ABSTRACT

Introduction Medial epicondyle fracture of the humerus is a common injury in childhood. There is uniform agreement that minimally displaced fractures (dislocation ≤ 2 mm) can be treated nonoperatively with immobilisation. Open fractures, fractures with joint incarceration or ulnar nerve dysfunction require surgery. There is no common consensus in treatment of closed medial epicondyle fractures with >2 mm dislocation without joint incarceration or ulnar nerve dysfunction. We hypothesise that there is no difference in treatment outcomes between nonoperative and operative treatment.

Methods and analysis This is a multicentre, controlled, prospective, randomised noninferiority study comparing operative treatment to non-operative treatment of >2 mm dislocated paediatric medial epicondyle fractures without joint incarceration or ulnar nerve dysfunction. A total of 120 patients will be randomised in 1:1 ratio to either operative or nonoperative treatment. The study will have a parallel nonrandomised patient preference arm. Operative treatment will be open reduction and internal fixation. Nonoperative treatment will be upper limb immobilisation in long arm cast for 4 weeks. Data will be collected at baseline and at each follow-up up to 2 years. Quick-DASH is used as primary outcome measure. Secondary outcomes are patient-reported pain, differences in range of motion, Pediatric Quality of Life Inventory, cosmetic visual analogue scale and Mayo Elbow Performance Score.

Ethics and dissemination Ethical approval has been obtained from Helsinki University Hospital (HUS) ethical board HUS/1443/2019. Each study centre has obtained their own permission for the study. A written authorisation from legal guardian will be acquired and the child will be informed about the trial. Results of the trial will be disseminated as published articles in peer-reviewed journals.

Trial registration The trial has been registered at clinicaltrials.gov with registration number NCT04531085.

Strengths and limitations of this study

- This study is the first randomised controlled trial to examine the treatment and outcome of dislocated medial epicondyle fractures.
- This is a multicentre study with all five university hospitals in Finland participating.
- The trial has a blinded outcome assessor independent of treating and recruiting surgeons.
- Primary outcome measure (Quick DASH) is not validated for use in children.
- Treating surgeon is not blinded to the allocated treatment.

INTRODUCTION

The incidence of medial epicondyle fractures of the humerus in children and adolescents is ≥ 3 :100 000 and account for approximately 12%–20% of all paediatric elbow fractures,^{1 2} 30%–50% of these fractures are associated with elbow dislocation and 5%–18% are incarcerated.^{3 4} Dysfunction of ulnar nerve has been reported in 10%–16% of cases.³

Minimally displaced (≤ 2 mm) fractures without incarceration or ulnar nerve dysfunction are treated nonoperatively.^{5–10} There is no common consensus between paediatric surgeons how to treat medial epicondyle fractures with >2 mm dislocation.^{11 12} It has been suggested that incarcerated fractures and fractures with elbow dislocation should be treated operatively, and that competitive athletes should be treated operatively with lower threshold than children and adolescents without sporting activities.¹³

Grahn *et al*¹ conducted a controlled treatment trial based on prospectively collected data from ≤ 16 years old patients with more than 2 mm displaced nonincarcerated medial epicondyle fractures with a minimum follow-up of 1 year. Partial avulsion fractures were excluded, 41 were treated nonoperatively and 40 operatively. They found that neither the degree of primary fracture displacement with or without concomitant elbow dislocation nor the choice of treatment (open reduction and internal fixation (ORIF) or long arm cast) affected outcome. Normal elbow function was restored in 74/81 patients. All but one primarily nonoperatively treated patients had returned to the same or higher level of sport as preinjury, whereas six surgically treated patients had downgraded their sporting activities. Pain at medial humeral epicondyle either with direct contact or under load was reported by four nonoperatively and by six operatively treated children with normal sensation and elbow stability.¹ In a systematic review of the literature regarding treatment of medial epicondyle fractures, Kamath *et al*¹⁴ found operative treatment to be superior to conservative in terms of bony union. However, the review did not show differences in terms of pain or patient-reported outcome measures between the two treatment modalities. According to the study of Lawrence *et al*,¹⁵ there was no difference in outcome assessed by QuickDASH and elbow range of motion at 2 years from injury in 6 nonoperatively and 14 operatively treated athletes. Axibal *et al*¹⁶ showed similar results with no difference in the objective outcome in less than 1-year follow-up between 22 operated patients matched to 22 nonoperated patients.

