Abstract: Typhuloid fungi are a very poorly known group of tiny clavarioid homobasidiomycetes. The phylogenetic position and family classification of the genera targeted here, *Ceratellopsis*, *Macrotyphula*, *Pterula* *sensu lato* and *Typhula*, are controversial and based on unresolved phylogenies. Our six-gene phylogeny with an expanded taxon sampling shows that typhuloid fungi evolved at least twice in the *Agaricales* (*Pleurotineae*, *Clavariineae*) and once in the *Hymenochaetales*. *Macrotyphula*, *Pterulicum* and *Typhula* are nested within the *Pleurotineae*. The type of *Typhula* (1818) and *Sclerotium* (1790), *T. phacorrhiza* and *S. complanatum* (synonym *T. phacorrhiza*), are encompassed in the *Macrotyphula* clade that is distantly related to a monophyletic group formed by species usually assigned to *Typhula*. Thus, the correct name for *Macrotyphula* (1972) and *Typhula* is *Sclerotium* and all *Typhula* species but those in the *T. phacorrhiza* group need to be transferred to *Pistillaria* (1821). To avoid undesirable nomenclatural changes, we suggest to conserve *Typhula* with *T. incarnata* as type. *Clavariaceae* is supported as a separate, early diverging lineage within *Agaricales*, with *Hygrophoraceae* as a successive sister taxon to the rest of the *Agaricales*. *Ceratellopsis* *s. auct.* is polyphyletic because *C. acuminata* nests in *Clavariaceae* and *C. sagittiformis* in the *Hymenochaetales*. *Ceratellopsis* is found to be an earlier name for *Pterulicum*, because the type, *C. queletii*, represents *Pterulicum gracile* (synonym *Pterula gracilis*), deeply nested in the *Pterulicum* clade. To avoid re-combining a large number of names in *Ceratellopsis* we suggest to conserve it with *C. acuminata* as type. The new genus *Bryopistillaria* is created to include *C. sagittiformis*. The families *Sarcomyxaceae* and *Phyllotopsidaceae*, and the suborder *Clavariineae*, are described as new. Six new combinations are proposed and 15 names typified.

Key words: Agaricomycetes, basidioma evolution, Clavariaceae, clavarioid fungi, Pleurotineae, Sclerotium, Typhulaceae.

Taxonomic novelties: New suborder: *Clavariineae* Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, New family: *Phyllotopsidaceae* Locquin ex Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, *Sarcomyxaceae* Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, New genus: *Bryopistillaria* Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, New combinations: *Bryopistillaria sagittiformis* (Pat.) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, *Macrotyphula megasperma* (Berthier) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, *Macrotyphula phacorrhiza* (Reichard: Fr.) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, *Typhula podocarpi* (Crous) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, Typification: Lectotypification: *Ceratella ferryi* Quél. & Fautrey, *Clavaria aculina* Quél., *Clavaria microscopica* Malbr. & Sacc., *Pistillaria aciculata* Durieu & Lév. ex Sacc., *Pistillaria aculeata* Pat., *Pistillaria acuminata* Fuckel, *Pistillaria attenuata* Syd. & P. Syd., *Pistillaria carestiae* Ces. in Bres. & Sacc., *Pistillaria equiseticola* Boud., *Pistillaria helena* Pat., *Pistillaria juncicola* Bourdot & Galzin, *Pistillaria queletii* Pat., *Pistillaria sagittiformis* Pat., *Sclerotium complanatum* Tode, *Typhula brunaudii* Quél., Epitypification: *Pistillaria acuminata* Fuckel, *Pistillaria queletii* Pat., *Pistillaria sagittiformis* Pat., *Sclerotium complanatum* Tode.

INTRODUCTION

Clavarioid fungi have club- or coral-shaped basidiomata with the hymenium fully exposed and include at least 540 species (Corner 1950, Kirk *et al.* 2008). Phylogenetic studies have demonstrated that clavarioid basidiomata have arisen multiple times from ancestors with agaricoid or corticioid basidiomata in several lineages of *Basidiomycota* (Pine *et al.* 1999, Dentinger & McLaughlin 2006), but molecular phylogenies of clavarioid fungi and allied taxa are far from being complete. Clavarioid lineages are known to have evolved in the *Agaricales*, *Cantharellales*, *Gomphiales*, *Hymenochaetales*, *Russulales*, *Thelephorales* and *Trechisporales* among the *Agaricomycetes* (Pine *et al.* 1999, Hibbett & Binder 2002, Hibbett 2004, Dentinger & McLaughlin 2006, Birkebak *et al.* 2013), but fully supported multigene phylogenies are lacking in most cases and details as to how transitions to a clavarioid basidioma type have occurred are vague. A

more comprehensive taxon sampling and addition of more molecular markers is still needed in many groups, including clavarioid fungi, to better understand the evolution of basidioma configuration.

In this study, we target a group of clavarioid fungi with tiny basidiomata (Fig. 1A–K), here referred to as “typhuloid” following e.g. Corner (1950), Petersen (1974), Petersen *et al.* (2014), and Olariaga *et al.* (2016). Corner (1950: 145) characterised typhuloid fungi by their: i) small basidiomata and limited growth, ii) distinct stipe and fertile head, iii) simple hymenium, iv) epiphytic habitat on wood, stems or leaves, rather than being terricolous, v) smooth, white ellipsoid spores, vi) monomitic, generally clamped hyphae, and vii) agglutination of the hyphae on the surface of the stem. Three genera were regarded as typhuloid, *Typhula*, *Pistillaria* and *Pistillina* (Corner 1950), and were separated from pteruloid fungi (*Deflexula*, *Pterula*) with a dimorphic hyphal system and from *Ceratellopsis* with highly reduced

clavarioid basidiomata with generally sterile apices. Berthier (1976), in his monograph “*Typhula* and allied genera”, treated typhuloid fungi in a broader sense and considered *Ceratellopsis*, *Macrotyphula*, *Pterula* and *Typhula* to represent a natural group without proposing any family classification. *Hirticlavula elegans*, a member of Clavariaceae producing minute, hairy basidiomata, has also been considered somewhat typhuloid (Petersen et al. 2014), and limits between typhuloid fungi and other reduced clavarioid fungi are not always clear. Typhuloid fungi represent one of the most overlooked, poorly known and enigmatic groups of homobasidiomycetes. The family classification of these fungi is uncertain or based on weakly supported phylogenies with a

very limited taxon sampling. *Macrotyphula* and *Typhula* were previously placed in Clavariadelphaceae (Corner 1970, Hawksworth et al. 1995), but recent classifications place both genera in Typhulaceae together with *Sclerotium* (Kirk et al. 2008, Knudsen & Vesterholt 2012). The family classification of *Ceratellopsis* is even more controversial. Initially included by Corner (1970) in Clavariadelphaceae, Jülich (1982) accommodated it in Typhulaceae. Hawksworth et al. (1995) and Begerow et al. (2018), probably following Corner, included it in Gomphaceae, although *Ceratellopsis* lacks the synapomorphic characters of this family, such as pistillarin, ampullate septa and cyanophilous, ornamented spores (Hosaka et al. 2006). As no

molecular data of *Ceratellopsis* has been available, its phylogenetic relationships and classification have remained doubtful. Besides the above-mentioned genera treated by Berthier (1976), *Mucronella* and *Hirticlavula*, both producing tiny clavarioid basidiomata, have been assigned to the Clavariaceae based on molecular data (Birkebak *et al.* 2013, Petersen *et al.* 2014). Regardless of their phylogenetic origin, all typhuloid fungi share similar taxonomic problems. For many species of those genera only the type specimen or very few collections are known, species limits are unclear and distribution data are meagre. Molecular data of only a handful of species are available in public sequence repositories and the high morphological diversity of the group remains poorly sampled.

Typhula and segregated genera, Macrotyphula, and phylogenetic position of Typhulaceae

The phylogenetic position of Typhulaceae has been inferred from only two species, *Typhula phacorrhiza* and *Macrotyphula fistulosa*, type of *Typhula* and *Macrotyphula*, respectively. Through analyses of a 5-locus dataset, Matheny *et al.* (2006) recovered Typhulaceae in the hygrophoroid clade (Agaricales) with phylogenetic confidence, as sister to the Hygrophoraceae in a supported clade encompassing Pterulaceae and members of two pleurotoid agaric genera (*Sarcomyxa serotina* and *Phyllotopsis* spp.) (Fig. 1L–N). Binder *et al.* (2010), employing a broader taxon sampling of the Agaricomycetes, recovered also Typhulaceae as sister to Hygrophoraceae but without support, while Pterulaceae was supported as closely related to Stephanosporaceae instead (Binder *et al.* 2010). Other studies have not been able to confirm or reject the inclusion of Typhulaceae in the hygrophoroid clade, but recovered agaric or pleurotoid genera, such as *Phyllotopsis*, *Pleurocybella*, *Tricholomopsis*, as sister taxa of Typhulaceae with phylogenetic confidence (Dentinger & McLaughlin 2006, Lodge *et al.* 2014). Dentinger *et al.* (2016) resolved for the first time several deep nodes of the Agaricales through a 208-locus dataset containing 35 taxa of Agaricales, and found that the hygrophoroid clade, as defined by Matheny *et al.* (2006), was paraphyletic. Also, *Hygrocybe conica* (Hygrophoraceae) was recovered as sister to the Clavariaceae, while Pterulaceae (*Pterula multifida*; recovered in the hygrophoroid clade by Matheny *et al.* (2006)), appeared in a branch with *Pleurotus ostreatus*. Thus, the results by Dentinger *et al.* (2016) question the inclusion of the Typhulaceae in the hygrophoroid clade. In addition to its uncertain phylogenetic position, the monophyly of Typhulaceae has not been tested appropriately.

Two genera, *Typhula* and *Macrotyphula*, are currently accepted in Typhulaceae (e.g. Berthier 1976, Knudsen & Vesterholt 2012). *Macrotyphula* differs from *Typhula* in having large, yellow-brown basidiomata (30–300 mm) that never arise from sclerotia and non-amyloid spores (Berthier 1976). In contrast, *Typhula* includes species with smaller basidiomata (generally under 10 mm long) that often arise from sclerotia and usually have amyloid spores. Some *Typhula* species are important plant pathogens that cause economic loss in cereal crops (e.g. Ekstrand 1955). These are popularly known as “snow moulds”, producing symptoms known as “Typhula blight” (Matsumoto *et al.* 2001, Hoshino *et al.* 2008). Several economically important species like *T. incarnata* and *T. ishikariensis* have been subjected to extensive research on

their ecology, physiology and genetics (e.g. Matsumoto 1992, Vergara *et al.* 2004, Blunt *et al.* 2015, Chang 2015, Koch 2016). Generic limits of *Typhula* are not fully delineated and lack a complete consensus. Probably due to the fact that its species show diverse basidioma morphologies, sclerotial anatomy and asexual morph states (Berthier 1976), a number of genera have been segregated from *Typhula*, such as *Cnazonaria*, *Dacryopsella*, *Gliocoryne*, *Phacorrhiza*, *Pistillaria*, *Pistillina*, *Scleromitra* and *Sphaerula*. These genera have been used to a certain extent. Of these, Corner (1950) recognised *Pistillaria* (with *Cnazonaria*, *Gliocoryne*, *Scleromitra* and *Sphaerula* in synonymy), *Pistillina* and *Typhula* (with *Phacorrhiza* in synonymy). Donk (1954) adopted also *Pistillaria*, *Typhula* and *Pistillina*, and further synonymised *Dacryopsella* under *Pistillina*. *Pistillaria* has been recognised generally based on a ceraceous consistency of the fresh fruitbodies, horny when dried, and the absence of sclerotia (Corner 1950, 1970, Pilát 1958), but generic limits between *Pistillaria* and *Typhula* have been long debated (Corner 1950, Bourdot & Galzin 1928, Donk 1954, Berthier 1976). *Pistillina* has been distinguished by basidiomata with a globose fertile part (Corner 1950). Berthier (1976), after examining extensive material and type specimens available, merged all these genera under *Typhula* (*Sphaerula*, *Scleromitra* and *Dacryopsella* were not treated in the monograph), but recognised *Cnazonaria*, *Gliocoryne*, *Pistillaria* and *Pistillina* as subgenera. After the publication of Berthier's monograph, a few authors have continued to use *Pistillaria* and *Pistillina* at the generic level (Shiryayev & Kotiranta 2007, Kaygusuz & Çolak 2017, Begerow *et al.* 2018, Petersen & Læssøe 2019). Recently, the new monotypic genus *Tygervalleyomyces* was described in Typhulaceae based on analyses of the 28S region (Crous *et al.* 2017). The asexual morph of *Tygervalleyomyces podocarpi*, the only known morph, is similar to the asexual morph of *Typhula crassipes* (Berthier 1976, as *Typhula corallina*) in the cylindrical conidia with a truncate base, and in fact these two species have highly similar 28S sequences (98 %) and nested within a larger highly supported clade containing other *Typhula* species (Crous *et al.* 2017). In view of this, the status of *Tygervalleyomyces* needs to be re-evaluated in the light of a phylogeny with a broader sampling of *Typhula* species. Olariaga & Salcedo (2013) synonymised *Typhula* and *Macrotyphula* due to the fact that *T. phacorrhiza* formed a monophyletic group with *Macrotyphula* in previous analyses (Pine *et al.* 1999, Hibbett 2007), as well as morphological similarities. The designation of *T. phacorrhiza* as lectotype of *Typhula* by Donk (1933) has been considered unfortunate (Berthier 1976, Olariaga 2009, Olariaga & Salcedo 2013), because *T. phacorrhiza*, with long filiform basidiomata and unique compressed sclerotia, is an atypical species in *Typhula* (Remsberg 1940, Corner 1950, Berthier 1976). In fact, *T. phacorrhiza* shares many features with *M. fistulosa*, i.e. the pale brown, large basidiomata, the stipe surface with thin hyphae and caulotrichomes, the basal tomentum formed by thick-walled, scarcely septate hyphae and the presence of a hyaline, striped encrustation on the medulla hyphae (Olariaga & Salcedo 2013). Molecular phylogenetic analyses show that these species are closely related and nested in the Agaricales (Binder *et al.* 2010). Nevertheless, taxon sampling in phylogenetic studies of Typhulaceae is extremely poor and the synonymy of *Typhula* and *Macrotyphula* needs to be further explored.

The type of *Sclerotium* is conspecific with the type of *Typhula*

The genus *Sclerotium*, also included in *Typhulaceae* (Kirk et al. 2008), is currently treated as an artificial genus that accommodates fungi producing sclerotia but not, or rarely, a sexual morph (Xu et al. 2010). Tode (1790) included originally eight species in *Sclerotium*, of which Fries (1821) treated *S. complanatum* in the first place and Clements & Shear (1931: 411) thus selected this species as the type of *Sclerotium*. A number of authors, especially during the XIXth century, described numerous species in *Sclerotium*, including ascomycetous and basidiomycetous fungi (e.g. Fries 1822, Léveillé 1843, Duby 1830, Desmazières 1848, Rostrup 1866), and numerous plant pathogens (Xu et al. 2010). Until now, 464 names have been described or combined in *Sclerotium* (Index Fungorum, viewed on 11 June 2019) and it is evident that species assigned to *Sclerotium* have multiple evolutionary origins, but very few attempts to disassemble it have been made (Xu et al. 2010). With the end of the asexual-sexual morph dual nomenclature, many names in *Sclerotium* may turn out to have priority over species names in use. Several early authors observed that some *Sclerotium* species appeared in connection or directly attached to basidiomata of *Typhula* species (e.g. Berkeley 1837, Léveillé 1843 (as *Clavaria*), Rostrup 1866). *Sclerotium complanatum*, type of *Sclerotium*, is characterised by producing compressed sclerotia attached to the substrate by a small stalk (Tode 1790) which conform to those produced by *T. phacorrhiza* (Berkeley 1837, Rostrup 1866, Schröter 1889). Thus, it is generally accepted that *S. complanatum* is a synonym of *T. phacorrhiza* (Xu et al. 2010, Kaygusuz & Çolak 2017), although only Remsberg (1940) has proposed this synonymy according to our search. Other authors attributed *S. complanatum* to the sclerotial morph of *T. gyrans* (Fries 1874, Corner 1950, Donk 1962), but this view appears to have been abandoned. In the meantime, the taxonomic identity of *S. complanatum* has not been reassessed and the name remains untypified. As currently asexual names compete with sexual names for priority, the possible synonymy of *S. complanatum* and *T. phacorrhiza* would make *Sclerotium* and *Typhula* taxonomic synonyms, and all *Typhula* names in use, including those being applied to economically important plant pathogens, would have to be transferred to the older and equally sanctioned genus *Sclerotium*. Examining in depth the taxonomic concept of *S. complanatum* and proposing a typification is thus of paramount importance to deal with a possible scenario of undesirable nomenclatural changes.

The poorly known genus *Ceratellopsis*, a possible earlier synonym of *Pterulicum*

Ceratellopsis differs from *Typhula* in having minute filiform basidiomata with a sterile apex and a non-corticate stipe (Corner 1950, Berthier 1976). Short basidia up to 20 µm have also been suggested to be a diagnostic character (Jülich 1982). *Pterulicum gracile*, called *Pterula gracilis* until very recently (Leal-Dutra et al. 2020), strongly resembles species of *Ceratellopsis* because of its minute white basidiomata with a sterile apex, at least at early stages of development (Corner 1950, Berthier 1976), but it differs microscopically in having skeletal hyphae, typical for

Pterulaceae, 2-spored basidia and no stipe (Corner 1950, Olariaga 2009). Furthermore, we have made collections with very minute basidiomata with a clearly delimited stipe suggesting *Ceratellopsis*, but having skeletal hyphae as typical in *Pterulaceae*. Limits between *Ceratellopsis* and *Pterulaceae*, thus, are not always clear-cut.

