## Abstract

**Summary:** The neuronal synapse is underpinned by a large and diverse proteome but the molecular evidence is spread across many primary datasets. These data were recently curated into a single dataset describing a landscape of ~ 8000 proteins found in studies of mammalian synapses. Here we describe programmatic access to the dataset via the R/Bioconductor package **Synaptome.db**, which enables convenient and in-depth data analysis from within the Bioconductor environment. Synaptome.db allows users to obtain the respective gene information, e.g. subcellular localization, brain region, gene ontology, disease association and construct custom protein-protein interaction network models for gene sets and entire subcellular compartments.

**Availability and implementation:** The package Synaptome.db is part of Bioconductor since release 3.14,

<https://bioconductor.org/packages/release/data/annotation/html/synaptome.db.html>, it is open source and

---

---

available under the Artistic license 2.0. The development version is maintained on GitHub

(<https://github.com/lptolik/synaptome.db>). Full documentation including examples is provided in the form of vignettes on the package webpage.

## 7 1 Introduction

8 The proteomes of the presynaptic and postsynaptic compartments  
9 mediate information processing in the brain via complex and highly  
10 dynamic molecular networks. Sorokina et al., 2021 systematically  
11 curated 58 proteomic studies from 2000 to 2020, to produce a  
12 comprehensive dataset describing > 8000 proteins expressed at the  
13 mammalian synapse (1). The set includes 29 post synaptic proteome  
14 (PSP) studies (2000 to 2019) contributing to a total of 5560 mouse,  
15 human and rat unique gene identifiers; 18 presynaptic studies (2004 to  
16 2020) resulting in 2772 unique gene IDs, and 11 studies for whole  
17 synaptosomes reporting 7198 unique gene IDs.  
18 Each synaptic component was annotated with relevant metadata based on  
19 the respective study (author, year, method, subcellular compartment,  
20 brain region) and associated with function and disease information  
21 according to Gene Ontology and Human Disease Ontology. Figure 1, A  
22 shows studies aggregating pre- (right panel) and postsynaptic (left panel)  
23 compartments with numbers of identified proteins, while Figure 1, B  
24 shows the brain regions, annotated from the studies with respective  
25 numbers of proteins. It could be seen that coverage highly varies  
26 between regions, as the most of collected studies were performed on the  
27 whole brain, hippocampus, cerebellum and cerebral cortex.  
28 Furthermore, the protein–protein interactions (PPI) were obtained for the  
29 pre- and post-synaptic proteomes based on combined human, mouse and  
30 rat data from BioGRID (2), Intact (3) and DIP (4). Interaction sources  
31 were filtered for methods that produce data on direct physical

32 interactions with the highest confidence. The interaction data from each  
33 database was extracted in the PSI-MITAB format

34 To merge the datasets we standardised the IDs used, by mapping each  
35 onto Entrez gene IDs. To extract only direct interactions, the 'interaction  
36 type' column was then filtered for the PSI- MI terms “association”  
37 (MI:0914), “physical association” (MI:0915) and 'direct interaction'  
38 (MI:0407) and their 63 child-terms. Some of the source data used an  
39 obsolete interaction type MI:0218, “physical interaction” which could  
40 still be used, since it was updated to association and physical association,  
41 which we both include. PPIs based on the interaction types: “genetic  
42 interaction” (MI:0208) (including “suppression” (MI:0796) and  
43 “synthetic” (MI:0794)), “colocalization” (MI:0403), “genetic  
44 interference” (MI:0254) and “additive genetic interaction defined by  
45 inequality” (obsolete term, MI:0799) were excluded from the final set as  
46 these methods are designed to include both direct and indirect  
47 interactions.

48 To maximise confidence in direct physical interactions we also excluded  
49 predicted interactions and interactions obtained by Co-IP experiments  
50 (spoke models), filtering out the PSI-MI terms like “Pull-down”,  
51 “Affinity technology”, etc.