In light of current findings, we applied for ethical review board approval to conduct a randomised noninferiority trial with the hypothesis being that conservatively treated medial epicondyle fractures fare as well as operatively treated.

METHODS AND ANALYSIS

Study design

The study is designed as a multicentre parallel-group noninferiority randomised controlled trial (RCT) that complies with the Consolidated Standards of Reporting Trials guidelines (figure 1). A patient preference arm will be available. Patient recruitment will be done at all university hospital areas of Finland (Helsinki, Kuopio, Oulu, Tampere, Turku). The study is coordinated by Helsinki University Central Hospital, Children's Hospital Pediatric Orthopedic Unit (HUS New Children's Hospital, Stenbäckinkatu 9 C, 00029 HUS, Finland). Trial data analysts and person performing the recruitment will be unaware of the assigned treatment. The study is overseen by an external study monitor according to trial data monitoring protocol provided by HUCH Clinical Research Institute (Clinical Research Institute HUCH P.O. Box 700, FI-00029 HUS, Helsinki, Finland, <https://hyksinstituutti.fi/services/monitoring-services/?lang=en>). The trial

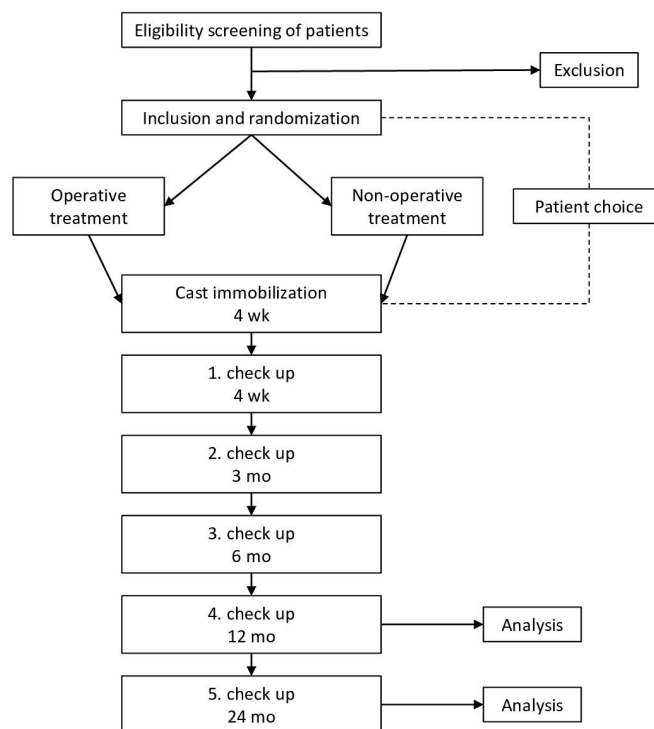

Figure 1 Flowchart of the study.

is registered at clinicaltrials.gov. Any changes in study protocol will be uploaded to the trial registry.

Patient recruitment

All patients with a medial epicondyle fracture referred to the aforementioned hospitals will be screened for eligibility by a specialist of either hand surgery, paediatric surgery, paediatric orthopaedics or orthopaedics. If inclusion criteria are met, written consent is asked from the guardian. Patients and parents are given a written informed consent regarding the trial. The patient version is age adjusted for easier understanding according to the Finnish Investigators Network for Pediatric Medicines (www.finpedmed.fi).

Inclusion criteria

Patients aged 7–16 years presenting with a ≥ 2 mm displaced nonincarcerated medial epicondyle fracture with or without concomitant elbow dislocation and normal ulnar nerve function.

Exclusion criteria

Pathological fracture, open fracture, systemic bone disease, concomitant fracture or injury of the same upper limb requiring operative intervention, and other disease-preventing participation in full follow-up regime and range of motion exercises.