As pointed out by Donk (1954), Konrad & Maublanc (1937) introduced *Ceratellopsis* based on the validly published but illegitimate *Ceratella* Pat. (Patouillard 1887; later homonym of *Ceratella* Hook. f. 1844) and explicitly indicated *Ceratellopsis queletii* as the type of *Ceratellopsis*. While Donk (1954) followed this typification, Corner (1950), noted that *C. queletii* might represent a rudimentary *Pterula*, and he selected instead *Ceratellopsis aculeata* as type so that *Ceratellopsis* could be used with certainty and not reduced to a synonym of *Pterula*. This choice, nevertheless, is not permissible (Turland et al. 2018; Art. 7.8) since the original type indication of *Ceratellopsis* by Konrad & Maublanc (1937) is unequivocal and irrevocable. Also, Olariaga (2009) proposed tentatively that *C. queletii* might be a synonym of *Pterulicum gracile*, but up to present, no consistent and stable interpretation of *C. queletii* has been provided and the taxonomic status of *Ceratellopsis* remains unresolved. Twenty-four names have been described or combined in *Ceratellopsis*, but several of them represent *P. gracile* (Berthier 1976) or *Typhula* species.

The confirmation that *C. queletii*, type of *Ceratellopsis*, is a synonym of *P. gracile* would have important consequences in the classification of *Pterulaceae*. The family, centered on the genus *Pterula*, has included several clavarioid genera with a dimitic hyphal system (Corner 1970). Based on molecular studies, four resupinate genera (*Aphanobasidium*, *Coronicium*, *Merulicum*, *Radulomyces*; Larsson 2007, Larsson et al. 2004) and the polyporoid *Radulotubus* (Zhao et al. 2016) were later transferred to *Pterulaceae*. In the light of analyses of the ITS, 28S and RPB2 regions, employing a rich taxon sampling of the *Pterulaceae*, Leal-Dutra et al. (2020) elucidated generic limits in the family. This study discovered *Pterula* to be polyphyletic and splits its species into the new genus *Myrmepterula*, *Phaeoapterula* and *Pterulicum*, leaving in *Pterula sensu stricto* a handful of species around *Pterula plumosa*. *Deflexula* was shown to be paraphyletic because some species nest in the *Pterula* clade, while the type *D. fascicularis* is in the *Pterulicum* clade. In total, 46 names earlier treated in *Pterula* and *Deflexula* were combined in *Pterulicum*, a genus up to then monospecific. *Pterula gracilis* was found to belong to the *Pterulicum* clade and accordingly combined as *Pterulicum gracile*. In this framework, would the synonymy between *C. queletii* and *P. gracile* be confirmed, the name *Ceratellopsis* (1937) would have priority over *Pterulicum* (1950). Thus, the identity of *C. queletii* needs urgent clarification.

In the present study, we expand the taxon sampling of typhuloid fungi based on the multigene datasets used by Matheny et al. (2006) and Binder et al. (2010). With these data, our main goals were to: 1) provide a robust phylogenetic hypothesis for typhuloid fungi, especially for *T. phacorrhiza* (type of *Typhula*), types of genera segregated from *Typhula*, *Sclerotium complanatum* (type of *Sclerotium*) and *Ceratellopsis* species; 2) test the monophyly of *Typhula*; 3) assign typhuloid fungi to appropriate families; and 4) propose an updated nomenclature in the light of a robust multigene phylogeny.

MATERIAL AND METHODS

Molecular techniques

DNA was extracted from fresh (stored in 1 % SDS extraction buffer) basidiomata, using a DNeasy Plant Mini Kit (Qiagen) according to the manufacturer's instructions. The following six gene regions were amplified: 1) nu5.8S rDNA, the 5' end of the nuclear 28S rDNA (spanning domains D1–D2), part of the nuSSU rDNA (ca. 1 600 bp), *RPB1* (900 bp; A–C), *RPB2* (5–7 region, ca. 1 100 bp) and *EF-1 α* (1 100 bp). The ITS (ITS1–5.8S–ITS2) and 28S regions were amplified in one piece using the primers ITS5–LR7, or otherwise as separate pieces: ITS using ITS5–ITS4, (White *et al.* 1990); and 28S using LR0R–LR5 (or LR3) and LR3R–LR7 (Vilgalys & Hester 1990). The same primers were used for sequencing. The ITS was sequenced using the primers ITS1–ITS4 and/or in a few instances ITS5, 5.8S and ITS3. The SSU region was amplified in one piece employing primers NS1–NS8 or in two pieces using NS1–NS4 and NS3–NS8 (White *et al.* 1990). PCR products of the *RPB1* region were obtained using gRPB1-A (Stiller & Hall 1997) and fRPB1-C rev primers (Matheny *et al.* 2002). The sequence spanning *RPB2* regions 5–7 was amplified in one piece, using fRPB2-5F and bRPB2-7R, or if required, in two pieces with primers fRPB2-5F-gRPB2-6R and bRPB2-6F-bRPB2-7R (Liu *et al.* 1999, Matheny 2005). For samples that did not successfully amplify or for sequencing, *Typhula*-specific primers were designed for the *RPB2* region and used in different combinations (Table 1). The *EF-1 α* region was PCR amplified and sequenced employing 983F and 2218R primers (Rehner & Buckley 2005). *Typhula*-specific primers of the *EF-1 α* region were designed and used for PCR amplification and sequencing of problematic samples (Table 1). PCR amplifications were performed using Illustra™ Hot Start Mix RTG PCR beads (GE Healthcare, UK) in a 25 μ L volume, containing 3 μ L of genomic DNA, 10 μ M of each primer and distilled water. PCRs were conducted in Applied Biosystems GeneAmp® PCR System 9700 and 2720 Thermal Cyclers. Amplifications were performed using the following program: initial denaturation at 95 °C for 5 min, followed by 35–40 cycles of 95 °C for 45–60 s, 52–58 °C for 50 s, 72 °C for 1 min, followed by a final extension at 72 °C for 10 min. PCR amplifications of protein-coding genes follow O'Donnell *et al.* (2011, *RPB1*) and Hansen *et al.* (2013, *RPB2*, *EF-1 α*). PCR products were purified using the enzymatic method Exo-sap-IT (USB Corporation, Santa Clara, California, USA). When multiple bands were amplified in the *RPB1* and *RPB2* regions, PCR products were

size-fractionated in a 1 % agarose gel, stained with GelRed™ (Biotium Inc.), visualised over a UV trans-illuminator, excised and purified using QIAquick spin columns (Qiagen). Purified PCR products were sequenced at Macrogen Europe service (www.macrogen.com).

Type specimens, taxon and molecular sampling

Type specimens of small typhuloid fungi available at E, FH, M, PC, S and UPS herbaria were examined: *Ceratella ferryi*, *Ceratellopsis carestiae*, *C. rickii*, *C. acuminata*, *C. equiseticola*, *Clavaria aculina*, *C. microscopica*, *Pistillaria attenuata*, *P. juncicola*, *Pterulicum gracile*, *Typhula brunaudii*, *T. crassipes*, *T. sclerotioides*, *T. sphaeroidea*, *T. subhyalina* and *T. uncialis*. Material deposited in G (customs blocked the loan), PAD (not available on loan) and SAPA (several contact attempts unsuccessful) could not be examined. The notation "!" indicates that type or other original material was examined by us. Cultures of the taxa collected and described in this study were deposited in the CBS-KNAW culture collection at the Westerdijk Fungal Biodiversity Institute.

For molecular analyses, types and other species of genera considered to be typhuloid or assigned to *Typhulaceae* were sampled, namely *Ceratellopsis*, *Macrotyphula*, *Pterulicum gracile*, *Typhula* s.l. and *Sclerotium*. A collection identified as *C. acuminata*, with skeletal hyphae, was included to test the limits between *Ceratellopsis* and *Pterula*. Nucleotide sequences were aligned in the six-gene dataset (nu5.8S rDNA, nu28S rDNA, nu18S rDNA, *RPB1*, *RPB2* and *EF-1 α*) assembled by Binder *et al.* (2010; TreeBASE no. S10185), in order to preliminarily explore their phylogenetic affinities. Nucleotide sequences were aligned in AliView (Larsson 2014). This alignment was subjected to a maximum likelihood (ML) analysis using the "RAxML HPC2 on XSEDE" tool (Stamatakis 2014) in the CIPRES Science Gateway (Miller *et al.* 2010), starting from a random tree. A GTR-GAMMA model with four rate categories was selected for tree inference. For branch confidence, 1 000 ML bootstrap replicates were conducted with a GTRCAT model (ML-BP). Targeted typhuloid taxa nested in Agaricales (ML-BP 92 %), except for *Ceratellopsis sagittiformis* that was placed in Hymenochaetales. Based on this analysis, a first 6-locus (5.8S, 28S, 18S, *RPB1*, *RPB2*, *EF-1 α*) dataset (the Agaricales matrix) was prepared to phylogenetically place typhuloid fungi among the Agaricales. Three taxa, *Amylocorticium cebennense*, *Plicaturopsis crispa* and *Serpulomyces borealis*, were included as outgroup for rooting purposes based on previous studies (Binder *et al.* 2010). A second dataset with the same molecular markers (the Pleurotineae matrix) included *Typhulaceae*

Table 1. Newly designed *Typhula*-specific primers for the *RPB2* and *EF-1 α* (5'-3') regions.

Locus	Primer	Sequence	PCR	Sequencing
<i>EF-1α</i>	1007F-Typh	SCGAGGAYCGTTCAACGAG		X

Table 2. Sequenced specimens used in this study, with GenBank accession numbers for 5.8S, 28S, 18S, RPB1, RPB2 and EF-1 α regions. Numbers in parentheses following the species names indicate multiple collections of a species. The GenBank accessions of sequences generated in this study are in **bold**. Asterisks indicate sequences obtained from genome data through the JGI portal (<https://jgi.doe.gov/>). Abbreviations of datasets are: ag = Agaricales, cl = Clavariineae; hy = Hymenochaetales, pl = Pleurotineae.

and closely related families, with a more species-inclusive sampling than in the Agaricales matrix. *Cantharocybe gruberi* was used as an outgroup based on analyses of the Agaricales matrix. A third 28S alignment (the Clavariaceae matrix) was constructed based

on Birkebak et al. (2013) to infer phylogenetic relationships of Ceratellopsis within the Clavariaceae, and employed *Anomoporia bombicina*, *A. kamtschatica* and *Podoserpula pusio* as outgroup taxa. A fourth 4-locus (5.8S, 28S, 18S, RPB2) dataset (the

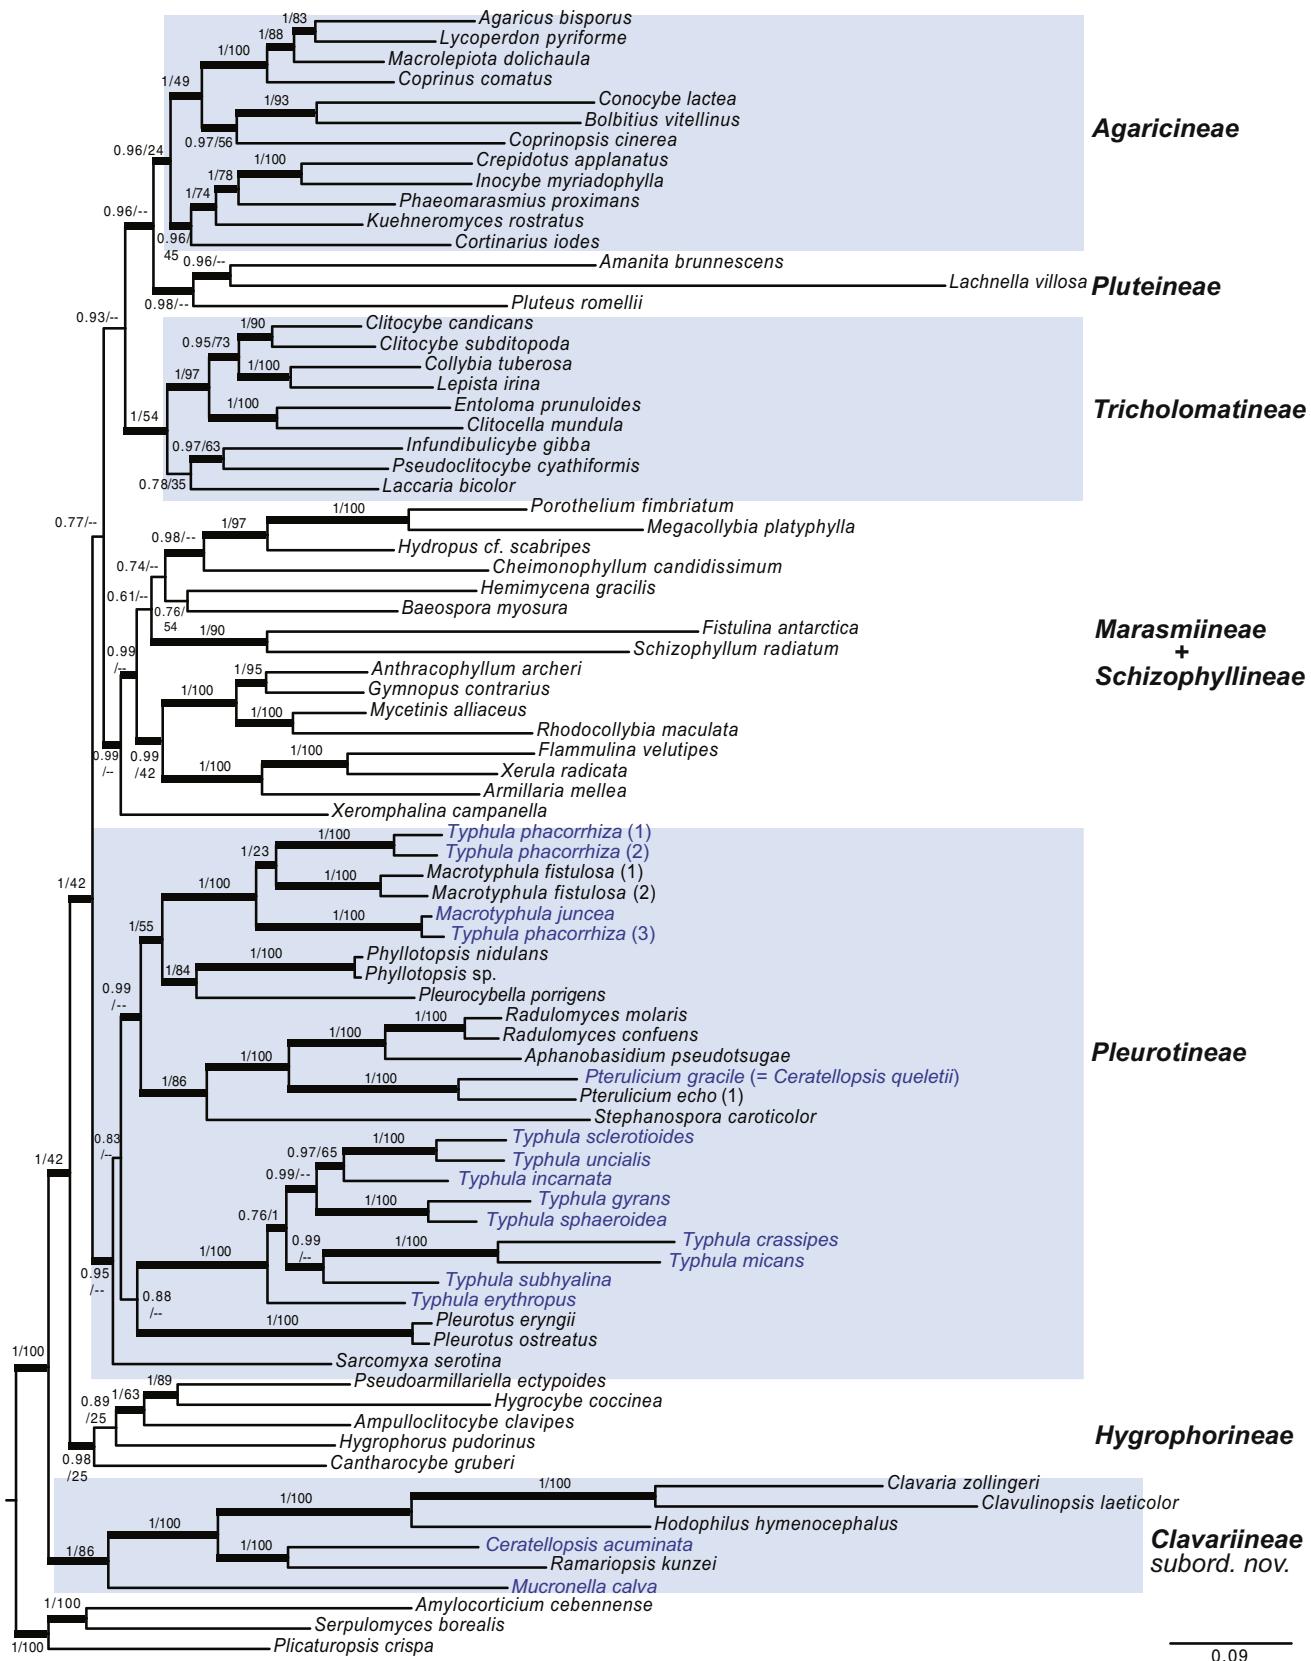

Fig. 2. Bayesian inference 50 % majority rule consensus phylogram of the Agaricales from 5.8S-18S-28S-RPB1-RPB2-EF-1 α sequence data, with the placement of typhuloid fungi (in blue font). Bayesian posterior probabilities (PP) and Maximum Likelihood bootstrap values (ML-BP) are shown on branches, ordered as PP/ML-BP. Thickened branches received support at least in one analysis (ML-BP \geq 70 % and/or PP \geq 95 %). Suborder names recognised within the Agaricomycetes are indicated on the right side.

Hymenochaetales matrix) was assembled to further explore phylogenetic relationships of *C. sagittiformis* within the *Hymenochaetales*. Sequences of *Calocera cornea* were set as outgroup.

