1 **Abstract**

2 The role of carbonic anhydrase XII (CAXII) in the chemoresistance of glioblastoma is  
3 unexplored.

4 We found CAXII and P-glycoprotein co-expressed in neurospheres derived from 3/3 patients  
5 with different genetic backgrounds and low response to temozolomide (time to recurrence: 6-  
6 9 months). CAXII was necessary for the P-glycoprotein efflux of temozolomide and second-  
7 line chemotherapeutic drugs, determining chemoresistance in neurospheres.

8 Psammaplin C, a potent inhibitor of CAXII, re-sensitized primary neurospheres to  
9 temozolomide by reducing temozolomide efflux via P-glycoprotein. This effect was  
10 independent of other known temozolomide resistance factors present in the patients. The  
11 overall survival in orthotopic patient-derived xenografts of temozolomide-resistant  
12 neurospheres, co-dosed with Psammaplin C and temozolomide, was significantly increased  
13 over temozolomide-treated ( $p < 0.05$ ) and untreated animals ( $p < 0.02$ ), without detectable signs  
14 of systemic toxicity.

15 We propose that a CAXII inhibitor in combination with temozolomide may provide a new  
16 and effective approach to reverse chemoresistance in glioblastoma stem cells. This novel  
17 mechanism of action, via the interaction of CAXII and Pgp, ultimately blocks the efflux  
18 function of Pgp to improve glioblastoma patient outcomes.

19

## 1 **Introduction**

2 Glioblastoma (GB) is the most common and lethal adult primary brain tumor. The standard-  
3 of-care treatment comprises surgery, followed by radiotherapy and chemotherapy, then  
4 maintenance chemotherapy. Chemotherapy is based on the drug temozolomide (TMZ). With  
5 treatment, the increase in median survival rate for all patients is two months, while the  
6 median overall survival is 12-15 months (1). In the subset of GB patients with the  $O^6$ -  
7 methylguanine-DNA methyltransferase (MGMT) promoter methylated, the two year survival  
8 is higher at approximately 40% (1).

9 GB stem cells (SC), a subpopulation of GB that govern tumor initiation and recurrence, are  
10 particularly difficult to eradicate with chemotherapy (2). One cause is an elevated expression  
11 of P-glycoprotein (Pgp), an efflux pump that recognizes a broad spectrum of  
12 chemotherapeutics as substrates, including TMZ (3,4). The co-administration of a Pgp  
13 inhibitor with chemotherapy has met with limited success however, owing to serious side  
14 effects and toxicity (5). The identification of an alternative and safer mechanism to counter  
15 Pgp-mediated drug resistance in GB SC is of high unmet need.

16 Tumor acidosis is a hallmark of cancer (6). Membrane-bound carbonic anhydrases IX and/or  
17 XII (CA, EC 4.2.1.1) maintain the intracellular/extracellular pH for efficient Pgp activity (7),  
18 and optimal tumor growth, invasion and metastasis (6).

19 CAIX and CAXII specific inhibitors are increasingly being investigated as potential  
20 antitumor agents (8). Inhibitors of CAXII indirectly reduce Pgp activity and re-sensitize solid  
21 tumors to Pgp substrates with a magnitude similar to tariquidar, a validated Pgp inhibitor (9).  
22 CAXII and Pgp mRNA were detectable in GB patient (Tissue Cancer Genome Atlas,  
23 <https://cancergenome.nih.gov>), but CAXII ([http://www.proteinatlas.org/ENSG00000074410-](http://www.proteinatlas.org/ENSG00000074410-CA12/pathology)  
24 [CA12/pathology](http://www.proteinatlas.org/ENSG00000085563-CA12/pathology)) and Pgp ([http://www.proteinatlas.org/ENSG00000085563-](http://www.proteinatlas.org/ENSG00000085563-CA12/pathology)

1 [ABCB1/pathology](#)) proteins were poorly detectable by immunohistochemistry. This trend led  
2 us to hypothesize that CAXII and Pgp may be co-expressed in specific GB niches, e.g. SC-  
3 enriched niches, with CAXII maintaining optimum pH for Pgp activity.  
4 CAXII is overexpressed in aggressive GB (10) and is a negative prognostic factor in  
5 infiltrating astrocytoma (11). CAXII is also highly expressed in 3D-culture of GB cells  
6 (neurospheres, NS) (12), a mimic of cancer-derived GB SC. The therapeutic implications  
7 surrounding CAXII have been poorly investigated in GB or GB SC. Here, we demonstrate  
8 that CAXII mediates resistance to TMZ in GB SC in a Pgp-dependent manner. We show that  
9 the combination of a CAXII inhibitor and TMZ substantially improve TMZ efficacy against  
10 GB SC in GB NS-patient-derived xenografts (GB-NS-PDX), and that this effect is  
11 independent of known factors of TMZ-resistance.

