Abstract

Objectives

The objectives of this study were to determine whether conducting a clinical audit was achievable in a group of centres that perform interventional cardiac procedures and to report the success and complications rates in dogs diagnosed with patent ductus arteriosus (PDA).

Methods

This was a multi-centre, European-wide, prospective study. Patient data were entered into a bespoke database prior to commencing interventional closure of PDA in all animals undergoing this procedure during the study period. The database was designed to gather clinical audit information, after completion of the procedure, such as discharge outcome, complication rate and medium-term outcome.

Results

A total of 339 cases were included from five participating centres. The process of performing clinical audit was achieved in all centres. Successful discharge outcome was 95.9% with a complication rate of 4.1%. The procedure-related mortality was 0.6%. 149 cases (43.9%) were either lost to follow-up or had not yet had a follow-up within the time period. Of the remaining 169 cases in which follow-up was available, 157 (92.9%) had a successful medium-term outcome

Conclusions

This study demonstrates that the process of performing a clinical audit is achievable in veterinary clinical interventions across different centres. These results provide a benchmark for future comparison in our ongoing clinical audit and validate the

1 process of clinical audit for other centres performing cardiac interventions. The use
2 of clinical audit should be considered in other aspects of veterinary medicine.

23 **Abstract**

24 Objectives

25 The objectives of this study were to determine whether conducting a clinical audit
26 was achievable in a group of centres that perform interventional cardiac procedures
27 and to report the success and complications rates in dogs diagnosed with patent
28 ductus arteriosus (PDA).

29 Methods

30 This was a multi-centre, European-wide, prospective study. Patient data were
31 entered into a bespoke database prior to commencing interventional closure of PDA
32 in all animals undergoing this procedure during the study period. The database was
33 designed to gather clinical audit information, after completion of the procedure, such
34 as discharge outcome, complication rate and medium-term outcome.

35 Results

36 A total of 339 cases were included from five participating centres. The process of
37 performing clinical audit was achieved in all centres. Successful discharge outcome
38 was 95.9% with a complication rate of 4.1%. The procedure-related mortality was
39 0.6%. 149 cases (43.9%) were either lost to follow-up or had not yet had a follow-up
40 within the time period. Of the remaining 169 cases in which follow-up was available,
41 157 (92.9%) had a successful medium-term outcome

42 Conclusions

43 This study demonstrates that the process of performing a clinical audit is achievable
44 in veterinary clinical interventions across different centres. These results provide a
45 benchmark for future comparison in our ongoing clinical audit and validate the

68 Introduction

69 Clinical audit remains in its infancy in veterinary medicine, but is an emerging aspect
70 of clinical governance (<https://vetaudit.rcvsk.org/>). Clinical papers in veterinary
71 journals are dominated by research that documents new knowledge, often following
72 randomisation of differing cohorts, with the aim of progressing and evolving novel
73 methods or techniques. By contrast, clinical audit aims to measure standards of care
74 or service set by that research and to monitor established techniques or processes
75 to ensure they are working as expected. Research typically requires ethical approval
76 whereas clinical audit does not [1].

77 Clinical audit has been in place for surgical and interventional cardiac procedures in
78 human medicine for over 30 years. Since 1988, the British Cardiovascular
79 Interventional Society has been collating outcome data for consultant cardiologists
80 who perform percutaneous coronary intervention in the United Kingdom [2]. Their
81 aim was to create a registry of all percutaneous coronary intervention procedures to
82 assess quality of care, drive improvements and provide a benchmark. The first
83 publication of their findings was in 1990 [3]. In 2011 management of the British
84 Cardiovascular Interventional Society registry was moved to the National Institute of
85 Cardiovascular Outcomes Research (<https://www.nicor.org.uk/about-nicor/>) [4]. The
86 results and reports from this audit (<https://www.bcis.org.uk/public-reports/>), as well as
87 individual outcomes data, are viewable in the public domain. Outcome clinical audit
88 monitors the success and complication rates of an established technique or
89 procedure. If audit is used appropriately and efficiently, it can be an effective tool for
90 improvement. Or, put more simply, audit helps to find out whether or not a method or
91 process is attaining an established standard, with the potential to drive further

92 improvements in outcomes. Analyses with implementation of improvements and
93 subsequent re-audit are important features of the clinical audit cycle.

94 As interventional procedures become more commonplace in veterinary cardiology,
95 audit becomes an important tool to assess current clinical standards, or as a means
96 of benchmarking for new centres and individuals embarking on interventional
97 procedures.

98 Interventional closure of PDA in dogs is now well-established [5–7] and is offered by
99 an increasing number of specialist centres. However, within this relatively new but
100 fast-growing field, individual centres may evolve their procedural techniques and
101 processes differently, with different associated complications. Therefore there is a
102 need to perform an audit in order to share the details of those methods along with
103 their complication rates and to help improve the collective standards.

104 The primary objective of the study was to determine whether conducting a clinical
105 audit was achievable in a group of centres performing interventional cardiology.

106 Secondary objectives were to provide benchmark data for success and complication
107 rates, using the procedural techniques and processes described by our centres for
108 PDA closure.

110 **Materials and Methods**

1
2
3 111 This was a multicentre prospective study involving five cardiology referral centres in
4
5 112 Europe: Willows Referral Centre, England (WLS), HeartVets, England (HVT),
6
7
8 113 University of Edinburgh Royal (Dick) School of Veterinary Studies, Scotland (EDN),
9
10 114 University Hospital for Companion Animals, Copenhagen, Denmark (CPH), AniCura
11
12 115 Oslo Animal Hospital, Norway (OSL). Data was collected from November 2015 to
13
14
15 116 April 2021. The lead author (MM) had significant input in interventional training in all
16
17 117 centres except EDN.

