ACKNOWLEDGEMENTS

First, I would like to thank my supervisors, Dr. Pedro Soares and Dra. Teresa Rito, for guiding me through the past 2 years, always helping in the most difficult times and for opening my eyes for such a rich and full of potential field.

To Professor Martin Richards and his team for kindly providing the sample dataset.

To my colleagues, now more than friends. Erica, Mafalda and Carolina, you truly made me a better human. You helped me grow, not only academically but as a person. Our time together was key to keep my sanity.

To my family, for allowing me to follow my dreams and aspirations and for supporting me in all my endeavours.

At last, to my boyfriend. Thank you for the flicker of hope you gave me to keep pursuing my passion and my happiness, for the patience and kind words when I was down and for always having my hand.

To everyone that at some point came into my life. All of you led me here.

This master project is inserted in a project to investigate the genetic legacy on the slave trade ("From Portugal back to Africa: uncovering the African roots of present-day Portuguese" - TDC/SOC-ANT/30316/2017).

STATEMENT OF INTEGRITY

I hereby declare having conducted this academic work with integrity. I confirm that I have not used plagiarism or any form of undue use of information or falsification of results along the process leading to its elaboration.

I further declare that I have fully acknowledged the Code of Ethical Conduct of the University of Minho.

ABSTRACT

Africa is believed to be the birthplace of the first Anatomically Modern Human at 200 ka. This first form of *Homo sapiens* colonized Africa first and had one thing in common: the haplogroup of the mitochondrial DNA (mtDNA) L. Around 60 ka occur the Out-of-Africa migration, and from then on there were certain period of increased migration from Africa to mainly Europe and Southwestern Asia, mainly associated with optimal climatic conditions. More recently, with the globalization and the discovery of the New World, some European countries started to export slaves from Africa to Europe and the Americas. Since mtDNA is maternally inherited and is non-recombining, it is the “perfect” way to follow of lineages and migratory movements, allowing the study of the sources of displaced populations.

In order to attempt to understand the main source of population within Africa that migrated to Europe, Southwestern Asia, North and South America, a phylogeographic analysis of the L haplogroup was performed using 6658 human mtDNA sequences from Africa, Europe, Southwestern Asia, North and South America. Using phylogenetic reconstruction, a molecular mtDNA clock to date the events and Founder analysis we were able to reconstruct the history of the haplogroup L all over the world and visualize the peaks of migration from Africa to the other continents.

Two main events of migration from Africa occurred: one at 8000 years and the other at 500 years. Geographically, the source of populations at these time-frames are clearly different in some aspects, such as the appearance of South African lineages in Europe, Southwestern Asia and the Americas only in historical migrations (500 years ago). When associating this fact with world history, we can correlate this with the Trans-Atlantic Slave Trade route, a massive forced movement of over 10 million African from the 16th century on.

Genetic studies associated with ancestry aid us in better comprehend history. In here, we were able to uncover a bit more about the L haplogroup’s history, not only in Africa but all over the world, about the Trans-Atlantic Slave Trade and the genetic evidences left behind that are still present to this day.

Keywords: Africa, Founder analysis, mtDNA, Phylogeography, Transatlantic Slave Trade.

RESUMO

Acredita-se que África é o berço do Ser Humano anatomicamente moderno, há 200 000 anos. Esta primeira forma de *Homo Sapiens* colonizou África e tinha um facto em comum: o haplogrupo do ADN mitocondrial (mtDNA) L. Há cerca de 60 000 anos ocorreu a primeira migração para fora de África (“Out-of-Africa”), e a partir daí existiram períodos de maior migração de África para a Europa e o Sudoeste Asiático, principalmente associados com condições climáticas ótimas. Mais recentemente, com a globalização e a descoberta do Novo Mundo, alguns países europeus começaram a exportar escravos de África para a Europa e as Américas. Uma vez que o mtDNA é herdado por via materna e não sofre recombinação, é a forma “perfeita” de seguir linhagens e movimentos migratórios, permitindo o estudo da fonte das populações deslocadas.

Numa tentativa de compreender a principal fonte de população de África que migrou para a Europa, o Sudoeste Asiático, a América do Norte e do Sul, foi feita uma análise filogeográfica do haplogrupo L com 6658 sequências de mtDNA humano de África, Europa, Sudoeste Asiático, América do Norte e do Sul. Com reconstrução filogenética, relógio molecular de mtDNA para datar eventos e análise de Fundador, conseguimos reconstruir a história do haplogrupo L em todo o mundo e visualizar os picos de migração de África para outros continentes.

Ocorreram dois principais eventos de migração: um há 8000 anos e outro há 500 anos. Geograficamente, as populações-origem destes períodos são claramente distintas em alguns aspectos, como a presença de populações do sul de África nos restantes continentes apenas nas migrações históricas (500 anos). Quando associamos este facto com a história mundial, podemos relacioná-lo com a rota Transatlântica de tráfico de escravos, que movimentou à força mais de 10 milhões de africanos a partir do séc. XVI.

Os estudos genéticos associados à ancestralidade ajudam-nos a compreender melhor a história. Neste trabalho conseguimos revelar um pouco mais sobre o haplogrupo L, não só em África, mas em todo o mundo, sobre a rota Transatlântica de tráfico de escravos e as ligações genéticas deixadas que ainda hoje estão presentes.

INTRODUCTION

It is part of the Human nature to be curious about our origins and consequently to work as hard as possible to achieve answers. There are demographic and migratory events in Human history that need further explanation. With this in mind this thesis is organized in four chapters. On the first chapter an explanation is provided on the importance of mitochondrial DNA (mtDNA) in ancestry studies, the concept of phylogeography, the theories of the origin of modern humans and the expansion of mankind and the influence of slavery in the current mtDNA gene pool worldwide. The second chapter includes a list of all the methods used to answer the aims of this thesis, being the results shown on the third chapter. The last chapter is the discussion of the results: and that includes reviewing the results obtained and contextualising these results within the area of phylogeography. Also, the discussion contains the assessment of the goal's completion and future perspectives.

1. MITOCHONDRIAL DNA

1.1. THE MITOCHONDRIA

Mitochondria are organelles present in the majority of eukaryotic cell. Their main function is to produce metabolic energy (Alberts et al., 1994).

Mitochondria were firstly observed in 1840, but only in 1925 they were implied in the respiratory chain (Ernster and Schatz, 1981). Almost 30 years later, in 1957, mitochondria received the popular denomination “powerhouse of the cell” by the biologist Philip Siekevitz (Siekevitz, 1957), due to their capability of generating most of the chemical energy needed to power the cell's biochemical reactions. Structure-wise, each mitochondrion is composed of an outer membrane and an inner membrane, with high motility and they have the capability of fusion and fission with other mitochondria (Chan, 2006; Karbowski and Youle, 2003). Mitochondria have a morphology that drastically changes according to the cell, including variation inside the same cell (Detmer and Chan, 2007), and they vary in number and location according to the cell type.

Functionally, mitochondria are linked to important roles such as signalling, cellular differentiation, apoptosis and autophagy, steroid and lipids synthesis, controlling the cell cycle and growth and regulation of the membrane potential and the cellular metabolism, beside the most notorious function of producing the cell's energy in the form of adenosine triphosphate (ATP) (McBride et al., 2006).

1.2. THE MITOCHONDRIAL GENOME

Mitochondrial DNA is the genetic material inside the mitochondria. The human mtDNA was the first mitochondrial genome to be completely sequenced in 1981 (Anderson et al., 1981). A single mitochondrion can have up to 10 copies of mtDNA, each with 16569 base pairs, according to the revised Cambridge Reference Sequence (rCRS), compiled in an extremely compact circular double stranded conformation without histones (Andrews et al., 1999).

The mtDNA sequence contains 37 genes, of which 28 are located on the H-strand (the “heavy” strand, rich in guanine) and 9 on the L-strand (the “light” strand, rich in cytosine by complementarity) distributed as shown in Figure 1. As mentioned previously, the mitochondria are extensible involved on the cell energy production, with 13 genes related with respiratory chain complexes, producing enzymes used on the oxidative phosphorylation, an ATP producing mechanism (Sharma and Sampath, 2019). Of the other genes, 2 encode for rRNA and 22 for tRNA.

A major part of the mtDNA genome is the control region, with 1.1 kb, located between positions 576 and 16024 (Figure 1). This region contains the transcription and regulation factors, the origin of replication for the H-strand (Crews et al., 1979) and, importantly, three hypervariable sections: HVS-I, HVS-II and HVS-III. These sections are fundamental in the study of human population genetics, mainly in the early stages of archaeogenetics, even though the last section (HVS-III) has a more focused application in forensic sciences and it is less variable (Brandstätter et al., 2004). Although earlier archaeogenetic studies used exclusively HVS-I and HVS-II to genetically characterise the human populations, in the last two decades, the sequencing of the complete mtDNA genome allowed a much higher resolution and previous concepts about the history of worldwide populations were revisited.

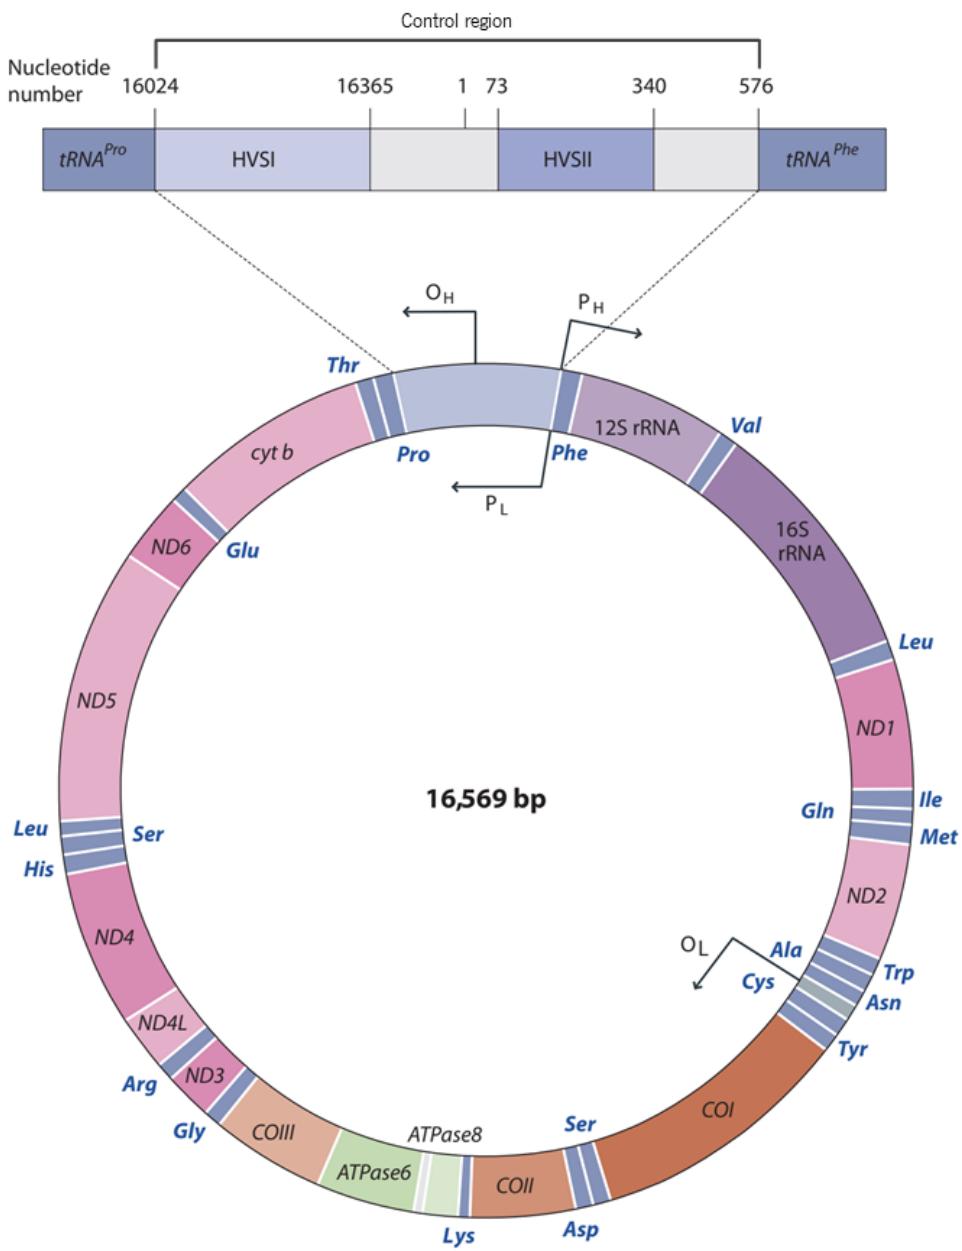

Figure 1 - Representation of the human mitochondrial genome.

mtDNA has 16569 bp compiled in a circular conformation. It has 37 genes organized in two strands: The H-strand ("heavy"), with 28 genes, and the L-strand ("light"), with 9 genes, all depicted in the figure. Emphasis on the control region and two of the hypervariable regions, HVS-I and HVS-II. Adaptation from (Jobling et al., 2014)

1.3. MITOCHONDRIA IN POPULATION STUDIES

Mitochondrial DNA has several characteristics that make it the ideal subject for human population studies:

1.3.1. Heritage and Lack of recombination

mtDNA is inherited almost exclusively by the maternal lineage, although some cases of paternal inheritance have been reported (Luo et al., 2018; Schwartz and Vissing, 2002) but given the small amount of occurrences, these situations are considered extremely rare and possibly associated with abnormal processes. The male mtDNA, present in the sperm's mitochondria, is marked to be destroyed with a ubiquitin tag once inside the fertilized oocyte (Sutovsky et al., 1999). So, even though mitochondria are capable of performing recombination, this has never been observed in the context of human evolution (Jobling et al., 2014).

In general, being exclusively maternally inherited, presents a slight disadvantage, since mtDNA only presents the maternal side of the story. Thus, for a better picture of the evolutionary history, there is the need to integrate all the available genetic information with the mtDNA inferences, like using autosomes, Y-chromosome and incorporating other data from other fields of research (like archaeology and palaeontology) (Vibranski and Long, 2016).

1.3.2. Number of copies

Unlike nuclear DNA where a single copy exists, each cell contains hundreds of mitochondria and thus, thousands of mtDNA copies. As a result, it is widely used on ancient DNA (aDNA) studies and forensic cases from degraded samples, where mtDNA is easier to find than nuclear DNA, that tends to be in very low concentrations (Pääbo, 1989).

1.3.3. Mutation rate

Just like nuclear DNA, mtDNA also suffers mutations (deletions, insertions and/or base substitutions), although in a faster mutation rate, up to 10 times faster, that allows the tracing of the maternal side of the human evolution more accurately in the timeline of most recent aspects of

human history. This is often attributed to the high exposure of mitochondria to reactive oxygen species on the course of oxidative phosphorylation (Shokolenko et al., 2009) and also the fact that mtDNA is not protected by histones. Besides the exposure to reactive oxygen species, the established mutational patterns can also be due from nutritional changes, alteration of life style and climate changes. It is known that there has been periodic migrations by archaic and modern humans, driven by climate changes and the lack of food, which contributed to the genetic diversity and variability of the different haplogroups (Rito et al., 2013).