Randomisation

After agreeing to participation in the trial, patients are randomised according to a computer-generated randomisation list¹⁷ to either operative or nonoperative treatment. Randomisation ratio is 1:1, block size is 10. Prior to

the recruitment, assigned arm of the RCT trial has been placed in sealed envelopes. Each study centre receives a set of 10 consecutive envelopes at a time. Allocation sequence is kept at the main study centre (HUS, New Children's Hospital) where it is unavailable to recruiting physicians. Patient allocation in the trial is determined as the patient opens the assigned envelope.

Patient's choice arm

Patients who meet inclusion criteria, but refuse participation in the randomised trial are offered to choose treatment method (operative or nonoperative) and continue in a prospective parallel patient preference arm that otherwise follow the same treatment and follow-up (FU) protocol as the RCT.

Baseline

Standard anterior–posterior and lateral radiographs of the elbow will be obtained after closed reduction of the possible elbow dislocation. All participants in either the RCT or patient's choice arm undergo cone-beam or normal CT before treatment initiation. Initial fracture dislocation will be calculated from the CT scans in three planes (anterior–posterior, cranial–caudal and medial–lateral) and both radiographs (anterior–posterior and lateral) using the method described by Edmonds *et al.*¹⁸ Date of injury, method of injury, patient's age at time of injury, sex, injured side, dominant hand and main sport or musical instrument as well as level will be documented. Motor and sensory function as well as range of motion of both upper limbs will be assessed. Carrying angle (degrees) and valgus stress test will be assessed if possible for both limbs.

Intervention

Nonoperative treatment means upper limb immobilisation with forearm in neutral pronation with a long arm cast for 4 weeks. Treatment is started after baseline examination.

Operative treatment is scheduled after baseline examination and is to be done within 7 days from injury. During sedation, both elbows are stress-tested using the valgus stress test, any instability is documented, carrying angle of both elbows are measured. Procedure of preference is ORIF with cannulated nonresorbable 4.0 mm screw with or without washer. If the fracture fragment is too small or fragmented for screw fixation, 1.6 mm–1.8 mm Kirshner-wires and/or bone anchor are used. After fracture fixation, the injured side is again stress tested. Radiographs (anterior–posterior and lateral) documenting the fixation are taken. Long arm cast with forearm in neutral pronation is applied for 4 weeks. Time from injury to surgery, fixation method, length of surgery (min) and surgeon's level of training (consultant, registrar) will be documented. Hardware is not routinely removed.

All patients will receive a written exercise plan explaining the active and passive range of motion (ROM) exercises that are to be performed at a minimum three

times per day from cast removal. Physiotherapy will be offered if guardians and/or patients feel that no progress in ROM after 2 weeks of home exercises.

Blinding

This trial tests a clinical intervention that is not suitable for protection against treatment bias. Recruiter will be blinded. Consultant on duty will perform randomisation and allocation. Nonoperative treatment will be started immediately after recruitment. ORIF will be performed by surgeon on duty. Surgeon is not blinded. Trial data are collected at each appointment at the outpatient clinic by a physician not related to the trial. Statistician analysing trial data are blinded to treatment group.

Outcome measure

Follow-up is set at 1, 3, 6, 12 and 24 months from initiation of treatment with the option of ending the FU at 12 months if patients are pain free with full ROM in relation to uninjured side. Elbow standard radiographs (anterior–posterior and lateral) are taken at each appointment from 3 months on until bone union is achieved or trial ends (table 1).

Patients will be examined at the paediatric orthopaedic outpatient clinic. On each appointment, active and passive ROM of both upper limbs (elbow extension–flexion, pronation, wrist extension–flexion) as well as carrying angle are measured using a goniometer. Stability of both elbows is assessed using the moving valgus test¹⁹ and the valgus stress test.²⁰ Distal sensation is examined by Semmes-Weinstein monofilaments.²¹ Signs of cold intolerance will be assessed. Grip strength is measured with a dynamometer.