18
19
20 118 All dogs were client-owned, had been diagnosed with a PDA and were scheduled for
21
22
23 119 interventional device closure. Written consent was given by all owners and
24
25 120 comprehensive physical and echocardiographic examinations were performed by a
26
27
28 121 Diplomate in cardiology or resident under supervision. Where indicated by the
29
30 122 presence of clinical signs or cardiomegaly on echocardiography, thoracic
31
32 123 radiographs were performed at the discretion of the clinician. Echocardiographic
33
34
35 124 measurements of the PDA diameter at the levels of the ostium (sometimes termed
36
37
38 125 the minimal ductal diameter) and ampulla (in the location of where a device would be
39
40 126 implanted) were made prior to the procedure [8,9].

41
42
43 127

44
45
46 128 **Clinical Audit database**

47
48
49 129 Patient data of all consecutive cases intended for PDA interventional closure were
50
51
52 130 included. Participating centres entered their data, during the patient preparation time
53
54 131 prior to the procedure, into a bespoke database using Microsoft Excel spreadsheet ^h.

55
56
57 132 The primary objective of the database design was that it was quick and easy to
58
59
60
61
62
63
64
65

133 complete, and the outcomes simple to enter at the time of the post-intervention
134 examination, prior to discharge.

135 Data recorded included: date, patient identification, breed, age, body weight, initials
136 of the lead interventionalist, discharge outcome, complications, medium-term
137 outcome, total radiation and additional comments (Fig. 1).

138 Discharge outcome had a binary entry of either 1 (yes) or 0 (no) using the following
139 definition: at the time of recovery and discharge from of the hospital, there had been
140 a successful procedure and closure of the PDA with no more than trivial residual
141 PDA flow using criteria previously described [10], on a post-procedural
142 echocardiographic examination within 24 hours of the procedure. Above this column
143 heading for successful discharge outcome was a percentage (%), which would
144 automatically update with each new case entry.

145 Complications had a binary entry of either 1 (yes) or 0 (no) using the following
146 definition: clinically significant event during the procedure, needing some form of
147 clinical intervention/treatment such as any complication resulting in a clinical decision
148 to abort the procedure, any complication that led to death in the peri-interventional
149 period or in the following few days, dislodgement/embolisation of the device,
150 ventricular fibrillation needing defibrillation, significant lameness, device infection or
151 thrombus formation, rupture or tearing of a vessel resulting in haemorrhage or failure
152 to cannulate the access vessel.

153 Medium-term outcome had a binary entry of either 1 (yes) or 0 (no), or could be left
154 blank if not yet obtained, i.e. follow-up was still pending. The definition of successful
155 medium-term outcome was: device in place and dog not in congestive heart failure

156 (CHF) and not needing cardiac medications in the following three-to-12 month period
157 with no ongoing clinical signs.

158 Above the column headings for discharge outcome, complication and medium-term
159 outcome, the percentage (%) total was displayed, which would automatically update
160 with each new case entry (ignoring blank cells where appropriate).

161 Total radiation was recorded as total radiation dose and/or time, depending upon the
162 centre's facilities, provided by the image-intensifier software. Total radiation dose in
163 milliGray was a combination of radiation dose at low-dose screening and high-dose
164 recording. The column heading for total radiation dose was set to report a mean
165 dose and/or time for the collective case series.

167 Procedural Technique

168 The procedural technique is similar to that previously described [5]. However, as
169 there were differences, particularly for vascular access, and because outcomes or
170 complications may be related to the technique, the procedure is described in detail.

171 All procedures were all performed by two veterinary cardiologists (lead and
172 assistant) at every centre. Dogs were primarily placed in right lateral recumbency,
173 under general anaesthesia. The right femoral area was clipped and aseptically
174 prepared for surgery before transfer to a radiolucent table designed for fluoroscopy.
175 The left hind leg was positioned to expose the right femoral area and the right hind
176 leg was tied slightly caudally to extend the stifle and hip joints. Antibiotics were given
177 one hour prior to surgery; the choice of perioperative antibiotic use was set by
178 individual practice policy.

179 Transoesophageal echocardiography (TOE) was performed in dogs weighing greater
180 than 10 kg (but dependent upon the individual case) for imaging and measurement
181 of the PDA as well as for additional procedural guidance, similar to that previously
182 described [9,11,12].

183
184 Trans-arterial approach for Amplatz Canine Duct Occluder ⁱ (ACDO).

185 The right femoral artery was accessed via a surgical cut-down, close to the inguinal
186 region. Two absorbable stay sutures ^j were placed around the isolated femoral artery
187 and a cannula placed using the modified Seldinger technique. While the assistant
188 held these two sutures, proximally and distally, to control any haemorrhage, the lead
189 interventionalist used a 24 G intravenous Seldinger-compatible cannula (which had a
190 funnel-shaped hub) into the arterial lumen. The stylet was then removed. A 0.018”
191 guidewire was then advanced through the lumen of the catheter into the artery and
192 the cannula removed. A 4 French (Fr) or 5 Fr vascular access catheter and dilator ^k
193 (dogs weighing </> five kg respectively) were passed over the wire and into the
194 artery. Once placed, the wire and dilator were removed, and the distal suture ^j ligated
195 to occlude the femoral artery. The vascular access catheter was sutured to the skin
196 to prevent accidental removal during the procedure. In one centre (EDN), for large
197 dogs, a larger vascular access catheter was placed (through which the delivery
198 sheath could be passed). To achieve this a 16 G cannula was inserted into the
199 isolated femoral artery, the stylet removed and then a 0.035” wire advanced into the
200 femoral artery. The cannula was then removed and replaced with a larger 7 Fr
201 vascular access sheath ^l.