Heteroplasmy (the presence of more than one type of mtDNA genome inside the same cell (Stefano et al., 2017)) occurs in 90% of the population, with up to 20% implied in certain mitochondrial diseases (Ye et al., 2014), like cardiovascular diseases, diabetes and some forms of cancer (Dimauro and Davidzon, 2005). The bottleneck effect is also an important mechanism of mutation management. As mentioned in the previously, heteroplasmy is a very common situation and it is associated with this mechanism, where the mutated or the wild-type (the one inherited by maternal lineage) sequences tend to be more or less replicated, according to its benefit for the cell and the individual (Zhang et al., 2018).

The consecutive accumulated mutations in the germinal cells, where the mutated mtDNA is transmitted to the offspring, leads to new variants in the population and eventually to the creation of new haplogroups.

1.4. OTHER GENETIC STUDIES

Besides mtDNA, other genetic systems, for example Y-chromosome and autosomal data (at its highest level, whole genome data), can be used to study human population.

Y-chromosome presents the male side of the genetic history of a population, being inherited only by males and it also lacks recombination in most of the chromosome. Compared with mtDNA, it shows a much lower mutation rate. The difficulty to access the sequence diversity, associated with the low mutation rate and a very high number of repetitive regions, made it more challenging to characterize SNPs used in human population studies. In recent years though the Y-chromosome has been gaining a new breath, with more and more studies regarding its genetic history and

evolution (Cruciani et al., 2011). Migration mainly dominated by males, often associated with pastoralism, are observed only in Y-chromosome variation, having left no signal on the rest of the genome or the mtDNA (Haak et al., 2015; Henn et al., 2008) .

Whole-genome analysis uses the nuclear genome information for population studies. Given the large amount of data implied in this type of studies, and the complexity, since 99.9% of the genome is shared by every human (Li et al., 2014), genome-wide studies used to be very expensive and time-consuming. With the increasing interest in the past few years and the continuously decrease in sequencing prices, nowadays it is a much faster and more efficient process, with more data available to the public, that also led to the improvement of statistical method of analysis (Chakravarti, 2015). When compared with Y-chromosome and mtDNA, genome-wide presents a disadvantage in the migratory records, since the nuclear DNA is subject to recombination, many population and migratory markers and other important artefacts are lost due to the admixture with the sink population (Rito et al., 2019).

2. POPULATION STUDIES

2.1. ARCHAEOGENETICS

Archaeogenetics is a relatively new discipline, that consists in the “application of molecular genetics to study the human past” with the contribution of both archaeology and genetics (Soares et al., 2010). Although this field of study began in the 1960s with studies led by Cavalli-Sforza, observing traits like human blood groups and lactase persistence, known to be inherited characteristics, and correlating them to linguistic and ethnic groupings, it was only later that this discipline was named by the archaeologist Colin Renfrew (Sokal, 2001).

The development of techniques like Polymerase Chain Reaction (PCR) and Sanger DNA sequencing in the 1980s and the next-generation sequencing techniques in the 2000s, combined with the advantages of the use of mtDNA, allowed a deep assessment of genetic variation. In recent years, it also allowed the sequencing of small and degraded DNA samples from archaeological sites (aDNA), providing a more in-depth study of ancient civilizations and giving a new strength to the archaeogenetics field (Marske, 2016).

2.2. PHYLOGEOGRAPHY

Phylogeography is the integration of phylogenetics and geography in the study of population history, by establishing lineages and their evolution throughout time and space (Avise, 2000). The main tools used in phylogeography are phylogenetic trees, the geographical distribution of the established lineages and molecular clocks, in combination with other areas like archaeology, paleoanthropology, paleoclimatology and ethnology (Cruzan and Templeton, 2000). Integrating all or some of these aspects, it is possible to shed light on the modern geographic distribution of a given species, by presenting its origin and dispersal patterns.

2.2.1. Phylogenetic trees

A phylogenetic (or evolutionary) tree is a diagram that contains branches connected by nodes. The structure of the trees consists in three parts: root, node and branches. While the branches represent lineages, the nodes represent the common ancestor (real or theoretical), where the lineages started to diverge. The root, when present, is the representation of the common ancestor of all the individuals present on the tree, and it defines the directionality of it. At the end of each branch there is a terminal node, also known as leaf, that represent modern sampled sequences (Scott and Baum, 2016).

As a whole, the tree is the visual representation of the evolutionary relationship between individuals. In phylogenetic trees these evolutionary relationships are based on genetic mutations or the lack of them (Choudhuri, 2014).

2.2.2. Tree construction

Trees can be rooted (Figure 2A) or unrooted (Figure 2B). Usually, the trees are rooted by using an outgroup: an individual that, although it is related closely to the data, it is far enough to not be represented in between the other branches. The same data can be presented without the root, but it will only show the relation between branches without indicating ancestrally (Choudhuri, 2014).

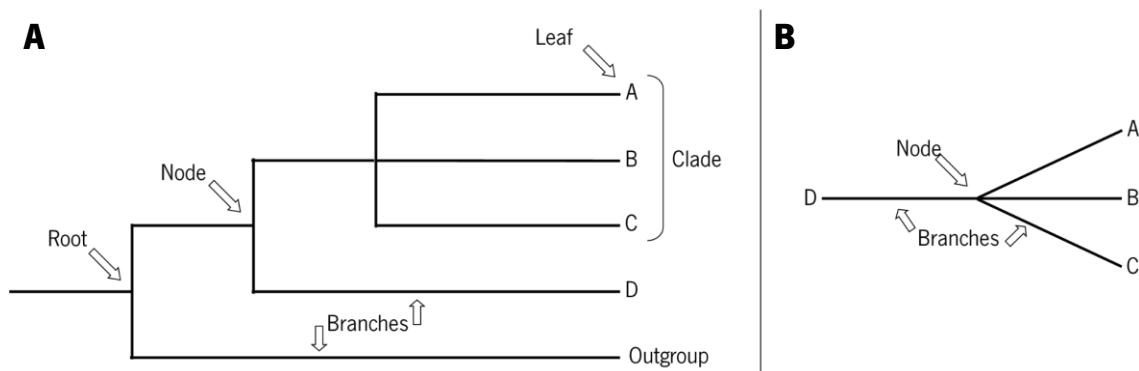

Figure 2 - Representation of phylogenetic trees and terminology.

A: Rooted tree with an outgroup; B: Unrooted tree showing relationships between branches.

There are two different methods to build the phylogenetic trees: distance-based and character-based. For the distance-based approach, the distance between each sequence is calculated and the tree is formed. Methods such as UPGMA (unweighted pair-group method with arithmetic mean)

and Neighbour-joining (NJ) are employed. Trees generated by NJ clustering are the more common, since it generates the shortest sum of branch lengths. Even though this method has its benefits (e.g. faster calculations), character-based methods are preferable when it comes to phylogeography analysis. The character method is based on the aligned sequences organized by similarity of characters. This better presents the evolutionary processes, as it accounts for the occurrence of mutations and alterations in repetitive motifs. Maximum-Parsimony, Maximum-Likelihood (ML) and Bayesian methods are the most used character-based methods.

Maximum-Parsimony

In this method, the length of each branch is calculated according to the number of polymorphisms along it. The algorithm creates all possible trees and then chooses the one with the smallest branches, the one that minimizes the total number of character-state changes. This methodology requires a low computational power but tends to lead to statistical inconsistencies called “long branched attraction”, where two independent samples that have fast evolving characters are grouped together, regardless of their true evolutionary relationships (Freudenstein, 2016).

Maximum-Likelihood

This method generates all the combinations to multiples unknown parameters and then, given the predefined evolutionary model, it estimates which tree is more likely to represent said data. The parameters can be branch length, sequence alignment, nucleotide substitution model, among others, and are what defines the models tested. This is a very demanding computational method (Dhar and Minin, 2016).

Bayesian Inference

This method, instead of only presenting one single tree, presents a set of trees and the probability of each, after repeated Markov Chain Monte Carlo (MCMC) simulations. This approach is also very demanding in terms of computational capacity and has been more and more used in phylogenetics and specifically in phylogeography (Yang, 2016).

There are no perfect methods to create the most precise tree. For this reason, better results are obtained using an integration of various methodologies, since they complement each other and when used together may produce more reliable results.

2.2.3. Median Networks

In many occasions, due to homoplasy (multiple occurrences of mutations in the same position of mtDNA), a single phylogenetic tree is not the most accurate representation of data, as loops or reticulations, can be generated, when multiple evolutionary equally parsimonious reconstructions are possible. To show the different possible evolutionary routes, structures called networks depict a better image. For mtDNA the most used are the median networks (Bandelt et al., 1995). This type of network converts the variant sites to binary characters and then link the samples by their distance to each other. Reticulations can originate large hyperdimensional cubes when there is a large amount of data. To prevent this complication, a set of rules has been devised to eliminate some of the more likely occurrences, including a weighting scheme where fast sites are given a higher probability of recurrence (Nakhleh and Morrison, 2016).

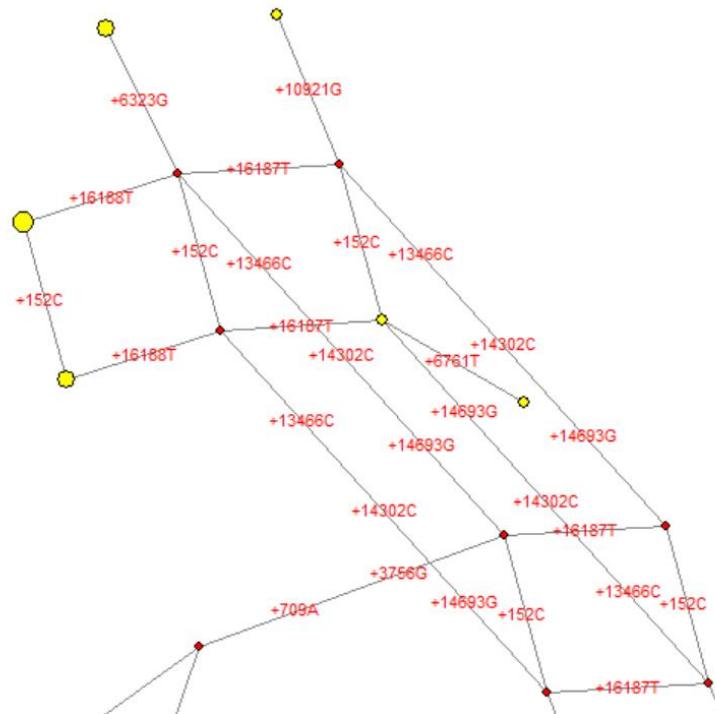

Figure 3 - A network diagram rendered with Network 10.0.1 and Network Publisher 1.1.0.7 software (www.fluxus-engineering.com). The yellow dots represent individuals and the red dots represent reticulations.

2.2.4. Founder Analysis

Founder analysis is a quantitative method of phylogeographic analysis. It aims to identify, scale and date the migrations of a population to a new territory, by evaluating the diversity of lineages that came from a specific geographic population (the “source”) and settled in a specific location (the “sink”), also dating the time that it took for this diversity to occur.

This method of analysis was firstly proposed by Richards and colleagues in 2000 (Richards et al., 2000) and has since been used in the search of the founder lineages of the world. Although being a good method of analysis, the complex mathematical knowledge that its application requires, made it scarcely used. Recently, using the principles of the original methodology, a user-friendly program was developed, to facilitate the founder calculations (Vieira et al., 2020).

Founder analysis aims to identify common sequence or clades between a hypothetical source and sink populations (Figure 4). Following that identification, the subclades in the sink are isolated and the diversity accumulated in the new regions is used to estimate the time of migration using a molecular clock.

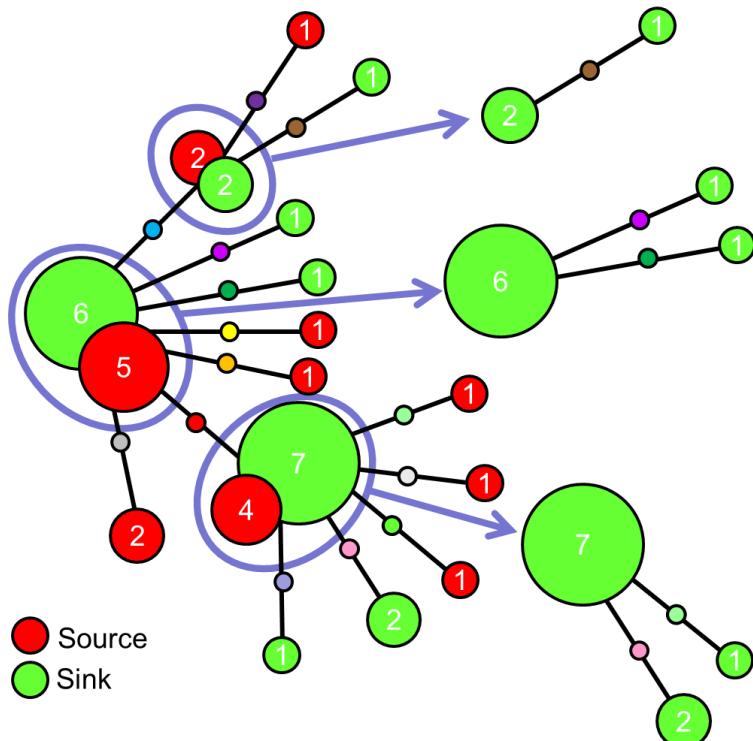

Figure 4 - Representation of the Founder analysis process.

Common sequences (present or inferred) in a source and a sink population are detected in a phylogenetic tree or network. Diversity of each clade in the sink is used to estimate the time of migration.

Common mtDNA mutations and reverse gene flow can present a challenge to the founder analysis. As to surpass this problem, several criteria have been developed to select what can or cannot be considered a founder group. *f0* is the least restrictive criterium, as it considers all the samples in the data both source and sink. In *f1* and *f2* criteria, for a clade to be consider founder, the sequence type must display either one or two further derived branches, respectively, in the source populations.

Each founder will display a point estimate for the time of migration and a standard error for that estimate. Those parameters will allow each lineage to be statistically allocated to each predefined migration time (Figure 5) (Richards et al., 2000). The migration patterns will be established through the statistical allocation of all founder clades. While the first methodology would allocate lineages into specific migrations (Figure 5.A), the researcher can also perform an unbiased scan by selection equally-distant migration times and by observing the distribution of lineages across time (figure 5.B) (Soares et al., 2012).

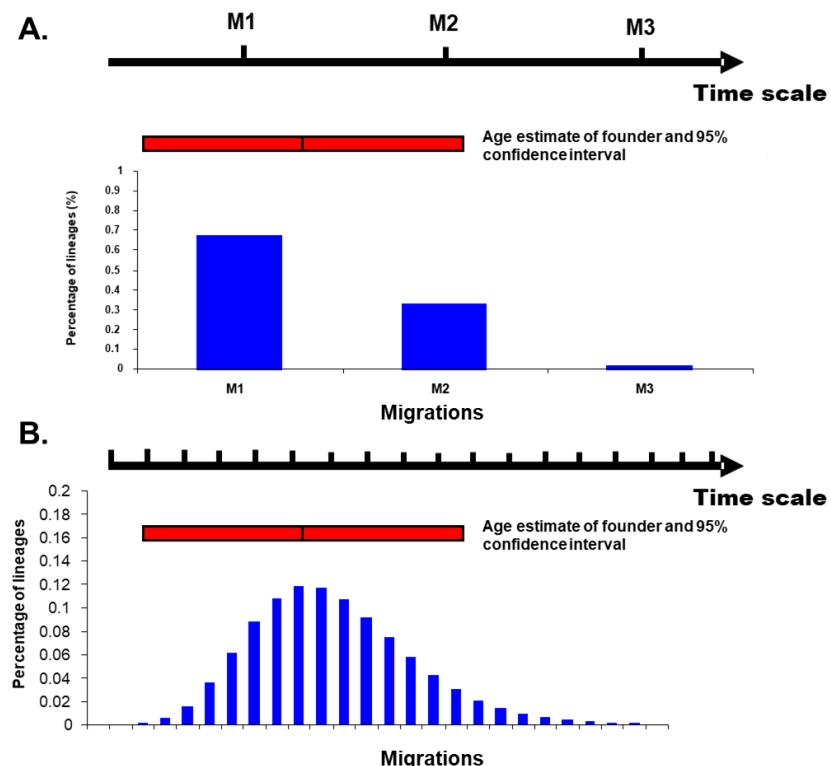

Figure 5 - Statistical distribution of a founder type across:

A) three predefined migrations (M1 to M3) and, **B)** across multiple equally-spaced migration events.

