ABSTRACT

Bitter leaf (Vernonia amygdalina Del.) plant is a tree species that is highly cultivated in Nigeria for its nutritive and therapeutic values. This study aimed to determine the antioxidant and antigenotoxicity effects (in vitro) of 52 accessions of V. amygdalina collected from six geopolitical zones of Nigeria (North East, North West, North Central, South South, East and West) by evaluating the 2,2-diphenyl-1-picrylhydrazyl (DPPH) and nitric oxide (NO⁻) scavenging antioxidant activities, flavonoid and phenolic contents as well as ethidium bromide-induced DNA (deoxyribonucleic acid) damage of bitter leaf. The results showed that accessions MN628016 (Oshimili South, Delta State) and MN628010 (Akoko Edo, Edo State), respectively had higher amounts of flavonoid (287.19 mg/g/FW) and phenolic (307.90 mg/g/FW) contents. The accessions MN627984 (Ikpoba Okha, Edo State) and MN627975 (Owerri, Imo State) had the highest nitric oxide (85.73%) and DPPH radical scavenging inhibitory effect (98.92%). The highest percentage fragmented DNA (45.05%), was observed in Allium cepa roots homogenised and mixed with ethidium bromide followed by the A. cepa roots homogenised and mixed with the leaf extract of V. amygdalina accession MN627977 (36.12%). However, V. amygdalina accessions MN628008 (457.62%, Warri North, Delta State) had the highest percentage increase of fragmented DNA followed by MN628024 (395.04%, Oshimili North, Delta State), MN628015 (345.54%; Aniocha North, Delta State) and MN627984 (342.04%; Ikpoba Okha, Edo State) while accession MN628010 (7.32%; Akoko Edo, Edo State) had the lowest. Accession MN628010 which possessed the highest amount of phenolic content had the lowest percentage increase of fragmented DNA and accession MN627984 which possessed the highest nitric oxide radical scavenging inhibitory effect was among the accessions with the highest percentage increase of fragmented DNA. The findings of this study suggest that the observed lowest percentage of fragmented DNA of A. cepa roots growth induced with the solution of ethidium bromide and treated with V. amygdalina accessions MN628010 extracts (antigenotoxic) could be as a result of the high antioxidant activities in the V. amygdalina accessions. In summary, the findings of this study showed that the 52 V. amygdalina accessions obtained from different locations of Nigeria will help to combat ethidium bromide induced genoxicities and any other genotoxicant that may lead to different complications in plant (A. cepa roots), as all the accessions possessed antioxidant and antigenotoxic properties, as such, possessed comparable amount of natural antioxidant activities and antigenotoxicity.

Key words: Antioxidant, antigenotoxicity, bitter leaf, accessions, ethidium bromide, *Allium cepa*

INTRODUCTION

Vernonia amygdalina Del. is a herb that belongs to the Asteraceae family. It mainly grows in tropical Africa. It is wide spread in West Africa and well distributed in Asia. In Africa, it is commonly called bitter leaf and different local names have been used by various local languages of the continent. It is called *ewuro* in Yoruba, '*etidot*' in Ibibio, *onugbu* in Igbo, *ityuna* in Tiv, *ilo* in Igala, *oriwo* in Edo, *grawa* in Amharic, *chusar-doki* and *shawaka* in Hausa [1] and it is called *origbo* in Urhobo language [2].

Bitter leaf is generally cultivated as annuals. However, a small number of it could be grown as perennials in different parts of the world [3]. As demonstrated in animal studies, its leaf extracts may also prevent, delay or destroy carcinogenic cells, prevent metastasis of cancerous cells in the body by inhibition of anti-apoptotic transcription factors [4, 5, 6].

Oxidation is a chemical reaction that can yield free radicals, resulting in series of reactions that may destroy the cells of organisms. Compounds that prevent oxidation are called antioxidants [7,8]. Plants contain high amounts of numerous redox-active antioxidants such as polyphenols, carotenoids, ascorbic acids, DPPH and flavonoids which combat against harmful oxidative cell damage of organisms [8].