## 12 **Methods**

13 **Reagents and plasticware.** Plasticware for cell cultures was obtained from Falcon (Becton  
14 Dickinson, Franklin Lakes, NJ). Electrophoresis reagents were obtained from Bio-Rad  
15 Laboratories (Hercules, CA). The protein content of cell lysates was assessed using a BCA  
16 kit from Sigma Chemicals Co. (St. Louis, MO). Unless specified otherwise, all reagents were  
17 purchased from Sigma Chemicals Co.

18 **Compounds synthesis and CAXII inhibition.** Compounds were synthesized as in  
19 Supplementary Information (**Scheme 1**). CAXII activity was measured as detailed previously  
20 (13).

21 **Cells.** Primary human GB cells (CV17, 010627, No3) were obtained from surgical samples  
22 from Neurosurgical Units, Universities of Torino and Novara after written informed consent,  
23 and were used within passage 5. The samples were designated as patient#1, patient#2 and  
24 patient #3. Researchers performing the experiments were unaware of the genetic background  
25 or clinical outcome of the patients. The study was performed in accordance with the

1 Declaration of Helsinki and was approved by the Bio-Ethical Committee of University of  
2 Torino (#ORTO11WNST).The histological diagnosis of GB was performed according to  
3 WHO guidelines. *MGMT* methylation was detected by methylation-specific polymerase chain  
4 reaction and capillary electrophoresis (14). *EGFR* amplification, *IDH1/2* and *TP53*  
5 mutations, 1p/19q co-deletion were examined as described in (15). Cells were cultured as  
6 differentiated/adherent cells (AC) or NS as previously described (16), with minor  
7 modifications (17). For AC, DMEM supplemented with 1% v/v penicillin-streptomycin, 10%  
8 v/v fetal bovine serum (FBS; Lonza, Basel, Switzerland) was used. For NS, DMEM-F12  
9 medium was supplemented with 1 M HEPES, 0.3 mg/ml glucose, 75 µg/ml NaHCO<sub>3</sub>, 2  
10 mg/ml heparin, 2 mg/ml bovine serum albumin, 2 mM progesterone, 20 ng/ml EGF, 10 ng/ml  
11 b-FGF. AC were obtained from dissociated NS cells, centrifuged at 1,200 × g for 5 min and  
12 seeded in AC medium. *In vitro* clonogenicity and self-renewal, and *in vivo* tumorigenicity  
13 were reported in (3). Cell phenotypic characterization is detailed in the Supplementary  
14 Materials. *Mycoplasma spp* contamination was assessed by PCR every 3 weeks;  
15 contaminated cells were discharged.

16 **Immunoblotting.** 20 µg protein extracts from whole cell lysate were subjected to SDS-  
17 PAGE and probed with the following antibodies: anti-CAXII (goat, #ab219641; Abcam,  
18 Cambridge, UK), anti-CAIX (rabbit, # ab15086; Abcam), anti-Pgp (mouse, clone C219;  
19 Millipore, Billerica, MA), anti-caspase 3 (mouse, clone C33, GeneTex, Hsinhu City,  
20 Taiwan). Plasma membrane-associated proteins were evaluated in biotinylation assays (7).  
21 Anti-β-tubulin (rabbit, # ab6046; Abcam) and anti-pancadherin (mouse, clone CH-19; Santa  
22 Cruz Biotechnology Inc., Santa Cruz, CA) antibody were used to confirm equal protein  
23 loading in whole cell and plasma-membrane associated extracts. In co-immunoprecipitation  
24 experiments, 100 µg of plasma membrane-associated proteins were immunoprecipitated with

1 anti-CAXII and anti-CAIX antibodies, using PureProteome protein A and protein G Magnetic  
2 Beads (Millipore).

3 **Flow cytometry.** Five $\times 10^5$  cells were re-suspended in culture medium containing 5% v/v  
4 FBS, incubated with anti-CAXII (Abcam) or anti-Pgp (mouse, clone MRK16; Kamiya,  
5 Seattle, WA) antibody, followed by the secondary Alexa488-conjugated antibody, fixed with  
6 4% v/v paraformaldehyde and analyzed by the Guava® easyCyte flow cytometer, (InCyte  
7 software, Millipore). Control experiments included incubation of cells with non-immune  
8 isotypic antibody, followed by secondary antibody.