2.2.5. Molecular Clock

The understanding of mutations and the time that they take to happen is pivotal in phylogeny, and for this a reliable molecular clock is essential since it allows us to date the divergences between branches and consequently the division of each clade and subclade. Theoretically, evolution occurs in a steady rate, making it possible to use all the accumulated diversity to pinpoint certain occurrences in a temporal perspective (Bandelt et al., 2002). Since molecular clocks allow us to estimate ages of lineages, they make possible to calculate the minimum arrival age of each founder cluster in the sink, using the before mentioned founder analysis (Richards et al., 2000).

Most mathematical models behind the dating of evolutionary events assume that the mutation rate is known and constant. Most use either the coding or the non-coding region of mtDNA. One example of this is the estimated function 1.80×10^{-7} substitutions/nucleotide/year in the HVS-I section of the control region of mtDNA (non-coding), developed by Forster and co-authors (Forster et al., 1996). Another example is the mutation rate estimated by Mishmar and colleagues of 1.26×10^{-8} substitutions/nucleotide/year in the coding region (Mishmar et al., 2003). The approaches based on only a determined part of the mtDNA present many problems, for example, the mutation rate differs in the coding region compared to the non-coding region (the non-coding region has a ten folds higher mutation rate than the coding region) (Howell et al., 2007). Other problem is that it presumes that the substitution rate is a linear relation between the accumulation of mutations and time, without taking into consideration the weight of the natural selection. It has also been shown that the oldest branches have a higher rate of synonymous mutations than younger branches. This is caused by the effect of purifying selection that occurs earlier on slightly pathogenic mutations (mostly non-synonymous) whose selective strength decreases later on as most deleterious mutations will hardly survive to older clades. This fact once again shows that a linear approach is not correct, since the short-term and the long-term mutation rate are not the same (Kivisild et al., 2006).

A recalibrated molecular clock, that uses the entire mitochondrial genome (coding and non-coding regions), was presented in 2009 by Soares and colleagues (Soares et al., 2009). They proposed a mutation rate of 1.665×10^{-8} substitutions/nucleotide/year, that translates to approximately 1 mutation per 3624 years, that is further mathematically adjusted for the effect of purifying selection (Figure 6).

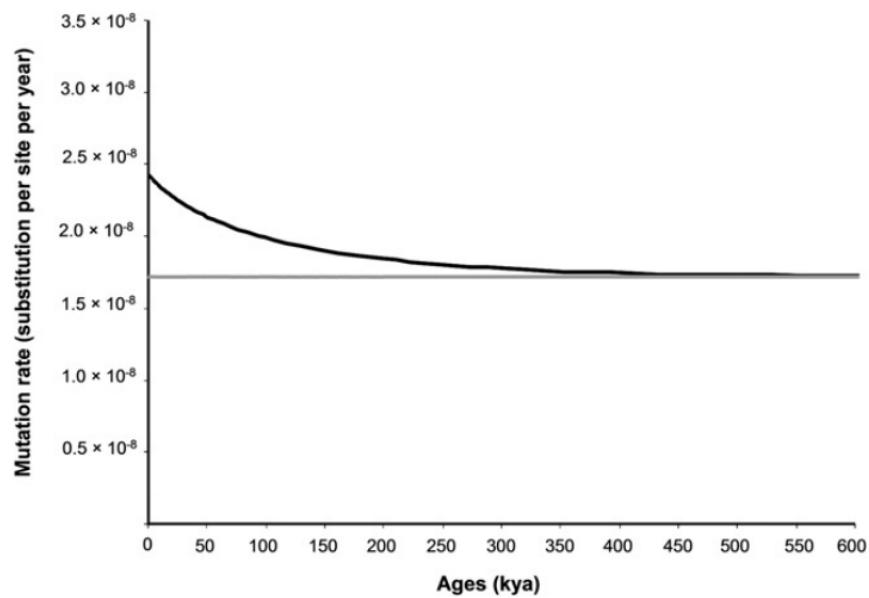

Figure 6 - mtDNA mutation rate variation through time.

The black curve represents the mtDNA mutation rate and the grey line represents the interspecific (long term) mutation rate (Soares et al., 2009).

3. AFRICAN MTDNA PHYLOGEOGRAPHY

3.1. ORIGIN OF ANATOMICALLY MODERN HUMAN

The origin of the Anatomically Modern Human (AMH) has been subject of extensive studies from multiple areas, leading to the conjecture of many theories to explain the rise and dispersion of *Homo sapiens*.

One of the theories is known as the Out-of-Africa model. It proposes that AMH arose as a new species in 200-150 ka in Africa and later expanded to other parts of the world, replacing the existent populations of hominids. This theory implies that the archaic hominid forms did not have any genetic input in the AMH and so all human population ancestry can be traced back to Africa 200 000 years ago (Relethford, 2008).

Another theory is the Multiregional evolution model, that suggests that the appearance of the AMH occurred in multiple events simultaneously across Europe, Asia and Africa, as the result of a coalescence of existing archaic populations (Relethford, 2008). This theory was proposed attempting to explain how some human traits are present in all three continents without known gene flow between them, while others are clearly region-associated traits retained during the evolutionary process. To justify the apparent similarity between populations, the defenders of this model attribute it to an equilibrium of gene flow, selection and genetic drift (Relethford, 2001; Wolpoff et al., 1984).

The most consensual perspective of these theories is actually a combination of them, with an African origin and a variable degree of gene flow in and out of Africa during the migrations and repopulations. To truthfully pinpoint the moment that the *Homo sapiens* appeared is extremely difficult, since it was a gradual evolutionary process that lasted a few hundred thousand years, as the scientific studies prove it (Rito et al., 2019).

The fossil findings of Omo I, dated 190 to 200 ka (Figure 7.1) (Fleagle et al., 2008; McDougall et al., 2005) and Herto, dated 154 to 160 ka in Ethiopia (Figure 7.2) (White et al., 2003), among other less significant fossilised evidences, support the paleoanthropological and archaeological assumption that the AMH arose in eastern Africa, even though the oldest AMH fossil found were in fact the Jebel Irhoud remains, in Morocco, with approximately 315 ka (Figure 7.3) (Hublin et al.,

2017). This discrepancy in data shows that the origin conclusion is yet unreliable and needs to be further studied.

In archaeogenetic analysis there is also a lack of consensus regarding the geographic location of the AMH, since different analytical methods and genetic markers present different results. Although all of them agree with the African origin, there is still a debate when it comes to specify a region in Africa or even a route for these first migratory events (Rito et al., 2013) as represented in Figure 7.

Genome wide studies suggest a southern African origin (Henn et al., 2011; Tishkoff et al., 2009), congruent with the results of many autosomal genomic studies, that show an early divergence between Khoesan population (southern) and the rest of the african population, displaying a clear difference between northern and southern populations (Gronau et al., 2011; Veeramah et al., 2012). When it comes to gender-specific markers, the Y-chromosome, portrayer of the male lineage, albeit the small amount of data available, shows a central/western origin of the male lineage (Cruciani et al., 2011) with a coalesce time of almost 350 ka (Mendez et al., 2013), while the mtDNA, that represents the maternal lineages, has given ambiguous signals. The mtDNA lineages diverges in 2 branches: L1'6 and L0 (Rito et al., 2013). L1'6 is in agreement with the origin of Y-chromosome, or at least associated with the northern part of the continent, since there are no actual records of the north of Africa. This is due to depopulation that occurred 75-65 ka ago associated with climate changes, around the same time that L3 appeared and migrated out-of-Africa (Soares et al., 2012). The region was repopulated again around 40-20ka from Eurasia (Macaulay et al., 1999; Olivieri et al., 2006). L0 shows a different story: the most probable origin of this haplogroup is in the south, where it still prevails in Khoesan populations and Bantu speakers (Barbieri et al., 2013; Chen et al., 1995). These differences make it still a mystery where AMH come from.

Mitochondrial Eve is the most recent common female-lineage ancestor and lived around 150-200 ka ago, when the AMH population was about 10000 people. According to human genetics, Mitochondrial Eve is the point of convergence in the maternal tree of life, meaning the only past woman with an unbroken female lineage to this day (Cann et al., 1987). The exact location of the Mitochondrial Eve is yet unknown due to the difficulty to pin-point it using phylogeography, since there is no deeper lineage, but the nucleotide diversity in the HVS-I region of mtDNA suggests a central African placement (Figure 7) (Soares et al., 2016).

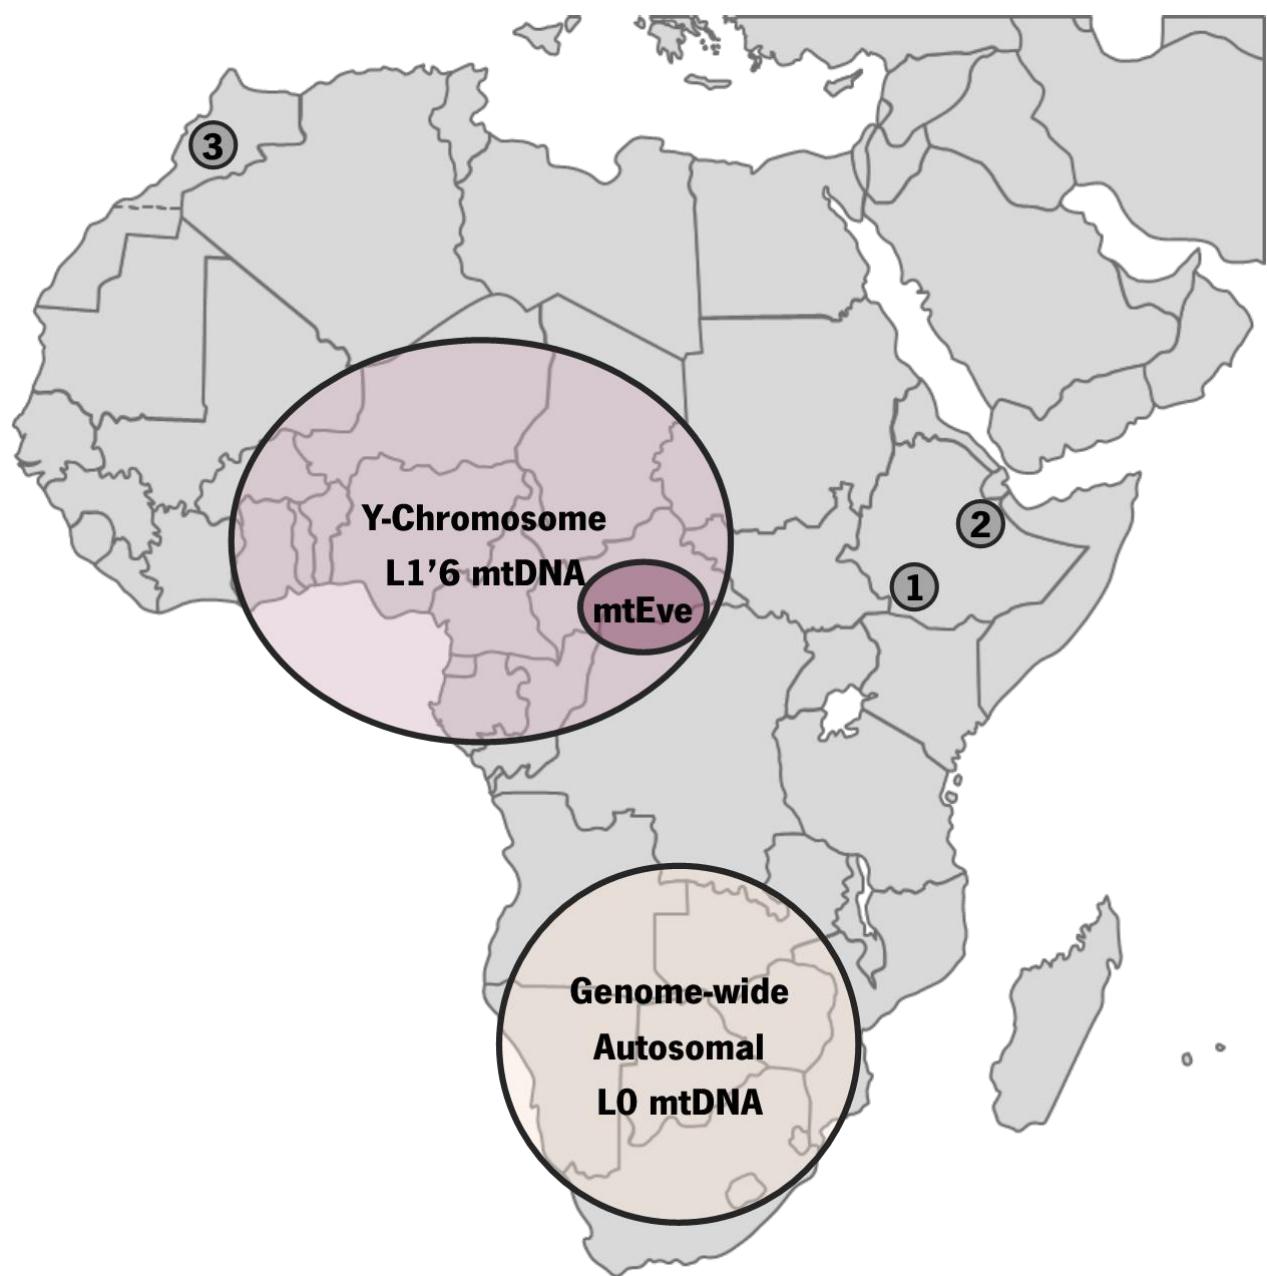

Figure 7 - Representation of the different hypothesis for the origin of Anatomically Modern Human.

Numbers 1, 2 and 3 represent the location of the major fossil findings. **1** - Omo I (Southeastern Ethiopia); **2** - Herto (Northeastern Ethiopia); **3** - Jebel Irhoud (Morocco). The circles represent the possible points of origin of AMH according to the different genetic analysis: Whole-genome and the mitochondrial haplogroup L0 point to a southern origin, while the Y-chromosome and the mitochondrial haplogroups L1'6 point a central/western origin, where it is presumed to be mitochondrial Eve's location.

3.2. HAPLOGROUPS

An haplogroup consists in a group of similar haplotypes with a common ancestor. A haplotype is a set of DNA variations, or polymorphisms, that tend to be inherited together (Blumberg et al., 2016). The first haplogroups to be classified were A, B C and D in Native Americans (Torroni et al., 1993), and from then, the next haplogroups found were named in alphabetic order. Nomenclature of the haplogroups consists in capital letters and the subsequent subclades are named by alternation between numbers and lower-case letters. It is important to note that in some cases the haplogroup is an offshoot of another and does not obey the normal naming rules, for example the haplogroup M and N diverge from L3.