202 A 4 Fr or 5 Fr pigtail measurement catheter^m was passed through the vascular
203 access catheter to the aorta, just dorsal to the PDA. Angiography was performed
204 using a pressure injectorⁿ (15 mL/sec to a maximum pressure of 750 psi).
205 Approximately 1 mL/kg of iodinated contrast^o (up to a maximum of 20 mL for dogs
206 that weighed greater than 20 kg) was injected through the pigtail catheter.

207 A recording of the angiogram was then reviewed and measurements of the PDA
208 were made. To allow for the magnification of the image on the screen,
209 measurements were based on a scale taken from the spacing markers on the pigtail
210 catheter within the aorta. Similar to the echocardiographic measurements, the
211 pulmonary ostium and ampulla diameters were both measured. If the transthoracic
212 echocardiographic, TOE and angiographic measurements differed significantly, then
213 the imaging modality that was considered to be the optimal image by the lead
214 clinician was selected as the most representative of the true diameter.

215 An ACDO device size was based a waist diameter (Fig 2) being 1.75 to 2.0 times
216 greater than the pulmonary ostium [5], with an additional secondary consideration
217 that the width of the shoulders (Fig 2) of the ACDO was at least 2 mm greater than
218 the internal diameter of the ampulla.

219

220 Method of Amplatz Canine Duct Occluder deployment

221 The ACDO was deployed as previously described [6]. The size of the delivery sheath
222 for large dogs was that recommended by the manufacturer of the ACDO, but for
223 smaller dogs and depending upon the diameter of the femoral artery, a delivery
224 sheath one Fr smaller was frequently used. The ACDO was routinely removed from
225 its loader to check safe attachment (ie. that the ACDO was properly screwed onto

226 the wire) and in small dogs the ACDO was reloaded into a smaller loader (one Fr
1
2
3 227 size smaller), then flushed with heparinised saline to remove all air bubbles. A
4
5 228 haemostatic valve was attached to the delivery sheath ^p. A 145 cm safety J-wire ^q
6
7 229 was placed through the vascular access sheath into the aorta and the sheath
8
9
10 230 removed, while the assistant held the stay sutures to control haemorrhage. At one
11
12 231 centre (EDN), the sheath was not removed if a 7 Fr vascular sheath had been
13
14 232 inserted into the artery and a 5 Fr delivery sheath used to deploy the ACDO. The
15
16
17 233 delivery sheath (4 - 7 Fr) with its dilator ^r was passed over the wire and into the aorta.
18
19 234 The guidewire was then advanced through the PDA into the pulmonary artery. On
20
21
22 235 occasions this step required guidance with a curved end-hole catheter ^s inserted into
23
24 236 the delivery sheath. The dilator and delivery sheath were then passed over the wire
25
26
27 237 into the pulmonary artery, ensuring neither the wire nor the dilator or sheath passed
28
29 238 proximal to the pulmonary valve, to avoid triggering arrhythmias in the right
30
31
32 239 ventricular outflow tract. Once in position, the wire and dilator were removed together
33
34 240 leaving the delivery sheath within the pulmonary artery. The ACDO within the loader
35
36 241 was then passed through the haemostatic valve, and into the delivery sheath and the
37
38
39 242 loader was retracted. Under fluoroscopic imaging +/- TOE guidance, the ACDO was
40
41 243 then advanced and deployed across the ostium of the PDA and within the ampulla
42
43
44 244 [6]. The TOE imaging facilitated correct device placement, helping to ensure the
45
46 245 protruded distal disc (Fig 2) was positioned close to the ostium as the body (portion
47
48
49 246 proximal to the waist) of the ACDO was released [9]. The ACDO was held in place
50
51 247 for five minutes in all centres except one (EDN) who waited for 10 minutes, prior to
52
53
54 248 release, during which time measurements of the waist and shoulders of the ACDO
55
56 249 (Fig 2) to assess the device sizing were made. A small bulging of the distal disc
57
58 250 caused by constriction from the ostium on the ACDO was expected and compression

251 of the shoulders of the ACDO (Fig 2) by the walls of the ampulla were observed.
252 Flow around and through the ACDO was monitored with TOE during the procedure
253 and auscultation under the drape after deployment. Blood pressure and
254 electrocardiographic monitoring were observed for any Branham response and
255 increase in diastolic blood pressure. Failure of any bulge warranted an evaluation
256 for the risk of ACDO under sizing. A gentle 'push and pull' test was performed to
257 ensure the ACDO was sized correctly. If the device dislodged, then the ACDO was
258 removed by careful retraction into, while advancing forward, the delivery sheath, and
259 a larger device was implanted. An angiogram was repeated, by hand injection and
260 prior to release if there was any doubt about sizing or excessive residual flow,
261 otherwise it was performed after detachment from the delivery cable. Prior to
262 unscrewing, the sheath was advanced close to the screw interface in order to protect
263 the ductal and aortic walls from damage caused by the screw end of the wire, as it
264 detaches from the ACDO.

265

266 Transvenous approach for Amplatz Vascular Plug 2 ^t

267 An Amplatz vascular plug 2 (AVP2) was used in dogs in which the size of the
268 delivery sheath was likely to be too large or difficult for an arterial approach. A
269 transvenous approach via a surgical cutdown was by the femoral vein (dogs > 2.5
270 kg) or the left jugular vein (dogs < 2.5 kg). Otherwise, vascular access was similar to
271 that described above.