Sequence alignment and phylogenetic analyses

Sequences were edited and assembled using Sequencher v. 4.10.1 (Gene Codes Corp., Ann Arbor, MI) and deposited in GenBank (Table 2). Additional sequences were downloaded

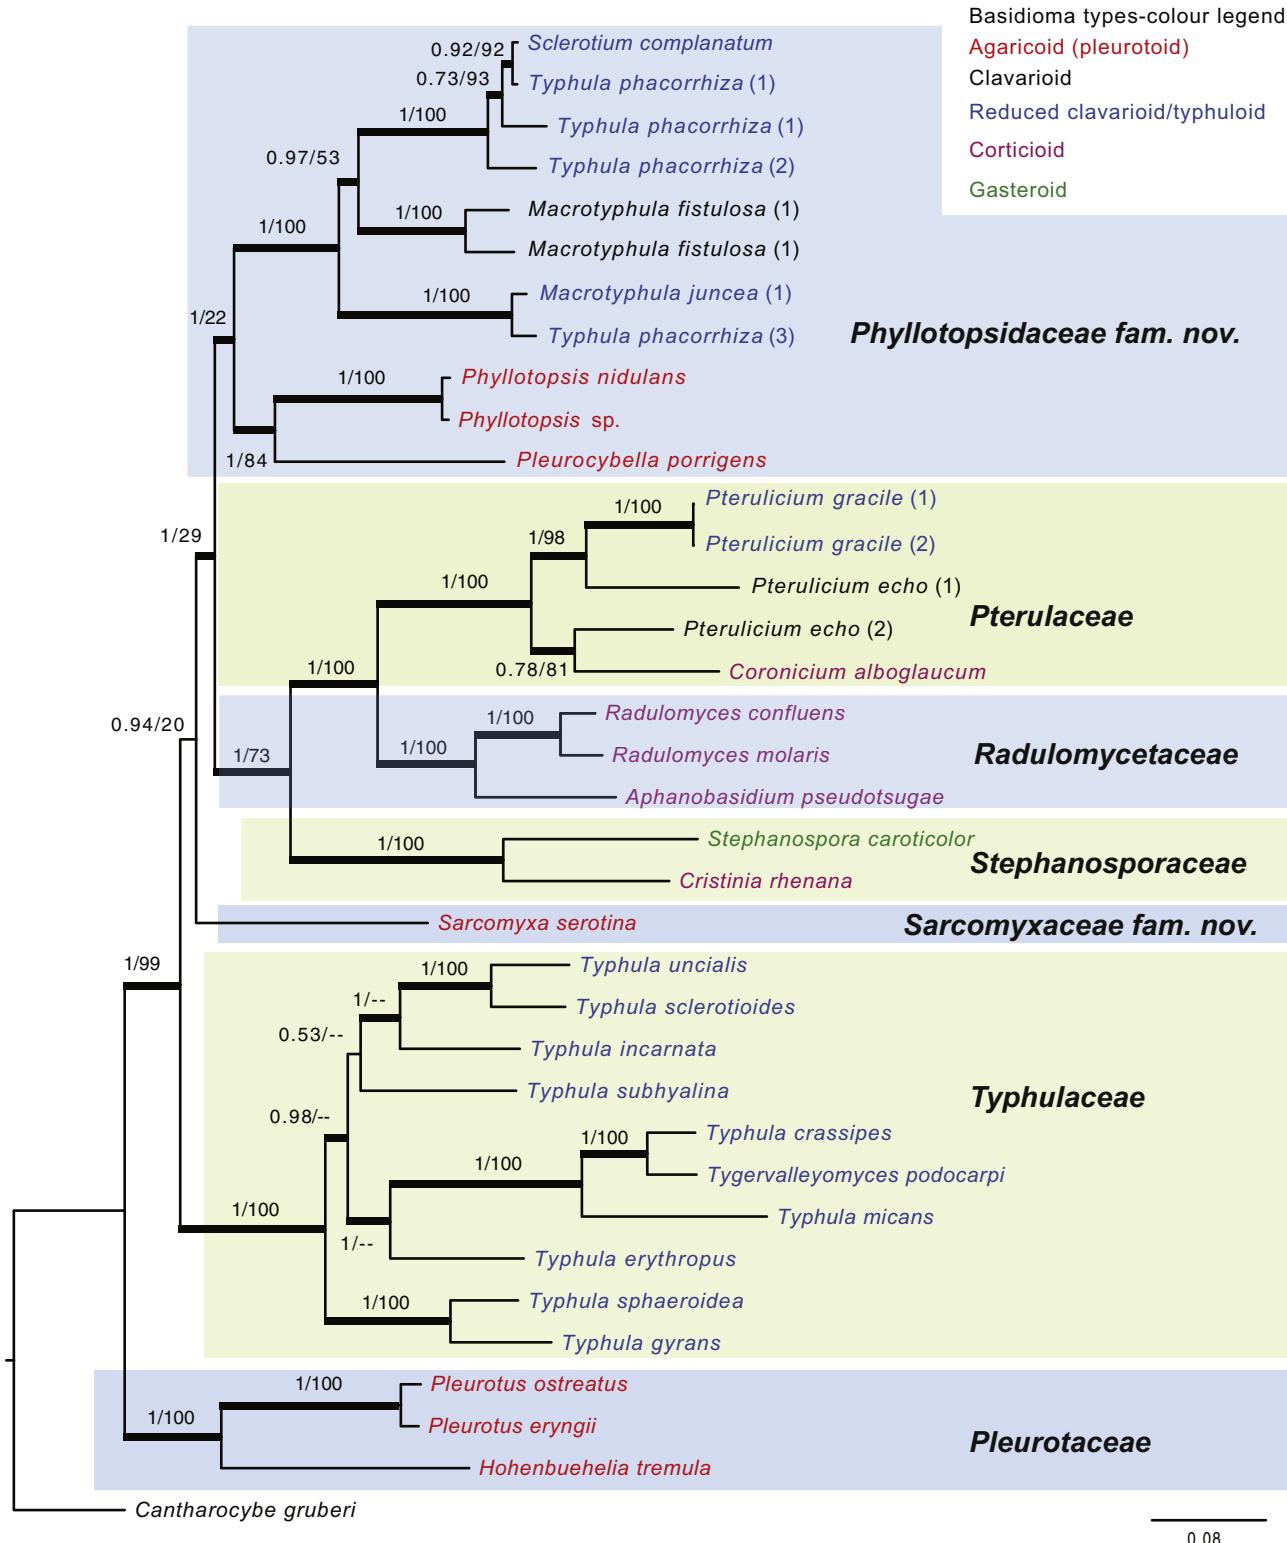

Fig. 3. Bayesian inference 50 % majority rule consensus phylogram of the Pleurotineae from 5.8S-18S-28S-RPB1-RPB2-EF-1 α sequence data. Bayesian posterior probabilities (PP) and Maximum Likelihood bootstrap values (ML-BP) are shown on branches, ordered as PP/ML-BP. Thickened branches received support at least in one of the analyses (ML-BP \geq 70 % and/or PP \geq 95 %). Family names recognised within the Pleurotineae are marked with colour boxes. Basidioma types are indicated with different colours for ingroup taxa.

from GenBank and from the following genomes through the MycoCosm portal (Grigoriev *et al.* 2014): *Agaricus bisporus*, *Coprinopsis cinerea* (Muraguchi *et al.* 2015), *Laccaria bicolor* (Martin *et al.* 2008), *Onnia scaura*, *Phellinus ferrugineofuscus*, *Plicaturopsis crista* (Kohler *et al.* 2015), *Pterulicium gracile* (Varga *et al.* 2019, deposited as *Pterula gracilis*), *Radulomyces confluens* and *Trichaptum abietinum* (Table 2). Nucleotide sequences were aligned manually using Aliview (Larsson 2014). Protein-coding genes were translated to amino acids to determine intron positions. In order to check gene-tree congruence, each individual gene-region was analysed using a ML approach, as explained above. Gene congruence was assessed manually by comparing supported clades among single-gene genealogies (Mason-Gamer & Kellogg 1996). Clades were considered in conflict if a supported clade (ML-BP >70 %) for one marker was contradicted with significant support by another one. Since no conflict was detected, markers were concatenated in the Agaricales, Typhulaceae and Hymenochaetales alignments. Introns were excluded and the third codon position was partitioned in the protein-coding genes (*RPB1*, *RPB2* and *EF-1 α*). Each matrix was subjected to ML and Bayesian analyses. ML analyses were conducted as explained above. Bayesian analyses were implemented in MrBayes v. 3.2.6 (Ronquist *et al.* 2012), using two parallel runs of eight Metropolis-coupled Markov chain Monte Carlo (MCMCMC) chains for 30 M generations, starting from a random tree, and sampling one tree every 1000th generation from the posterior distribution. Substitution models were sampled across the GTR space during the MCMC simulation (Ronquist *et al.* 2012). Stationarity was assumed when average standard deviation of split frequencies fell below 0.01. A burn-in sample of 30 000 trees was discarded. To assess branch confidence, a 50 % majority rule consensus tree was computed with the remaining 30 002 trees using the SUMT command of MrBayes. Bayesian posterior probability (PP) values ≥ 0.95 were considered to be significant. The alignments and respective phylogenetic trees were deposited in TreeBASE, study number S25967.

RESULTS

Origins of typhuloid fungi within Agaricales and Pleurotineae

A total of 118 (21 5.8S, 23 28S, 18 18S, 13 *RPB1*, 23 *RPB2*, 20 *EF-1 α*) sequences were generated for this study (Table 2). The Agaricales matrix comprised 81 taxa and contained 6 292 unambiguously aligned nucleotide positions (161 nu5.8S, 1 480 nu28S, 1 745 nu18S, 861 *RPB1*, 1 056 *RPB2* and 989 *EF-1 α*), with all genes available for 86.4 % of taxa. The Pleurotineae matrix had 39 taxa and contained 6 215 unambiguously aligned nucleotide positions (159 nu5.8S, 1 418 nu28S, 1 732 nu18S, 863 *RPB1*, 1 056 *RPB2* and 987 *EF-1 α*), with all genes available for 72.2 % of taxa. The Bayesian analysis of the Agaricales and Pleurotineae datasets reached average standard deviations of split frequencies > 0.01 after 12 195 000 and 425 000 generations, respectively. The Bayesian majority rule consensus tree of the Agaricales was fully resolved and many deeper branches received high support by Bayesian PP (Fig. 2). The majority of these branches were, however, not supported by ML-BP (< 70 %). Typhuloid fungi do not form a monophyletic group.

Specimens with skeletal hyphae nest in *Pleurotineae* (*Pterulicium gracile*) and in *Clavariiinae* (*C. acuminata*). Sequences of the specimen of *P. gracile* collected by us (IO.14.142) were identical to those obtained from the available genome of *P. gracile* (CBS 309.79) (Fig. 3), employed also by Leal-Dutra *et al.* (2020). *Clavariiinae* forms a strongly supported clade (PP 1, ML-BP 86) that is resolved as an early diverging lineage within Agaricales (PP 1). *Ceratellopsis acuminata* forms a highly supported clade with *Ramariopsis kunzei* (PP 1, ML-BP 100). The remaining Agaricales form a strongly supported monophyletic group (PP 1), within which *Ampulloclitocybe clavipes*, *Cantharocybe gruberi*, *Hygrocybe coccinea*, *Hygrophorus pudorinus* and *Pseudoarmillariella ectypoides*, corresponding to the Hygrophoraceae, constitute a strongly supported lineage in the Bayesian analysis (PP 0.98), as a sister group to the rest of the Agaricales (PP 1). The suborders Agaricinae (PP 0.96), the Tricholomatinae (PP 1), the Marasmiinae (PP 0.99) and the Pluteinae (PP 0.95) also received high support in the Bayesian analysis. *Xeromphalina campanella*, previously assigned to the hygrophoroid clade, is supported as an early diverging sister lineage to the Marasmiinae (PP 0.99). Species of *Typhula* and *Macrotyphula* form a well-supported clade together with other pleurotoid, clavaroid, corticioid and gasteroid species (PP 0.95) that is referred to the Pleurotineae. The Agaricales (ag) and Pleurotineae (pl) phylogenies (Figs 2, 3) show similar supported nodes in the Pleurotineae, except that the Pleurotaceae formed a sister group to the rest of the Pleurotineae in both Bayesian and ML analyses of the Pleurotineae matrix (PP 1, ML-BP 99). In all analyses *T. phacorrhiza* is nested within a monophyletic *Macrotyphula* (ag PP 1, ML-BP 100; pl PP 1, ML-BP 100). A specimen identified as *Sclerotium complanatum* is nested within a clade of three *T. phacorrhiza* collections in the analyses of the Pleurotineae matrix. The *Macrotyphula* clade is encompassed in a larger supported clade together with *Phyllotopsis* and *Pleurocybella porrigens* (pl PP 1). *Stephanospora caroticolor*, *Cristinia rhenana*, Pterulaceae and Radulomycetaceae (*Aphanobasidium*, *Radulomyces*) form a strongly supported clade (pl PP 1, ML-BP 73) sister to the *Macrotyphula* clade, *Phyllotopsis* and *Pleurocybella porrigens*. All *Typhula* species but its type *T. phacorrhiza*, form a distinct separate lineage (pl PP 1, ML-BP 100). It includes the types of *Cnazonaria*, *Dacryopsella*, *Gliocoryne*, *Phacorrhiza*, *Pistillaria*, *Pistillina*, *Scleromitra*, *Sphaerula* and *Tygervalleyomyces*. *Typhula* is a sistergroup to the clade formed by *Macrotyphula*, *Phyllotopsis*, *Pleurocybella porrigens*, Pterulaceae and Stephanosporaceae in the Pleurotineae phylogeny (Fig. 3), albeit without support (pl PP 0.94). *Pleurotus* and *Hohenbuehelia tremula* are supported as a sistergroup to the rest of the Pleurotineae in the Pleurotineae phylogeny (Fig. 3, PP 1, ML-BP 99).

The Clavariaceae phylogeny

The Clavariaceae matrix comprised 53 taxa and contained 1 505 unambiguously aligned nucleotide positions (28S rDNA). Bayesian and ML analyses produced very similar topologies (Fig. 4). Species of *Mucronella* form a highly supported sister group to the rest of the Clavariaceae (PP 1, ML-BP 100). *Clavaria*, *Camarophyllopsis*, *Hodophilus* and *Hirticlavula elegans* form a highly supported monophyletic group (PP 1, ML-BP 84), characterised by lacking clamp connections on context hyphae in all species but *Clavicorona taxophila*. Three species of

Ceratellopsis form a distinct clade with several environmental sequences (uncultured *Basidiomycota* in GenBank). The relationships of the *Ceratellopsis* clade to the other genera with clamp connections, *Ramariopsis* and *Clavulinopsis*, are not resolved with support.

The Hymenochaetales phylogeny

The *Hymenochaetales* matrix contained 37 taxa and 4 239 unambiguously aligned characters. The majority rule consensus tree of the Bayesian analysis is provided in Fig. 5. The *Hymenochaetales* is recovered as monophyletic with

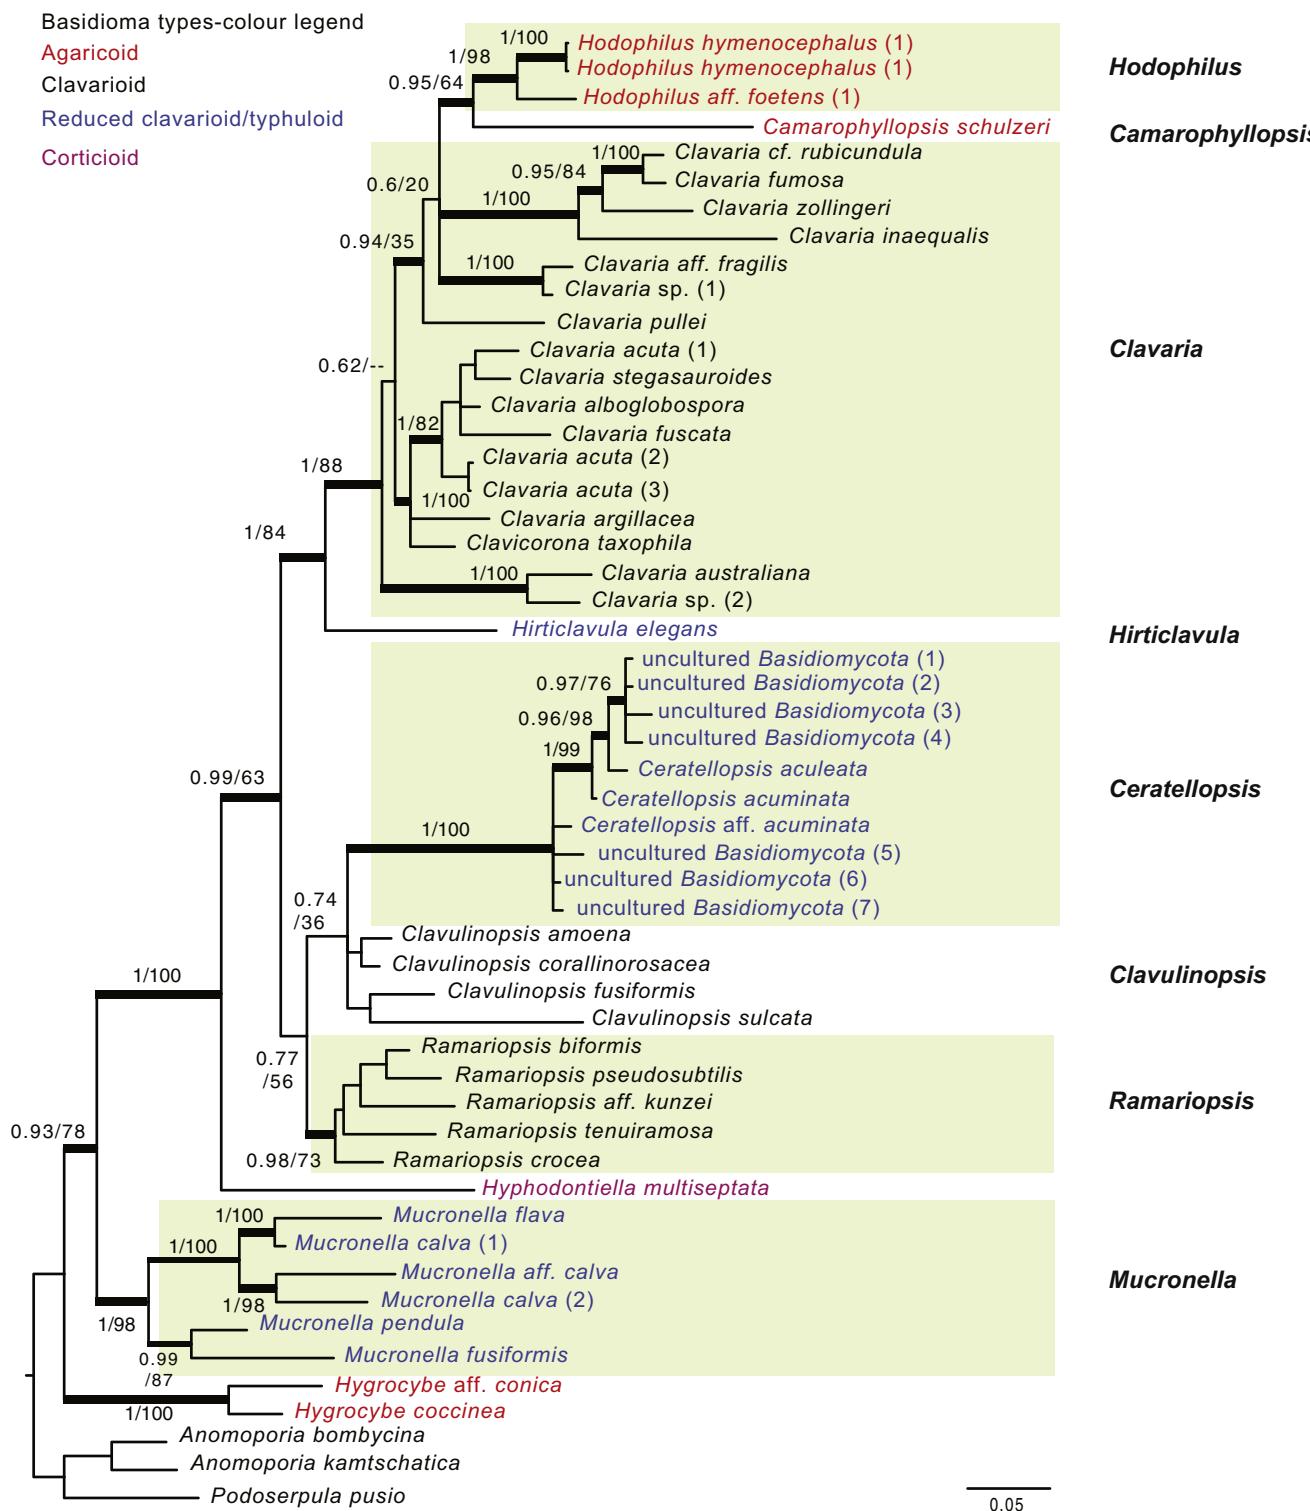

Fig. 4. Bayesian inference 50 % majority rule consensus phylogram of the Clavariineae from 28S sequence data. Bayesian posterior probabilities (PP) and Maximum Likelihood bootstrap values (ML-BP) are shown on branches, ordered as PP/ML-BP. Thickened branches received support at least in one analysis (ML-BP \geq 70 % and/or PP \geq 95 %). Basidioma types are indicated with different colours for ingroup taxa.