The most ancient haplogroups are located in Africa (L0'1'2'3'4'5'6) and all lineages found outside of Africa belong to L3, a strong argument for the out-of-Africa expansion theory. L3 divides in M and N outside the African continent, both present in Asia, Oceania and the Americas, but in Europe only N is present (Richards et al., 2016). U is derived from R that is derived from haplogroup N and has currently a large representation in Europe and in North Africa, mainly due to the back-flow of populations (González et al., 2007). In 2009, Soares *et al.* proposed a global mtDNA phylogenetic tree considering the updated molecular clock (Soares et al., 2009). In it, it is possible to visualize the clear separation between within and outside African haplogroups.

3.3. EVOLUTION AND MIGRATIONS

The different African haplogroups arose as a result of evolutionary forces, such as migrations, climate changes, and many others. Here they will be described according to their order of appearance, according to the estimated time of emergence for each clade: L0, L1, L5, L2, L6, L4, L3, clustered in L0 and L1'6, based on the works of Behar *et al.* (Behar et al., 2008), Rito *et al.* (Rito et al., 2013; Rito et al., 2019), Rosa and Brehem (Rosa and Brehem, 2011), Salas *et al.* (Salas et al., 2002) and Soares *et al.* (Soares et al., 2012; Soares et al., 2009; Soares et al., 2016). The phylogenetic tree of the Human mitochondrial DNA according to Soares et al. is represented in Figure 8.

The superhaplogroup L started to differentiate around 180-190 ka. Around 150 ka, L0 was the first branch to arise in sub-Saharan Africa. It comprises the subhaplogroups L0a'b'd'f'g'k. L0d was the first to appear, approximately 100 ka, and together with L0k, they make over half of the

maternal genetic pool. They are present mainly in Khoesan population of South Africa, but also in the click-speaking population of Tanzania and Angola. It was believed that L0f and L0a'b'g appeared in East Africa 80-90ka, but according to Rito et al. in 2019, this clade arose in the south and then migrated to East Africa around 70ka, where it remains to this day. Present at a smaller scale, L0a arose around 40-45ka in eastern Africa, although currently is spread all over the continent. This subhaplogroup has relatively short branches, indicating a recent evolution and population growth.

L1 separated from the remaining L1'6 between 140 and 150 ka and later branched in L1c and L1b. L1c coalesced 80-85 ka in central and western Africa. It has a 70% prevalence in the Pygmy maternal legacy and also 18-25% in the Bantu population in Angola, demonstrating a possible common ancestor between these populations within L1c. L1b has a similar origin point, although more turned to the coastal area. To note that this subhaplogroup has a very recent coalescence time, around 10 ka, indicative of a recent evolution and growth.

L5 has been previously classified as L1e. It appeared around 120 ka and it is observed in a very low frequency. It is originally from eastern Africa and has a noticeable gene flow to Pygmies and the Fali population located at the north of Cameroon.

L2 split from the main branch around 90 ka. Together with L3, it composes of 70% of the sub-Saharan maternal variation. This haplogroup subdivided in L2a'b'c'd'e. L2a is the most frequent and more widely spread haplogroup in Africa, going from the Tuareg population of Nigeria and Mali, through the Fali population, the Pygmies of Gabon and the Bantus of Mozambique. With a coalescence time of approximately 50 ka, L2a is hypothesised that it has a central African origin and then, starting 10ka migrated to the rest of the continent via the better conditions with the onset of the Holocene (Silva et al., 2015), followed by the Bantu expansion and later the trans-Saharan slave trade. It is also the most common sub haplogroup present in the African American population, due to the Atlantic Slave Trade that occurred in the 18th century, with slaves mainly from West Africa. The rest of the subhaplogroups coalesce around 60 ka and have a western central point of origin and still remain in this region.

L6 is a recent branch, with a coalescence time close to 20 ka, even though the divergence of the main branch is dated around 105 ka. It is mainly found in Ethiopia and Yemen, which leads to a probable point of origin in the eastern region, although it is still unknown.

L4 split from L3 around 85 ka, in north-eastern Africa. Nowadays it isn't very common. The subhaplogroup L4b coalescence time is very close to the haplogroup appearance, and it is mainly located in Tanzania and Ethiopia, much like L4a, also present in Ethiopia and in Sudan, but with a more recent coalescence time, close to 55 ka.

L3 appeared around 70 ka in eastern Africa and it is now widely spread in the entire continent. Some subhaplogroups of L3 can be linked to specific regions of Africa. L3h appeared 65 ka and is located in the northwest and the southeast of Africa. L3b'd appeared after, around 60 ka, and it is found mainly in central/south Africa, particularly Rwanda. L3f as a coalescence time of 50 ka and is found all over the continent, while L3e, with 40 ky, is found mainly in the central/south, but also has a small representation in the north of about 5%. This haplogroup is the origin of the other haplogroups present all over the world. Around the time of coalescence, it started to migrate out-of-Africa through the Middle East, branching out in M (60 ka) and N (70 ka), that populated the rest of the planet. Due to backflow, M and N are also present in Africa.

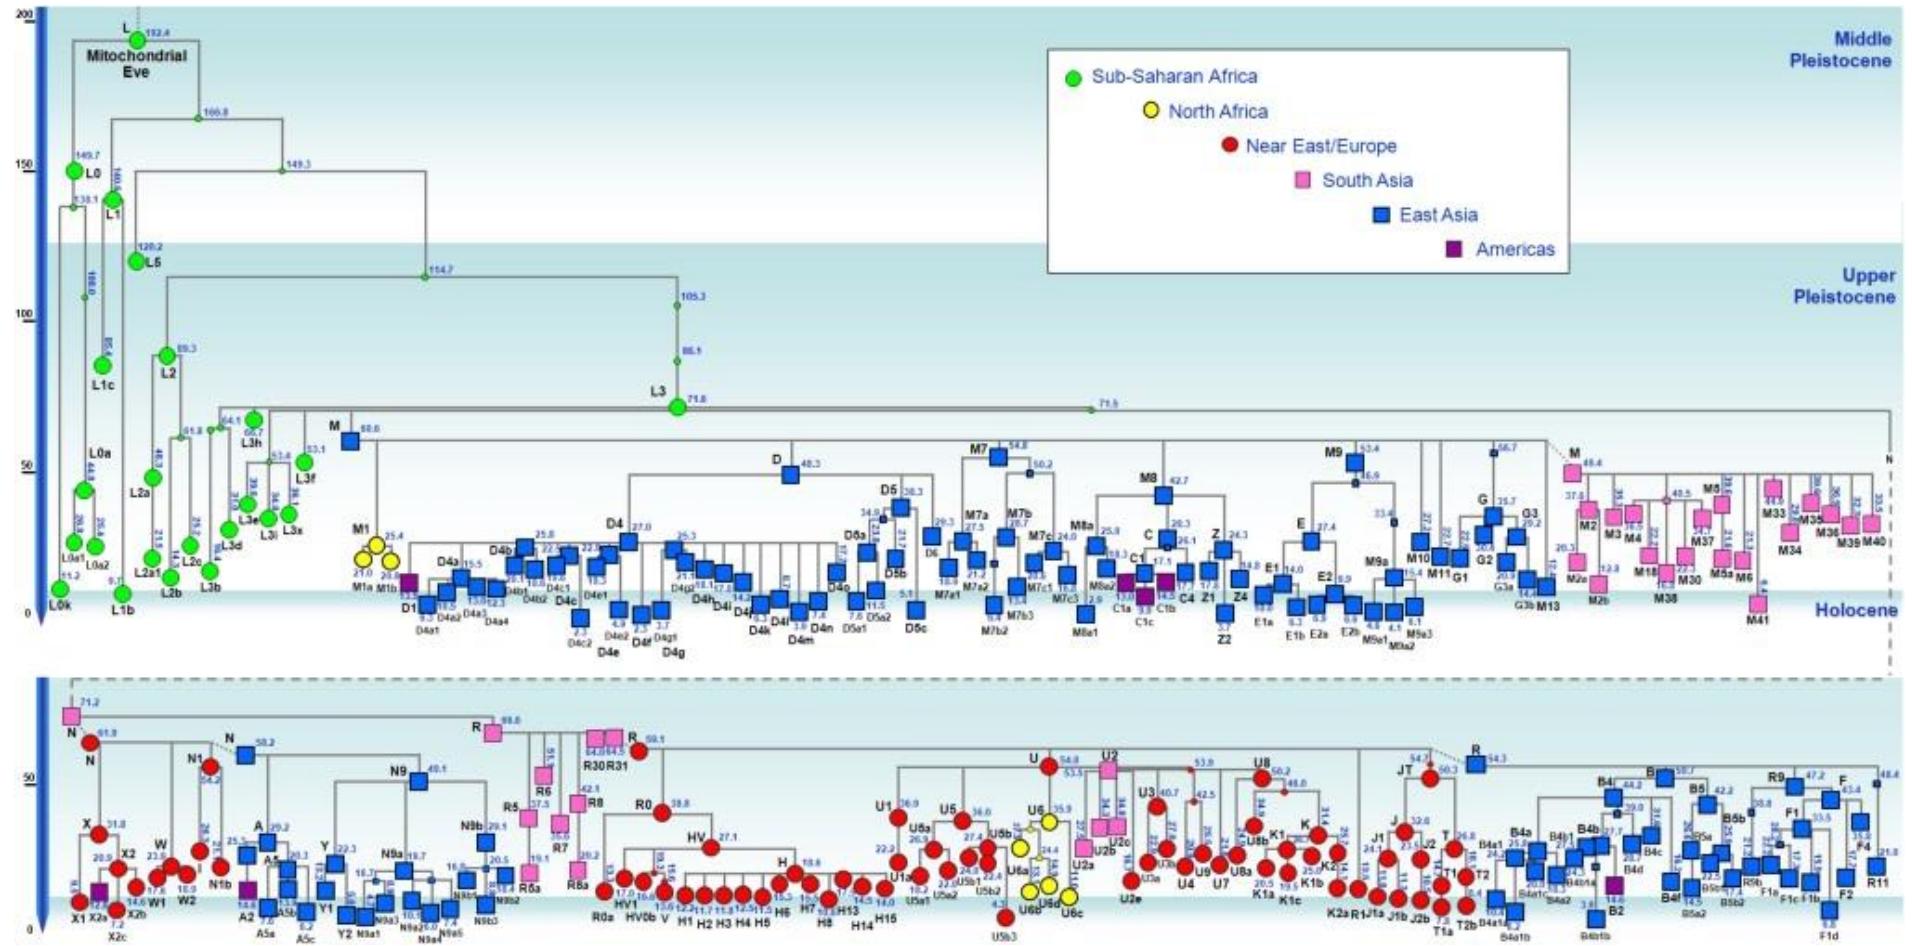

Figure 8 - Human mitochondrial DNA phylogenetic tree.

The first Anatomically Modern Human (mitochondrial Eve) arose in Africa around 200 ka and colonized the rest of the world in a single exit out of Africa, carrying haplogroup L3. Regions are differentiated through different colours and shapes and years are expressed in ka (Soares et al., 2009).

3.3.1. Causes and routes

It is known that there were periodic migrations of AMH mainly due to climate changes. Climate affects and determines the existence of plants and animals, necessary for human sustenance and is often appointed as the main contributor for the spread of *Homo sapiens* and its diversification. These factors are also associated with a phenomenon called bottleneck, a sharp reduction in population size which leads to a drastic reduction of genetic diversity that have caused diversity to be reduced at some points in the past (Soares et al., 2016).

Given the importance of the climatic changes, the migrations described next will be divided in periods known as MIS (Marine Isotopic Stage), based on the book *Africa from MIS 6-2* (Stewart and Jones, 2016), Blome *et al.* (Blome et al., 2012) and Rito *et al.* (Rito et al., 2013). These climate changes caused the intermittence of conditions in Africa, varying between the different regions, with periods of extreme drought to period of high levels of humidity and ice.

MIS 6

This period occurred between 190 ka and 130 ka. It was probably in this MIS that the AMH and the mtEve appeared and the haplogroups L0 and L1'6 arose.

The first migration registered was from central Africa (assuming a point of origin of the mtEve) to south, where L0 arose, around 150 ka. While L1 stayed in western Africa, L2'6 migrated to east Africa, 130 ka (Figure 9.A).

This period is characterised as glacial, with refugees in west Africa and, also known as tropical, and in the south, where the climate changes were not as intense, with intermittent periods of both dry and wet conditions, as is represented in Figure 10.

MIS 5

Between 130 ka and 70 ka, this period was known as the Warm Interglacial Period. It was in this time frame that L2 arose in the west after a migration from the L2'6 cluster in the east (~ 80ka) and the L5 branch diverged in the east (120 ka), according to Soares et al. (Soares et al., 2016) (Figure 9.B).

The haplogroup L0 started to branch out, with the subhaplogroups L0a'b'f'k possibly traveling from the south to the east, starting in the beginning of this MIS, and only two of them (L0a'b) arriving to eastern Africa nearly at the end of this period (76 ka), according to (Soares et al., 2016). This scenario was recently revised, however, with the migration from South to East Africa only taking place around 70 ka (Rito et al., 2019).

The Saharan region was, at this time, a “green” environment, with favourable condition for the migratory periods. The eastern region was a very desirable destination, due to the increase of the temperature and a reduction of the moisture levels, creating a very suitable place for growing resources and for population growth (Figure 10).

MIS 4

Lasting only 10 ky, between 70 ka and 60 ka, it was in this period that the out-of-Africa migration of L3 occurred, granting it a very important place in AMH history, as is shown in Figure 9.C. While the Out-of-Africa Migration involved only the East African L3 haplogroup, influences from the South (in the form of the before-mentioned migration of L0) might have been crucial in starting this expansion (Rito et al., 2019).

In this MIS began the Last Glacial Period (LGP), that lasted until MIS 2. As it is seen on Figure 10, the climate above the Sahara was extremely arid, causing this region to become desertified and depopulated. In contrast, the sub-Saharan regions had high moisture levels, with particular the southern part of the Nile Valley, close to the Horn of Africa, the point of exit for the out-of-Africa expansion, was considered a refugee, with permanent bodies of water. In the south, a region known as Namaqualand, in Namib, had high population density (Viehberg et al., 2018).

MIS 3

Lasting from 60 ka to 30 ka, it was in this period that the AMH started to populate the rest of the world. In the Middle East (southwestern Asia), L3 started to branch into M and N, this one later diverging in R and U. These haplogroups, particularly sub-branches of M and U, M1 and U6 respectively, repopulated the north of Africa, in a process known as backflow, nearly at the end of

MIS 3. Since these populations had some level of mtDNA differentiation to the rest of African haplogroups, there is a clear distinction between the sub-Saharan and the Mediterranean coast populations.

Climatic conditions in the west improved considerably, making it more suitable for human occupation, and L3b'c'd migrated to this area around 50ka, and later on L3e travelled the same route, 37ka (Figure 9.C).

MIS 2

This period began 30 ka and lasted until 15 ka. At the end of the LGP, it was at this time that the Last Glacial Maximum (LGM) was reached, meaning that the ice-sheets had achieved the maximum growth in Europe. In terms of migration this period seems to display little movement of people.

MIS 1

This period began 15 ka and it lasts until the current days. The Holocene, the current geological period, started approximately 11,5 ka. It is characterized by a general improvement of weather and relative moisture conditions (Weldeab et al., 2007). The Sahel Belt, located between the Saharan desert and the tropical forests, became a humid and fertile landscape at this time and until 6 ka, allowing the formation of migratory corridors, North/South and East/West (Triska et al., 2015). In this period migrations of sub-Saharan lineages moved from West, Central and Eastern Africa into Northern Africa crossing the Sahel belt and ultimately reaching Europe.