272 Retrograde catheterisation of the PDA was performed using a curved end-hole
273 catheter ^s and guidewire ^u. A 145 cm safety J-wire ^q was placed through the end-hole
274 catheter into the pulmonary artery. Once in the location of the PDA, the J-wire was

275 exchanged for a soft tipped 0.035” straight wire ^u. This was used for retrograde
276 catheterisation of the PDA, passing the wire into the aorta, followed by the catheter.
277 Once in aorta, the end-hole catheter was exchanged for a multi-hole multi-purpose
278 angiographic catheter ^v in order to perform angiography, with the side-holes partially
279 inside the ampulla, but the tip of the catheter in the aorta.

280 Angiography and measurements were performed and described as above.

281

282 Method Amplatzer Vascular Plug deployment

283 The procedural method of deployment of the AVP2 was similar to that described for
284 Amplatzer vascular plugs and Amplatzer duct occluders [7,13]. The selected size of
285 AVP2 device was based on 1.3 to 1.5 times greater than the diameter of the
286 ampulla. All AVP2s < 8 mm in diameter were delivered via a 4 Fr sheath ^r. The AVP2
287 was routinely removed from its loader to ensure safe attachment then reloaded and
288 flushed with heparinised saline to remove air bubbles. A haemostatic valve ^p was
289 attached to the delivery sheath or catheter. The multi-hole catheter was removed,
290 leaving the wire in place. The delivery sheath with its dilator was passed over the
291 wire. Once in place, the wire and dilator were removed together leaving the delivery
292 sheath within the aorta. The AVP2, within its loader, was passed through the
293 haemostatic valve, and into the delivery sheath by advancing the delivery wire,
294 before retracting the loader free of the haemostatic valve. The AVP2 was then
295 advanced under fluoroscopic imaging. The distal and middle discs were deployed
296 and gently retracted to fill the ampulla, before the proximal disc was deployed across
297 the ostium. The AVP2 was held in place for five minutes in all dogs prior to release,
298 during which time the body of the AVP2 was measured to assess the device sizing.

299 Prior to unscrewing the delivery wire, as with the ACDO, the sheath was advanced
300 close to the screw interface in order to protect the pulmonary arterial wall from
301 damage caused by the sharp end of the screw of the mandrill.

302

303 Surgical Closure

304 For both ACDO and AVP2 methods, the access vessel was ligated proximal and
305 distal to the arteriotomy/venotomy site using the preplaced absorbable stay suturesⁱ.
306 The subcutaneous fat was closed over these sutures and vessel with absorbable
307 sutures and the skin closed routinely.

308

309 Post intervention examination

310 Physical and echocardiographic examinations were repeated to assess procedure
311 outcome. Echocardiography was performed within 24 hours of the procedure.

312 The patient was usually discharged the day after the procedure unless it had been in
313 advanced CHF. Sutures were removed by the primary veterinarian after 10 days.

314 Follow-up echocardiography was performed at one to three months at the referral
315 centre or by the referring veterinary cardiologist if the case was a tertiary referral.

316 Additional examinations were performed according to degree of cardiac compromise
317 at initial presentation, owner finances and willingness to travel.

320 Statistical analyses were performed using PAST 4 software [14]. Data were
321 examined visually and formally for normality. Continuous data are expressed as
322 median and interquartile range (IQR), and categorical data as counts and
323 percentages.

324 The relationship between discharge outcome and medium-term outcome and body
325 weight and age was examined with a Spearman Rank Sum correlation.

326 To compare groups, an independent samples *t*-test was used for continuous data
327 and chi-squared or Fisher's Exact tests for categorical data. Formal statistical
328 comparisons were made only where raw data were available, and where few cases
329 are reported in both groups only summaries are provided. Statistical significance was
330 set at 0.05.

331 332 **Results**

333 A total of 339 dogs (Fig. 3) were included in this clinical audit (WLS = 219, HVT = 50,
334 EDN = 38, CPH = 19, OSL = 13). An ACDO was used in 310 dogs and AVP2 was
335 used in 23 dogs (WLS = 12, HVT = 9, CPH = 2). Additionally there were six dogs in
336 which a device was not successfully deployed.

337 There were 54 crossbreeds, which were primarily first crosses with poodle breeds
338 (cavapoo, Cockerpoo, Labradoodle). Sixty-two pure breeds were represented, of
339 which the most common were Cocker spaniel (n = 31), German shepherd dog (n =
340 19), Border collie (n = 18), cavalier King Charles spaniel (n = 16), Labrador retriever
341 (n = 12) and English Springer spaniel (n = 11). The median age was eight months
342 (IQR four months to 20 months). There were 57 (16.8%) dogs under four months of
343 age and 81 (23.9%) over two years of age. The median body weight (Fig. 4) was 7.9

344 kg (IQR 4.9 to 24 kg, range 1.5 to 58.4 kg). There were 19 dogs in the weight range
345 1.5 to 2.9 kg, of which 12 (63%) received an AVP2. A total of 55 dogs (16.2%) were
346 under 3.9 kg. There were 15 dogs over 30 kg (4.4%).

347 The smallest dog that received an ACDO was a 2.1 kg, 2.4 month-old Border terrier
348 and the smallest with an AVP2 was a 1.5 kg, four month-old Chihuahua. The largest
349 dog that received an ACDO was a 58.4 kg, 21 month-old Newfoundland, and the
350 largest with an AVP2 was an 11.7 kg, 55 month-old cavalier King Charles spaniel.