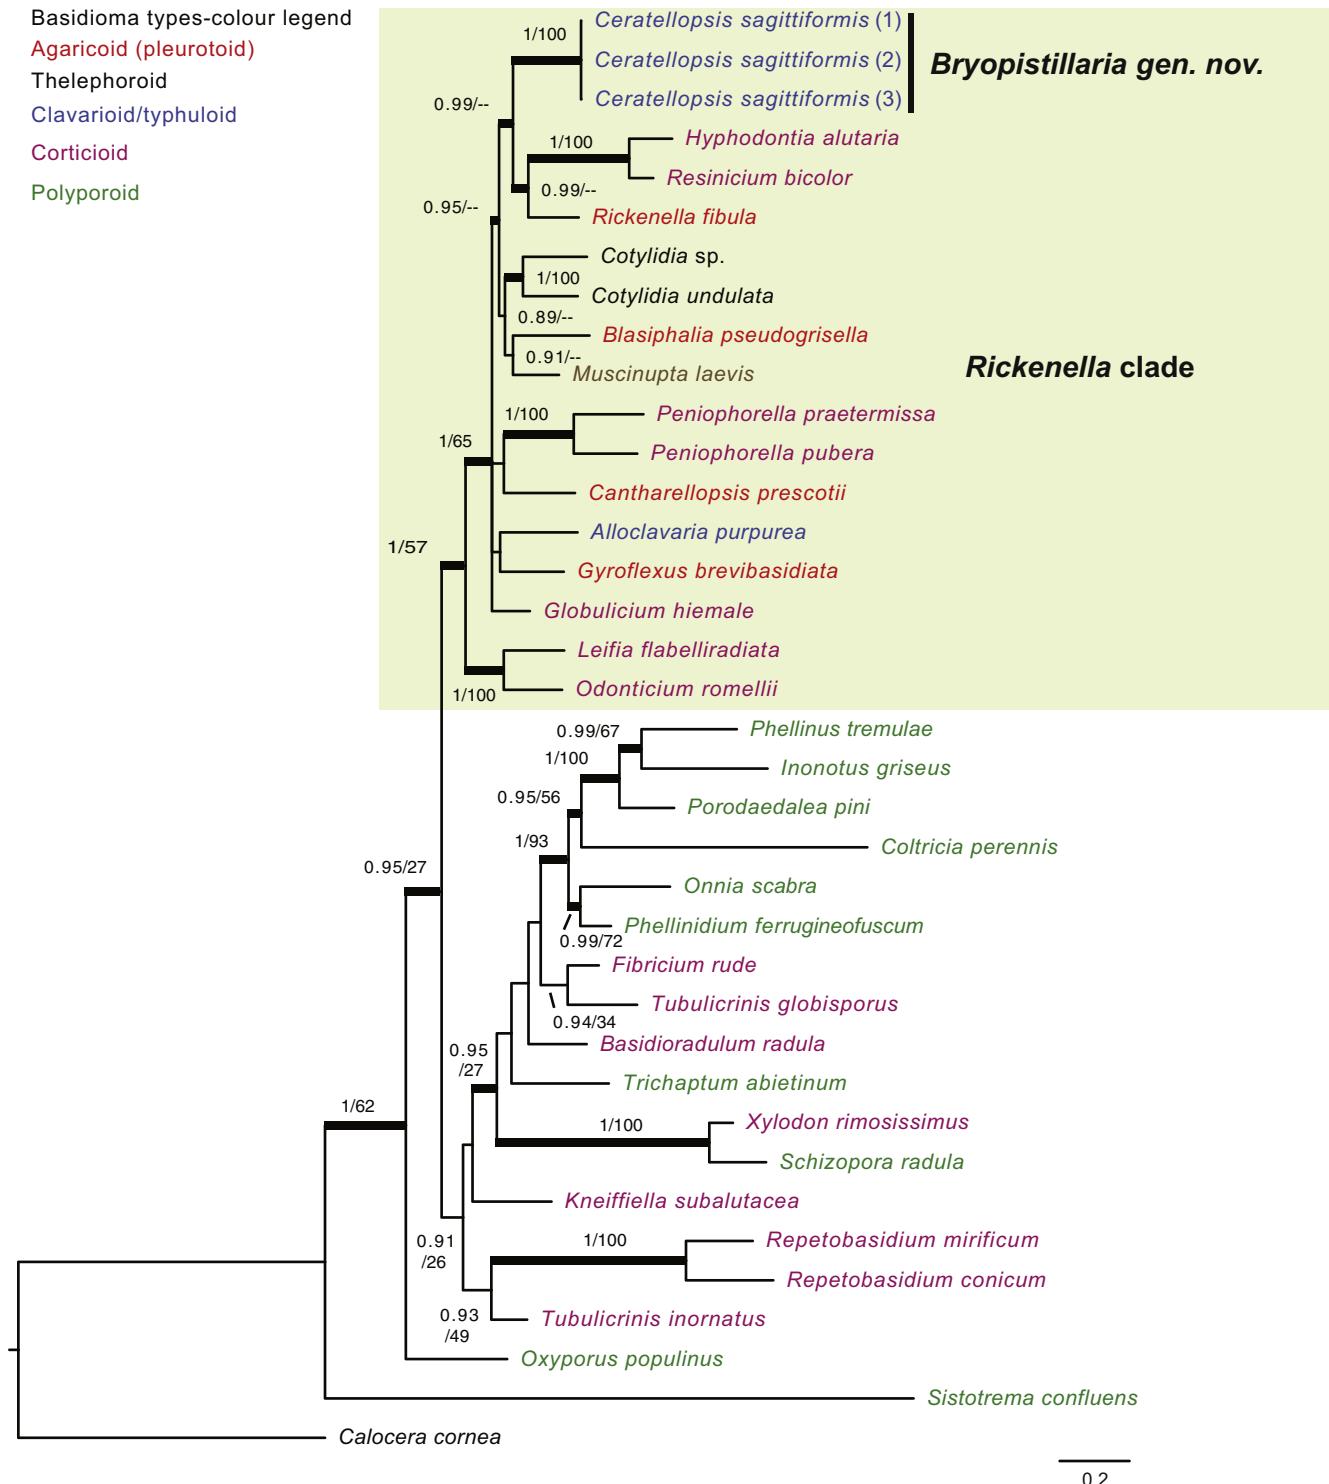

Fig. 5. Bayesian inference 50 % majority rule consensus phylogram of the hymenochaetoid clade from 5.8S-18S-28S-RPB2 sequence data. Bayesian posterior probabilities (PP) and Maximum Likelihood bootstrap values (ML-BP) are shown on branches, ordered as PP/ML-BP. Thickened branches received support at least in one analysis (ML-BP \geq 70 % and/or PP \geq 95 %). Basidioma types are indicated with different colours for ingroup taxa.

high support in the Bayesian analysis (PP 1, ML-BP 62). It comprises two larger clades: a) a clade containing *Coltricia*, *Kneiffiella*, *Xylodon* and *Hymenochaetaceae*, corresponding to clades C–F in Larsson et al. (2006), along with two species of *Repetobasidium* (PP 0.91, ML-BP 26); and b) a clade corresponding to the *Rickenella* clade (clade B in Larsson et al. 2006) (PP 1, ML-BP 57). Within the *Rickenella* clade, the three *Ceratellopsis sagittiformis* specimens are encompassed in a well-supported clade (PP 1, ML-BP 65) with species of

agaricoid (*Blasiphalia*, *Cantharellopsis*, *Gyroflexus*, *Rickenella*), clavarioid (*Alloclavaria*), corticoid (*Globulicium*, *Hyphodontia*, *Peniophorella*, *Resinicium*), cyphelloid (*Muscinupta*) and thelephoroid (*Cotylidia*) basidiomata. The position of *Hyphodontia alutaria* and *Resinicium bicolor* is in conflict; both species form a supported monophyletic group with *Rickenella fibula* and *C. sagittiformis* in the Bayesian analysis (PP 99), as opposed to a monophyletic group with *Cotylidia* spp. in the ML analysis (ML-BP 75).

Taxonomy

Clavariinae Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **subord. nov.** MycoBank MB831365.

Basidiomata clavarioid, more rarely agaricoid with waxy decurrent gills, or corticioid. Hyphal system monomitic, or more rarely dimitic. *Basidiospores* hyaline, usually thin-walled, smooth or ornamented, usually with multiguttulate contents, sometimes with amyloid or dextrinoid reactions, usually with a cubic apiculus. *Basidia* claviform, with up to 4 sterigmata, chiasmic, sometimes characteristically long (< 50 µm) or short (> 20 µm), occasionally sometimes with a loop-like basal clamp (*Clavaria* subgen. *Holocoryne*). *Cystidia* usually absent. *Pileipellis* either a hymeniderm or a trichoderm with rounded terminal elements in genera with agaricoid basidiomata. *Basal tomentum* composed of narrow, usually < 2 µm broad thick-walled hyphae in clavarioid genera

(*Ceratellopsis*, *Clavaria*, *Clavulinopsis*, *Ramariopsis*), possibly also in other stipitate genera. *Clamp connections* present or absent, sometimes restricted to basidia. Saprotrrophic on dead wood, herbaceous plants or leaves, or biotrophic with grasses and bryophytes. Presence of *EF-1α* intron 21 (numbering according to [Matheny et al. 2007](#)) in some genera (absent in *Ceratellopsis*).

Type family: *Clavariaceae* Chevall.

Notes: This suborder contains a single family. Similar isotopic ratios to those found in the *Hygrophoraceae* suggest that at least non-lignicolous members of *Clavariaceae* have some kind of biotrophic association with plants ([Birkebak et al. 2013](#)), whereas genera occurring on dead plant remnants are probably saprotrophic (*Ceratellopsis*, *Mucronella*, *Hirticlavula*). Very narrow and slightly thick-walled hyphae in the basal tomentum and mycelium

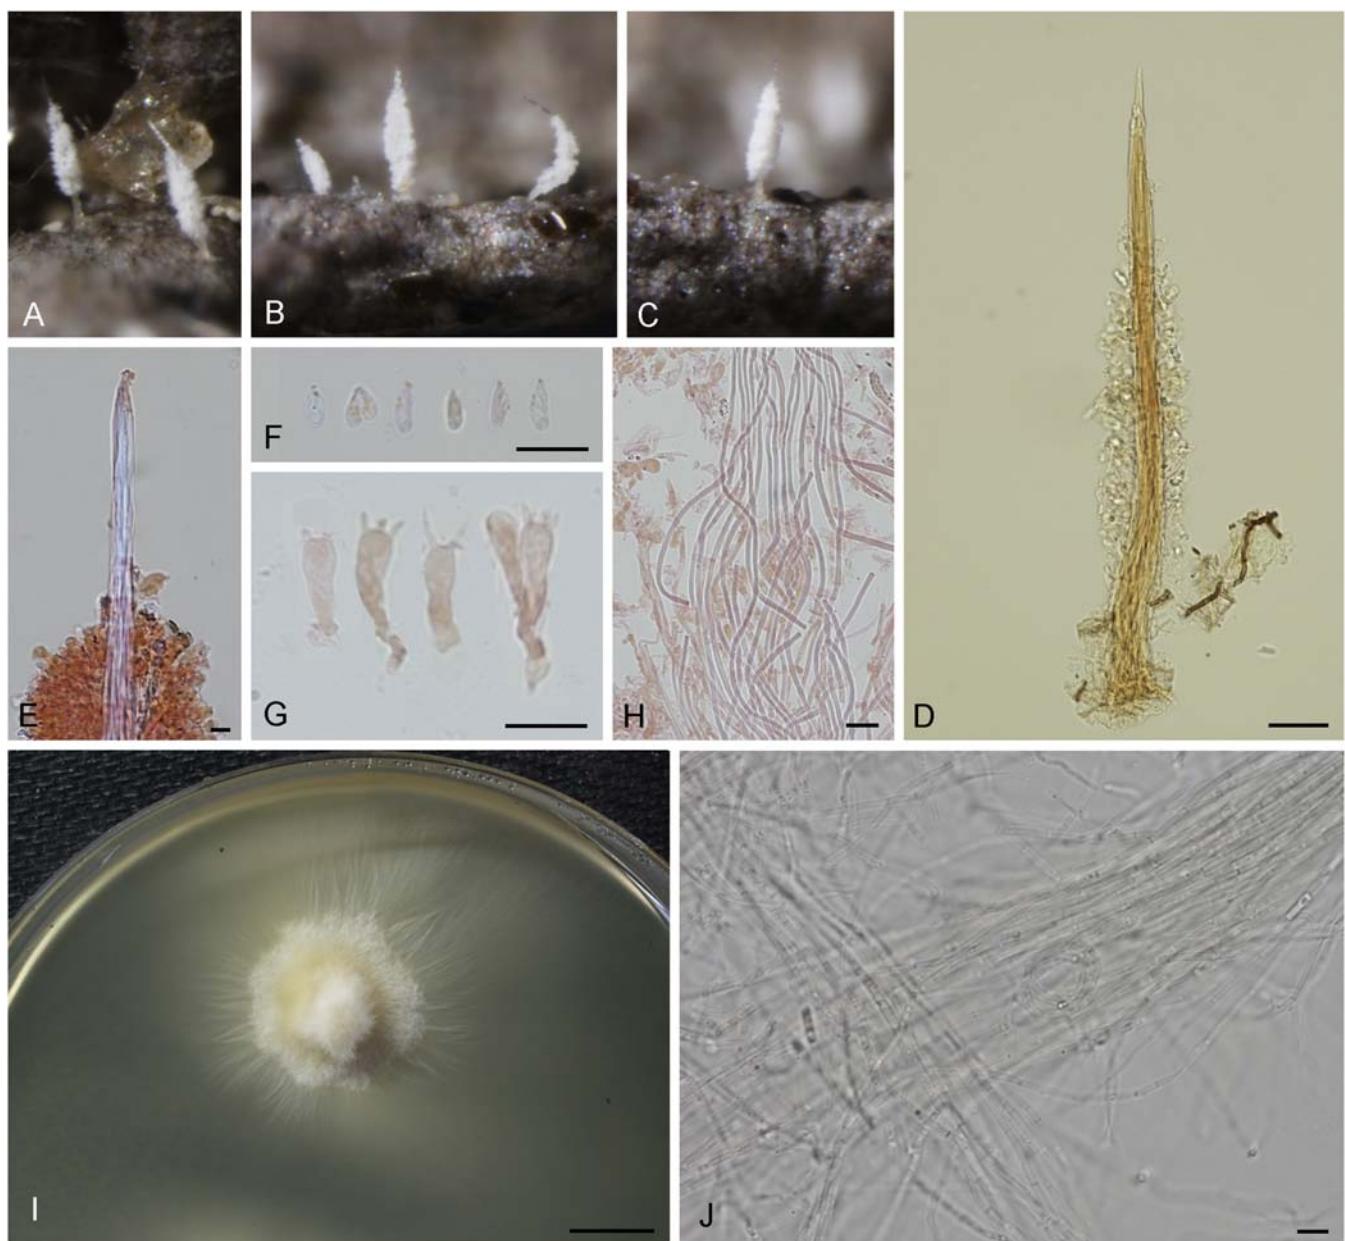

Fig. 6. *Ceratellopsis acuminata* (epitype, Huhtinen 15/07, S). **A–C.** Dried basidiomata. **D.** Basidioma observed using a light microscope. **E.** Close-up of basidioma apex. **F.** Basidiospores. **G.** Basidia. **H.** Medullar hyphae resembling skeletal hyphae. **I.** One-year-old culture in MEA, kept at 5 °C (culture ex-epitype, CBS 146691). **J.** Hyphae from cultured mycelium (culture ex-epitype, CBS 146691). Mounting media were Melzer's reagent (D), Congo Red in ammonia (E–H) and water (I). Scale bars: D = 100 µm, E–H = 10 µm; I = 10mm. Photographs I. Olariaga.

are characteristic for many species of Clavariaceae, including species in *Clavaria*, *Clavulinopsis*, *Ramariopsis* (Olariaga 2009) and *Ceratellopsis* (Fig. 6) and it might be a synapomorphic character of the Clavariinae. The presence of EF-1 α intron 21, absent in the rest of the Agaricales (Matheny et al. 2007) seems so far unique to some Clavariaceae (*Clavaria*, *Clavulinopsis*, *Camarophyllopsis*).