Genotoxicity is the ability of different agents to cause damage to genetic material. Antigenotoxicity is the ability of different agents (generally called antigenotoxic agents) to decrease the DNA mutilation initiated by genotoxic agents. *V. amygdalina* extracts may suppress, delay, or kill cancerous cells which includes induction of apoptosis as determined in cell cultures and animal studies [9].

V. amygdalina has received substantial research attention on its nutritional status. A lot of work has been carried out on *V. amygdalina* to investigate the antioxidant activities such as total phenolic content, total flavonoid content, 2,2 diphenyl-1-picryl-hydrazyl (DPPH) radical scavenging activity, ferric ion reducing antioxidant power (FRAP), reducing power as well as thiobarbituric acid reactive substances (TBARS) with substantial results [18]. However, little or no research work has been carried out to compare the antioxidant activities of *V. amygdalina* accessions obtained from different locations. Also, the determination of antigenotoxic properties of *V. amygdalina* from different locations have not been reported to the best of our knowledge.

This research will help to elucidate the antioxidant activities and antigenotoxic properties of *V. amygdalina* accessions collected from different parts of Nigeria. The findings of this study will help in combating ethidium bromide induced genotoxicities and any other genotoxicants that may lead to different complications (such as mutation, DNA fragmentation etc) in plant (*Allium cepa* roots). The findings of the study also have beneficial effect to humans in creating awareness on the accessions with the highest and lowest antioxidant activities of *V. amygdalina*.

The focus of this study was to determine the antioxidant and antigenotoxicity effects of accessions of *V. amygdalina* by evaluating the 2, 2-diphenyl-1-picrylhydrazyl (DPPH)

and nitric oxide (NO⁻) scavenging antioxidant activities, flavonoid and phenolic contents as well as ethidium bromide-induced DNA damage of bitter leaf.

MATERIALS AND METHODS

Collection of samples

Fifty two samples of bitter leaf (*V. amygdalina*) were collected from 6 geopolitical zones of Nigeria (North East, North West, North Central, South South, East, and West). They were identified, authenticated, and assigned voucher IDs and deposited as herbarium specimens (Appendix I).

The study involved the antioxidant activities and antigenotoxic properties assessment of the *V. amygdalina* accessions, to determine which accession has the most antioxidant activities and antigenotoxic properties. The antioxidant assays include: 2,2-diphenyl-1picrylhydrazyl (DPPH) radical scavenging activity, total flavonoid contents, total phenol contents and nitric oxide (NO-) scavenging activity. The antigenotoxic properties was ascertained using the DNA fragmentation assay and *Allium cepa*.

Aqueous extraction of V. amygdalina

The fresh leaves were rinsed with clean water and air dried at room temperature by spreading on the laboratory table for 24 h. The samples (50 g each per accession) were weighed, blended with 100 ml of water until a homogenous formulation was obtained. The formulation was filtered with a piece of muslin cloth and the filtrate was preserved in the refrigerator (4°C) until ready for use.

Analysis of 2,2-Diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity of bitter leaf

The free radical scavenging ability of the sample extracts against DPPH free radical was estimated using the method described by Marcocci *et al.* [10]. Methanol solution (0.9 ml) and (0.1 ml) of the sample were mixed with 0.1 ml of 0.15% DPPH solution. The reaction mixture was incubated for 30 min in the dark at room temperature. The control contained all reagents without the samples and methanol was used as the blank. All reaction mixtures were done in triplicates and the DPPH radical scavenging activity of bitter leaf was determined at absorbance of 517 nm and expressed as the inhibition percentage of free radical of the sample after calculation using the following formula:

$$RSA (\%) = A_c - A_t \qquad X \ 100$$

Where,

RSA (%) = Percentage of DPPH discoloration; $A_c = Absorbance of DPPH solution;$ $A_t = Absorbance of the solution when the sample was added at a particular level.$

Analysis of Nitric Oxide radical scavenging activity of bitter leaf

The scavenging effect of bitter leaf on nitric oxide (NO⁻) radical was measured according to the method of Marcocci *et al.* [10]. Organic sample homogenate (0.2 ml) was added in the test tubes of 1 ml sodium nitroprusside solution (25 mm). The test