351 The criteria for a successful discharge outcome were met in 325 (95.9%) of cases
352 (Fig. 3). In 10 (3.2%) of the ACDO cases a first attempt had been made with a
353 device that pushed/pulled through, or did not have any bulging of the distal disc, and
354 was replaced by a larger device.

355 A total of 14 cases (4.1%) were recorded as not having a successful discharge
356 outcome, of which 13 (3.8%) were recorded as also having a procedural
357 complication (Table 1); the single case that was not recorded as a procedural
358 complication was in advanced CHF and had an unexplained sudden death 16 hours
359 post-procedure. The procedure-related mortality was 0.6% (two cases): one dog had
360 a dissection of the ductal or pulmonary arterial wall and died during surgery and one
361 dog developed severe bradycardia following closure during intervention, then died
362 three days later. Six dogs (Table 1) were not closed interventionally due to
363 procedural complications. Five dogs were intended for ACDO placement and one for
364 an AVP2 placement. In one of the five dogs, a femoral arterial approach was made
365 for an intended ACDO placement, but that was unsuccessful, then during the same
366 procedure, a jugular approach was made for an intended AVP2 placement, but that
367 was also unsuccessful. Two of the six dogs, were recorded as having subsequent

1 368 successful surgical ligation of their PDA. Five cases had interventional closure but
2 369 also complications (Table 1). Three of these developed hind limb lameness, in the
3
4 370 limb used for access, immediately after the procedure. All dogs were Cocker
5
6
7 371 spaniels (two females, one male), unrelated and from the same centre (WLS).
8
9 372 Neurological examination by a board-certified neurologist ruled out iatrogenic
10
11 373 femoral nerve damage in all dogs. One of these dogs had ultrasound and CT-
12
13 374 angiography of the affected limb, revealing oedema and ischemia in multiple thigh
14
15 375 muscles (possibly due to microthrombi) and a thrombus in the right popliteal vein.
16
17 376 Symptomatic treatment with analgesia (three of three dogs) and clopidogrel (two of
18
19 377 three dogs) was started and complete resolution of the clinical signs occurred within
20
21 378 24 hours in one dog, four days in another dog and two months in the final dog.
22
23
24
25
26
27 379 For the medium-term follow-up, seven dogs were excluded either because they died
28
29 380 or the procedure was unsuccessful, these dogs had all been recorded as having a
30
31 381 failure of successful discharge outcome. A further 149 cases (43.9%) were either lost
32
33 382 to follow-up or had not yet had a follow-up within the time period. Of the remaining
34
35 383 169 cases in which follow-up was available, 157 (92.9%) had a successful medium-
36
37 384 term outcome (Fig. 3, Table 2). Of the 12 dogs without a successful medium-term
38
39 385 outcome, 10 had pre-existing complications, of which eight were receiving
40
41 386 medications for CHF and two had significant pulmonary arterial hypertension.
42
43 387 Another two dogs suffered an unexplained sudden death, one at 15 days and the
44
45 388 other at three months post-closure. In three of the dogs that initially continued on
46
47 389 medications for CHF, the diuretics and other CHF treatment were stopped,
48
49 390 remaining only on pimobendan long-term.

391 We examined the relationship of discharge outcome and medium-term outcome with
392 age and bodyweight. We found no significant relationships ($P > 0.05$, data not
393 shown).

394 The total radiation exposure dose was recorded in 282 cases (out of 339 dogs,
395 83.2%). The median radiation dose was 15.6 milliGray (mGy) (IQR 9.7 to 21.3 mGy,
396 range 1.1 to 89.2 mGy). The exposure time was recorded in 210 cases with a
397 median of 4.41 minutes (IQR 3.2 to 6.8 mGy, range 1.5 to 19.5 mGy). For the cases
398 in which an ACDO was used, the median total radiation dose was 15.2 milliGray
399 (IQR 9.6 to 21.2 mGy, range 1.1 to 89.2 mGy) and median exposure time was 4.3
400 minutes (IQR 3.1 to 6.2 mGy, range 1.5 to 19.5 mGy); for the AVP2 cases the mean
401 total radiation dose was 20.3 milliGray (IQR 16.8 to 23.9 mGy, range 9.1 to 50.0
402 mGy) and median exposure time was 8.1 (IQR 5.0 to 10.2 mGy, range 2.5 to 13.5
403 mGy) minutes. The AVP2 cases took significantly longer with a significantly greater
404 radiation dose ($P = 0.009$).

406 Discussion

407 The study demonstrates that a clinical audit is achievable on a real-time and
408 prospective basis in veterinary centres that perform cardiac interventional
409 procedures. Centres can use this auditing process to monitor their outcomes and
410 complications year to year. Any deficiencies in outcomes should be identifiable and
411 addressed by adjusting processes, techniques or training methods in order to raise
412 the standard and drive forward continuous improvement. The findings from our
413 clinical audit may help to provide a benchmark by which others can compare their
414 outcomes and, importantly, allow the profession to raise the standard of care for

1 415 patients and their owners. This is similar to the mission of National Institute of
2
3 416 Cardiovascular Outcomes Research (NICOR) (<https://www.nicor.org.uk/about-nicor/>),
4
5 417 which is to provide accurate data on cardiovascular outcomes for the public,
6
7 418 healthcare providers and the medical profession in order to improve the quality of
8
9
10 419 care and outcomes for patients [4]. Our clinical audit provided outcome measures,
11
12 420 identified complications and highlighted areas for improvement for the future.
13
14