The beginning of MIS 1 was a period of a large-scale populational expansion, not only in Africa, but all over the world, with particular importance in the Southwest of Asia and in Europe. The improvement of the climatic conditions let to a recolonization of these regions in the early Holocene, with the majority of the migrations being through the Middle East, except the Iberian Peninsula that received a large inflow of migration via the Strait of Gibraltar (Cerezo et al., 2012; Hernández et al., 2015; Skorecki and Behar, 2013). In this same period, in the last few millennia, two major migrations to place in Africa: The Bantu expansion and the trans-Saharan slave trade.

The expansion of Bantu speakers is believed to have started from Nigeria/Cameroon where African populations developed agricultural practices. It is believed that they have taken two main routes to Southern Africa: through the West, along the coast towards the South, to Angola, South Africa and Botswana, around 3.5 ka; and to East, towards the Great Lakes, reaching Uganda approximately 2.5 ka and later Mozambique (1.8 ka) (Figure 9.E). This migration caused a forceful retreat of other populations: San, a population of hunter-gatherers known for their click consonants, went further south, into the Kalahari Desert, becoming even more isolated, and the Pygmies eventually adopted the Bantu language (Silva et al., 2015).

L2 became widespread in the continent around this period, in West, Central and Southeast Africa associated with the Bantu expansion and in the northwest due to the trans-Saharan slave trade. The trans-Saharan slave trade happened after the repopulation of the Sahara, in early to mid-Holocene, when the weather conditions were at its best, and provided a significant flow between North/South and West/East Africa, also associated with the haplogroups L1b and L3e5 (Soares et al., 2016) (Figure 9.D). Also known as the Arab trade, this route was used to transport, besides slaves, gold and salt between the North of Africa, the Persian Gulf and the sub-Saharan region (Kehinde, 2014).

A part of the North-eastern African population later, 1500 years ago, migrated to Europe, in particular to the Iberian Peninsula, through the Strait of Gibraltar (Cerezo et al., 2012; Skorecki and Behar, 2013; Soares et al., 2010). This major migration is also known as the Muslim Conquest, that left a major imprint in Iberia, not only genetic but also cultural (Botigué et al., 2013). From then on, with the discovery and conquest of the New World, African migration as gained a whole new meaning. African populations were forcefully taken to Europe and the Americas as slaves around 500 years ago and, more recently, in search of better life conditions, migrated to the whole world.

The phylogeographic analysis across the last 200 thousand years allows for a complete understanding on the origin and geographic distribution of each of the African clades (Fig. 11) which will allow the tracing of each sequence outside Africa to an African region.

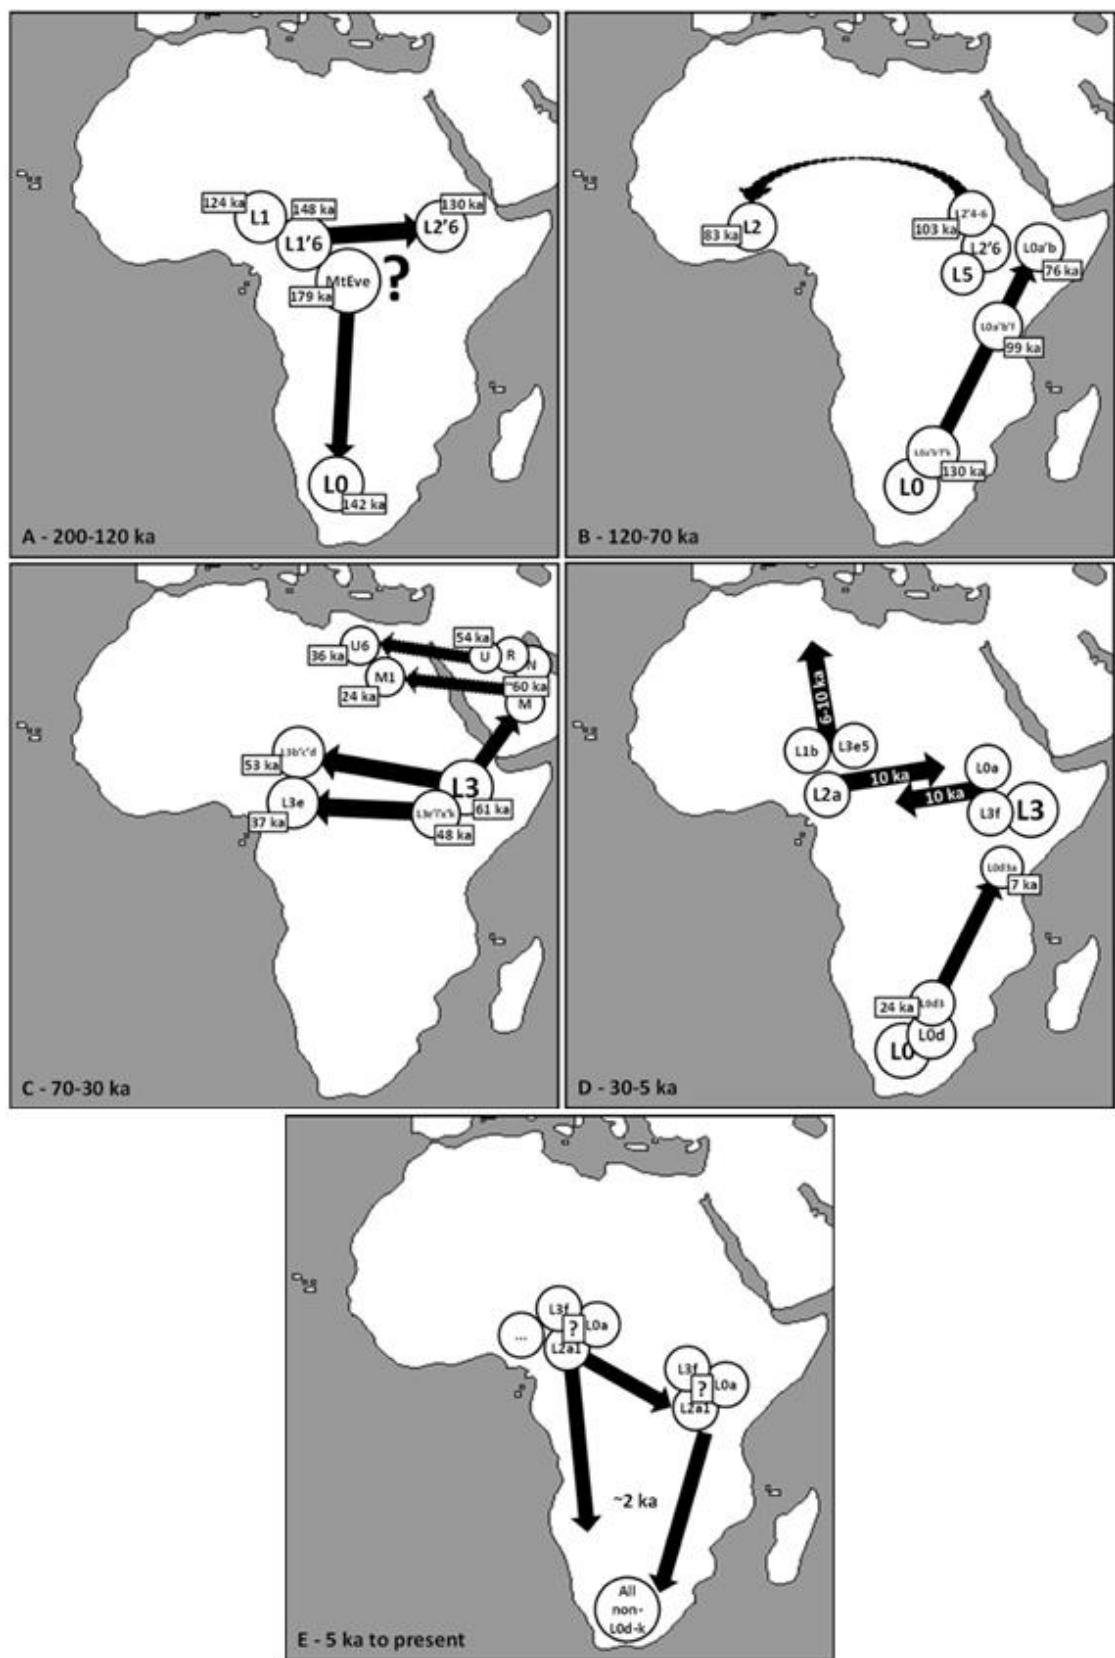

Figure 9 - Major human dispersals within Africa according to the phylogeographic mtDNA tree.
 Arrows only indicate the directionality and not the migratory route. The periods represented are: 200-120 ka (A), 120-70 ka (B), 70-30 ka (C), 30-5 ka (D) and 5 ka to (present). Some migratory paths and dating were updated by Rito et al. in 2019. Adapted from Soares et al. (Soares et al., 2016)

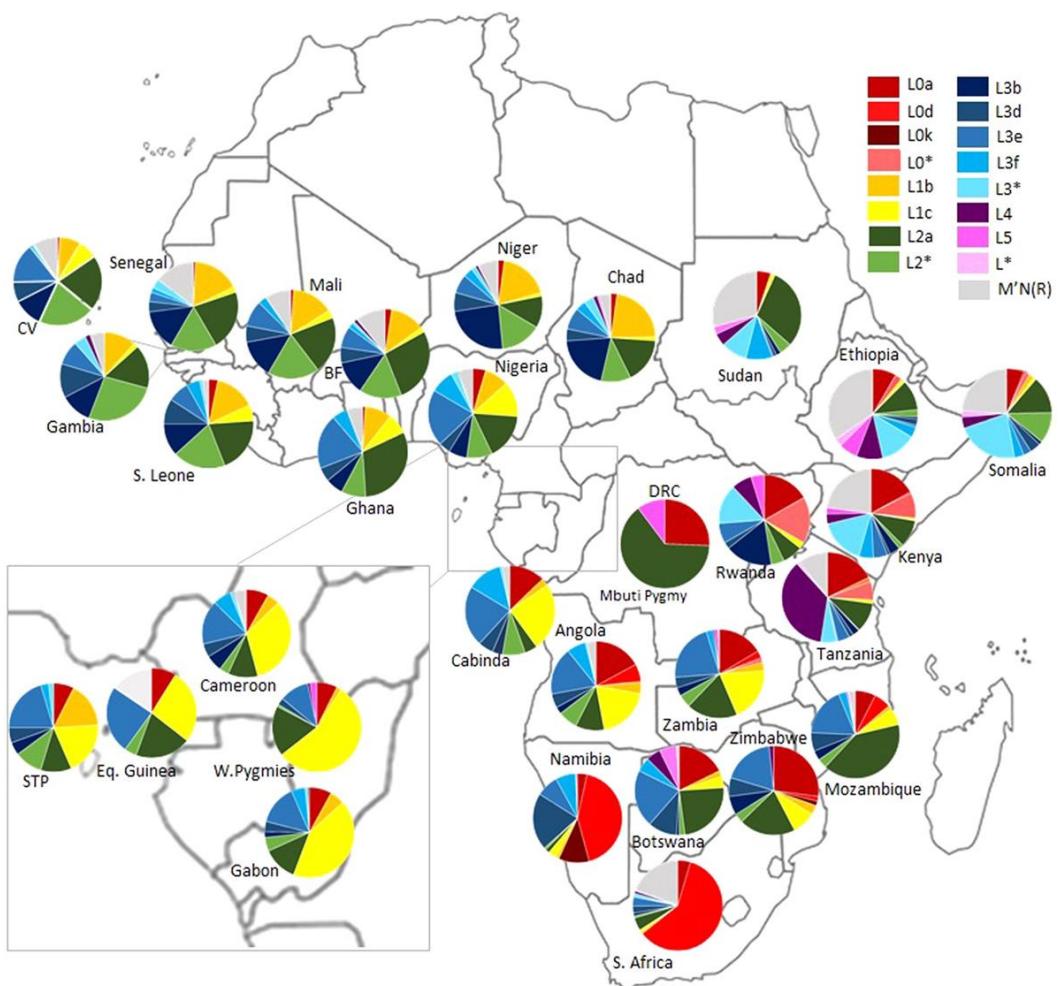

Figure 11 - Distribution of the major mtDNA haplogroups across Sub-Saharan Africa.
Figure obtained from (Silva et al., 2015).

4. AFRICAN INFLUENCES

4.1 SLAVERY

Enslavement became common around 11 ky (Hellie, 2020) in ancient civilizations, such as the Ancient Egypt, Ancient Greece and Ancient China that made use of these people to build their great architectural endeavours among many other tasks. At this time, slavery was used as a form of punishment for crime and other reasons (Harris, 2012).

Although not being a new practice, slavery gained new breath in the 15th century, when Portugal began to explore the African coast, mainly the central and western regions. In the 18th of June of 1452 the Pope Nicholas V issued a papal bull named *Dum Diversas* that granted the Portuguese King Afonso V the authorisation to consign people that did not believe in Catholicism to “perpetual servitude”. This authorisation was later extended to other countries, including the Americas in 1493. This was the trigger to the begin of the Slave Trade and the Colonialism. With time, the African population in the colonizing countries increased immensely, for example 10% of the population living in Lisbon in the mid-16th century was of African ascendance, arriving via de Atlantic Slave Trade (Earle and Lowe, 2006).

The first country to lawfully abolish slavery was Portugal in 1761 and later in its colonies, in 1869, but continued in many other countries (Figure 12). After this, in the 19th century there was an effect called as “Back to Africa”, where descendants of slaves decided to go back to the ancestor's countries, mainly coming from the Americas to western Africa.

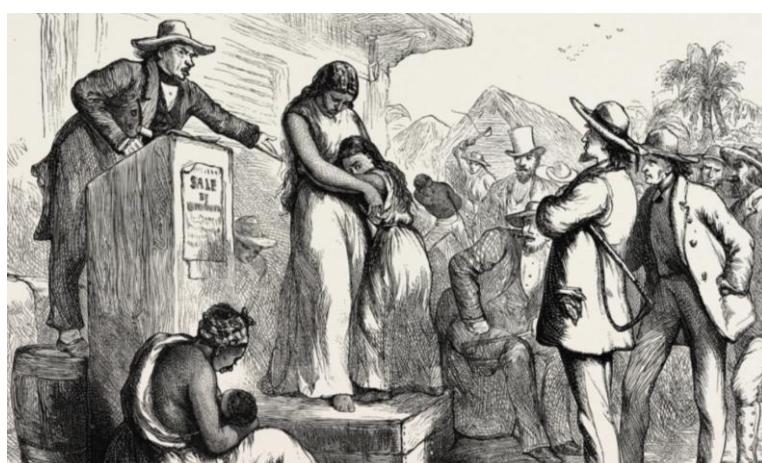

Figure 12 - Vintage engraving of a mother and daughter sold at Slave Auction, Southern USA in the 19th Century.

From: <https://www.history.com/topics/black-history/slavery>

4.2 THE ATLANTIC SLAVE TRADE

The Atlantic Slave Trade took place between the 16th and the 19th Century and was responsible for the transportation of over 10 million enslaved Africans to the Americas and Europe. This route was also used to transport textiles, arms and wine from Europe to Africa and sugar and coffee from the Americas to Europe, as shown on Figure 13.