9 **Proximity ligation assay (PLA).** The CAXII-Pgp interaction was measured with the  
10 DuoLink In Situ kit (Sigma Chemicals Co), as per the manufacturer's instructions. The  
11 method employs mouse anti-human Pgp (mouse, clone UIC-2, Millipore) or rabbit anti-  
12 human CAXII (#102344; NovoPro, Shanghai, China) antibodies. Cell nuclei were  
13 counterstained with 4',6-diamidino-2-phenylindole (DAPI). Cells were examined using a  
14 Leica DC100 fluorescence microscope (Leica Microsystem, Wetzlar, Germany). A minimum  
15 of five fields were examined for each experimental condition.

16 **Confocal microscope analysis.**  $1 \times 10^4$  NS cells were seeded onto glass coverslips and  
17 collected by cyto-spinning. Cells were fixed using 4% paraformaldehyde for 15 minutes,  
18 washed with PBS and incubated for 1 h at room temperature with an anti-human CAXII  
19 (NovoPRO) or an anti-Pgp (Millipore) antibody. Samples were washed 5 $\times$  with PBS and  
20 incubated for 1 h with tetramethylrhodamine isothiocyanate (TRITC)- or fluorescein  
21 isothiocyanate (FITC)-conjugated secondary antibodies (Sigma Chemicals Co.), respectively,  
22 then washed with PBS 4 $\times$  and deionized water 1 $\times$ . Cells were examined using a Leica TCS  
23 SP2 AOP confocal laser-scanning microscope. The number of yellow pixels, indicative of a  
24 Pgp-CAXII interaction, was calculated using the JACoP plug-in of the ImageJ software

1 (<https://imagej.nih.gov/ij>) and expressed as a percentage of the total green pixels  
2 (corresponding to Pgp) measured over a total of five fields per experiment.

3 **Pgp ATPase activity.** The assay was performed on Pgp-enriched membrane vesicles as  
4 detailed in (18). The rate of ATP hydrolysis, an index of Pgp catalytic cycle and a necessary  
5 step for substrate efflux, was measured. Results were expressed as nmol hydrolyzed  
6 phosphate (Pi)/min/mg proteins.

7 **Doxorubicin and temozolomide accumulation.** Doxorubicin content was measured  
8 fluorimetrically (7). The results were expressed as nmol doxorubicin/mg cell proteins. TMZ  
9 content was measured by liquid scintillation counting in cells incubated with 10  $\mu\text{M}$  [ $^3\text{H}$ ]-  
10 temozolomide (0.7  $\mu\text{Ci/ml}$ ; Moravek Biochemical Inc., Brea, CA) for 24 h. The results were  
11 expressed as nmol [ $^3\text{H}$ ]-temozolomide/mg cell proteins.

12 **LDH release.** The extracellular release of LDH, considered an index of cell damage, was  
13 measured as detailed previously (3). The extracellular LDH activity was calculated as a  
14 percentage of the total LDH activity in the dish.

15 **Cell viability.** Cell viability was evaluated using an ATPLite kit (PerkinElmer, Waltham,  
16 MA). The results were expressed as percentage of viable cells in each experimental condition  
17 versus untreated cells (considered 100% viable). To calculate the combination index (CI), NS  
18 were incubated with TMZ and compound **1**, alone and then in combination, over the range of  
19 concentrations  $10^{-10}$ -  $10^{-3}$  M. CI values were calculated using CalcuSyn software  
20 ([www.biosoft.com/w/calculusyn.htm](http://www.biosoft.com/w/calculusyn.htm)).

21 **Generation of Pgp- and CAXII-knocked out (KO) clones.** Five $\times 10^5$  cells were transduced  
22 with 1  $\mu\text{g}$  CRISPR pCas vectors (Origene, Rockville, MD) targeting *ABCB1/Pgp* or *CAXII*  
23 respectively, or with 1  $\mu\text{g}$  non-targeting vector (Origene), following the manufacturer's  
24 instructions. Stable KO cells were selected from medium containing 1  $\mu\text{g/ml}$  puromycin for 4  
25 weeks.