## Synaptome.db

52

69 We developed both packages as components of Bioconductor project (4),

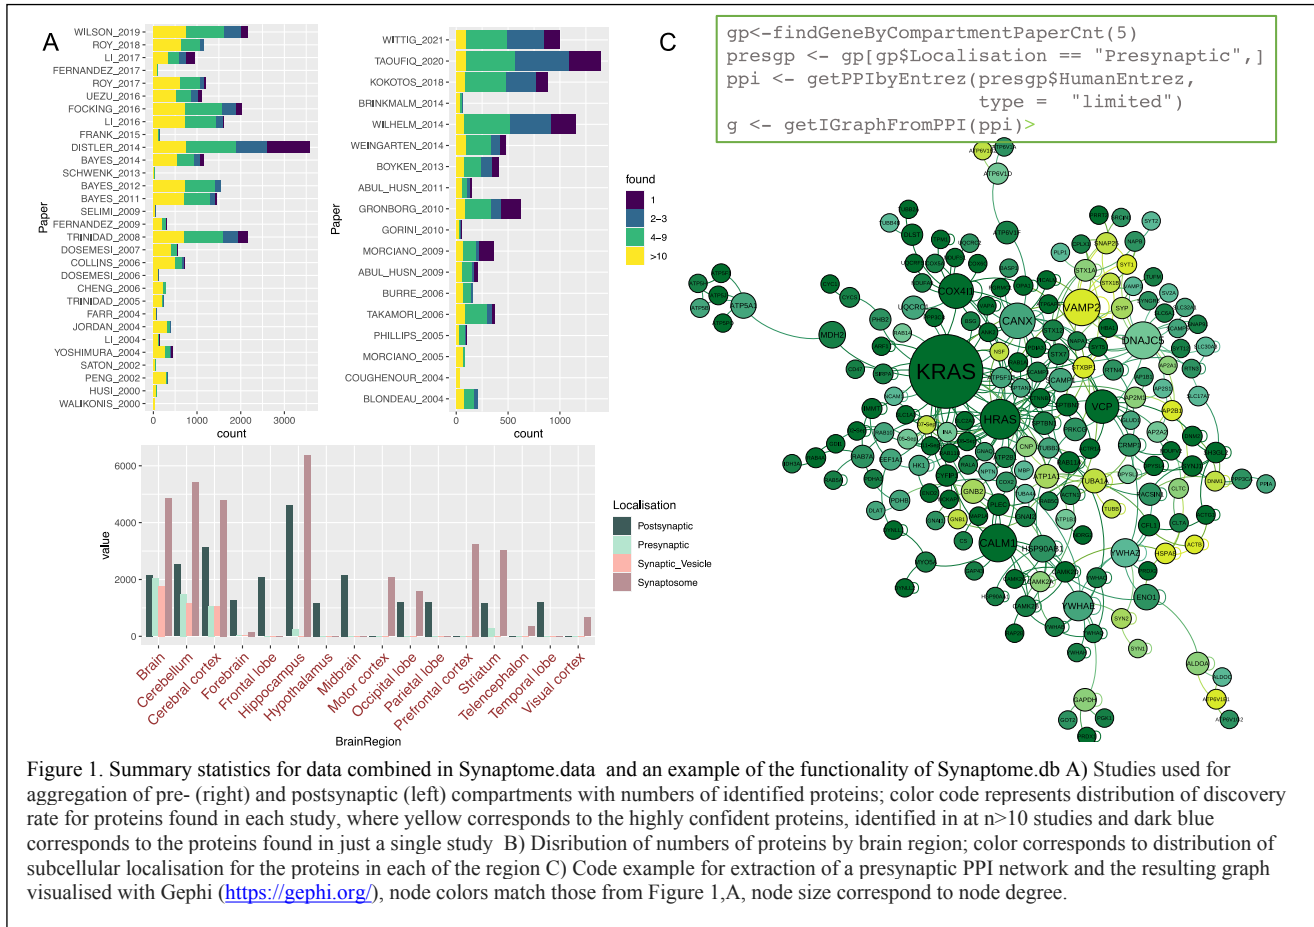

Figure 1. Summary statistics for data combined in Synaptome.data and an example of the functionality of Synaptome.db A) Studies used for aggregation of pre- (right) and postsynaptic (left) compartments with numbers of identified proteins; color code represents distribution of discovery rate for proteins found in each study, where yellow corresponds to the highly confident proteins, identified in at  $n > 10$  studies and dark blue corresponds to the proteins found in just a single study B) Distribution of numbers of proteins by brain region; color corresponds to distribution of subcellular localisation for the proteins in each of the region C) Code example for extraction of a presynaptic PPI network and the resulting graph visualised with Gephi (<https://gephi.org/>), node colors match those from Figure 1,A, node size correspond to node degree.

53

70 which is designed to facilitate rigorous and reproducible analysis of

54 This resulted in two large-scale PPI networks (4817 nodes and 27,788

71 biological data by building customised pipelines and workflows (5). The

55 edges for PSP and 2221 nodes and 8678 edges for presynaptic

72 incorporation into Bioconductor allows users to combine the synaptic

56 proteome).