Portugal was the first country to use this route to transport both slaves and supplies between Europe and its main colony, Brazil, followed by the United Kingdom, the North America and many others. The route consisted of three points: Africa (in particular the central and western regions, and in a much smaller scale the region of Mozambique, also a Portuguese colony), Europe (where the main slave markets were, for example Lisbon and Faro) and the Americas (Brazil, North America and Caribbean) (Thornton, 1998).

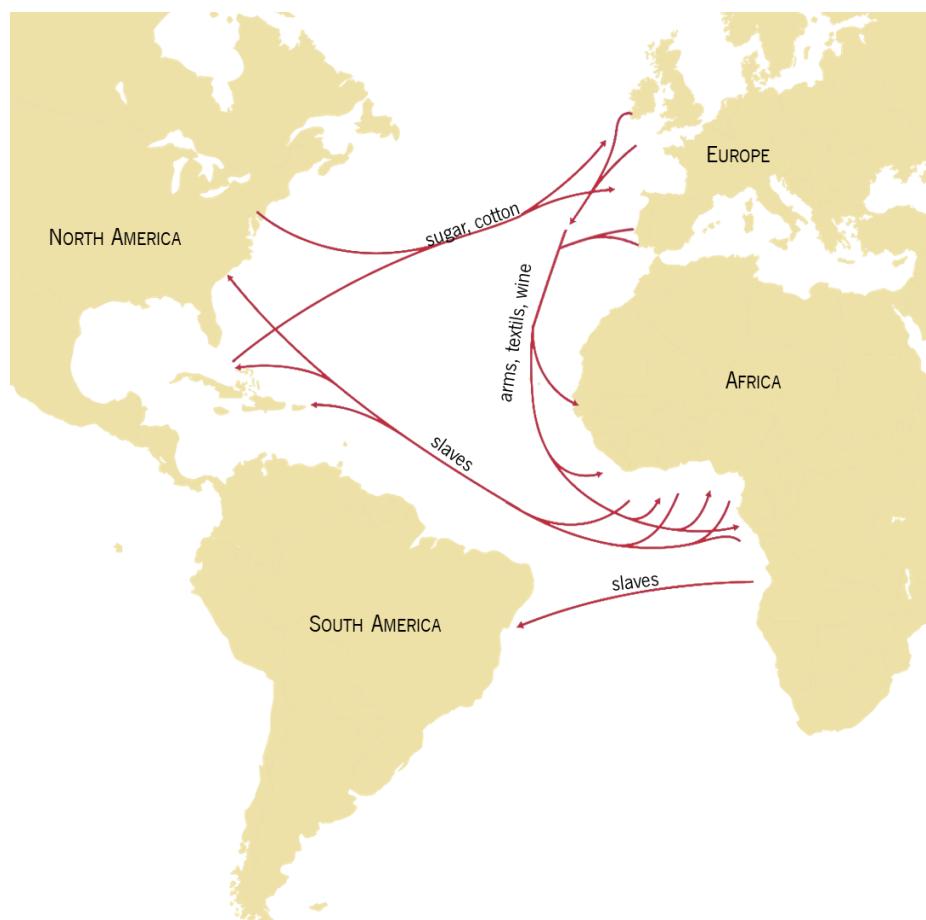

Figure 13 - Representation of the Atlantic Slave Trade.

Besides the transportation of slaves, this route also transported sugar, cotton, arms, textiles and wine, among other things, from and to the colonies.

The main ports used to carry out the slaves from Africa to the other continents were located in Western Africa, with two others in Southern Africa. Figure 14 represents the main ports locations, as well as the colonizing countries of the African regions.

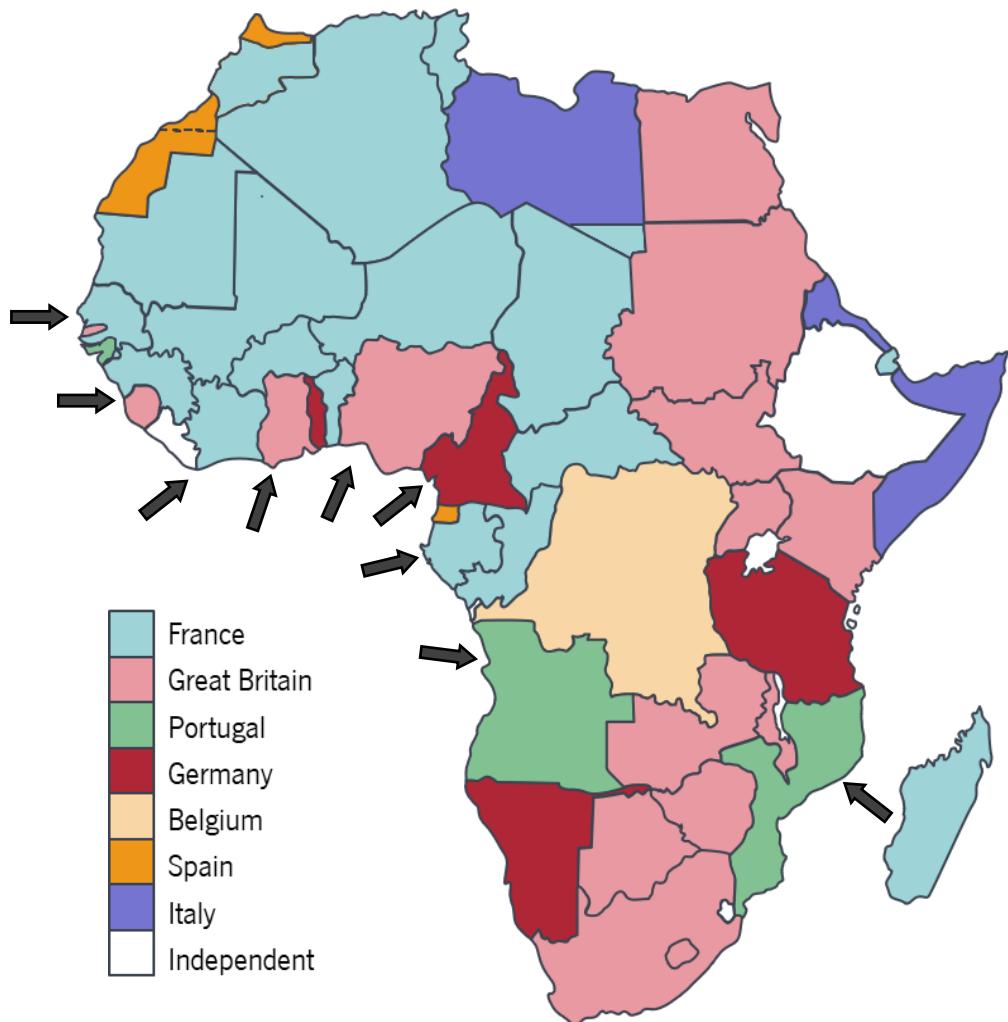

Figure 14 - Representation of the African colonies and the main ports of slave exportation.

The arrows point to the main ports used to carry out the slaves. Each colour represents a different colonizing country.

4.3 GENETIC INFLUENCE OUT-OF-AFRICA

Although over 60% of the slaves transported to the Americas were male, previous studies have presented a sex bias towards female presence, due to the multiple accounts of sexual exploitation (Micheletti et al., 2020). While in the former British colonies, as the Caribbean and the USA, slaves were forced to have multiple children, either to maintain the workforce to a maximum (Marable, 2015) or after given false promises of freedom (Deyle, 2005), in South America the European women were encouraged, including via payment, to marry and have children with the more light-skinned slaves, as an effort to weaken the African traces of the population, a practice known as “Branqueamento” (Meade, 2016). As a result, the African descentance is much more visible in the USA, also due to more recent events, such as the segregation period (LaVeist, 1993), while in South America we can observe a distributed presence of african ancestry, for example in Brazil, 28% of the “mostly white” mtDNA sample is of African origin (Alves-Silva et al., 2000).

When it comes to pinpoint the original African region from which the slaves were exported, there is vast evidence of mostly western-central descentance in countries such as Brazil, in agreement with the known trafficking routes. In the USA there is an overrepresentation of Nigerian descentance, mainly due to the migration within the Americas but also because slaves from this part of Africa were much more recently transported. The more expected origin would be western-central, as in South America, but since this was an earlier migration, with a high rate of mortality, there is a much smaller representation in the current population (Micheletti et al., 2020).

In Europe there is an absence of a visible African ancestry, because it was only a negotiation place, not retaining a large number of slaves. In Portugal there is a prevalence of haplogroups associated with western Africa (Pereira et al., 2000) and haplogroups from the north, such as U6, most likely linked to the geographic proximity between Iberia and Morocco, demonstrating the Arab influence in Portugal (Salas et al., 2004).

AIMS

The work here presented had three objectives:

- 1) To reconstruct and update the African mitochondrial DNA tree, representing the female line of descent of the African populations around the world;
- 2) To determine the phylogeography of mtDNA in the African continent, taking into account the multiple processes with demographic impact
- 3) To understand the source and time of migration of the African lineages outside Africa and correlate this information with the literature on slavery and the Slave Trade market.

Ultimately, these three objectives combined, allow to determine the founders carried during the slave trade from Africa to Europe and the Americas and also to trace the most probable source in Africa of each founder, that end up being the major goal and outcome of this thesis.

MATERIALS AND METHODS

1. DATASET

A dataset of both published and unpublished complete mtDNA sequences was compiled. This includes samples from NCBI and the 1000 Genome Project (Auton et al., 2015) but also unpublished samples generated in collaboration with the University of Huddersfield. In total, the dataset had 6759 samples. A thousand and one samples were excluded due to low quality, to being generated from individuals with mitochondrial disorders or being part of clinical studies (e.g., cancer research). At the end, the dataset was comprised of 6658 L-type sequences samples. A full list of the dataset is presented in Table S1 of Supplementary File 1.

The variations in the whole mtDNA samples were scored as variants when aligned with the revised Cambridge Reference Sequence (rCRS), then the samples were assigned to the respective haplogroup, considering each sequence variation, using the online software HaploGrep 2.0 (Weissensteiner et al., 2016).

2. PHYLOGENETIC RECONSTRUCTION

A phylogenetic tree was constructed using a reduced median algorithm of the software Network 10.0.1 and visualized in Network Publisher 1.1.0.7 add-on from Fluxus-Technology Ltd. In order to ease the visualization and reduce the amount of reticulations, mutations with high homoplasy were down-weighted. By default, Network 10.0.1 weights each position in 10, but positions 146, 150, 152, 195, 709, 16093, 16129, 16189, 16311 and 16362 were weighted down to 7. The polymorphisms 308-315, 310C, 3107N, 515-522, 16182C, 16183C, 16189, 16192C, 16518T and 16519C, along with insertions and deletions were removed, since they are described as unpredictable, very fast or poorly sequenced, meaning that they are unreliable for phylogenetic inferences.

To help make sense of the over-reticulated networks visualized, choices were made regarding the evolutionary paths: sequences were compared to a complete mtDNA tree available online, from Phylotree (van Oven and Kayser, 2009), and positions were checked in a reference table for relative

frequency of each mutation from *Soares et al* (Soares et al., 2009). Preference was given to rarer mutations in the basal branches. Other criteria, was considered, e.g. the number of individuals in each node, do define the pathway to follow.

After assembly, the trees were transcribed to Extensible Markup Language (XML), to be further analysed by founder analysis software (Vieira et al., 2020).

3. FOUNDER ANALYSIS

After the XML transcription, the samples were assigned as source, sink or undetermined, according to the models to test. Samples were geographically classified as:

Iberia: Samples were included in “Iberia” if labelled as Portugal and Spain.

Europe: Samples were included in “Europe” if labelled as Bermuda, Bulgaria, Cyprus, Czech Republic, Denmark, England, France, Germany, Greece, Hungary, Ireland, Italy, Netherlands, Poland, Russia, Serbia, Slovenia, Sweden, Switzerland and Wales

North America: Samples were included in “North America” if labelled as Barbados, Puerto Rico and USA

South America: Samples were included in “South America” if labelled as Bolivia, Brazil, Colombia, Dominican Republic, Mexico, Paraguay and Peru

Southwestern Asia: Samples were included in “Southwestern Asia” if labelled as Iran, Israel, Jordan, Kuwait, Lebanon, Oman, Saudi Arabia, Syria, United Arab Emirates, Yemen, India and Pakistan

Africa: Samples were included in “Africa” and subdivided in regional sections if labelled as

North Africa: Algeria, Egypt, Libya, Mauritania, Morocco, Sahrawi Arab, Tunisia; *Western Africa*: Benin, Burkina Faso, Cabo Verde, Ivory Coast, Gambia, Ghana, Guinea-Bissau, Guinea, Liberia, Mali, Niger, Nigeria, Senegal, Sierra Leone, Togo; *Eastern Africa*: Comoros, Djibouti, Ethiopia, Eritrea, Kenya, Madagascar, Mauritius, Rwanda, Seychelles, Somalia, South Sudan, Sudan, Tanzania, Uganda; *Central Africa*: Burundi, Cameron, Central African Republic, Chad, Congo, Democratic Republic of Congo, Equatorial Guinea, Gabon, São Tomé e Príncipe; *South Africa*: Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia and Zimbabwe.

The following migration models were considered for the founder analysis:

Table 1 - Migration models used in Founder analysis.

5 tests were performed, each with a different source-sink combination.

	Test 1		Test 2		Test 3		Test 4		Test 5	
	Source	Sink								
Africa	X		X		X		X		X	
Europe		X			X		X			
Iberia		X		X	X		X			
North America						X				
South America								X		
Southwestern Asia	X		X		X		X			X

The founder analysis was performed by an in-house developed software (Vieira et al., 2020).

Migrations were computed using the specific times of 500 years and 8000 years, the first correlated to the timeframe of the Slave Trade, and the other to accommodate all the other periods of migrations. The mutation rate was defined as 2643 years/mutation, based on studies of the African migrations to Iberia (Hernández et al., 2015) and in agreement with the curve described by Soares *et al.* (Soares et al., 2009).

The founder analysis was run in two fashions. First, we considered an unbiased analysis where founders were statistically allocated to equally-spaced migration events from 0 to 20,000 years, with hypothetical migrations every 200 years. This will allow to perform a scan of probable periods of migrations by checking periods with an increased probability of multiples founders entering at that period.

Following this scan, a model of migration will be established with specific migration times. This model will take into account not only the migration scan performed previously but also combining with information from history, archaeology, anthropology and palaeoclimatology.

In order to visualize the geographic distribution outside Africa of L lineages associated with each of the migration in our demographic model, we constructed frequency distribution maps with Surfer® v.8 (Golden Software) using Kriging algorithm. We could only use datasets that corresponded to population data, and given this, the software mostly comprised data from the 1000

Genomes Project, the HGDP and the newly data generated in Huddersfield with a few other available cases (Derenko et al., 2013; Matisoo-Smith et al., 2018). A map of the datapoints is displayed in Figure 15.

Figure 15 - Datapoints to be used in the frequency maps.

RESULTS

With the intent of understanding the timeframe of migration events from Sub-Saharan Africa into different regions, a Founder Analysis was performed scanning for the probabilistic distribution of founders across time (Figure 16). African population was assumed as the source population for all of the tests, with the addition of Southwestern Asia for Europe, Iberia, North and South America and Europe and Iberia for North and South America.