SCHOLARLY, PEER REVIEWED AFRICAN JOURNAL OF FOOD, AGRICULTURE, NUTRITION AND DEVELOPMENT June 2022

tube was incubated at 37°C for 2 h. An aliquot (0.5 ml) of the incubated solution was removed and diluted with 0.3 ml of Griess reagent (1% sulphanilamide in 5% H_3PO_4 and 0.1% naphthyl-ethylenediamine dihydrochloride). The absorbance of the chromophore formed was immediately read at 570 nm against distilled water as the blank. Absorbance of reagent blank was read as control. Results were expressed as percentage radical scavenging activity (RSA).

$$RSA (\%) = \frac{1 - \Delta \text{ Abs of sample}}{\Delta \text{ Abs of control}} X 100$$

Determination of total flavonoid content of bitter leaf extract

Total flavonoid content of bitter leaf extract was determined by calorimetric method as described by Jia *et al.* [11]. The leaf extract (250 μ l) was added to 1.25 ml distilled water and 75 μ l of 5% NaNO₂. After 5 min, 150 μ l of 10% AlCl₃.H₂O was added. Then after 6 min, 500 μ l of 1 M NaOH and 275 μ l of distilled water were added. The solution was properly mixed and the colour intensity of the mixture was read at 510 nm. Ascorbic acid solution (1%, w/v) was used as the standard and the concentration of flavonoid expressed in mg ascorbic acid equivalent/ml of the extract. The total flavonoid content was calculated using a standard curve with rutin (0-100 mg/l) as the standard.

Determination of total phenol content of the leaf extract

This was carried out according to the method described by Singleton and Rossi [12]. About 5 ml of Folin Ciocalteu reagent (5 ml) (10-fold dilution with distilled water) was added to 0.5 ml of the sample. After 3 min, 0.5 ml of saturated Na₂CO₃ solution (16 g/100 ml) and 3.5 ml of distilled water were added. Then the reaction mixture was kept in the dark for 90 min. The absorbance was read at 725 nm. Ascorbic acid solution (1% w/v) was used as the standard and the concentration of phenol expressed in mg ascorbic acid equivalent/ml of extract. Gallic acid solution was used for the preparation of calibration curve. Total phenolic contents of samples were expressed as milligrams of gallic acid equivalent (mg GAE)/100 g of dry weight.

Antigenotoxicity of V. amygdalina and DNA fragmentation assay

The outer papery brown layers of 12 onion bulbs (5-10 g), were peeled away and the dried basal root plate were cleaned. About 20 µL of the prepared ethidium bromide (0.03 g/mL) solution was injected into the *Allium cepa*. Which was then submerged in a 50 mL test tube containing water (control) or extract of *V. amygdalina* and was kept for 5 days. The *Allium cepa* roots were then collected for DNA fragmentation assay.

Deoxyribonucleic acid (DNA) fragmentation assay was estimated using Wu *et al.* [13] method. The 50 mg of *Allium cepa* roots were homogenized in 10 ml of a TE solution, containing 5 mmol Tris–hydrochloric acid, 20 mmol EDTA and 0.2% triton X-100 at pH 8.0. Aliquot of sample (1 ml) was centrifuged at high speed (27,000 × g for 20 min) to allow proper separation of the intact chromatin (pellet, B) from fragmented DNA (supernatant, T). Freshly prepared diphenylamine solution was used to assay for DNA content of the pellet and the supernatant fractions. Sample readings were monitored at 620 nm with spectrophotometer.

The percentage of fragmented DNA was calculated using the following formula;

Fragmented DNA (%) = T x 100 / (T + B); where, B = intact chromatin (pellets), T = fragmented DNA (supernatant)

Percentage decrease = decrease \div original number x 100. (If the answer is negative it is percentage increase).

Statistical Analysis

All results were represented as means \pm SD and all data were analyzed using analysis of variance (ANOVA). Significant difference between means was determined at 5% (P < 0.05) confidence level using Posthoc test least significant difference (LSD).