Clavariaceae Chevall., Fl. Gen. Env. Paris 1: 102. 1826. ["Clavariae"; "ordre"; considered family according to Art. 18.2].

Type genus: *Clavaria* Vaill. ex L. : Fr.

Genera: *Camarophyllopsis*, *Ceratellopsis*, *Clavaria*, *Clavulinopsis*, *Hirticlavula*, *Hodophilus*, *Hyphodontiella*, *Mucronella*, *Ramariopsis*.

Ceratellopsis Konrad & Maubl., Icon. Select. Fung. 6: 502. 1937.

Basionym: *Ceratella* Pat., Hymenomyc. Eur.: 137. 1887. [nom. illeg. Art. 53.1, later homonym of *Ceratella* Hook f. 1844].

Presumed saprobic on bark, dead wood or culms. *Basidiomata* gregarious, clavarioid, 0.2–1(–2) mm high, lanceolate with a sterile pointed apex, white. Stipe usually present, short, glabrous or pubescent. Hyphal system monomitic or dimitic. *Basidiospores* without iodine reactions. *Basidia* claviform, short, 10–16 μm long. *Generative hyphae* present in the medulla, unidirectional, cylindrical, septate, thick-walled, 1–2.5 μm broad, sometimes dextrinoid. *Skeletal hyphae* present in the medulla of *C. acuminata* and further undescribed species known by us. *Clamp connections* scattered.

Type: *Ceratellopsis acuminata* (Fuckel) Corner, typ. cons. prop.

Notes: The background of the name *Ceratellopsis* requires, however, further clarification as its type has been a matter of controversy. According to our nomenclatural study, *Ceratellopsis* is a validly published replacement name based on *Ceratella* Pat. and typified by *Pistillaria queletii*. The final epithet *Ceratella* was first employed by Quélét (1886) for an unranked infrageneric name. Later, although Patouillard (1887) referred to *Ceratella* as "CERATELLA (Quél.)" he did not have in mind *Clavaria* [unranked] *Ceratella* as the basionym of a new combination. As explained in the introduction of the Hyménomycètes (Patouillard 1887: VII), authors of generic names were cited between round brackets only when Patouillard's circumscriptions were absolutely different from the original ones. Therefore, we consider *Ceratella* as the name of a new taxon to be cited as "Ceratella Pat." (J. McNeill, pers. comm.) in agreement with Donk (1954) and the ING (Farr & Zijlstra 2020). Nevertheless, *Ceratella* Pat. (1887) is illegitimate as a later homonym of *Ceratella* Hook f. (1846). When *Ceratellopsis* was introduced, Konrad & Maublanc (1937) referred to it as a new name for "Ceratella (Quélét p.p.), Patouillard (1887)" and proposed *Ceratellopsis queletii* as the type, without providing a Latin description. Since *Ceratellopsis* was a replacement name for *Ceratella* Pat., and not a new taxon, *Ceratellopsis* is a validly published generic name even though it lacked a Latin description and was published later than 1935 (Art. 39.1), because such is not required for a replacement name. The type proposed for *Ceratellopsis* by Konrad & Maublanc is also in order, since *Ceratella queletii* was one of the three species listed under *Ceratella* Pat. (1887). A relevant fact that might have affected the typification of *Ceratellopsis* is whether the combination *Ceratella queletii* was validly published when Patouillard

erected *Ceratella* Pat. Patouillard (1887) listed *C. queletii* as "C. Queletii" without explicitly citing its basionym *Pistillaria queletii*. However, we interpret that Patouillard (1887: VI) gave an indirect reference to the basionym that fulfills conditions for valid publication of *C. queletii* (Art. 41.3 and 38.14) by explicitly stating that Tabulae Analytiae Fungorum, the place of publication of *Pistillaria queletii*, basionym *C. queletii*, was one of the main works on which he based his Hyménomycètes (Art. 41.4, Ex. 9), and because Patouillard himself was author of the basionym.

For details on our choice to suggest *C. acuminata* as the conserved type for *Ceratellopsis* see notes under *Pterulicum* and the Discussion.

Ceratellopsis acuminata (Fuckel) Corner, Ann. Bot. Mem. 1: 202. 1950. Fig. 6.

Basionym: *Pistillaria acuminata* Fuckel, Fungi Rhen. Exs. (suppl.) 4: no 1888. 1867.

Synonym: *Ceratella acuminata* (Fuckel) Pat., Essai Tax. Hyménomyc.: 49. 1900.

Basidiomata gregarious, 0.2–0.4 mm high, simple, with a short stipe and a sterile apex. Fertile part cylindrical to oblong, sharply delimited from the stipe and the apex, white, 0.1–0.3 × 0.02–0.04 mm. Stipe short, cylindrical, glabrous, hyaline white, 0.04–0.12 × 0.01–0.02 mm. Apex pointed, acute, hyaline white, 0.04–0.1 mm long. *Basidiospores* ellipsoid to pip-shaped, sometimes in tetrads, hyaline, without iodine reactions, (3–) 4–6 × (1.5–)2–3 μm . *Basidia* claviform, 2–4-spored, 10–16 × 3.5–4.5 μm , clamped. *Generative hyphae* cylindrical, hyaline, thin-walled, clampless, sometimes with scarce septa at the stipe base, 1–2.2 μm broad. *Skeletal hyphae* present in the medulla, cylindrical, refractive, slightly dextrinoid, 1.2–2.8 μm broad. *Colonies* on MEA 30–40 mm diam after 1 yr at 5 °C, superficial, effuse, convex, tomentose, hard-textured, with erect white tufts and strong smell reminiscent of *Scleroderma*. Reverse white. Margin regular and distinct. Vegetative hyphae cylindrical, closely septate, very slightly thick-walled, hyaline, 2.5–4 μm broad, with scattered *clamp connections*. *Asexual morph* not observed in culture.

Typus: **Germany**, Nassau, Johannsberger Schlosswald, ad pini sylv. folia putrida falae humus, Fuckel, Fungi Rhen. Exs. no 1888 (S-F128455 !), **lectotype** of *Pistillaria acuminata* designated here, MycoBank MBT387677. **Isolectotypes**: S-F128454 (!), S-F267533 (!), FH00608504 (!), K(M) 159801, M. **Sweden**, Härjedalen, Tänndalen, Hamrafjället Nature Protection Area, on dead leaves of *Dryas octopetala*, 4 Aug. 2015, S. Huhtinen 15/07 (S, **epitype** of *Pistillaria acuminata* designated here, MycoBank MBT389356). Culture ex-epitype: CBS 146691.

Known distribution: Denmark, Finland, France, Germany, Norway, Spain and Sweden.

Additional materials examined: **Denmark**, Sjælland, Bognæs skov, on leaves of *Leymus* on exposed beach, 26 Oct. 2019, T. Læssøe, DMS-10058526 (C). **Finland**, Perä-Pohjamaa, Rovaniemi, Lovevaara Nature Protection area, brookside herb-rich forest, on leaf litter under alders, 7 Sep. 2012, S. Huhtinen 12/15 (TUR 197690). **France**, Val-d'Oise, Montmorency, ad cortices, 1889, Boudier herbarium (PC). **Norway**, Finnmark, Nord Varanger, Varanger Peninsula, Fosefjellet (ca. 3 km NW of Vadsö), on hare dung (*Lepus timidus*) in moist chamber, 27 Jul. 1966, N. Lundqvist 4965g (UPS F-152857). **Sweden**, Gästrikland, Gävle, Lövudden, *Salix viminalis*, folia dejecta, 25 Jun. 1953, J.A. Nannfeldt 12806 (UPS F-152650, as *Ceratellopsis* sp.); Lycksele Lappmark, Saxnäs, Satsfjället, on dead fern stems, 28 Jul. 2010, K. Hansen, K. Gillen & I. Olariaga, IO.10.01 (S); Västergötland, Häkantorps, Äspås hållplats, on *Quercus robur* leaves, 2 Oct. 1955, S. Kilander (UPS F-152830).

Notes: *Ceratellopsis acuminata* differs from *C. aculeata* in having skeletal hyphae in the basidioma core. Another collection identified as *C. aff. acuminata* by us (ARAN-Fungi 11746) possessed also skeletal hyphae, but had longer and shorter basidiomata and nested in a different clade than the epitype of *C. acuminata* (Fig. 4). This substantiates the idea that an additional species of *Ceratellopsis* exists and when more specimens become available the species limits should be studied further.

Corner (1950: 203) mentioned a type collection of *Pistillaria acuminata* (that Donk had examined in ms) without providing a collection number or a herbarium. Since we believe that Corner's type indication did not fulfil requirements for achieving a valid typification (Art. 7.11), we propose here a lectotypification of *C. acuminata*. The four syntypes examined are very meagre. Therefore, we select as epitype a recent collection from which a living culture and several gene regions have been obtained. We found *C. acuminata* to have a very broad host range and distribution, and feel justified in selecting Swedish material collected on *Dryas* leaves as epitype.

Ceratellopsis aculeata (Pat.) Corner, Ann. Bot. Mem. 1: 200. 1950.

Basionym: *Pistillaria aculeata* Pat., Tab. anal. Fung. 1: 26. 1883.

Synonyms: *Ceratella aculeata* Pat., Essai Tax. Hyménomyc.: 49. 1900.

(?) *Pistillaria mucedinea* Boud., Bull. Soc. bot. Fr. 24: 308. 1878. [1877].

(?) *Ceratellopsis mucedinea* (Boud.) Corner, Ann. Bot. Mem. 1: 204. 1950.

Typus: No type specimen in the Patouillard herbarium (FH, PC).

Lectotype of *Pistillaria aculeata* designated here: Patouillard, Tab. Anal. Fung. 1: fig. 58. 1883. MycoBank MBT387467.

Specimens examined: Denmark, Lolland, Maribo Søndersø, on stems of *Cladum mariscus*, 9 Oct. 2000, T. Læssøe, DMS-376001 (C). Spain, Aragón, Huesca, on *Pinus* bark, 26 Feb. 2017, R. Blasco, ARAN-Fungi 13729; Basque Country, Gipuzkoa, Larraul, Usarrobi erreka, 9 Jun. 2012, I. Olariaga, ARAN-Fungi A3064020. Sweden, Öland, Norra Mossen, on damp, dead parts of *Cladum*, 2 Jul. 1988, S. Elborne, C-F-94548. UK, England, Wicken fen, on *Cladum mariscus*, 12 Aug. 1926, E.J.H. Corner (PC).

Notes: Medulla hyphae in *Ceratellopsis aculeata* are thick-walled and have scarce septa, as noted by Corner (1950). Originally described as occurring on fallen leaves, *C. aculeata* has been considered to typically occur on dead leaves of *Cladum mariscus* (Corner 1950, Hansen & Knudsen 1997). Specimens collected on bark or dead wood share a similar basidioma configuration, hyphae and spores.

As Corner (1950) suggested *Pistillaria mucedinea* is very close to *C. aculeata*. The small size of basidiomata (0.5–0.75 mm) and the 4-spored basidia described in the protologue support this view. Furthermore, our study of an authentic specimen kept at PC, collected on bark as described in the protologue, has scarcely septate thick-walled hyphae as observed in the material on *Cladum mariscus*. We agree with Corner (1950) and even suggest *P. mucedinea* might be conspecific with *C. aculeata* and list it as a possible earlier synonym. However, a better insight on species limits in *Ceratellopsis* needs to be acquired to further test this.

Names formerly placed in *Ceratellopsis* and imperfectly known, excluded here or illegitimate

Ceratellopsis aciculata (Durieu & Lév. ex Sacc.) Corner, Ann. Bot. Mem. 1: 200. 1950.

Basionym: *Pistillaria aciculata* Durieu & Lév. ex Sacc., Syll. Fung. 6: 759. 1887.

Typus: **Lectotype** designated here: Bory de Saint-Vincent & Durieu de Maisonneuve, Expl. Sci. Algérie 1(5): tab. 32, fig. 4. 1846. MycoBank MBT387461.

Notes: *Pistillaria aciculata*, published as a *nomen nudum* (Bory de Saint-Vincent & Durieu de Maisonneuve 1846), was invalid until Saccardo provided a description. The illustration provided by Bory de Saint-Vincent & Durieu de Maisonneuve (1846) shows brown, pointed acute structures that do not look like a fertile fungus but rather incipient basidiomata of a marasmoid fungus. This figure is, to our knowledge, the only original element and it is accordingly proposed as lectotype.

Ceratellopsis asphodeli (Pat.) Corner, Ann. Bot. Mem. 1: 203. 1950.

Basionym: *Ceratella microscopica* var. *asphodeli* Pat., Cat. Pl. Cell. Tunisie: 66. 1897.

Typus: No type specimen in the Patouillard herbarium (FH, PC). No original illustration.

Notes: The 2-spored basidia and the presence of cystidia described in Patouillard (1897) suggest that *C. asphodeli* is a synonym of *Pterulicum gracile*. The pink tones can be present in *P. gracile* (Olariaga 2009).

Ceratellopsis biformis Khurana in Berthier, Bull. Soc. Linn. Lyon. 45: 190. 1976 [*nom. illeg.*, Art. 39, 40].

Notes: The description provided by Berthier (1976) based on Corner's notes of a fungus on *Quercus* leaves from India suggests that *C. biformis* may belong to *Ceratellopsis* as conceived here due to its narrow, 1.5–2 µm broad, medulla hyphae. Nevertheless, *C. biformis* was never validly published since neither a Latin diagnosis nor a type specimen were provided for it.

Ceratellopsis brondaei (Quél.) Corner, Ann. Bot. Mem. 1: 203. 1950.

Basionym: *Clavaria brondaei* Quél., Revue mycol. (Toulouse) 14(54): 65. 1892.

Typus: No type specimen in PC and TL.

Notes: Quélét (1892) described *C. brondaei* apparently based only on the Brondeau plate no. 165 ("Alb. 165"). The illustration provided in the protologue (plate 126, fig. 3), probably a reproduction of plate no. 165, shows a small white clavarioid fungus, said to grow in forest on soil among tiny mosses. The description, except the ecology, tallies with a species of *Ceratellopsis* as treated here, but in the absence of microscopic information and a type specimen, a reliable interpretation cannot be provided, as Corner (1950) stated.

Ceratellopsis caespitulosa (Sacc.) Corner, Ann. Bot. Mem. 1: 203. 1950.

Basionym: *Pistillaria caespitulosa* Sacc., Atti del Congr. bot. di Palermo. 1902.

Typus: [from Saccardo, Syll. Fung. 17: 202. 1905]: France, Côte d'Or, *in cortice emortuo Lonicerae periclymeni* [*Lonicera periclymenum*], PAD.

Notes: The denticulate "basidia" and the 1-septate biguttulate spores suggest that *C. caespitulosa* is an asexual morph fungus,

probably conspecific with *Isaria friesii* (Leotiomycetes, Ascomycota).

Ceratellopsis carestiae (Ces.) Corner, Ann. Bot. Mem. 1: 203. 1950.

Basionym: *Pistillaria carestiae* Ces. in Bres. & Sacc., Malpighia 11: 255. 1897.

Typus: Italy, Piemonte, Alagna Valsesia, sur ramis secchi *Syringa vulgaris*, 13 Oct. 1857, Ab. Carestia no 27 (S-F15983 !, ex Bresadola herbarium; **lectotype** designated here, MycoBank MBT387464).

Notes: The material constitutes an asexual fungal state growing on bark, very probably conspecific with *Isaria friesii*. The spore content, described as divided in two ("plasma bipartito") is due, in fact, to the 1-septate spores, as in *C. caespitulosa* (see above).

Ceratellopsis corneri Berthier, Bull. mens. Soc. linn. Lyon 43: 188. 1974.

Typus: France, Lyon, Soucieu-en-Jarrest, sur l'écorce pourrisante d'un arbre abattu (Gymnosperme?), Bussy, 11 Apr. 1970 (**holotype** G).

Notes: Due to the 4–6 µm broad medulla hyphae and the amyloid spores, *C. corneri* does not conform to *Ceratellopsis*. We consider it that *C. corneri* should be examined and compared to *Mucronella* instead.

Ceratellopsis dryopteridis (S. Imai) Corner, Ann. Bot. Mem. 1: 203. 1950.

Basionym: *Pistillaria dryopteridis* S. Imai, Sapporo Trans. Sapporo nat. Hist. Soc. 13(4): 386. 1934.

Typus: Japan, Ishikari province, Nov. probably at SAPA.

Notes: The filiform 1–5 mm long basidiomata and 9–12.5 µm long spores suggest that *C. dryopteridis* should not be excluded from *Ceratellopsis*. The spores of *C. dryopteridis* are asperulate and therefore a relationship with *Pterula* is suggested here, but the type specimen, if it exists, should be examined to confirm this.

Ceratellopsis equiseticola (Boud.) Corner, Ann. Bot. Mem. 1: 204. 1950.

Basionym: *Pistillaria equiseticola* Boud., Bull. Trimestr. Soc. Mycol. France 33(1): 13. 1917.

Typus: France, Saône-et-Loire, Clovey (?), ad caules Equiseti limosi [Equisetum fluviatile], May 1915, Boudier herbarium (PC !, as *P. equisetina*; **lectotype** designated here, MycoBank MBT387465).

Notes: As earlier suggested by Berthier (1976), we conclude that *C. equiseticola* is a synonym of *P. gracile* after examining type material.

Ceratellopsis graminicola (Bourd. & Galzin) Corner, Ann. Bot. Mem. 1: 204. 1950.

Basionym: *Pistillaria graminicola* Bourd. & Galzin, Hymenomyc. France: 139. 1928.

Typus: No type specimen in the Bourdot & Galzin herbarium (PC). No original illustration.

Notes: The 12–18 µm long, 2–4-spored basidia, small spores (6–7 × 4 µm) and narrow, 1.5–2.5 µm broad hyphae given in the original description would indicate that *C. graminicola* should be

retained in *Ceratellopsis*, rather than being conspecific with *P. gracile*. It might be conspecific with *C. aculeata* or *C. acuminata*, but details on its hyphal structure are necessary to provide a solid interpretation.