15 421 The successful discharge outcome in this audit was high and is almost identical to
16
17 422 that previously reported [15] in a larger population of dogs which included dogs
18
19
20 423 undergoing surgical ligation. Our data are also comparable to those for the
21
22 424 interventional closure of PDAs in 1762 children and adults, even though the NICOR
23
24
25 425 clinical audit reports a superior survival at 30 days of > 99.9%
26
27 426 ([https://www.nicor.org.uk/congenital-heart-disease-in-children-and-adults-congenital-](https://www.nicor.org.uk/congenital-heart-disease-in-children-and-adults-congenital-audit/)
28
29
30 427 [audit/](https://www.nicor.org.uk/congenital-heart-disease-in-children-and-adults-congenital-audit/)). Greater success rates in a patient population five times larger than ours may
31
32 428 reflect the greater experience in interventional cardiology within the field of human
33
34 429 medicine but, importantly, may also be a consequence of optimised techniques, and
35
36
37 430 superior training, protocols and post-operative management. The value of the
38
39
40 431 auditing process will come from identifying the procedural differences between
41
42 432 human and veterinary interventions, in order to inform on which modifications should
43
44 433 be introduced within the veterinary field and then re-auditing to see if outcomes are
45
46
47 434 improved.

48
49
50 435 Similarly, the complication rate for this clinical audit of 3.8% compares favourably to
51
52 436 those previously reported for ACDOs in dogs of up to 3% [16], especially since our
53
54
55 437 patient population was larger and data were collected from multiple centres. By
56
57 438 contrast, though, the complication rate for human PDA device closure in a three-year
58
59
60 439 clinical audit was < 0.01%. This included complications up to 30 days post closure
61

1
2
3 440 ([https://www.nicor.org.uk/congenital-heart-disease-in-children-and-adults-congenital-](https://www.nicor.org.uk/congenital-heart-disease-in-children-and-adults-congenital-audit/)
4 [audit/](https://www.nicor.org.uk/congenital-heart-disease-in-children-and-adults-congenital-audit/)). Our procedure-related mortality (0.6%) was one third that reported for
5 441 surgical closure in dogs (1.8) [17] and one quarter of the rate reported previously for
6 442 catheter-based PDA closure (2.6%) [15], though that also included the use of
7 443 embolisation coils. Clearly, advances have been made in reducing adverse
8 444 outcomes, but, compared to the complication rate in people, there are considerable
9 445 improvements to be made in interventional closure of canine PDA.
10 446

11
12 447 Complications were observed with both ACDOs and AVP2s. Five of the ACDO
13 448 cases and in one AVP2 case there were complications that led to failure to deploy
14 449 the device. As part of the auditing process, it was important to recognise and
15 450 quantify the separate stages of PDA closure that can lead to complications. This
16 451 allows centres to identify specific problematic stages of PDA closure, and focus
17 452 remedial efforts on them, whether they relate to vascular access, deployment of the
18 453 device or congestive status of the patient.
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34

35 454 An example of the usefulness of this approach comes from identification of lameness
36 455 as the source of nearly a quarter of the procedural complications. In all of the
37 456 affected dogs, the course of the lameness along with the absence of femoral nerve
38 457 injury were consistent with limb ischaemia, and in one dog, venous thrombosis was
39 458 confirmed. As far as the authors are aware, this has never been reported in dogs. In
40 459 people, deep vein thrombosis is a rare complication (0.05 - 2.4%) of cardiac
41 460 catheterisation and is most likely to happen if manual compression of the puncture
42 461 site occurs, or if concurrent venous puncture is performed [18–21]. Indeed, in infants
43 462 following venous access, the rate of deep vein thrombosis increases to
44 463 approximately 15.5% [21]. In all our affected dogs, venipuncture was not performed
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1 464 but our audit raises the possibility that Cocker spaniels may have a higher risk of
2 465 venous thrombosis. A much larger number of affected dogs and a detailed analysis
3
4 466 of the extent to which Cocker spaniels are represented within the referral centre
5
6
7 467 populations would be required in order for a breed predisposition to be confirmed, or
8
9
10 468 to justify a more aggressive anti-thrombotic policy in these dogs. However, by
11
12 469 identifying a possible (albeit unproven) breed disposition, our clinical audit allows
13
14 470 interventionalists to instigate minor modifications now that do not increase operating
15
16
17 471 time or expense, such as taking particular care not to inadvertently compress the
18
19 472 femoral vein in Cocker spaniels and then test the effect of this modification in a
20
21
22 473 future audit.

23
24
25 474 Alternatively, some aspects of procedural protocol that are already in place may
26
27 475 consume more operating time but remain justifiable following audit. For example, we
28
29
30 476 did not identify any haemorrhagic complications from the surgical cut-down
31
32 477 approaches to the femoral artery or jugular vein, or from the use of absorbable
33
34
35 478 sutures for vessel ligation.

36
37
38 479 Despite the prospective nature of the auditing process, medium-term follow-up
39
40 480 proved difficult with nearly half of all dogs lost to follow-up. Although this is not an
41
42
43 481 uncommon feature of clinical trials, adequate numbers of dogs are usually recruited
44
45 482 in trials, based on well-defined endpoints and *a priori* power analysis that take
46
47
48 483 dropout rates into account [22]. Auditing is uncontrolled, and monitors data from all
49
50 484 dogs undergoing a recognised intervention. Where dogs regain full health and return
51
52
53 485 to normal function, many owners may not see the need for cardiac re-assessment
54
55 486 and follow-up. Use of a software system as a standard centre protocol to generate
56
57 487 automated requests to consenting owners for feedback might improve this follow-up
58
59
60 488 process.