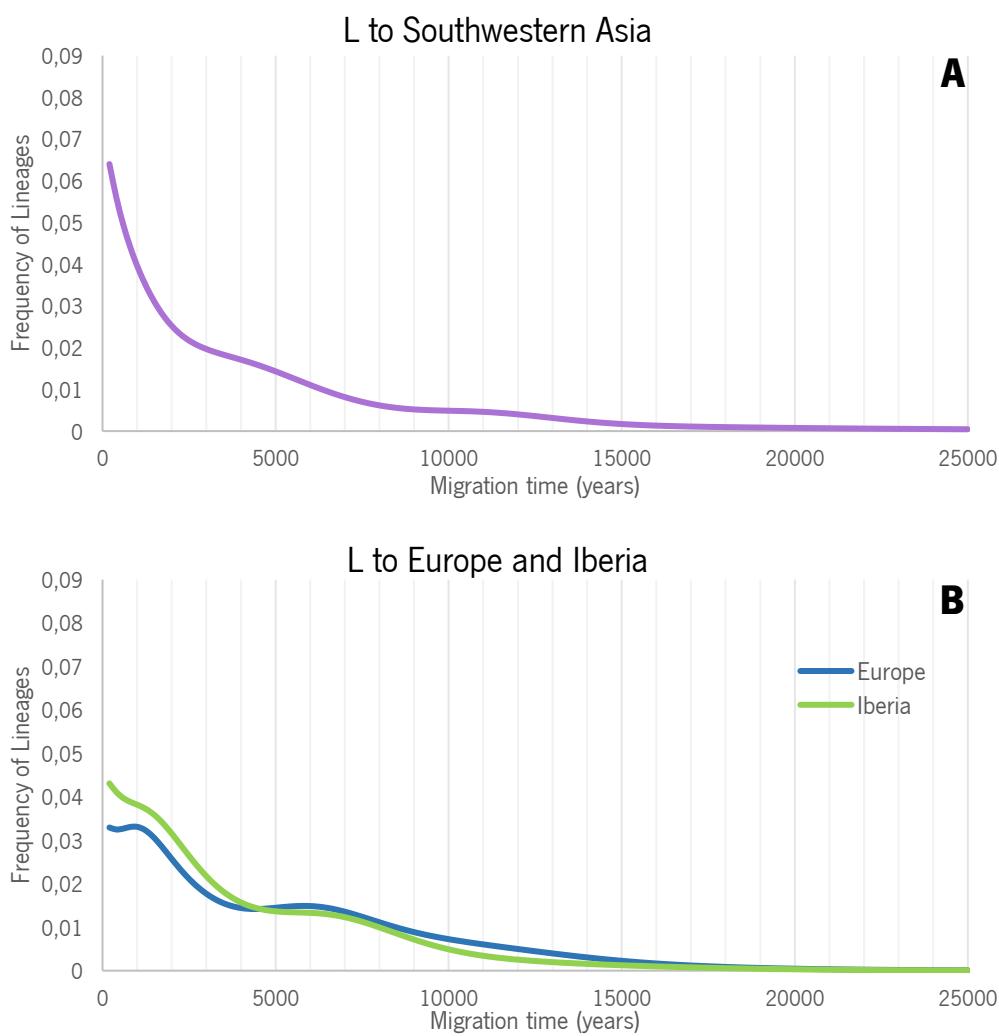

Figure 16 - Founder analysis for mtDNA L haplogroup.

The plots show probabilistic distributions of founder clusters across migration times for population expansion of mtDNA L lineages into Southwestern Asia (A), Europe and Iberia (B) and North and South America (C). Africa is assumed as the source population against Southwestern Asia, Africa and Southwestern Asia against Europe and Iberia, and Africa, Southwestern Asia, Europe and Iberia against North and South America.

L to North and South America

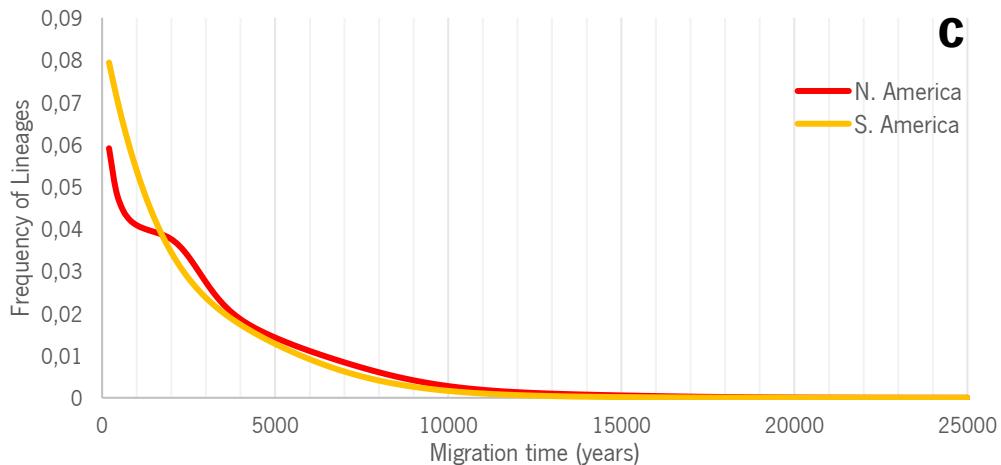

Figure 16 (continuation) - Founder analysis for mtDNA L haplogroup.

The plots show probabilistic distributions of founder clusters across migration times for population expansion of mtDNA L lineages into Southwestern Asia (A), Europe and Iberia (B) and North and South America (C). Africa is assumed as the source population against Southwestern Asia, Africa and Southwestern Asia against Europe and Iberia, and Africa, Southwestern Asia, Europe and Iberia against North and South America.

Southwestern Asia (Figure 16A) presents two very slight peaks, at 11000 years and at 5000 years and from 3500 years on the migratory probabilities increase exponentially till the present.

Europe and Iberia in specific (Figure 16B) have a similar dispersal between them as expected, with a peak at 6000 years and a more recent one, at approximately 1000 years, this last one more prominent in Iberia.

The Americas, both North and South, (Figure 16C) only present a rapid increase of migration probabilities in more recent years, which demonstrates that there was only recent migration of the haplogroup L to this continent.

Taking these results into consideration and taking into account known periods of population movements previously suggested from genetics, archaeology and palaeoclimatology, we selected two periods of migration in order to probabilistically part our data, one at 8000 years corresponding to the Holocene climatic optimum where movements likely occurred from Sub-Saharan Africa into North Africa and Europe, and one at 500 years, marking recent migrations, which includes the Atlantic Slave Trade. It is important to point out that more ancient migrations (before 10,000 years) as suggested before, will probabilistic be allocated into the 8000 years partition as well as more recent migrations older than 5,000 years as obtained in the scan for Arabia. In simpler terms, these partitions aim to split prehistoric migrations from historical ones.

Over 60% of L lineages found in Southwestern Asia are linked to recent migrations and only close to 40% are associated with Postglacial movements, as shown in Figure 17. Europe shows a very similar distribution of recent lineages and Postglacial while in Iberia it is possible to see a clear distinction between the recent migrations, that correspond to 67% of lineages, and the Postglacial movements. As expected, the Americas show a majority, over 85%, of recent lineages. The detection of postglacial lineages in North and South America is considered irrelevant, given that it is known that it was impossible at that time for migrations to occur between these continents and the percentage is mostly the results of statistical residues (large confidence intervals) from lineages that are mostly statistically allocated to modern periods.

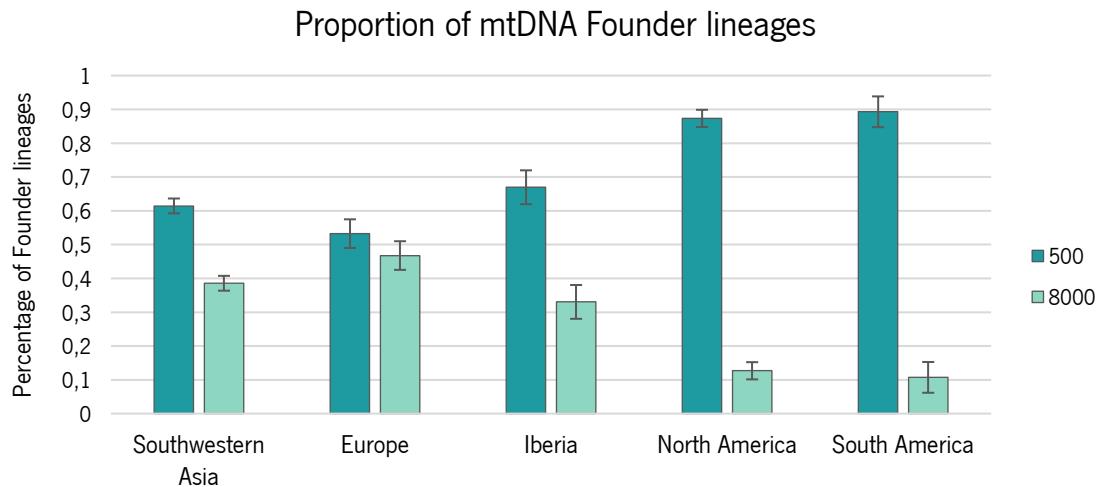

Figure 17 - Proportion of mtDNA L founder lineages in Southwestern Asia, Europe, Iberia, North America and South America.

Two migration periods were considered, taking into account the results of Figure 12: 500 years, that corresponds to recent migrations, and 8000 years, associated with the Postglacial Period.

As an attempt to understand where these lineages came from, a phylogeographic analysis of the source samples' locations was performed for founders statistically allocated to either recent or prehistoric migrations, with exception of North and South America, that only have recent migrations.

POSTGLACIAL PERIOD

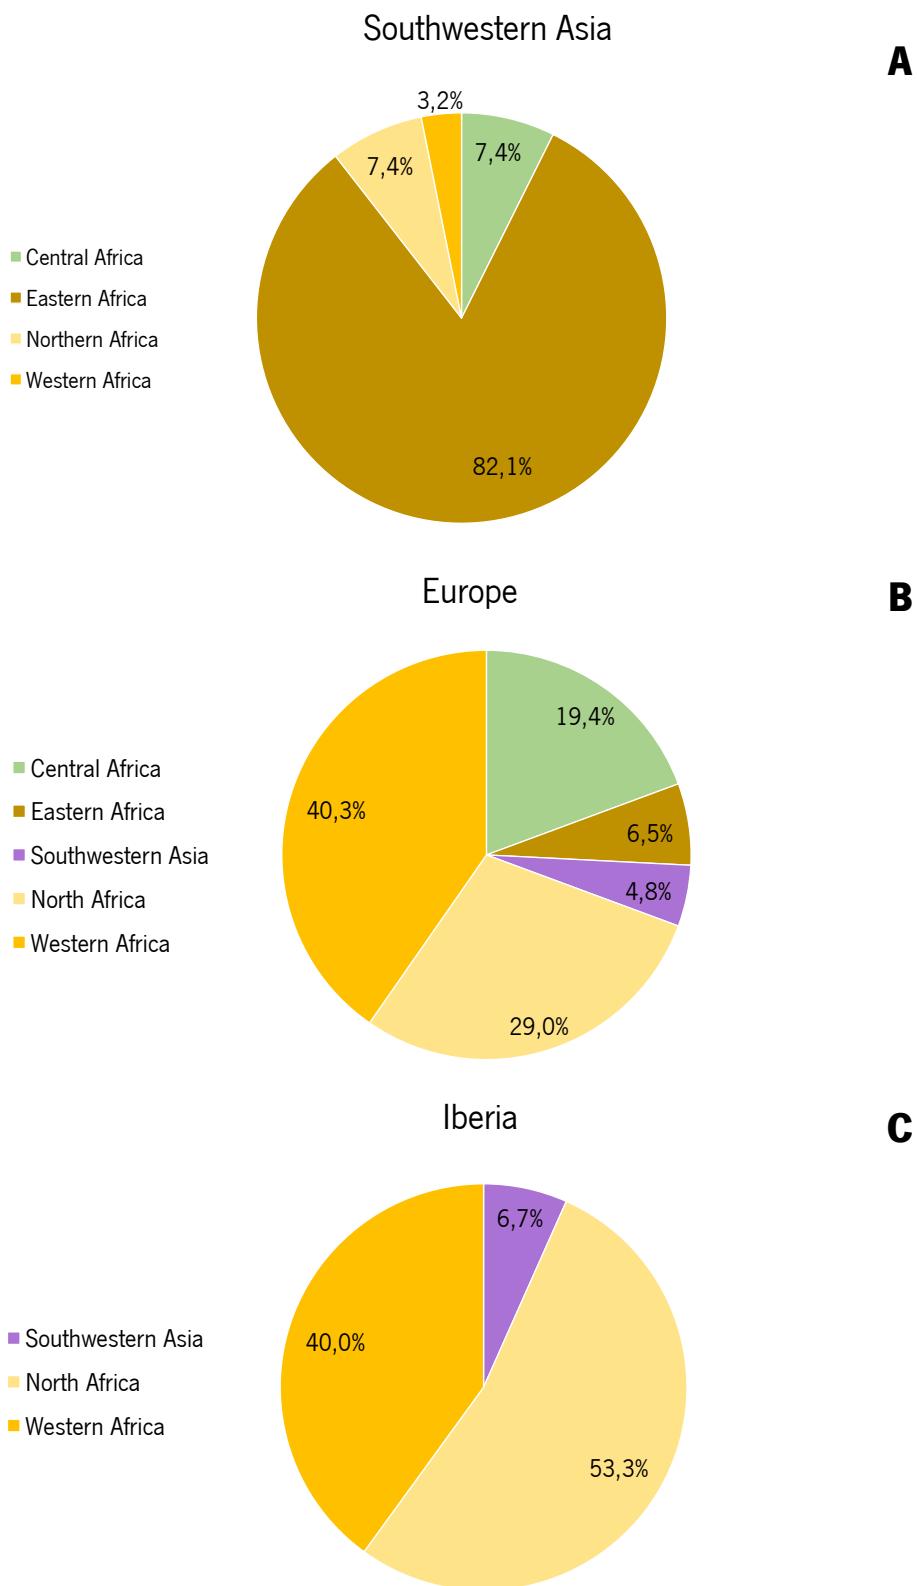

Figure 18 - Proportion of the point of origin of the lineages detected in the Founder Analysis at the Postglacial Period in Southwestern Asia (A), Europe (B) and Iberia (C).

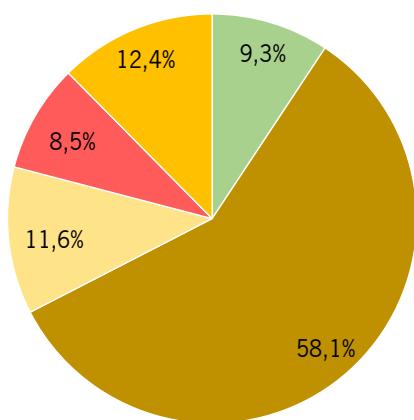

Figure 18 presents the percentage of lineages from the different source regions that were detected at the Postglacial Period, 8000 years ago. Figure 18A shows the Southwestern Asia sink population, with source population from Africa, and has an overwhelming percentage of 82,1% came from Eastern Africa, 7,4% from Central Africa, 7,4% from Central Africa and 3,2% from Western Africa. Most common lineages include L0a2a2a+16188G, L2a1+16189C+143A+16309G+16192T, L3d1a1a, L3e3a and L3f1b+16292T. Figure 18B shows Europe sink population, with source populations from Africa and Southwestern Asia. Western Africa represents 40,3%, North Africa 29%, Central Africa 19,4%, Eastern Africa 6,5% and Southwestern Asia 4,8%. It mostly includes L1b1a lineages (L1b1a+185C+14016A, L1b1a+189G, L1b1a6 and L1b1a+1462A), L3f1b and L3d1b1. Figure 18C shows the Iberian sink population with source populations from Africa and Southwestern Asia. The majority of lineages came from North Africa, 53,3%, 40% from Western Africa and at last the Southwestern Asia with 6,7%, mostly represented by L1b1a6 and L3f1b. To note that none of the figures above show lineages from South Africa.