Ceratellopsis helenae (Pat.) Corner, Ann. Bot. Mem. 1: 204. 1950.

Basionym: *Pistillaria helenae* Pat., Tab. Anal. Fung. 1: 26. 1883.

Typus: No type specimen in the Patouillard herbarium (FH, PC).

Lectotype designated here: Patouillard, Tab. Anal. Fung. 1: fig. no. 57. 1883. MycoBank MBT387466.

Notes: The forked or sparsely branched basidiomata, with a tendency to be caespitose, and the presence of a distinct stipe, suggest that *C. helenae* is a synonym of *Typhula crassipes*. Although basidiomata of *T. crassipes* are usually simple, we have observed branched basidiomata as those depicted in the lectotype figure. Also, 2-spored basidia and incarnate tones are sometimes present in *T. crassipes* (Olariaga 2009). Corner (1950) compared *C. helenae* to *P. gracile*, but the latter lacks a stipe.

Ceratellopsis kubickae Pilát, Česká Mykol. 12(4): 217. 1958.

Typus: Czech Republic, prope Třeboň, ad folium putridum *Salicis aurita* [Salix aurita], 15 May 1958, Kubíčka (PRM 655767).

Notes: Pilát (1958) described *C. kubickae* as monomitic and compared it with *P. gracile*. Berthier (1976) investigated the type material and proposed that *C. kubickae* is a synonym of *P. gracile*, and that Pilát (1958) overlooked skeletal hyphae. In our opinion, the 2-spored basidia and the absence of a stipe in *C. kubickae* support it is a synonym of *P. gracile*.

Ceratellopsis mucosa (Berk. & M.A. Curtis) Corner, Ann. Bot. Mem. 1: 205. 1950.

Basionym: *Typhula mucosa* Berk. & M.A. Curtis, Grevillea 2(14): 18. 1873.

Typus: USA, South Carolina, Society Hill, in herb. mort., 1852, Carolina inf. No. 3832 (**syntypes** FH 596847, K).

Notes: The original description is very meagre, and we are unable to propose a reliable interpretation without checking type material. Corner (1950) failed also to provide a specific interpretation and stated that *C. mucosa* "may be *Ceratellopsis*, *Pterula*, or a rudimentary *Pistillaria*".

Ceratellopsis rickii (Oudem.) Corner, Ann. Bot. Mem. 1: 205. 1950.

Basionym: *Mucronella rickii* Oudem., Ned. kruidk. Archf., 3 sér. 2(3): 667. 1902.

Synonym: *Cazonaria rickii* (Oudem.) Donk, Meded. Bot. Mus. Herb. Rijks Univ. Utrecht 9: 99. 1933.

Typus: The Netherlands, Limburg, Valkenburg, in caulis herbarum praesertim *Asparagi* off. [*Asparagus officinalis*], May 1901, J. Rick, herb. Oudemans (**holotype** L). **Isotype:** Bourdot & Galzin herbarium (PC !).

Notes: Jülich (1980) reduced *C. rickii* to a synonym of *P. gracile* after examining type material. We confirm this synonymy based on characters seen on the cited isotype.

Ceratellopsis rosella (Fr.) Corner, Ann. Bot. Mem. 1: 206. 1950.

Basionym: *Pistillaria rosella* Fr., Epicr. syst. mycol.: 587. 1838. [1836–1838].

Typus: No type specimen in the Fries herbarium (UPS). No original illustration.

Notes: The pink colour described in the protologue is almost unique to *T. micans* among typhuloid fungi and we thus agree with Berthier (1976) in considering *C. rosella* a synonym of *T. micans*.

Ceratellopsis sydowii (Bres.) Corner, Ann. Bot. Mem. 1: 206. 1950.

Basionym: *Clavaria sydowii* Bres. in Sydow, Hedwigia 35: (61). 1896.

Typus: **Germany**, Saxony, Muskau, O.L. Bergpark, *ad ramulos Robiniae pseudoacaciae*, Jul. 1895, P. Sydow, Mycot. March. 4405 (**syntypes** CHRB, MIN, NCU).

Notes: The caespitose growth habit on dicot. bark, pale pink colour ("dilute carnei"), long basidia (24–26 µm) and spore size mentioned in the protologue (9–10 × 5–5.5 µm) suggest that *C. sydowii* is a synonym of *T. crassipes*.

Ceratellopsis terrigena Berthier, Bull. Soc. Linn. Lyon 43(6): 188. 1974.

Typus: **France**, Rhône, Lyon, Izéron, sur terre nue d'un talus en sous-bois, 7 Aug. 1966, CL. 29 (**holotype** G).

Notes: Due to its 1.5–3.5 µm broad medulla hyphae *C. terrigena* does not conform to *Ceratellopsis* as here defined. Also, the presence of striking protruding cystidia is unknown for any other species of *Ceratellopsis*. The shape of cystidia and the absence of clamp connections may suggest *C. terrigena* to be allied with *Alloclavaria* in the *Rickenella* clade (*Hymenochaetales*).

Ceratellopsis thujicola (Kauffman) Corner, Ann. Bot. Mem. 1: 206. 1950.

Basionym: *Pistillaria thujicola* Kauffman, Pap. Mich. Acad. Sci. 9: 207. 1929 [1928].

Typus: **USA**, Michigan, Alger: Rock River, on inner side of *Thuja occidentalis* on loose bark, 8 Sep. 1927, C.H. Kauffman (**holotype** MICH11745).

Notes: The up to 10 mm long branched basidiomata do not conform clearly to *Ceratellopsis* as here defined, and we thus exclude it from this genus. The type material should be examined to propose a more precise interpretation.

Ceratellopsis tremula (Sacc.) Corner, Ann. Bot. Mem. 1: 207. 1950.

Basionym: *Pistillaria ferryi* subsp. *tremula* Sacc. in Sacc. & D. Sacc., Syll. Fung. 17: 202. 1905.

Typus: **Italy**, Padova, horto botanico Patavino, *ad fructum putrem Trichosanthis anguineae* [*Trichosanthes sanguinea*], ubi *Botrytis vulgaris* et *Acremoniella atra*, Feb. 1904 (**syntype** PAD).

Notes: The 3–5 mm long basidiomata, 2-spored basidia and 8–11 µm long spores conform to *P. gracile*, but the type specimen needs to be examined to confirm the synonymy. Although this synonymy is listed in Index Fungorum (2019, viewed on 11 June 2019), it has not been otherwise proposed to our knowledge.

Pleurotineae Aime, Dentinger & Gaya, Biol. J. Linn. Soc.: 10.1111/bij.12553, 16. 2015.

Phyllotopsidaceae Locquin ex Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **fam. nov.** MycoBank MB831374.

Basidiomata pleurotoid or clavarioid and sometimes arising from a sclerotium. Spore deposit white to salmon pink. **Hyphal system** monomitic. **Basidiospores** hyaline, cylindrical, allantoid or sub-globose, smooth, without iodine reactions. **Cheilocystidia** sometimes present in pleurotoid genera. **Clamp connections** present, rarely absent. Saprotrrophic.

Type genus: *Phyllotopsis* E.-J. Gilbert & Donk ex Singer

Representative genera: *Macrotyphula*, *Phyllotopsis* and *Pleurocybella*.

Notes: *Macrotyphula*, *Phyllotopsis* and *Pleurocybella* were suggested to be closely related by Dentinger & McLaughlin (2006) and our analyses confirm that they form a monophyletic group. Despite this, no obvious synapomorphic characters support the relationship between the typhuloid *Macrotyphula* and the pleurotoid *Phyllotopsis* and *Pleurocybella* (Moncalvo et al. 2002). All three genera contain saprotrophic species, mostly lignicolous, and possess clamp connections.

Macrotyphula R.H. Petersen, Mycologia 64: 140. 1972. *nom. cons. prop.*

Type: *Clavaria fistulosa* Holmsk.: Fr. (synonym: *Macrotyphula fistulosa* (Holmsk. : Fr.) R.H. Petersen).

Synonyms: *Sclerotium* Tode, Fung. mecklenb. sel. 1: 2. 1790 : Fr., Syst. Mycol. 2: 246. 1822. *nom. rej. prop.* **Type:** *Sclerotium complanatum* Tode : Fr. (synonym: *Typhula phacorrhiza* (Reichard : Fr.) Fr.).

Claviariadelphus subgen. *Typhulopsis* Corner, Ann. Bot. Mem. 1: 692. 1950 [*nom. inval.* Art. 40.3, two species were indicated as type].

Macrotyphula megasperma (Berthier) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **comb. nov.** MycoBank MB831762.

Basionym: *Typhula megasperma* Berthier, Bull. Soc. Linn. Lyon 45: 78. 1976.

Macrotyphula phacorrhiza (Reichard : Fr.) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **comb. nov.** MycoBank MB831761.

Basionym: *Clavaria phacorrhiza* Reichard, Schriften Berlin. Ges. Naturf. Freunde 1: 315. 1780. ["*Clavaria phacorrhiza*"] : Fr., Syst. mycol. 1: 495. 1821.

Synonyms: *Sclerotium complanatum* Tode, Fung. Mecklenb. Sel. 1: 5. 1790.

Typhula phacorrhiza (Reichard : Fr.) Fr., Observ. Mycol. 2: 298. 1818. ["*Typhla*"].

Phacorrhiza filiformis Grev., Scott. Crypt. Fl. 2: 93. 1824 [*nom. nov.* based on *Clavaria phacorrhiza* Reichard]

Typhula phacorrhiza var. *complanata* (Tode) Sacc., Syll. Fung. 6: 745. 1888. [* *complanata*].

Typus: **Lectotype** of *Clavaria phacorrhiza*: Sowerby, Col. Fig. Eng. Fung. 2: tab. 233. 1798, as "phacorrhiza", designated by Olariaga & Salcedo (2013: 42). **Lectotype** of *Sclerotium complanatum* designated here: Tode, Fung. Mecklenb. 1: tab. 1, fig.

9. 1790. MycoBank MBT387906. **Germany**, Bayern, Oberbayern, Landkreis Miesbach, valley Kleinthal near Miesbach, in a garden under *Ribes nigrum* and *Ribes rubrum*, on wet litter of various plants, mostly of *Ribes*, 2 Mar. 1992, F. Brand, *Microf. Exs. No. 49* (UPS, as *Sclerotium complanatum*; **epitype** of *Sclerotium complanatum* designated here; **Isoeotypes** in B, BPI, CANB, DAOM, FH, GZU, H, HAL, HMAS, LE, M, MA, NMW, PRM, TNS). MycoBank MBT389352.

Specimens examined: **Austria**, prope Tullnerbach, *in silva "Wiener Wald, ad petiolas Fraxini excelsioris* L., C. de Keissler, Krypt. Exs. 1840 (PC, as *Sclerotium complanatum*). **France**, Pyrénées atlantiques, Borce, Le Gave d'Aspe, on the ground, among *Rubus idaeus* and *Myrrhis odorata*, 12 Oct. 2014, J.C. Zamora & I. Olariaga, IO.14.200 (S); without locality, dans les bois, parmi les tas de feuilles pourries, Desmazières, *Pl. Crypt. N. France, Ed. 1536* (PC, as *Sclerotium complanatum*). **Spain**, Navarre, Basaburua, Oroketa, Loiandi, on the ground among needles under *Picea abies*, 27 Oct. 2017, I. Olariaga, J. Martín, J. Teres & J.M. Riezu, ARAN-Fungi 7446. **Sweden**, Skåne, Eriksdal, Vitabäckskällan Nature Reserve, on wet ground under *Alnus*, 3 Oct. 2014, N.-O. Nilsson & I. Olariaga, IO.14.167 (S); Uppland, Uppsala-Näs, Vreta, in a compost-heap, 18 Oct. 1975, L. Jonsell, *Fung. Exs. Suec.* 3249 (PC).

Typhula phacorrhiza var. *heterogenea* Berthier, Bull. Soc. Linn. Lyon 45: 197. 1976.

Typus: **USA**, Idaho, Priest River, *inter foliis Alni tenuifoliae [Alnus tenuifolia]*, 19 Oct. 1920, Weir 16943 (CGE, **holotype**).

Notes: This taxon, due to its gelatinised sclerotia with normal epidermoid layer (Berthier 1976), may also belong to *Macrotyphula*. The type material appears to have lost its basidiomata (Berthier 1976) and we find it premature to place it in *Macrotyphula*.

Pterulaceae Corner, Beih. Nova Hedwigia 33: 194. 1970.

Type genus: *Pterula* Fr. : Fr.

Representative genera: *Allantula*, *Coronicium*, *Dimorphocystis*, *Merulicum*, *Pterula*, *Pterulicum*.

Pterula Fr. : Fr., Syst. Orb. Veg. 1: 90. 1825.

Basionym: *Anthina* [unranked] *Pterula* (Fr.) Fr., Syst. Mycol. 3: 285. 1832; Fr., idem.

Type: *Pterula plumosa* (Schwein. : Fr.) Fr., selected by Donk (1954: 472).

Pterulicum Corner, Ann. Bot. Mem. 1: 699. 1950. *Type:* *Pterulicum xylogenum* Corner

Synonyms: *Ceratellopsis* Konrad & Maubl., Icon. Select. Fung. 6: 502. 1937. *Type:* *Ceratellopsis queletii* (Pat.) Konrad & Maubl. (synonym *Pterulicum gracile* (Desm. & Berk.) Leal-Dutra, Dentinger, G.W. Griff.), typ. rej. prop.

Deflexula Corner, Ann. Bot. Mem. 1: 695. 1950. *Type:* *Deflexula fascicularis* (Bres. & Pat.) Corner

Notes: Since the type of *Ceratellopsis* nests in *Pterulicum* (Fig. 3), the correct name for *Pterulicum* is *Ceratellopsis* under the current nomenclatural rules. A proposal to preserve the current usage of *Ceratellopsis* and *Pterulicum* is, however, in preparation (see Discussion).

Pterulicum gracile (Desm. & Berk.) Leal-Dutra, Dentinger & G.W. Griff. in Leal-Dutra, Griffith, Neves, McLaughlin, McLaughlin, Clasen & Dentinger, IMA Fungus 11(2): 15. 2020.

Basionym: *Typhula gracilis* Desm. & Berk. in Berk, Ann. Nat. Hist., Ser. 1, 1: 202. 1838. ["*Typhula?* *gracilis*"].

Synonyms: *Clavaria gracilis* (Desm. & Berk.) P. Karst., Bidrag Kändedom Finlands Natur Folk 37: 181. 1882. ["*Cl?* *gracilis*"; nom. illeg., later homonym of *Clavaria gracilis* Bolton and C. *gracilis* Pers. : Fr., Art. 53].

Pistillaria acicula Bourdot & Galzin, Hymenomyc. France: 139. 1928. ["1927"].

Pistillaria juncicola Bourdot & Galzin, Hymenomyc. France: 138. 1928. ["1927"].

Typus: **UK**, without locality, ex Desmazières herbarium (PC, not found, **lectotype** designated in Corner (1950: 515) by type indication). **Isolectotype:** UPS (!).

Additional materials examined: **France**, Charente-Maritime, Saintonge, maïs [*Zea mays*], P. Brunaud, Quélét herbarium (PC !, **lectotype** of *Typhula brunaudii* designated here, MycoBank MBT387470); Côte-d'Or, Noidan, sur tiges séches de *Coix lacryma-jobi*, Fautrey, Jun. 1892, Fungi Sel. Gall. Exs. no 6203 (PC !, **lectotype** of *Ceratella ferryi* designated here, **isolectotypes**: BR, ILL, MIN, UPS, MycoBank MBT387491); Rhône, Saint Priest, les Bouys, vers le Souey, "sur joncs [*Juncus*] purrisants", H. Bourdot, 27 Sep. 1918, Bourdot 24978 (PC !, **lectotype** of *Pistillaria juncicola* designated here, MycoBank MBT387471); Seine-Maritime, environs de Rouen, sur jonc [*Juncus*], Apr. 1880, A. Le Breton, Quélét herbarium (PC !, **lectotype** of *Clavaria aculina* designated here, MycoBank MBT387469); Seine-Maritime, Rouen, sur les joncs [*Juncus*] morts et humides, forêt de Noumare (?), A. Malbranche, (PC !, **lectotype** of *Clavaria microscopica* designated here, MycoBank MBT387468). **Germany**, Brandenburg, Finkenkrug pr. Nauen, *ad folia culmosque graminum*, *Calamagrostis epigei* [*Calamagrostis epigejos*], Agrostidis albae [*Agrostis alba*] etc., Mycot. Mar. no. 4803 (S F15411 !, **lectotype** of *Pistillaria attenuata* designated here, **isolectotypes**: FH00608505 (!), MICH, MycoBank MBT387678). **Lectotype** of *Pistillaria queletii* designated here: Patouillard, Tab. Anal. Fung. 1: fig. 45. 1883. MycoBank MBT389354. **Sweden**, Skåne, Kristianstads kommun, Balsberget Nature Reserve, on dead standing *Juncus effusus* stalks, at damp place, N.-O.

Nilsson & I. Olariaga, 2 Oct. 2014, IO.14.142 (S, **epitype** of *Pistillaria queletii* designated here, MycoBank MBT387907).

Notes: In order to contribute to nomenclatural stability, an epitype specimen that represents *P. gracile* is proposed above for *Pistillaria queletii* (see Discussion). No good and recent specimen of *P. gracile* from France was available to epitypify *C. queletii*. Nevertheless, European material of *P. gracile* is morphologically and genetically homogeneous — ITS and 28S sequences available from France, Germany and Canada (CBS 309.79, CBS 325.58, CBS 554.85) are identical or nearly so to the sequences obtained by us from Sweden — and therefore we epitypify *C. queletii* using a specimen of *P. gracile* collected in Sweden.

Sarcomyxaceae Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **fam. nov.** MycoBank MB831375.

Basidiomata pleurotoid, with gelatinous context in pileus. Gills slightly decurrent, crowded, forking. Stem lateral, floccose. Spore deposit white. *Basidiospores* cylindrical to allantoid, amyloid. *Basidia* claviform, (2–)4-spored, clamped. *Cheilo-* and *pleurocystidia* fusiform to clavate, more or less thick-walled. *Pileipellis* and part of trama gelatinised. *Clamp connections* present. Saprotrrophic, lignicolous.