73 PPI networks and protein annotation with external genomics

57 Combined these provide a unified and configurable resource for

74 (org.Hs.eg.db, org.Mm.eg.db, and org.Rn.eg.db packages (6-8),

58 constructing customised networks for the synaptic proteome. The

75 transcriptomics (via various ChipDB packages (9), mutations and

59 resulting network model is available in a SQLite implementation from

76 polymorphism analysis (via PolyPhen.Hsapiens.dbSNP131 (10) to name

60 Edinburgh DataShare <https://doi.org/10.7488/ds/3771> and EBRAINS.

77 just a few examples. Results of analysis could be presented in domain-

61 Although highly extendible, the SQLite implementation requires specific

78 specific manner by, for example ggbio (11) or KaryoploteR packages

62 database-related expertise restricting its use to specialist bioinformatics

79 (12) (see the example below). Synaptome.db can be also used to provide

63 researchers; while gene information and network models stored in the

80 annotation for experimental datasets, or as a source for hypothesis

64 database provide the much-in-demand resource for the broader

81 generation and experimental design.

65 community of the molecular neuroscientists. To make the database more

66 widely accessible we developed the Bioconductor package

82 **2 Implementation**67 **synaptome.db**, which enables direct access to the data (embedded into

83 To comply with the requirements of Bioconductor the database itself was

68 the satellite package **synaptome.data**) from within the R environment.84 wrapped into an AnnotationHub (13) package, **synaptome.data**, that

1  
2  
3 85 fetches most recent version of the database from Edinburgh DataShare site  
4 86 and caches it for further use. The `synaptome.db` package provides a simple  
5 87 API for extracting the data from the database without understanding of the  
6 88 underlying database structure or using other database related skills. Users  
7 89 with SQL experience can still also query the database directly via  
8 90 `synaptome.data` package using the schema described in (J).

91 **2.1 Synaptome.db functionality**

92 The functions implemented in the current release were designed to  
93 support the most frequent user queries: When?, and by whom?, was my  
94 favorite gene (or list of genes) identified? Was my gene/list found pre- or  
95 post-synaptically? and how often? Was it found in a specific brain  
96 region? and which diseases it is associated with?

97 Functions `findGenesByEntrez` and `findGenesByName`  
98 return the following identifiers for genes specified by Entrez ID or gene  
99 name, respectively: GeneID (internal database ID), MGI ID, Human  
100 Entrez ID, Mouse Entrez ID, Rat Entrez ID, Human gene name, Mouse  
101 gene name and Rat gene name. Here, Internal GeneID corresponds to our  
102 unique database ID, which helps to resolve ambiguity across the external  
103 IDs, for example where a mouse Entrez gene IDs matches the same  
104 Human one, etc. Internal GeneIDs can then be used to extract subcellular  
105 compartment (`getAllGenes4Compartment`) or brain  
106 region (`getAllGenes4BrainRegion`)

107 protein composition, and for extracting PPIs for selected molecules  
108 (`getPPIbyIDs`), as shown in Figure 1. It is also possible to get  
109 Human disease information (HDO provided) for any subset of Human  
110 Entrez IDs (`getGeneDiseaseByEntres`), internal Gene IDs and  
111 Human gene names. As it is based on manually curated data,  
112 `synaptome.db` provides a literature provenance trail  
113 (`getGeneInfoByIDs`)  
114 for each of its data points, including details such as Localisation (one of  
115 the following: presynaptic, postsynaptic, synaptosome), PaperPMID  
116 (PMID for the publications where the genes were reported), Paper  
117 (papers where specific genes were reported in a format  
118 `FIRSTAUTHOR_YEAR`), Year, SpeciesTaxID (species on which the  
119 original experiment was performed on), BrainRegion (Brain region  
120 where the specific genes were identified, according to the paper).  
121 Where a users wants to check whether query set of proteins have  
122 previously been identified as synaptic, we enabled a quick check by  
123 command `getGenes4Compartment` and  
124 `getGenes4BrainRegion`, where one needs to provide  
125 Compartment Id and Specie TaxID or/and BrainRegion ID, along with  
126 the list of internal Gene Ids for the proteins obtained from experiment.  
127  
128 Given that the diversity across synaptic proteomics datasets (e.g. low  
129 overlap between some synaptosome datasets) could easily be due to

Downloaded from https://academic.oup.com/bioinformatics/advance-article/doi/10.1093/bioadv/vbac086/6825339 by guest on 15 November 2022

Figure 2. Distribution of synaptic genes over the Human Chromosomes. A) Circos Diagram showing the distribution of pre, post and synaptosome genes on each chromosome. B) The localisation of presynaptic genes on the Human chromosomes.