489 Despite the limitations to numbers, our audit demonstrates that interventional PDA
490 closure is safe and offers a very good medium-term outcome, especially in dogs that
491 do not have pre-existing CHF or pulmonary arterial hypertension. Sudden death was
492 uncommon, with most medium- and long-term deaths attributable to refractory CHF.
493 Three dogs had unexplained sudden death at two days, five days and three months.
494 There is little information regarding sudden death in the veterinary literature, with
495 most medium and long term deaths attributable to refractory CHF. One case of
496 cardiac arrest is reported immediately postoperatively after ACDO placement [15].
497 Several major complications of transcatheter PDA closure are reported in the human
498 literature [23], which could result in acute deterioration in the short to medium-term.
499 One recent human case report describes a late aortic dissection adjacent to the
500 Amplatz Duct Occluder device [24].

501 An important feature of auditing is that it can also monitor the impact of achieving
502 clinical outputs on the clinicians themselves. This is relevant to health and safety in
503 the workplace but also has ramifications for patient safety too. In our audit, we
504 recorded radiation exposure times. All the centres in this audit use pulsed rather
505 continuous fluoroscopy, which can reduce the total radiography dose by as much as
506 80% [25], especially during prolonged procedures. However, we found that auditing
507 radiation exposure also proved a useful training aid and acted as a reminder of the
508 radiation risk. There was a broad range of exposure times across centres that likely
509 reflected the broad range of complexities encountered and operator experience
510 during interventional PDA closures, and which not only mirrors previously published
511 exposure times for PDA closure in dogs [6] but also those in children [26]. Thus, our
512 audit strongly suggests that there are limitations to fluoroscopic-guidance and
513 supports the use of additional imaging modalities such as TOE, already employed by

514 some of the centres in this audit, to help reduce radiation exposure, particularly in
515 complex cases.

516 Another key difference by performing a clinical audit over publishing a clinical trial or
517 case series, is its continuous process, and evolving nature that allows changes in
518 approach, equipment and experience in single or multiple centres to be compared
519 with baseline levels of performance. If outcomes are favourable, these then
520 establish levels of performance for future comparisons. A good example of this from
521 our audit is the incorporation of the AVP2 device to close PDA in very small dogs
522 that, at other centres, may have instead undergone surgical ligation of their PDA.
523 For new techniques to become established, it is important that they compare
524 favourably with those already in place. Here, we provide success and complication
525 rates that can be compared with published surgical complication rates in similar
526 sizes of dogs [27] and larger dogs undergoing surgical closure by ACDO [15]. In
527 retrospective studies it is possible for there to be under-reporting if some cases get
528 'forgotten' when a procedure is aborted prior to commencement so that the
529 procedure is not recorded in the clinical records; in this clinical audit patient details
530 were entered prior to commencement.

531 We were unable to identify an association between outcome and body weight or age.
532 This is a novel finding and somewhat surprising but nonetheless important because
533 audits are more valuable when they represent the entire patient population, and the
534 bodyweight range in our audit was approximately double that previously published
535 [15]. Prior to audit, the authors considered technical aspects, such as vascular
536 access and device sizing in very small dogs, or anaesthetic risks in very young dogs
537 as factors that contribute to adverse outcomes. Our complication rate was low and
538 this may have limited our ability to detect a difference if one does exist.

539 Nevertheless, it is encouraging that even when performed in very small (under 3 kg)
540 or very young (under four months old) dogs, interventional PDA occlusion does not
541 appear to involve an increased risk of short or medium-term complications. Our
542 finding that one quarter of our patient population was older than two years of age is
543 consistent with a previous report [28]. This should be of significant concern to the
544 veterinary community, since, in general, the characteristic loud, palpable, continuous
545 left heart base murmur along with bounding pulses is present in most cases from a
546 very young age and almost pathognomonic for the condition. This could be
547 addressed through appropriate training at undergraduate and primary care level.
548 Future auditing would determine whether or not remedial efforts had been
549 successful.

550 An important step when performing clinical audit is critical reflection on information
551 gained during analysis, which is part of the re-audit cycle. Following our initial
552 examination of the data, we wanted to look in more detail at specific risk factors that
553 experience or clinical research have found to relate to outcomes in PDA, however,
554 our initial audit design did not allow for this. Following discussion, we have decided
555 to update our audit data collection spreadsheet to include pre-operative “high-risk,
556 low risk” cases, based on pre-defined risk factors such as presence of CHF,
557 pulmonary arterial hypertension or significant arrhythmia necessitating antiarrhythmic
558 therapy. Future audits will allow us to examine these risk factors in more detail and
559 evaluate whether they do indeed influence outcome. The database also need to be
560 modified to identify cases, that were not successful due to complications, which
561 device had been planned and by which route vascular access was attempted. It
562 might also be useful to record the total procedural time.

Conclusions

In conclusion, this clinical audit demonstrated that the process of performing an audit is achievable in veterinary cardiac interventions. The successful discharge outcome rate for interventional PDA closure of 96.9% falls short of the standards set in human medicine (> 99.9%) and thus there is room for improvement. Nevertheless, we were able to establish a benchmark for other centres to consider for their own clinical audit. The numbers in this audit were too small to provide individual audit by centre or by the individual, but in due course these may also become feasible. We encourage all centres performing similar procedures to undertake their own clinical audit, which would help to identify areas for improvement and ensure standards are met in training new colleagues in these procedures. Finally, the implementation of clinical audit could be applied to a wide range of other clinical procedures and should be considered in other aspects of veterinary medicine.

Table 1. Complications encountered and the notes made to explain the nature of the complications. All these 13 dogs were recorded as having both an unsuccessful 'discharge outcome' and a 'complication'. An entry of a – indicates no-recording.