Type genus: *Sarcomyxa* P. Karst.

Only genus: *Sarcomyxa*.

Notes: The family contains a single genus with unique pleurotoid basidiomata, gelatinised pileipellis, fusiform to clavate cheilo- and pleurocystidia and amyloid spores (Knudsen & Vesterholt 2012). Due to its isolated position within the *Pleurotineae* (Figs 2, 3), a new family is coined to accommodate *Sarcomyxa*.

Typhulaceae Jülich, Biblioth. Mycol. 85: 393. 1982 ["1981"]

Type genus: *Typhula* (Pers. : Fr.) Fr.

Typhula (Pers.) Fr., Obs. Mycol. 2: 296. 1818: Fr., Syst. Mycol. 1: 494. 1821, *nom. cons. prop.*

Basionym: *Clavaria* [unranked] *Typhula* Pers. : Fr., Syn. Meth. Fung. 1: XVIII. 1801

Type: *Typhula incarnata* Lasch, *typ. cons. prop.*

Synonyms: *Pistillaria* Fr., Syst. Mycol. 1: 496. 1821: Fr., *idem*.

Type: *Pistillaria micans* (Pers. : Fr.) Fr., selected by Clem. & Shear, Gen. Fungi: 345. 1931 (synonym *Typhula micans* (Pers. : Fr.) Fr.).

Cnazonaria Corda in J. Sturm, Deutschl. Fl., Pilze 2: 55. 1829.

Type: *Clavaria setipes* Grev. (synonym *Typhula gyrans* (Batsch : Fr.) Fr.).

Scleromitra Corda in Sturm, Deutschl. Fl., 3 Abt., 2: 59. 1829.

Type: *Scleromitra coccinea* Corda (synonym *T. micans* (Pers. : Fr.) Fr.).

Phacorrhiza Pers., Mycol. Eur. 1: 192. 1822 : Fr., Syst. Mycol. 3 (Index): 140. 1832. Type: *Phacorrhiza sclerotiooides* (Pers. : Fr.) Pers. (synonym *Typhula sclerotiooides* (Pers. : Fr.) Fr.).

Pistillina Quél., Compt. Rend. Assoc. Franc. Avancem. Sci. 9: 671. 1881. ["1880"]. Type: *Pistillina hyalina* Quél. (synonym *Typhula subhyalina* Courtec.).

Sphaerula Pat., Tab. Anal. Fung. 1: 27. 1883. Type: *Sphaerula capitata* Pat. (synonym *Typhula capitata* (Pat.) Berthier)

Gliocoryne Maire, Bull. Soc. Bot. France 55: 121. 1909. Type: *Clavaria uncialis* Grev. (synonym *Typhula uncialis* (Grev.) Berthier)

Dacryopsella Höhn., Anz. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. 1, 124: 50. 1915. Type: *Dacryopsis typhae* Höhn. (synonym *T. subhyalina* Courtec.).

Tygervalleyomyces Crous, Persoonia 39: 387. 2017. Type: *Tygervalleyomyces podocarpi* Crous.

New combinations in *Typhula*

Typhula podocarpi (Crous) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen **comb. nov.** MycoBank MB831376.

Basionym: *Tygervalleyomyce podocarpi* Crous, Persoonia 39: 387. 2017.

Notes: The asexual and only known morph of *T. podocarpi*, described from South Africa, conforms to that of *Typhula crassipes*, described from Germany (Berthier 1976). The ITS region of *T. podocarpi* differs in 23 positions from that of European specimens of *T. crassipes* and we thus consider *T. podocarpi* to be a separate species.

Rickenellaceae Vizzini, Micol. Veg. Medit. 25(2): 144. 2010.

Type genus: *Rickenella* Raithelh.

Representative genera: *Alloclavaria*, *Atheloderma*, *Blasiphalia*, *Bryopistillaria*, *Cantharellopsis*, *Contumyces*, *Cotylidia*, *Ginnisia*, *Globulicium*, *Gyroflexus*, *Loreleia*, *Muscinupta*, *Odonticium*, *Peniophorella*, *Resinicium*, *Rickenella*, *Sidera*, *Skvortzovia* and *Tsugacorticium*. Excluded from *Rickenellaceae*: *Repetobasidium*.

Notes: Genera in the *Rickenella* clade have been assigned to the *Repetobasidiaceae* (Zhang et al. 2018), often left without family assignation (Kirk et al. 2008, Knudsen & Vesterholt 2012), or included in the family *Rickenellaceae* (Begerow et al. 2018). Our analyses suggest that *Repetobasidium* does not nest in the *Rickenella* clade, and *Repetobasidiaceae* cannot therefore be used to accommodate genera in the *Rickenella* clade. Consequently, we adopt *Rickenellaceae* as the correct placement for genera in this clade, excluding *Repetobasidium* so that *Rickenellaceae* is not superfluous as when erected by Vizzini (2010).

Bryopistillaria Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **gen. nov.** MycoBank MB831377.

Etymology: From ancient Greek ("bryon", moss), referring to its habitat on bryophytes, and from *Pistillaria*, referring to its similarity with several species placed in that genus.

Biotrophic on mosses, and maybe in addition saprobic on dead leaves and culms. *Basidiomata* gregarious or fasciculate (2–5 basidiomata), simple clavarioid, 0.6–1 mm high, initially lanceolate and with sterile apex, then cylindrical or claviform, with rounded fertile apex, white. Stipe short or absent, cylindrical, glabrous or pubescent. Hyphal system monomitic. *Basidiospores* without iodine reactions, smooth. *Basidia* claviform, 16–21 µm long. *Medulla* hyphae parallel-arranged, cylindrical, septate, thin-walled, 3–4 µm broad, without iodine reactions. *Clamp connections* absent.

Type: *Bryopistillaria sagittiformis* (Pat.) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen

Bryopistillaria sagittiformis (Pat.) Olariaga, Huhtinen, Læssøe, J.H. Petersen & K. Hansen, **comb. nov.** Fig. 7. MycoBank MB831378.

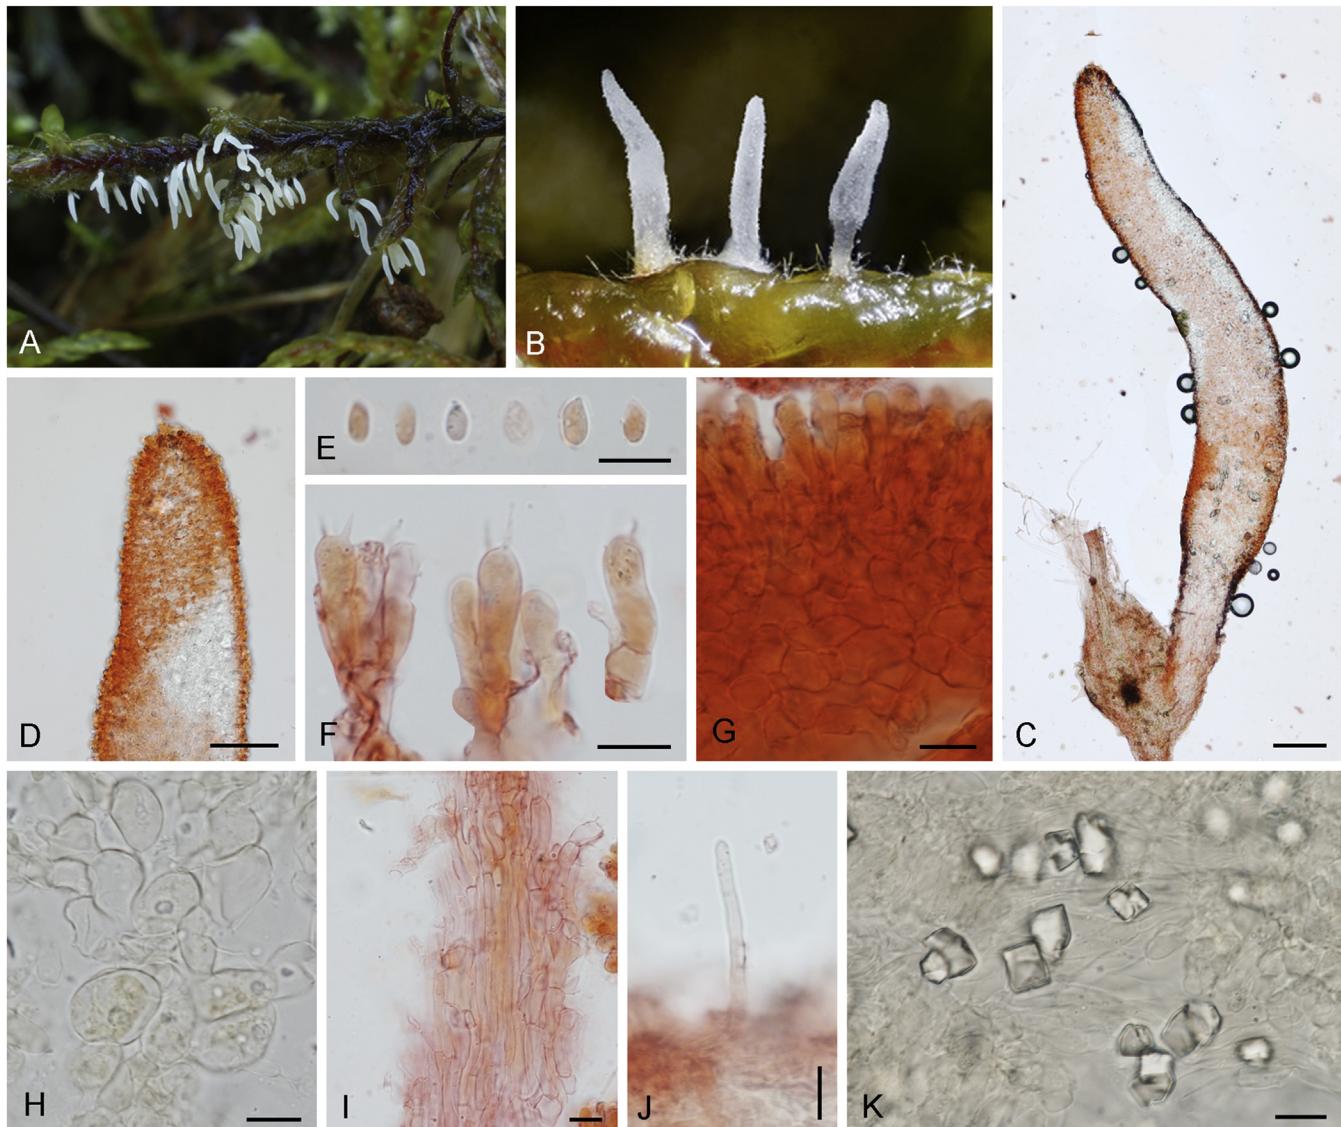

Fig. 7. *Bryopistillaria sagittiformis* (epitype, IO.15.85, S). **A.** Basidioma growth habit. **B.** Close-up of basidiomata. **C.** Basidioma observed using a light microscope. **D.** Close-up of basidioma apex. **E.** Basidiospores. **F.** Basidia. **G.** Hymenium section showing a subhymenium with globose to subglobose cells. **H.** Subhymenium cells. **I.** Thin-walled septate hyphae. **J.** Caulinar hair. **K.** Crystals. Mounting media were Melzer's reagent (H, K) and Congo Red in ammonia (C–G, I–J). Scale bars: C = 100 µm; D = 50 µm; E–K = 10 µm. Photographs I. Olariaga, except B–C by J.H. Petersen.

Basionym: *Pistillaria sagittiformis* Pat., Tab. Anal. Fung. 1: 26. 1883 ["sagittæformis"]

Synonym: *Ceratellopsis sagittiformis* (Pat.) Corner, Ann. Bot. Mem. 1: 206. 1950. ["sagittæformis"].

Basidiomata gregarious or caespitose in groups of 2–5 basidiomata, 0.7–1.2 mm high, simple, with a short stipe. Fertile part narrowly claviform, sharply delimited from the stipe, white, 0.6–0.1 × 0.15–0.3 mm. Stipe short, cylindrical, glabrous or with sparse hairs, hyaline white, 0.1–0.4 × 0.1–0.2 mm. Subiculum spreading out on the substratum among basidiomata. Apex pointed and sterile in very young basidiomata, hyaline white, then obtuse and fertile. **Basidiospores** ellipsoid, sometimes in tetrads, hyaline, smooth, without iodine reactions, 4.5–6.5(–8) × 3–3.5(–4) µm. **Basidia** claviform, (1–2–)4-spored, 16–23 × 4.5–7 µm, clampless. **Subhymenium** composed of globose to subglobose hyphae, thin-walled, hyaline, 4–10(–12) µm broad. **Generative hyphae** cylindrical to fusiform, hyaline, thin-walled, clampless, 2.5–6(–9) µm broad, without iodine reactions. Hyphae on the stipe surface cylindrical, thin-walled, clampless, 3–3.5 µm broad. **Caulinar hairs** sparse,

cylindrical, thin-walled, up to 50 × 3 µm. Subiculum formed by cylindrical hyphae, thin-walled, straight, branching at right angles, clampless, 3–4 µm broad. Skeletal hyphae absent. **Crystals** sometimes present among the medulla hyphae, bipyramidal or sphaeroid. Attempts to obtain cultures from shed spores on MEA unsuccessful.

Typus: **Lectotype** designated here: Patouillard, Tab. Anal. Fung. 1: fig. 56. 1883. MycoBank MBT389355. **Estonia**, Otepää, Karula National Park, Peräjärve forest trail, on living *Pleurozium schreberi*, 13 Sep. 2015, I. Olariaga, IO.15.85 (S, **epitype** designated here; **isoepitype** in UPS). MycoBank MBT387918.

Known distribution: Denmark, Estonia, Finland, France, Sweden.

Additional materials examined: **Denmark**, Lolland, Biowide plot 120, Hejrede Sø, 5 Nov. 2014, T. Læssøe & T. Olariaga, IO.14.163 (S); Uppland, Uppsala, the cemetery wall, southeast corner adjacent to Carolinaparken, on low mosses (*Tortula ruralis*), 12 Sep. 1932, S. Lundell (UPS F-152985, as *Ceratellopsis* cf. *sagittiformis*).

Notes: The original plate of *B. sagittiformis* shows a fungus with a fertile apex, 2-spored basidia and aseptate medulla hyphae reminiscent of skeletal hyphae. Corner (1950) suggested this plate might correspond to a *Pterula* species, but this view cannot be verified, as no type specimen appears to exist in the Patouillard herbarium (FH, PC). Instead, we interpret *B. sagittiformis*, as a species with obtuse fertile basidiomata at least when not extremely young, medulla hyphae 3–4 µm broad, lacking clamp connections and occurring usually, though apparently not strictly, on living mosses (Hansen & Knudsen 1997). It is possible that mosses are always present but not necessarily act directly as substrate for the basidiomata. Accordingly, we propose an epitype specimen to stabilise its current interpretation (Corner 1950, Hansen & Knudsen 1997).

Key to genera that contain species that can be considered typhuloid

1. Lichenised; growing on a thallus containing green algae..... *Multiclavula*
1. Non-lichenised; not associated with green algae..... 2
2. Basidia with transverse septa; on living bryophytes..... *Eccronartium muscicola*
2. Basidia without septa; on various substrates incl. bryophytes 3
3. Clamp connections verticillate on context hyphae..... *Lutypha sclerotiophila*
3. Clamp connections absent or simple when present..... 4
4. With a sclerotium..... 5
4. Without a sclerotium..... 7
5. With skeletal hyphae; smell phenolic when fresh..... unbranched forms of *Pterula scleroticola*
5. Without skeletal hyphae; smell not phenolic (living basidiomata)..... 6
6. Sclerotium compressed; sclerotial rind normal (i.e. with cells rooting in the medulla) with medulla gelatinised; basidiomata brown; fertile part cylindrical..... *Macrotyphula phacorrhiza* and *M. megasperma*
6. Sclerotium usually not compressed, sclerotial rind inverse (i.e. with cells not rooting in the medulla), if normal, with medulla rarely gelatinised; basidiomata brown or with other colours, fertile part cylindrical to convex..... *Typhula* p.p.
7. With skeletal hyphae..... 8
7. Without skeletal hyphae..... 9
8. Stipe absent; protruding hymenial cystidia producing conidia; basidia 2-spored; spores 9–16 × 3.5–7 µm; smell phenolic when fresh..... *Pterulicum gracile*
8. Stipe short; hymenial cystidia absent; basidia 1–4-spored; spores smaller; smell not phenolic..... *Ceratellopsis* p.p.
9. Spores ornamented..... *Ramariopsis* p.p.
9. Spores smooth..... 10
10. With hymenial cystidia..... 11
10. Without hymenial cystidia..... 13
11. Fertile part more or less cylindrical; terricolous; clamps absent; caulocystidia absent..... “*Ceratellopsis*” *terrigena*
11. Fertile part globose to spatulate; on dead plant remnants; clamp connections sometimes present; caulocystidia sometimes present..... 12
12. Spores ellipsoid, fusiform or sigmoid..... *Physalacria*
12. Spores broadly ellipsoid to subglobose..... *Actiniceps* (= *Chaetotyphula*)
13. Basidiomata < 2 mm high; apex sterile and pointed at least in young basidiomata..... 14
13. Basidiomata higher, if < 2 mm high then apex fertile even in young basidiomata..... 15
14. Medulla hyphae < 2.5 µm broad; subhymenial hyphae not swollen, < 2.5 µm broad; on dead plant remnants; clamps (always?) present..... *Ceratellopsis* p.p.
14. Medulla hyphae 2.5–6(–9) µm broad; subhymenial hyphae globose to subglobose, 4–10(–12) µm broad; often on living mosses; clamps absent..... *Bryopistillaria sagittiformis*
15. Basidiomata pale brown; usually > 10 mm high; spores inamyloid..... *Macrotyphula* p.p.
15. Basidiomata if > 10 mm high then colour not brown; spores amyloid or not..... 16
16. Clamps present and abundant on hyphae in the context..... 17

16. Clamps absent or restricted to basidia and loop-like.....19
17. Not positively geotropic; fertile part and stipe usually sharply delimited; growing usually on dead leaves or stems of plants.....*Typhula* p.p.
17. Usually positively geotropic; fertile part and stipe not clearly differentiated; growing on highly decayed wood or polypores.....18
18. With gloeocystidia; spores subglobose.....*Dentipratulum*
18. Without gloeocystidia; spores ellipsoid.....*Mucronella*
19. Basidiomata < 1.5 mm high; stipe with 150–250 µm long erect hairs with obtuse ends; on dead wood.....*Hirticlavula elegans*
19. Basidiomata larger, hairs absent or considerably shorter; terrestrial or on leaves and herbaceous remnants of plants.....20
20. On plant remnants; spores usually amyloid.....*Typhula* p.p.
20. Terrestrial; spores non-amyloid.....*Clavaria*

DISCUSSION

Evolution of typhuloid fungi and family delimitation in the Agaricales and the Pleurotineae

This study provides the most robust phylogenetic hypothesis for typhuloid fungi to date, and it resolves for the first-time relationships with other genera in the Agaricales. Terminal nodes recovered in our Agaricales analyses using ML and Bayesian approaches are consistent to a great extent with those obtained by Matheny *et al.* (2006). In addition, several more basal nodes received support when analysed using a Bayesian method (Figs 2, 3), while ML bootstrap values were low for most of those. As RAxML does not allow for a free model-choice, the same dataset was analysed using IQ-TREE (Nguyen *et al.* 2015) and Garli (Zwickl 2006), but the supported topology was identical and bootstrap values were similar to those obtained in RAxML. It has long been known that Bayesian PP tend to be higher than ML bootstrap values (e.g. Susko 2009), and have been claimed to refer to different properties of phylogenetic confidence (García-Sandoval 2014). Although our dataset is the most comprehensive ever assembled for typhuloid fungi, it might still contain too little molecular characters to reconstruct the comparatively deep divergences among clades. In any case, it was highly expected that novel supported topologies would be recovered for the first time when more taxa were added to the analyses, even if many nodes so far only received support in the Bayesian analyses.

