18
19

20 **Abstract:** What conditions favor the evolution of elaborate sexual ornaments? In freshwater
21 killifishes, Sowersby et al. (2021) found that larger sexual ornaments were negatively
22 associated with locomotive performance. While selection clearly favored large ornamental
23 fins in environments with fewer predators, there was no clear association between large
24 ornamental fins and differences in life-history strategy. This finding illustrates that habitat
25 differences in predation risk have the potential to influence the evolution of secondary sexual
26 traits such as ornaments through natural selection.
27

28 **Main text:** Sexual ornaments are known to come in many different shapes and sizes, but the
29 reasons for these differences in morphology are less well understood (McCullough et al.,
30 2016). Mating success (Andersson, 1982) and predation risk (Gadgil and Bossert, 1970) have
31 been put forward as two of the primary evolutionary drivers of sexual ornaments in animals.
32 In animals with sexual ornaments or conspicuous displays of courtship, mate choice (Suk,
33 2002) and competition for access to mates (Goldberg et al., 2019) appear to have strongly
34 influenced the evolutionary divergence of sexual ornaments across species and taxa. Male
35 killifish with larger ornamental fins are expected to have higher mating success, trading off
36 with impaired locomotion and potentially a greater risk of predation. The potential for
37 predation risk and differences in life-history strategy to drive evolution of sexual ornaments
38 remains an underexplored topic. To that end, the killifishes (Suborder: Aplocheiloidei),

39 which exhibit significant differences in the pace of life-history (investment in current versus
40 future reproduction) and habitat type (difference in predation risk), present an ideal model
41 system to further explore this topic.

42

43 Competition for access to mates is widely known to influence the evolution of secondary
44 sexual ornaments, increasing chances for mating success, at a potential cost to survival
45 (Andersson, 1982). Secondary sexual traits therefore constitute an important investment into
46 reproduction, with many either targets of inter- and/or intrasexual selection. In this study,
47 Sowersby et al. (2021) predicted that predation risk and the pace of life-history will influence
48 the evolution of secondary sexual traits in killifishes. Killifish species in ephemeral and low-
49 predation risk environments with faster life histories should have larger male ornamental fins.
50 To test these predictions, the authors assessed habitat type as a proxy for predation risk and
51 the pace of life history across both sexes and several species of killifish. Using a
52 macroevolutionary comparative framework, they measured swimming performance in 19
53 species (N = 259) and fin and body area in 28 species (N = 227) under a standardized
54 common garden setting.

55 As predicted, they found negative associations for swimming performance (Fig. 1A) and risk
56 of predation (Fig. 1B) with residual total fin area in killifishes. In addition, the authors found
57 that the position of different fins on the body has a significant impact on swimming
58 performance in killifish. This often-overlooked fact can explain the mixed or even
59 contradictory findings of previous studies investigating the costs of secondary sexual traits.
60 The authors also found that sexual dimorphism was greater in ephemeral habitats, where
61 predation risk is lower, compared to both generalists and permanent habitats (Fig. 1C). In
62 contrast, they found no clear evidence for the influence of different life history strategies (fast
63 or slow) on ornamental fin size (Fig. 1D). However, and in accordance with prior studies, the
64 authors note that this could be influenced by the subtle and often difficult-to-detect costs of
65 bearing and maintaining sexual ornaments, rather than an effect of pace of life-history (Clark
66 and Dudley, 2009, Narayan, 2021, Narayan and Wang, 2021).

67

68 The authors demonstrate that in killifish, the evolution of sexual dimorphism in ornament
69 size is favored in ephemeral habitats, even at the cost of impaired locomotion, but not in
70 permanent habitats, likely due to the higher risk of predation in these environments. They did
71 not, however, find evidence for the co-evolution of male ornaments with pace of life-history.
72 Possible limitations to this study include habitat as a proxy for predation risk, and

73 fluctuations in abiotic factors across different types of habitats, which may also influence
74 ornamental fin evolution. Overall, this study by Sowersby et al. (2021) demonstrates that in
75 killifish, predation risk more than the pace of life history influences the evolution of large
76 sexual ornaments.