ACDO: Amplatz Canine Duct Occluder, AVP2: Amplatzer Vascular Plug 2, CHF: Congestive heart failure, PDA: Patent ductus arteriosus

Breed	Weight (kgs)	Age (mths)	Total radiation (mGy)	Radiation time (mins)	Intended device	Device Size (mm)	Notes
Chihuahua	3.0	12	12.2	12.1	AVP2	-	Attempt to catheterise the right ventricle was made but progressive bradycardia and hypotension. Procedure aborted.
Chihuahua	3.3	36	-	7.50	ACDO	4	Dissection of the ductal-pulmonary arterial wall during catheterisation, dog died shortly afterwards
Cocker Spaniel	5.5	2.2	-	-	ACDO	-	Duct was disproportionately large requiring a 6 F delivery sheath, artery tore during attempts to insert sheath; dog was closed surgically.

Cocker Spaniel	6.1	3	22.8	5.2	ACDO	8	Lameness of right hind limb post interventional closure. Received physiotherapy.
Cocker Spaniel	10.3	16	24.6	6	ACDO	8	Lameness of right hind limb post interventional closure, possible thromboembolism.
Cocker Spaniel	12.8	3	9.4	3	ACDO	7	Lameness of right hind limb post interventional closure.
Crossbreed	3.2	9	75.5	23	ACDO	5	Duct was short, in unusual position and angle, ACDO dislodged 30 minutes later. PDA reversal occurred 1 week later
Crossbreed	17.0	156	23.7	4.3	ACDO	12	ACDO embolised in recovery; dog was already in CHF requiring medications
Dobermann Pinscher	29.2	8	89.2	14.4	ACDO	-	Dislodgement of device due to unusual shape of PDA, had surgical ligation
German Shepherd Dog	15.6	7	15.6	5.4	ACDO	10	Developed device infection four weeks post-op

Irish Setter	5.6	31	37.0	3.4	ACDO	12	Bradycardia post release (24 beats per minute). Died three days later.
Pomeranian	2.4	9	26.7	19.5	ACDO, then AVP2	-	Attempts to catheterise the femoral artery failed (for an intended ACDO placement), the procedure was switched to a jugular approach for an intended AVP2 placement, but during right ventricular catheterisation a progressive bradycardia and hypotension developed and the procedure was aborted.
Welsh Corgi	3.9	3	8.3	-	ACDO	9	Intraabdominal haemorrhage due to distal aorta perforation, dog lived and duct was occluded

Table 2. Patient description as well as device and type of complications in the 12 dogs recorded as not have a good 'medium term outcome'.

ACDO: Amplatz canine duct occluder, AVP2, Amplatzer vascular plug 2, CHF: Congestive heart failure, CKCS: Cavalier King Charles Spaniel, GSD: German shepherd, PAH: Pulmonary Arterial Hypertension

Breed	Weight (kgs)	Age (mths)	ACDO (mm)	AVP2 (mm)	Comments
Border Collie	16.4	10	14		Sudden death three months post-procedure
Chihuahua	5.1	2	5		Severe PAH, appeared to be improved with sildenafil prior to intervention, producing a continuous but low flow left-to-right flow of 2.4 m/s. However remained in right CHF afterwards
CKCS	7.5	32	5		Marked cardiomegaly with CHF continued to require CHF medications
Cockerpoo	6.6	3	5		Continuing CHF and impaired systolic dysfunction, requiring medications
Cross breed	8.6	29	10		Had PAH prior to surgery, reduced with sildenafil producing a continuous but low flow left-to-right flow of 2.1 m/s, and then closed. Continued with right sided CHF requiring medications
Cross Breed	11.2	24	12		Continuing CHF with cardiomegaly & ventricular arrhythmias, requiring medications
Cross Breed	3.5	3		10	CHF and Mitral Dysplasia, remained on pimobendan

GSD	32.6	72	10		Mild cardiomegaly and continued on pimobendan
Labrador	7.0	8	10		Continued in CHF despite closure and requiring medications
Spanish Waterdog	4.5	2	6		Left ventricle remained dilated with poor systolic function and remained on pimobendan
Standard Poodle	8.4	4	10		CHF and cardiomegaly remained on medications
Siberian husky	20.0	5	14		Sudden death five days post-procedure

Journal of Veterinary Cardiology

The following information is required for submission:

Author contribution

The ICMJE recommends that authorship be based on the following 4 criteria:

1. Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work; AND
2. Drafting the work or revising it critically for important intellectual content; AND
3. Final approval of the version to be published; AND
4. Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Please specify the contribution of **each author** to the paper, e.g. study concept or design, data collection, data analysis or interpretation, writing the paper, others, who have contributed in other ways, should be listed as contributors.

Mike Martin – all aspects from study design to writing

Brigite Pedro – study design, data collection, critical revision & writing, final approval

Dave Dickson – study design, data collection, critical revision & writing, final approval

Joao Neves – data collection, critical revision & writing, final approval

Jo Harris – data collection, critical revision & writing, final approval

Yolanda Martinez Pereira – data collection, critical revision & writing, final approval

Maria Ines Oliveira – data collection, critical revision & writing, final approval

Jakob L Willesen – data collection, critical revision & writing, final approval

Liva Vatne – data collection, critical revision & writing, final approval

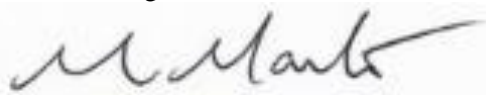

Geoff Culshaw – data collection, critical revision & writing, final approval

Chris Linney – study design, data collection, critical revision & writing, final approval

As **Corresponding Author** I hereby confirm that all listed authors in the submission meet these Criteria.

Corresponding author:... Mike Martin