RESULTS AND DISCUSSION

The analysis of antioxidant activities of bitter leaf (V. amygdalina) accessions showed that the accession MN628016 had the highest flavonoid content while MN627995 had the lowest flavonoid content (Fig. 1). The accession MN628010 had the highest phenolic content while the accession MN628009 had the lowest phenolic content (Fig. 2). Flavonoids are the primary category of phenolic compounds amongst the several categories, in which plants are grouped. They have strong antioxidant activities and are inherently occurring in plants. Flavonoids have positive effects on human health as studies on flavonoid by-products have shown a wide array of antibacterial, antiviral, anti-inflammatory, and anticancer activities [14,16]. V. amygdalina accession MN628016 had significantly highest flavonoid content when compared with the flavonoid contents of other V. amvgdalina accessions while MN627995 had significantly the lowest flavonoid content (Fig. 1). V. amygdalina accessions MN628010 had significantly highest phenolic content while MN628009 had significantly the lowest phenolic content, when compared with the other V. amygdalina accessions (Fig. 2). The results of this study suggest that phenolic and flavonoid contents may be the major contributors for the antioxidant activity of the V. amvgdalina accessions collected.

The mode of action of antioxidants is applied by preventing reactive oxygen species formation either by inhibition of enzymes or chelating trace elements which are involved in free radical generation, scavenging reactive species and augmenting the activity of the antioxidant enzymes [8,14,15]. MN627984 accession of *V. amygdalina* had the highest percentage inhibitory effect of nitric oxide while MN628021 had the lowest percentage inhibitory effect of nitric oxide (Fig. 3). Sodium nitroprusside in aqueous solution at physiological pH generates nitric oxide, which spontaneously interacts with oxygen to produce nitrite ions which are estimated by the use of Griess reagent. Nitric oxide has an unpaired electron that acts as a free radical that has a very important role in the pathogenesis of pain, inflammation, cancer, and so on [16].

The electron donation ability of natural products could be measured by 2,2-diphenyl-1picrylhydrazyl radical (DPPH), purple-colored solution bleaching [17,18]. The method

FOOD, AGRICULTURE, VOlume 22 No. 4 SCIENCE June 2022

ISSN 1684 5374

TRUST

is based on scavenging of DPPH through the addition of a radical species or antioxidant that decolorizes the DPPH solution. The measure of color change is relative to the strength and potency of the antioxidants in the extracts. In the present study, all the different accessions of *V. amygdalina* collected showed significantly higher DPPH inhibition percentage. However, MN627975 accession of V. amygdalina had the highest percentage inhibitory effect of DPPH ($98.92\% \pm 1.59$) while MN627990 had the lowest percentage inhibitory effect of DPPH ($46.38\% \pm 13.98$) (Fig. 4).

The results of this study suggest that the different accessions of V. amygdalina contain phytochemical constituents that are capable of donating hydrogen to scavenge free radical and the phenolic components present in the different accessions of V. *amygdalina* collected, might be responsible for the nitric oxide scavenging effect. Studies have shown that scavengers of nitric oxide such as phenolic compounds compete with oxygen leading to the reduced production of free radicals [11,14].

Post Hoc Analysis with ANOVA on the antioxidant activities and antigenotoxic properties of V. amygdalina Accessions

The overall antioxidant results were analysed using the ANOVA with LSD as shown in Table 1. At $P_{0.05}$; LSD = 16.113; there was significant difference (*) between the mean values of phenol and flavonoid, phenol and DPPH as well as phenol and nitric oxide (P < 0.05). There was non-significant (ns) difference between DPPH and nitric oxide (P > 0.05). 0.05) in the overall antioxidant results. However, when the specific ANOVA data for DPPH and nitric oxide was analysed at $P_{0.05}$; LSD = 1.9304; there was significant difference between the mean values of DPPH and nitric oxide (P < 0.05).

The antioxidant results that were significant at $P_{0.05}$ were further analysed at $P_{0.01}$; LSD = 21.4122; the results showed that there was highly significant difference (**) between the mean values of phenol and flavonoid, phenol and nitric oxide, phenol and DPPH, flavonoid and DPPH as well as flavonoid and nitric oxide (P < 0.01).

