed gray contours correspond to $\mathbf{O 1}$ and the gray contours correspond to $\mathbf{O 5}$. The optimum of the objective $\mathbf{O 1}$ is at the point $\boldsymbol{x}^{*}=(0.50,0.50)$ marked with a gray disk, and the optimum of the objective $\mathbf{O 5}$ is at the point $\boldsymbol{x}^{*}=(1.00,1.00)$ marked with a gray circle. The black curve in Fig. 1b presents the constraint C1. In Fig. 1a, we obtain a solution $\boldsymbol{x}^{*}=(0.50,0.50)$ such that $f\left(\boldsymbol{x}^{*}\right)=(0.50,0.50)$ being an individual optimum of the objective $\mathbf{O 1}$ as well. In Fig. 1b, we have added the constraint $\mathbf{C} \mathbf{1}$ such that neither of the optima of the individual objectives is feasible. Now we get a solution $\boldsymbol{x}^{*}=(0.29,0.29)$ and $f\left(\boldsymbol{x}^{*}\right)=(0.71,0.71)$. This solution lies on the same line as where the individual optima are and the constraint is active.

In Table 5, test problems 2 and 3 are the same problem with different starting points. In test problem 2, we notice that MDBDC finds a solution having better values for both objectives than the solution obtained with MPB. However, if we change a starting point a little, like in test problem 3, both methods find equally good solutions. In general, we say that one solution is better than the other if it has better values for all the objectives. Even if both MDBDC and

MPB find a weakly Pareto stationary solution, one might find a better solution. Reason for this is a nonconvex feasible set in the objective space, since both local and global optima satisfy the Pareto stationarity condition (6). In the test problems performed, MDBDC obtains a better solution in 16 cases, the solutions are equally good in 36 cases, and both methods fail in test problem 10 with $n=500$. The better solutions obtained are bolded in Tables 5, 6 and 7.

In the computational point of view, MDBDC is a good alternative for MPB when objectives and constraints are DC functions, even if it may sometimes require more computational efforts. For instance, in test problem 8, MDBDC uses more function and subgradient evaluations in the cases where $n=10$ and $n=100$. However, compared with MPB, the solutions obtained with MDBDC are better in both of those cases. Another example about this kind of behaviour is seen in Fig. 1. In both test problems 2 and 16, we obtain a solution $\boldsymbol{x}^{*}=(0.00,0.00)$ and $f\left(\boldsymbol{x}^{*}\right)=(1.00,1.00)$ with MPB. As we see, in both of those cases MDBDC visits also this point but can still continue forward. Generally speaking about the computational efforts of MDBDC in the test problems, we notice that MDBDC uses less function and subgradient evaluations in 27 cases, the number of evaluations are on the same magnitude in 6 cases, and MPB uses less evaluations in 19 cases. However, in these 19 test problems, MDBDC finds a better solution in half of the cases.

In Tables 5, 6 and 7, the columns $n_{f}$ and $n_{\xi}$ for MDBDC contain the evaluations used in Algorithm 3 and Algorithm 1. These evaluations are analyzed in Tables 8 and 9. In some cases, like in test problem 8 with $n=250$, we use a relatively high number of function evaluations in Algorithm 1 even if we obtain only a small improvement in the last digits. However, Algorithm 1 is very crucial for instance in test problem 10 with all the values of $n$, since without Algorithm 1, we would not be able to continue from the starting point. To conclude, we might need a relatively high number of evaluations to be able to stop, but the Algorithm 1 produces also a new descent direction if a Clarke stationary solution is not obtained.

To summarize, MDBDC performs well in the test problems reported. Indeed, in the small test problems ( $2 \leq n \leq 100$ ), the average number of function calls is 238.81 and the average number of subgradient evaluations is 221.32 for MDBDC while the average number of

evaluations for MPB is 305.43. In the larger test problems reported ( $n>100$ ), the average number of function calls is 257.00 and the average number of subgradient evaluations is 224.60 for MDBDC while the average number of evaluations for MPB is even 5277.87. Thus, MDBDC uses less evaluations on average in the test problems reported. Furthermore, MDBDC uses significantly less evaluations and CPU time in test problems 13-15 and 18 with $n \geq 250$ than MPB. Additionally, by utilizing some kind of aggregation in MDBDC, it might be possible to decrease the number of evaluations needed even more.

## 5 Conclusions

We have proposed a new descent method for the multiobjective DC optimization (MDBDC) producing weakly Pareto stationary solutions, and the method is proved to be finitely convergent under mild assumptions. This method can be used by executing it several times with different starting points to obtain an approximation of the set of local weak Pareto optima. Other possibility is to use MDBDC as a part of some interactive method like in [29,30,33]. Additionally, it can be used to solve single-objective DC problems with DC constraints to obtain a Clarke stationary solution.

The numerical experiments show the good performance of the method. The results obtained by comparing MDBDC and the multiobjective proximal bundle method [27,30] validate the use of the method specially designed for multiobjective DC optimization instead of the method for general nonconvex multiobjective optimization. With more accurate model capturing the convex and the concave behaviour, we can learn more about the objectives and hence obtain better solutions. In future, the implementation of MDBDC could be improved by adding some sort of aggregation strategy [18,19]. Moreover, MDBDC could be used in some practical applications, like data classification or cluster analysis.