Typhulaceae, *Pleurotaceae*, *Pterulaceae*, *Stephanosporaceae*, *Sarcomyxa*, *Pleurocybella* and *Phylloptopsis* are resolved as a monophyletic group for the first time (Figs 2, 3), corresponding to the *Pleurotineae* (Dentinger *et al.* 2016). Our results confirm that *Sarcomyxa* and the *Typhulaceae* belong to *Pleurotineae* as anticipated by Dentinger *et al.* (2016). The back-bone of the *Pleurotineae* phylogeny is fully resolved (Fig. 3) and suggest that *Macrotyphula* and *Typhula*, with a typhuloid basidioma configuration, might have evolved from a pleurotoid ancestor. The phylogenetic relationships of *Phylloptopsis*, *Pleurocybella* and *Sarcomyxa*, of debated family placement, are also resolved in our Bayesian *Pleurotineae* phylogeny (Fig. 3). These three pleurotoid genera have been placed, not always together, in families containing white-spored agarics, such as *Marasmiaceae*, *Mycenaceae*, *Pleurotaceae* and *Tricholomataceae* (e.g. Jülich 1982, Moncalvo *et al.* 2000, Kirk *et al.* 2008, Begerow *et al.* 2018), or even *Pterulaceae* (Begerow *et al.* 2018), but previous phylogenies did not support any of these family placements

(e.g. Matheny *et al.* 2006, Binder *et al.* 2010). Based on our phylogenies and the high Bayesian PP (Figs 2, 3), we propose the new family *Sarcomyxaceae* to encompass *Sarcomyxa* and validate the family *Phylloptidaceae* to accommodate *Macrotyphula*, *Phylloptopsis* and *Pleurocybella*. On the other hand, *Pterulaceae* and *Radulomycetaceae*, recently split sister families (Leal-Dutra *et al.* 2020), contains an assemblage of fungi with clavarioid, corticioid and polyporoid basidioma types (Zhao *et al.* 2016), monomicic or dimitic, defined as “morpho-anatomically a very diverse family with colourless spores” (Begerow *et al.* 2018), but well-supported in molecular phylogenies (Fig. 3; Matheny *et al.* 2006, Binder *et al.* 2010). All members of *Pterulaceae* and *Radulomycetaceae* studied when fresh (*Aphanobasidium filicinum*, *Pterula subulata*, *Pterulicum gracile*, *P. sclerotiicola*, *Radulomyces confluens*, *R. molaris*, and *R. rickii*) had a distinct phenolic or naphthalene odour, as sometimes described for *P. multifida* (e.g. Petersen 1999). It is thus suggested here that such an odour, produced by a probably unidentified fungal metabolite, may be a synapomorphic character of *Pterulaceae*, but further species must be tested to draw a final conclusion.

According to our results, the hygrophoroid clade as recovered by Matheny *et al.* (2006), is not monophyletic, because the *Hygrophoraceae*, the *Pleurotineae* and *Xeromphalina campanella*, all previously assigned to the hygrophoroid clade (Matheny *et al.* 2006), are encompassed in three independent lineages within the Agaricales (Fig. 2). The position of the *Hygrophoraceae* inferred from our analyses is not consistent with the 208-locus phylogeny by Dentinger *et al.* (2016), which placed *Hygrocybe conica* (*Hygrophoraceae*) and *Clavaria fumosa* (*Clavariaceae*) in a monophyletic group described as the *Hygrophorineae*. The dataset employed by Dentinger *et al.* (2016) contained 36 taxa of the highly diverse Agaricales and only a single taxon of the *Hygrophoraceae*. Phylogenetic analyses of a matrix with few taxa, even when the number of overall characters is large, can be subject to strong systematic biases and can be susceptible to long-branch attraction (Heath *et al.* 2008). In our preliminary analyses, *H. coccinea* nested in *Clavariaceae* when no other *Hygrophoraceae* were included in the matrix. With the addition of a few taxa of the *Hygrophoraceae* (Fig. 2), *Clavariaceae* and *Hygrophoraceae* do not form a monophyletic group, but are suggested to be successive sister taxa to the rest of the Agaricales. Our data indicates that Dentinger *et al.* (2016) recovered *H. conica* and *C. fumosa* in a monophyletic clade due to a long-branch attraction artifact and we anticipate that this clade will no longer be resolved when more species of *Hygrophoraceae* are included in phylogenomic

analyses of large multigene datasets. Following our phylogenetic hypothesis, we propose the new suborder *Clavariineae* to accommodate the *Clavariaceae*.

Typhula phacorrhiza* is a synonym of *Sclerotium complanatum* that nests in *Macrotyphula

Earlier hypotheses on the phylogenetic position of *Typhula* and *Typhulaceae* relied on a misidentified specimen of *T. phacorrhiza* (DSH96-059; Pine et al. 1999) that belongs to the *Macrotyphula juncea* species complex (Olariaga et al. in prep.). Therefore, this is the first time that *T. phacorrhiza* is included in a multigene phylogenetic study. As previously suggested, based on morphology (Olariaga & Salcedo 2013), *T. phacorrhiza* and *Sclerotium complanatum* belong to *Macrotyphula*. The bulk of species of *Typhula* form a distinct separate clade (referred to as the *Typhula*-core clade). Thus, our analyses confirm that the selection of *T. phacorrhiza* as type of *Typhula* is unfortunate (Berthier 1976, Olariaga & Salcedo 2013), also for the sake of nomenclatural stability. The examination of material deposited in herbaria under *S. complanatum* showed that this name is usually applied to sclerota of *T. phacorrhiza* (e.g. Pl. Crypt. N. France, ed. 1, no 536; Microf. Exs. no 49; Krypt. Exs. no 1840; see material examined under *T. phacorrhiza*) and that *S. complanatum* is a synonym of *T. phacorrhiza* as proposed long ago (Remsberg 1940). Furthermore, the *Typhula*-core clade contains the types of all genera segregated from *Typhula* at some point. Based on analyses of a more inclusive species sampling of *Typhula* (Olariaga et al., in prep), we consider it more appropriate to merge all those genera, as done by some authors (Berthier 1976, Knudsen & Vesterholz 2012), rather than splitting *Typhula* into several genera that could be recognised only with great difficulty.

A strict application of nomenclatural rules in the light of our phylogenetic hypothesis (Figs 2, 3) would result in a high number of undesirable name changes. The correct generic name for species of *Macrotyphula* and *T. phacorrhiza* would be *Sclerotium*. However, the adoption of *Sclerotium* for *Macrotyphula* species would be misleading, because nearly all *Macrotyphula* species lack sclerota and *Macrotyphula* is a well-established name. At the same time, species in the *Typhula*-core clade would need to be transferred to *Pistillaria*, the oldest alternative genus name for the group. Pathogenic species of *Typhula*, such as *T. idahoensis*, *T. incarnata* or *T. ishikariensis*, on which extensive literature has been published, would undergo name changes. Also, the epithet of *T. incarnata* would need to be changed to avoid creating a later illegitimate homonym of *Pistillaria incarnata* Desm. In order to preserve nomenclatural stability, two proposals are in preparation to conserve: 1) *Typhula* with *T. incarnata* as conserved type, and 2) *Macrotyphula* against *Sclerotium* (Olariaga et al. unpubl.). In accordance with our proposals, we combine in *Macrotyphula* two closely related taxa treated by Berthier in *Typhula* subgen. *Typhula*: *T. phacorrhiza* and *T. megasperma*.

***Ceratellopsis* s. auct. is polyphyletic and misapplied**

Despite our efforts to find good material, very few specimens of *Ceratellopsis* were available for this study. Besides those types examined by Berthier (1976), only a few more type specimens of *Ceratellopsis* could be located and examined. The type specimens of most names placed in *Ceratellopsis* appear to be lost and

can only be interpreted through their protogues. Most non-type specimens of *Ceratellopsis* were characterised by having a central medulla of narrow, thick-walled hyphae, a poorly differentiated subhymenium of cylindrical < 2 µm broad hyphae, a sterile basidioma apex, a well-delimited stipe, basidia < 20 µm long and spores < 8 µm long. Some of these collections had skeletal hyphae in the medulla, as also observed in the type specimens of *C. acuminata*, while other specimens assigned to *C. aculeata* and *C. mucidinea* had scarcely septate hyphae with thinner walls. Specimens identified as *C. sagittiformis* differed in having broader (up 3–4(–8) µm), more often septate medulla hyphae, a well differentiated subhymenium with swollen, globose to subglobose hyphae (4–10(–12) µm) and a basidioma apex becoming fertile. Three type specimens (*C. attenuata*, *C. equiseticola* and *C. rickii*) and several other specimens filed under the names *C. aculeata* and *C. acuminata* represent *P. gracile*, because they possessed skeletal hyphae, 2-spored basidia, acuminate cystidia and lacked a stipe. As earlier suggested (Corner 1950, Berthier 1976), several names originally described or combined in *Ceratellopsis* represent in fact *P. gracile*.

This study provides the first molecular data of *Ceratellopsis*. It resolves the genus as polyphyletic, with species belonging to both the *Clavariaceae* and the *Hymenochaetales*. Among the specimens sampled for the molecular phylogenetic study, those with a sterile pointed apex and narrow thick-walled medulla hyphae nest in the *Clavariaceae*. This position is supported by the fact that tiny clavarioid basidiomata are also known in other *Clavariaceae*, such as in *Hirticlavula* (Petersen et al. 2014) and *Mucronella* (Birkebak et al. 2013). Narrow hyphae on the base of the stipe, typical in *Clavariaceae* (Olariaga 2009), have also been observed in species of *Ceratellopsis*. For the first time, we demonstrate that skeletal hyphae are present in some species of *Ceratellopsis* and that it is not a unique character for *Pterulaceae* among typhuloid fungi. The species of *Ceratellopsis* placed in *Clavariaceae* differ from *P. gracile* in having basidia < 20 µm long, a well-delimited stipe and in lacking protruding acuminate cystidia. This lineage of *Ceratellopsis* conforms to Corner's (1950) concept of *Ceratellopsis*, i.e. "Ceratellopsis aculeata and the species which appear to resemble it", except for the presence of skeletal hyphae in some species. The examination of a specimen identified as *C. aculeata* by Corner (PC), with very narrow, scarcely septate medulla hyphae, confirms this view. In accordance with this, we conclude that *C. corneri* and *C. terrigena*, having medullar hyphae 4–6 µm and 1.5–3.5 µm broad, respectively, do not belong to this lineage and must be placed elsewhere (see Taxonomy).

The inclusion of *C. sagittiformis* in the *Rickenella* clade of the hymenochaetoid clade is a novel and unexpected find although material identified as *C. sagittiformis* is often associated with living bryophytes, as several members of the clade are (Korotkin et al. 2018). The *Rickenella* clade encompasses fungi with a diverse basidioma configuration (agaricoid, clavarioid, cypheloid, thelephoroid, corticioid, etc.) that often are associated with mosses (Larsson et al. 2006). Within the *Rickenella* clade, *C. sagittiformis* resembles *Muscinupta laevis* in having white basidiomata, in growing on living bryophytes and in lacking clamp connections (Eriksson & Ryvarden 1975, as *Cyphellostereum laeve*), but our phylogenetic analyses lack support to confirm a close relationship. Phylogenetic relationships within the *Rickenella* clade were previously explored using only ribosomal nuclear markers (5.8S and 28S; Larsson et al. 2006), and only recently using also the RPB2 region. Even with the addition of

the 18S and the *RPB2* regions and more taxa to the analyses of the hymenochaetoid clade, relationships within the *Rickenella* clade remain largely unresolved (Korotkin et al. 2018, Fig. 5). The three specimens of *C. sagittiformis* have identical sequences and formed a distinct lineage. Based on this and the fact that *C. sagittiformis* is the only bryophilous, reduced clavarioid species known to belong to the *Rickenella* clade, we propose the new genus *Bryopistillaria* to accommodate it (see Taxonomy).

Proposing a reliable and stable interpretation of *C. queletii*, type of *Ceratellopsis*, is necessary to be able to provide a solid interpretation of *Ceratellopsis*. The name *Ceratellopsis queletii* appears not to have been employed since its original description (Patouillard 1883). Regrettably, no type specimen exists in PC and FH (G. E. Tocci pers. comm.) and no original specimen is likely to be present in any other fungarium. The absence of a stipe, the sterile apex, the 2-spored basidia and the presence of protruding acuminate cystidia, clearly depicted in the original illustration of *C. queletii* selected here as lectotype, are characteristic of *P. gracile* (Corner 1950, Berthier 1976, Jülich 1980). The spore size estimated by Corner from the original Patouillard plate of *C. queletii* is smaller ($6 \times 3 \mu\text{m}$) than the range we have estimated ($8\text{--}8.5 \times 4.5\text{--}5 \mu\text{m}$) and the size reported by Quélet ("8 μm ?", 1884) for *C. queletii*. Spores in *P. gracile* are generally reported as slightly larger than our measure estimates from the Patouillard plate, but those are almost within the ranges published for *P. gracile*: $9\text{--}16 \times 4\text{--}7 \mu\text{m}$ (Corner 1950), $10.5\text{--}12.5 \times 5.5\text{--}5.6 \mu\text{m}$ (Berthier 1976), $10\text{--}14 \times 5.5\text{--}6.5 \mu\text{m}$ (Jülich 1980) and $8\text{--}11 \times 5\text{--}7 \mu\text{m}$ (Daniëls & Moreno-Arroyo 2007). Based on all this, we consider *C. queletii* a synonym of *P. gracile*, as already Corner (1950) suggested.

Leal-Dutra et al. (2020), using one of the specimens of *P. gracile* employed in our analyses (CBS 309.79), showed that it belongs to the *Pterulicum* clade. This taxonomic conclusion reduces *Pterulicum*, as recently circumscribed, to a later synonym of *Ceratellopsis* and the forty-six names combined in *Pterulicum* (Leal-Dutra et al. 2020), besides its type *Pterulicum xylogenum*, would have to be combined again in *Ceratellopsis*. In addition, a new genus name would be required for *C. acuminata* and *C. aculeata*. In order to avoid nomenclatural changes that may cause confusion, a proposal to conserve *Ceratellopsis* with *C. acuminata* as conserved type is in preparation. The acceptance of this proposal would preserve the current usage of *Ceratellopsis* and *Pterulicum*, typified by *P. xylogenum*, a presumed causal agent of culm rot disease of bamboo (Harsh et al. 2005) and possibly also of sugarcane (Corner 1952).

CONCLUSIONS

This study reveals that typhuloid fungi appeared several times among the Agaricomycetes and contributes to the understanding of fungal evolution and shifts of basidioma configuration. Novel phylogenetic hypotheses are provided for several groups of typhuloid fungi and pleurotoid agarics, and pertinent family and generic classifications are proposed. Future phylogenomic analyses will hopefully incorporate more taxa, including typhuloid fungi, and will serve to further test our phylogenetic hypotheses.

ACKNOWLEDGEMENTS

Bart Buyck's kind assistance to locate type specimens was indispensable during I.O.'s stay in PC herbarium. We thank also curator and assistants from C

(Christian Lange), G (Philippe Clerk), FH (Genevieve E. Tocci), K (Angela Bond), M (Dagmar Triebel), PAD (Rosella Marcucci) and TL (Paul Semandi) herbaria for sending us material on loan or providing valuable information on types kept at their institutions. Mari Azpiroz, curator of ARAN herbarium is deeply thanked for efficiently arranging loans of specimens from herbaria. We wish to thank Rafael Blasco for providing us with material of *Ceratellopsis* and Nils-Otto Nilsson for good guidance and help collecting typhuloid fungi in Scania (Sweden). Juan Ignacio Iturrioz is thanked for lending us a photograph of *Phyllocladus nidulans*. We express our gratitude to Francis Martin for kindly granting us permission to use partial sequences obtained from genomes of *Agaricus bisporus*, *Onnia scaura*, *Phellinus ferrugineofuscus*, *Radulomyces confluens* and *Trichaptum abietinum*. We are grateful to two anonymous reviewers for their insightful comments on the paper, as well as to L.A. Parra, J.C. Zamora and J. McNeill for advice on the nomenclatural status and the possibility to conserve the name *Ceratellopsis*. This study was funded by the Swedish Taxonomy Initiative (Svenska artprojekten) administered by the Swedish Species Information Center (ArtDatabanken), through grants 143/2013 and 22/2016 to I.O. A grant from the SYNTHESYS initiative funded a stay to examine collections kept in the Muséum national d'Histoire naturelle of Paris (PC).