The antioxidant results that were significant at $P_{0.01}$ were further analysed at $P_{0.001}$; LSD = 27.4959; the results showed that there was very highly significant difference (***)between the mean values of phenol and flavonoid, phenol and nitric oxide, phenol and DPPH as well as flavonoid and nitric oxide (P < 0.001).

In the present study, all the different V. amygdalina accessions collected in Nigeria showed significantly higher inhibition percentage at P<0.05, P<0.01, and P<0.001 (Table 1). The results of this study suggest that the leaves of the different accessions of V. amvgdalina contain phytochemical constituents that are capable of donating hydrogen to a free radical to scavenge the potential damage.

The antigenotoxicity results were also analysed (Table 1). At $P_{0.05}$; LSD = 1.5133; there was significant difference (*) between the mean values of Allium cepa roots with ethidium bromide (EB) and Allium cepa roots with ethidium bromide (EB) treated with *Vernonia amygdalina* (VA) (P < 0.05).

AN JOURNAL OF FOOD, AGRICULTURE, VOlume 22 No. 4 SCIENCE June 2022 TRUST

ISSN 1684 5374

The genotoxicity of ethidium bromide in experimental model has been evaluated [20]. Ohta et al. [20] also reported some work concerning the effects of ethidium bromide on plant DNA strand breaks and chromosomal aberrations. The expression of antigenotoxic property of commonly consumed V. amvgdalina accessions are shown in Fig. 5. The control A. cepa roots growth in water had the lowest percentage of fragmented DNA followed by V. amygdalina accession number MN628010. The highest percentage of fragmented DNA was observed in Allium cepa roots grown in ethidium bromide (control) followed by V. amygdalina accession MN627977. Percentage increase of fragmented DNA of commonly consumed bitter leaf accessions on A. cepa roots grown in ethidium bromide solution are presented in Fig. 6.

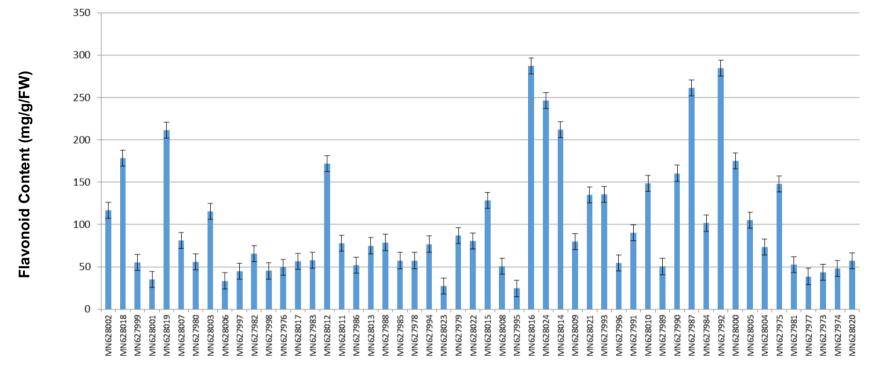

Interestingly, V. amygdalina accessions MN628008 indicated the highest percentage increase of fragmented DNA ($457.62\% \pm 4.11$) followed by MN628024, MN628015 and MN627984, while MN628010 had the lowest $(7.32\% \pm 2.83)$ (Fig. 6). The significant increase observed in the percentage of fragmented DNA of A. cepa roots growth in ethidium bromide solution when compared with the control (A. cepa roots growth in water only) may be as a result of the genotoxic effect of ethidium bromide solution. However, the significant decrease observed in fragmented DNA percentage of A. cepa roots growth in ethidium bromide solution treated with the commonly consumed V. amvgdalina accessions as compared with Allium cepa roots growth in ethidium bromide solution only may be related to the antigenotoxic activities of V. amygdalina accessions (Fig. 5).