Patients and guardians are requested to answer the following patient-reported outcome measures at each appointment; QuickDASH,²² Pediatric Quality of Life Inventory (PedsQL), PedsQL Pediatric Pain Questionnaire,²³ cosmetic visual analogue scale (VAS 0–100) and Mayo Elbow Performance Score (MEPS).²⁴

Time of returning to main sport or music and its level will be documented (weeks). Any adverse effects (wound infection, nerve damage) are documented as well as hardware problems and possible hardware removal as well as conversion of treatment during FU (cast to ORIF or ligament reconstruction).

Although QuickDash is not validated for use in under 18-year olds, it was selected as it has been used in the literature in evaluating results of fracture healing in adolescents, and it is available in both national languages (Finnish and Swedish).^{25 26}

Primary outcome

Statistically significant difference in QuickDASH score is 6.8^{25 26} at 12 months FU.

Secondary outcome

Difference in active ROM in comparison to uninjured arm, PedsQL, PEDS QL Pain module, Cosmetic VAS, MEPS, need for additional procedures.

Table 1 Data collection time points

	Baseline	Treatment Day 0	1.Check-up 4 weeks	2.Check-up 3 months	3.Check-up 6 months	4.Check-up 12 months	5.Check-up 24 months
Diagnosis, eligibility	x						
Randomisation	x						
Surgery or non-operative treatment		x					
Physical examination	x		x	x	x	x	x
Questionnaires			x	x	x	x	x
Computer tomography	x						
Standard radiograph	x		x	x	x	x	x

Sample size

Based on the results of Kazmers *et al*²⁵ and Aasheim and Finsen,²⁶ we assume clinically significant difference between the groups to be 6.8 and the SD of the QuickDASH score to be 10 points. With 0.05 significance level and 80% power, a noninferiority comparison would require 27 patients per group. Allowing a 20% dropout rate, the required sample would be 30 patients per group.

For subgroup analysis (less than 12 years vs 12 years and over), 30 patients per age group need to be collected. Assuming 50–50 split in the patients between the age groups, the sample size would be 60 per ORIF and nonoperated equalling a total of 120 patients.

Statistical analysis

Data will be analysed by using the Wilcoxon rank-sum test in Python V.3.8. (Python Software Foundation, Wilmington, Delaware, USA). Our null hypothesis is that there is no difference in outcome between nonoperative versus ORIF. Level of significance is set at $p < 0.05$.

Both treatment groups will be internally analysed for differences in primary outcome regarding age (less than 12 years vs 12 years and over) at time of injury and amount of initial fracture displacement (mm). Depending on group size, patient choice arm can be merged for analysis to same RCT group.

Patient and public involvement

Patients, caregivers or public were neither involved in the development of the research questions nor the planning of the study design. They are neither involved in the recruitment nor conduct of the study. Results of the study are published only in peer-reviewed journals, no other information of the results of the study are provided to the patients or caregivers. Patients or caregivers will not take part in assessment regarding possible burden of the interventions of this study.

ETHICS AND DISSEMINATION

There is no common consensus for dislocated (>2mm) medial epicondyle fractures. Treatment method varies by clinic and treating surgeon. Both ORIF and long arm cast are well-established treatment methods for humeral medial epicondyle fractures. If at any point an imminent problem in healing is observed, warranting a change in the treatment regimen, this will be done at the discretion of the treating physician regardless of the initial treatment allocation. The participants will be treated according to our best knowledge during and after the trial. Patients will not receive any compensation for participation. The Finnish Patient Insurance Centre will provide compensation for treatment injuries.

We have obtained national ethical approval from Helsinki University Hospital (HUS) ethical board HUS/1443/2019. A local permission to conduct the trial will be obtained by each study centre (Kuopio University Hospital, Oulu University Hospital, Tampere University Hospital and Turku University Hospital). A written authorisation from guardian will be acquired and child will be informed about the trial. Results of the trial will be disseminated as published articles in peer-reviewed journals. Authorship will follow the International Committee of Medical Journal Editors (ICMJE) recommendations.²⁷

Time schedule

Last patient FU is expected by the end of 2023 and publication by the end of 2024.

CONCLUSION

The goal of this study is to compare two well-established treatment methods of dislocated nonincarcerated humeral medial epicondyle fractures in 7–16-year-old patients.
