

## Trichilemmal cyst of the buttocks: case report and management

Fabbrocini G, Cacciapuoti S, Izzo R, Mascolo M, Staibano S, Monfrecola G. Departments of Dermatology, Federico II University, Napoli, Italy

Proliferating trichilemmal cyst (PTC) is a benign adnexal tumors of the skin, related to the isthmus of the hair follicle. PTC was described for the first time 1966 by Wilson-Jone, as "proliferating epidermoid cysts". Usually the lesion is encountered on the scalp; but wrist, elbow, mons pubis, vula, buttock, and chest are locations where it can be found. Malignant transformation has rarely been reported these lesions. Treatment mainly entails wide local surgical excision. We report a case of 30 years-old woman, with small PTC on buttock areas, treated with topical urea and salicylic acid peeling. Keratolytic action of urea can be used in the treatment of PTC, when they are small in size, and spread over a large area, which is's no possible perform a surgical excision.