*Synaptome.db*

1  
2  
3 130 differences in biochemical enrichment protocols and mass-spec setups, 165  
4 131 is likely that only a subset of proteins in each dataset described here are 166  
5  
6 132 truly synaptic. Figure 1, A demonstrates the distribution of proteins with 167  
7 133 different discovery rates over pre- and post- synaptic studies. It could be 168  
8  
9 134 seen that most stable (yellow) population makes more or less regular 169  
10 135 proportion, while the number of proteins discovered only in single 170  
11 136 studies (dark blue) varies between the datasets. To tackle this issue we 171  
12 137 enabled a few functions that use “count” (discovery rate, or number of 172  
13 138 protein identification in different studies) to enable custom filters for the 173  
14 139 proteins that were identified more frequently than others, thus, may 174  
15 140 correspond to more probable synaptic residents. One of them, 175  
16 141 `findGeneByPaperCnt`, selects the proteins from the total list of ~ 176  
17 142 8000, which were found more than defined “count” of studies, e. g. one 177  
18 143 can select the genes that were identified in more than 5 studies in all 178  
19 144 compartments. Another, `findGeneByCompartmentPaperCnt`,  
20  
21 145 allows similar filtering for specific compartment. 179  
22 146 The use of this command is illustrated in Figure 1C, where we selected 180  
23 147 the most confident protein set (for example, “count” = 5, proteins 181  
24 148 identified in at least 5 presynaptic studies). In addition, the command 182  
25 149 `findGeneByPapers` enables extraction of protein lists from specific 183  
26 150 studies, which can be listed with the command `getPapers`. 184  
27 151  
28 152 Finally, the package supports extraction of PPIs for the gene list or entire 185  
29 153 compartment/brain region and their export in a form of a network graph 186  
30 154 or a table (example code and network presented in Figure 1, C). Custom 187  
31 155 protein-protein interactions based on bespoke subsets of molecules can 188  
32 156 be extracted in two general ways: “induced” and “limited.” In the first 189  
33 157 case, the command will return all possible interactors for the genes 190  
34 158 within the whole interactome. In the second case it will return only 191  
35 159 interactions between the genes of interest. PPIs could be obtained by 192  
36 160 submitting list of EntrezIDs or gene names, or Internal IDs – in all cases 193  
37 161 the interactions will be returned as a list of interacting pairs of Internal 194  
38 162 GeneIDs. 195  
39 163  
40 164 To summarize, the package allows users to do the following: 196  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

- Finding a variety of Gene ID information for specific gene/lists(s)
- Finding molecular composition for specific compartments or brain regions
- Finding the most confident set of proteins for the total synaptosome or specific compartments
- Extracting the protein lists from specific papers
- Finding disease associations for selected genes
- Comparing user defined protein lists against specific compartments and/or brain regions
- Finding PPIs for selected genes/compartments/brain regions.
- Constructing custom PPI graphs and network models

(See Supplementary materials for package vignette and manual with detailed functionality)

**3 Example**

The following brief example demonstrates how the SynaptomeDB can be used in combination with other Bioconductor packages (Figure 2). We extracted a complete list of human gene IDs for each of the presynaptic compartment, the postsynaptic compartment and the entire synaptosome. For each of these gene sets we mapped genes onto the Human karyotype to get a distribution map of the respective gene positions across all human chromosomes using the `ggbio` package (11). We could then select genes that are annotated to any specific disorder, e.g. Alzheimer disease (AD). Supplementary Figure 1 shows the distribution of AD related synaptic genes across human chromosomes. The colour code corresponds to each gene’s subcellular localization. R code for the example is available from Supplementary materials.

**4 Conclusions**

We developed the Bioconductor packages `synaptome.data` and `synaptome.db` to provide a simple and intuitive access to the data in SynaptomeDB. These packages can easily be incorporated into custom bioinformatics data pipelines along with other annotations, experimental data and statistical methods exploiting the features of Bioconductor and

1  
2  
3 198 R for further analysis. We aim to update the package twice a year to 233 9.  
4 199 incorporate newly available datasets and are open to suggestions. 234