The highest percentage of fragmented DNA of *Allium cepa* roots growth induced with ethidium bromide solution and treated with V. amygdalina accessions extracts as shown in MN627977, MN627985, MN628009 and MN628013, may be as a result of the low phenolic contents, flavonoid contents, nitric oxide and DPPH radical scavenging activities in these V. amygdalina accessions. The lowest percentage of fragmented DNA of Allium cepa roots growth induced with ethidium bromide solution and treated with V. amygdalina accessions MN628010, MN628008, MN628024 MN628015 and MN627984 extracts (antigenotoxic) that were observed could be as a result of the high antioxidant activities in the V. amygdalina accession. This is in accordance with Hu et al. [21] who stated that antioxidant dietary supplement can reduce the level of DNA oxidative damage and protect normal cells against the adverse side-effects of some carcinogens.

The results of the correlation between the antioxidant activities and antigenotoxicity showed that no correlation was observed between the percentage of fragmented DNA of Allium cepa root induced with ethidium bromide and treated with V. amygdalina and flavonoid content ($r^2 = 0.1411$), nitric oxide radical scavenging activity ($r^2 = 0.0037$) and DPPH radical scavenging activity ($r^2 = 0.1539$). However, a strong positive correlation ($r^2 = 0.6708$) was observed between phenol content and percentage of fragmented DNA of Allium cepa root induced with ethidium bromide and treated with V. amvgdalina leaf extracts (Fig. 7). This suggests that the high phenolic content antioxidant activity could be responsible for the treatment of the genotoxic effect of increased percentage of fragmented DNA of *Allium cepa* root by significantly (P < 0.05) reducing the percentage of the fragmented DNA of Allium cepa root.

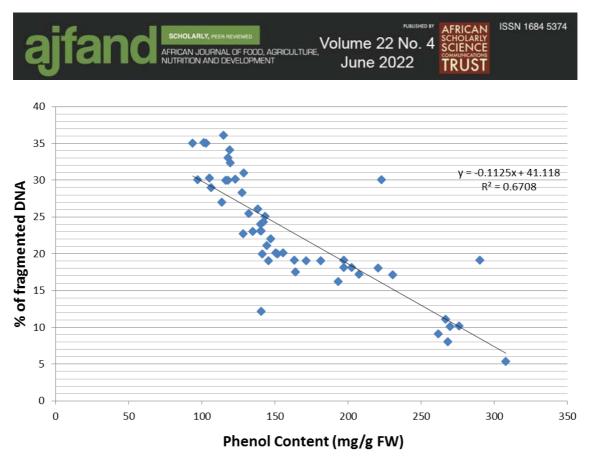

Figure 7: Correlation between phenol content and percentage of fragmented DNA of *Allium cepa* root induced with ethidium bromide and treated *V. amygdalina* leaf accessions collected

The change observed in the varying amount of antioxidant properties of *V. amygdalina* accessions in this study may be as a result of some environmental factors. Altitude, temperature, illumination, and moisture are important factors that could regulate the metabolism and accumulation of secondary metabolites [19]. Environmental differences such as: altitude, temperature, illumination, precipitation, humidity, soils in different production locations, could contribute to the differences in active ingredient contents and antioxidant activity of medicinal plants [19].

CONCLUSION

The results of this study showed that *V. amygdalina* accessions from different parts of Nigeria possesses flavonoids, phenolic content, natural nitric oxide and DPPH radical scavenging activities. Interestingly, the extracts of *V. amygdalina* significantly reduce the percentage of fragmented DNA of *A. cepa* roots growth induced with ethidium bromide. This suggests that the antigenotoxic property of *V. amygdalina* accessions could be because of its antioxidant activities. Generally, the lowest percentage of fragmented DNA of *A. cepa* roots growth was indicated in *V. amygdalina* accessions MN628010, MN628008, MN628024, MN628015 and MN627984. This could be because of the high antioxidant activities (phenolic content) in the *V. amygdalina* accessions as shown in the correlation results.

It is suggested that further studies be carried out to ascertain the impact of soil minerals and weather conditions in the investigated geographical regions on the morphological

characteristics of the *V. amygdalina* accessions collected as well as their antioxidants prowess.