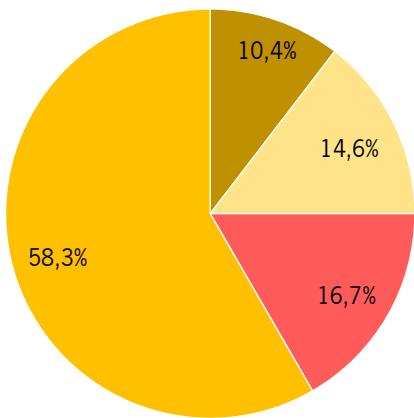

Figure 19 - Proportion of the point of origin of the lineages detected in the Founder Analysis at the Recent migrations (500 years ago) in Southwestern Asia (A), Europe (B), Iberia (C), North (D) and South (E) America.

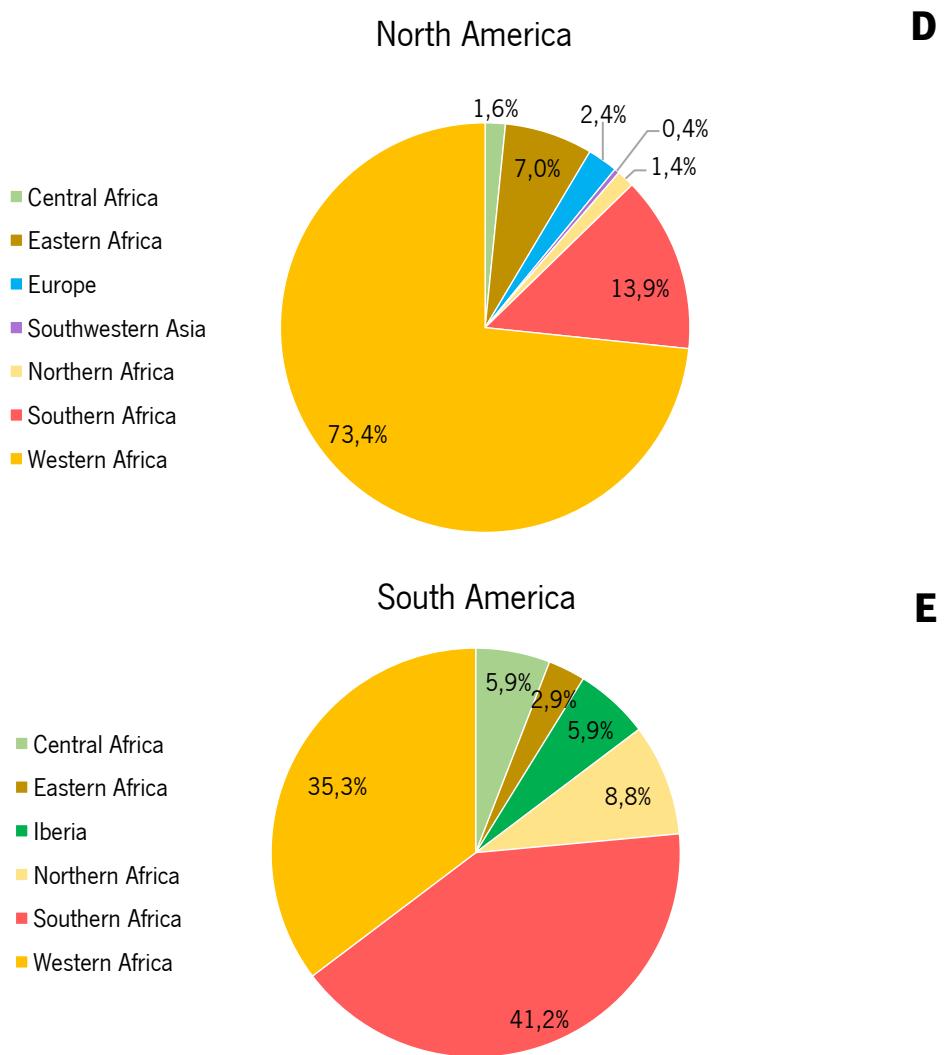

Figure 19 (continuation) - Proportion of the point of origin of the lineages detected in the Founder Analysis at the Recent migrations (500 years ago) in Southwestern Asia (A), Europe (B), Iberia (C), North (D) and South (E) America.

Figure 19 presents the percentage of lineages from the different source regions that were detected at the Recent Migration Period, 500 years ago, mostly associated with the Slave Trade. Figure 19A shows the Southwestern Asia sink population, with source population from Africa, and, as in the Postglacial period, the majority of the lineages is from Eastern Africa, 58,1%. Western Africa represents 12,4%, Northern Africa 11,6%, Central Africa 9,3% and Southern Africa 8,5%. No lineage displays a substantially higher frequency. Figure 19B shows the European sink population, with African and Southwestern Asia populations as source. Western African lineages are the most represented, with 54,2% followed by Northern Africa, with 14,5%, Southwestern Asia, with 9,6%, Eastern and Southern Africa with 8,4% each and Central Africa with 4,8%. The most common lineage at around 10% is L2a1l2+143A. Figure 19C shows the Iberian sink population, with Africa

and Southwestern Asia as source populations. Western Africa represents 58,3% of the lineages, while Southern Africa represents 16,7%, North Africa 14,6% and Eastern Africa 10,4%. No specific lineage shows an increased frequency. Figure 19D shows the North American sink population with Africa, Southwestern Asia, Europe and Iberia as the source populations. Western Africa has the most lineage representation, with 73,4%, followed by Southern Africa, with 13,9%, then Eastern Africa, with 7%. Europe represents 2,4% of the lineages, Central Africa 1,6%, Northern Africa 1,4% and Southwestern Africa 0,4%. Most common lineages are L1c3b2+16086C+16104T+14929T, L2a1f+16192T, L2a1f1, L3e2b+152C and L3f1b1a, all from a probable Western African source. Figure 19E shows the South American sink population, with Africa, Southwestern Asia, Europe and Iberia as the source populations. Southern Africa represents 41,2% of the lineages, Western Africa represents 35,3%, Northern Africa represents 8,8%, Iberia and Central Africa represent 5,9% each and Eastern Africa represents 2,9%. Most common lineages include L1c3b1a and L0a1b+5563A, most common in Angola and Zambia in the African dataset.

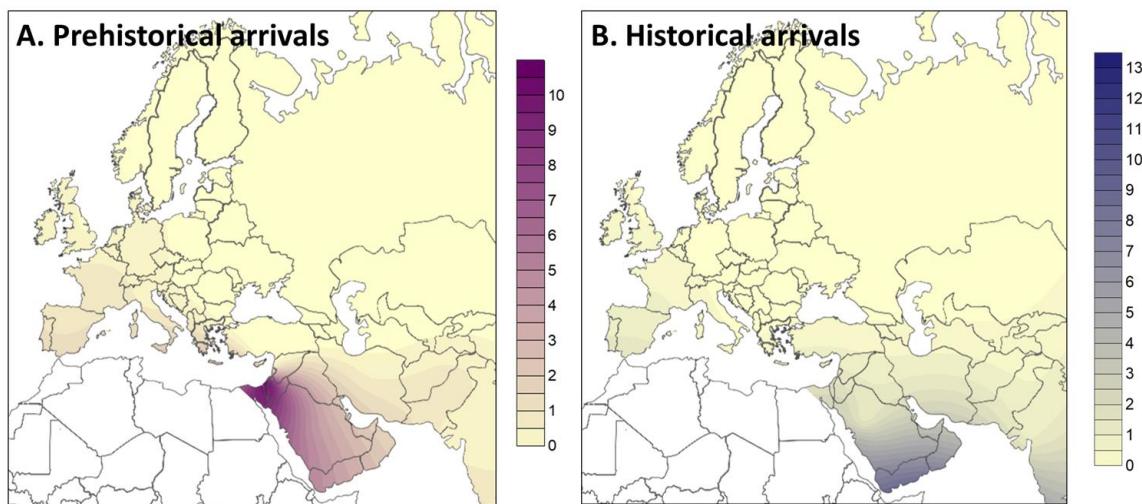

Figure 20 – Maps of geographic distribution frequencies of L lineages outside Africa associated with each of the migration in our demographic model.
(A) Prehistorical arrivals, at 8000 years and **(B)** Historical arrivals, at 500 years.

In terms of frequencies across Europe and Asia (Figure 20), it is possible to observe that considering both prehistorical (Figure 20A) and historical (Figure 20B) migration, the higher frequency is in Southwestern Asia. The Iberian Peninsula shows substantial frequencies of L sequences from both periods. However, the remaining Mediterranean Europe mostly shows lineages associated with prehistoric migration.

DISCUSSION

This work aimed to apply a phylogeographic approach to understand the presence of mtDNA lineages of African lineages outside Africa. In particular, we applied a methodology called founder analysis, that aims at establishing migration episodes and quantify the number of lineages involved in those migratory episodes. By studying the movement of sub-Saharan mtDNA L lineages into several parts of the world, namely North America, South America, Europe, Southwestern Asia and South Asia, it is possible to understand the performance of the founder analysis methodology, as in some particular cases, mostly North and South America, the migratory model is mostly known, related with the transatlantic slave trade, all related with the last few centuries.

In the Postglacial period, more specific at 8000 years ago, the climatic conditions in Africa were at the optimal point, particularly in the Sahel Belt. This region, which includes the Sahara Desert, became a migratory corridor, allowing populations from the sub-Saharan region to arrive to the North of Africa, and from there to Europe and Iberia (Triska et al., 2015). This phenomenon explains the majority of the results shown above in Figure 18. The high prevalence of Eastern African L lineages in Southwestern Asia (Figure 18A) is associated with the geographical proximity, where gene flow has occurred in both directions for most prehistorical and historical periods (Skorecki and Behar, 2013). In the case of Europe (Figure 18B) there is a high percentage of lineages that trace to Northern Africa but mostly from Western Africa and from Central Africa. In general, while not all lineages left traceable descendants in North Africa, the three are basically representing the same migration event - during the Holocene improvements of the conditions in the African Sahel, when populations moved from Western and Central Africa into North Africa (Rosa and Brehem, 2011) and then into Europe. The higher percentage of Western lineages reflects the easier crossing into Iberia, due to short distance in the Strait of Gibraltar. This trend is highlighted in the analysis considering only Iberia as the sink where all lineages basically fall into Western and Northern Africa (Figure 18C). Nevertheless, African lineages are observed on this period across most of Mediterranean Europe, leaving small traces of those events until the present (Cerezo et al., 2012).

Recent lineages, that in the Founder Analysis were represented by a migration at 500 years, are the result of migrations and gene flow at a time of globalization, with easier means of transport-

tation and most importantly transportation through the land was not the most probable means of travel in most cases. It was at this time that occurred the Trans-Atlantic Slave trade, that carried over 10 million people out of Africa into the Americas and, in a smaller percentage, to Europe (Earle and Lowe, 2006; Salas et al., 2004; Thornton, 1998). As so, most of the lineages found are associated with the origin of the slaves and the place where they embarked. It is known that most ports were located in the Western coast of Africa, and only two were located in the South, more particularly in Angola and Mozambique (Figure 14), hence the majority of the lineages found in Europe, Iberia and the Americas having their founder located in the West of Africa. As observed in the Postglacial Period, the geographical proximity of Eastern and Northern Africa still has a large impact in many lineages found in Southwestern Asia, Europe and Iberia, respectively, as it is expected that continuous gene flow occurred in the last few thousand years (Botigué et al., 2013; Pereira et al., 2000). Nevertheless, the Western source dominates the analyses showing that the Slave Trade was likely the major source of L lineages in Europe and Iberia.

One source that was absent in the analyses for Postglacial lineages but emerges in recent migrations is Southern Africa, mainly associated with the Slave Trade, since European countries had colonies there that were used as a source of slaves. Iberia, in particular, has a higher percentage of South African lineages when compared to Europe as a whole. This is linked to the fact that the Portuguese colonies in Africa, Angola and Mozambique, located in South Africa, with the exception of Guinea-Bissau, in the West. The main ports of slave commercialization in Europe were in Portugal - Lisbon and Faro - leaving behind an important imprint of lineages in the Iberian population (Earle and Lowe, 2006; Hernández et al., 2015; Pereira et al., 2000). Again, it is important to point out that slave trade involved transportation of people through sea allowing the “jumping” Southern Africa into Europe and the Americas. Lineages in South America are mostly related with a source in Angola.

Taking into account the countries that colonized the Americas and Africa, we can see a correlation between the lineages found North and South America and the colonizing country that carried them. While in North America (Figure 19D), primarily colonized by Great Britain and Spain, we can see over 70% of Western lineages, where the ports in Africa were located, in South America (Figure 19E) there is a distribution of lineages between West and South Africa. South America was colonized mainly by Portugal and Spain and since Spain had almost no colonies in Africa, the slaves either came from the Portuguese colonies, located in the South, or the Western colonies, first of Portuguese rule and later most of which belonged to France as evident in Figure 14.

CONCLUSION

Founder Analysis has the purpose of identifying, scaling and dating the migration of a certain population to a new territory, taking into account the diversity of lineages originally from a specific geographic location, identified as the source, and that later settled in a new location, identified as the sink. In this work, we performed this analysis to verify the time-frames of major migrations involving Sub-Saharan African lineages to Southwestern Asia, Europe, Iberia, North and South America. After confirming that there was a clear distinction between pre-historical migrations, around 8000 years ago, and historical movements, around 500 years ago - in here primarily linked to Trans-Atlantic Slave Trade - we were able to pinpoint the general location of the lineages in the source, giving us a clear picture from where the mtDNA L lineages found nowadays in the sink populations were carried out from and possibly the reason why.

As expected, not considering the statistical errors and a few undetected source lineages, there are no pre-historical migrations to the Americas, opposed to the clear signals observed in Europe, Iberia and Southwestern Asia. After taking into account the historical records of the Trans-Atlantic Slave Trade, it was also expected the results here shown – most L lineages found in North America where carried from the West of Africa, where the main slave ports were located.

It was observed, in agreement with other genetic studies, that there were clear signs of pre-historical migrations to Europe, Iberia and Southwestern Asia, following the geographical proximity. Meaning that we observed lineages that arrived to Southwestern Asia from Eastern Africa, and to Iberia arrived from Western and Northern Africa and to Europe in general from Eastern, Central and Western African. This also supports the previously introduced theory that the Sahel Belt and North Africa were migratory corridors to enter Europe and Iberia following the Glacial Period.

In historical lineages, it was observed a major influence of South Africa both in Iberia and South America. As mentioned before, Portugal colonized Angola and Mozambique - located in the South of Africa - where there were two important ports for slave exportation, and Brazil, in South America. At the time, Portugal was one of the most influential nations of the world, alongside Spain, controlling not only the main potencies of the New World but also the most important Slave Trade

markets, Lisbon and Faro. As a consequence, most of the slaves carried from Angola and Mozambique either came to Portugal for trading or went directly to Brazil, leaving this way an important imprint in L lineages in Iberia and South America.

To conclude, the genetic studies associated with ancestry, such as Founder Analysis, help us to better understand what happened long before us. This work in particular gave a new insight to lesser-known facts related to the Trans-Atlantic Slave Trade and the genetic evidences left behind that are still present to this day.