1 ***In Vitro* Plasma Stability.** Compound **1** was spiked into mouse plasma (Animal Resource  
2 Centre, Perth, Australia) to a concentration of 1000 ng/ml (DMSO/acetonitrile concentrations  
3 0.2/0.4% v/v) at 37 °C for 4 h. At various time points, plasma samples were snap-frozen and  
4 analyzed by LC-MS (Micromass Xevo triple quadrupole mass spectrometer, Waters Co.,  
5 Milford, MA) relative to calibration standards (**1** and diazepam as internal standard). The  
6 average concentration of test compound was expressed as a percentage of compound  
7 remaining relative to the sample quenched at 5 min.

8 ***In Vitro* Metabolic Stability.** Metabolic stability was performed by incubating 1 µM  
9 compound **1** with 0.4 mg/ml mouse liver microsomes (Xenotech, Tokyo, Japan) at 37 °C,  
10 adding a NADPH-regenerating system, and subsequently quenching with acetonitrile  
11 (containing diazepam as internal standard) at 2, 30 and 60 min. A species scaling factor was  
12 used to convert the *in vitro* clearance ( $CL_{int}$ ) to an *in vivo*  $CL_{int}$  (19). Hepatic blood clearance  
13 and hepatic extraction ratio ( $E_H$ ) were calculated as described (20).  $E_H$  was used to classify  
14 compounds as low (< 0.3), intermediate (0.3–0.7), high (0.7–0.95) or very high (>0.95)  
15 extraction compounds.

16 ***In Vitro* Cytochrome P450 (CYP) Stability.** Compound **1** (0.25 to 20 µM) was incubated  
17 with CYP substrate in human liver microsomes (batch #1410230; XenoTech LLC., Lenexa,  
18 KS, USA) at 37 °C. The total organic solvent concentration was 0.47% v/v. The reactions  
19 were initiated by adding a NADPH-regenerating system and quenched with ice cold  
20 acetonitrile containing analytical internal standard (0.15 µg/mL diazepam). Metabolite  
21 concentrations were determined by UPLC-MS (Waters/Micromass Xevo TQD triple-  
22 quadrupole) relative to calibration standards prepared in quenched microsomal matrix. The  
23 inhibitory effect of compound **1** was assessed based on the reduction in the formation of the  
24 specific CYP-mediated metabolite relative to a control for maximal CYP enzyme activity.

1 ***In vivo* tumor growth.** In dose-dependent experimental sets  $1 \times 10^6$  AC or NS cells, mixed  
2 with 100  $\mu$ l Matrigel, were injected subcutaneously in female BALB/c *nu/nu* mice (weight:  
3  $19.6 \text{ g} \pm 2.4$ ; Charles River Laboratories Italia, Calco). Animals were housed (5 per cage)  
4 under 12 h light/dark cycles in a barrier facility on HEPA-filtered racks and were fed with an  
5 autoclaved diet. Tumor dimensions were measured daily with calipers and growth calculated  
6 using the equation  $(L \times W^2)/2$ , where L = tumor length, W = tumor width. When the tumor  
7 reached a volume of  $50 \text{ mm}^3$ , animals were randomized (10 animals/group) and treated over  
8 2 cycles of 5 consecutive days (days: 1-5; 11-15 after randomization) as detailed in  
9 **Supplementary Figure S6.** Animals were euthanized by injecting zolazepam (0.2 ml/kg) and  
10 xylazine (16 mg/kg) i.m. at day 30. Hemocromocytometric analyses were performed with a  
11 UniCel DxH 800 Coulter Cellular Analysis System (Beckman Coulter, Miami, FL) on 0.5 ml  
12 of blood collected immediately after euthanizing, using commercial kits from Beckman  
13 Coulter Inc.

14 In a second experimental set,  $1 \times 10^6$  NS cells, stably transfected with the  
15 pGL4.51[luc2/CMV/Neo] vector encoding for luciferase (Promega Corporation), mixed with  
16 150  $\mu$ l sterile physiological solution, were stereotactically injected into the right caudatus  
17 nucleus into 6-8 week olds female BALB/c *nu/nu* mice (weight:  $20.3 \text{ g} \pm 2.4$ ), anesthetized  
18 with sodium phenobarbital (60 mg/kg) i.p. Tumor growth was monitored by *in vivo*  
19 bioluminescence (Xenogen IVIS Spectrum, PerkinElmer, Waltham, MA) at day 6, 14 and 24  
20 post-implantation. At day 7, animals were randomized (6 animals/group) and treated with 2  
21 cycles of 5 consecutive days (days: 7-11; 17-21 after randomization) as indicated in **Figure 5.**  
22 Animals were euthanized at day 30. Brains were fixed in 40  $\mu$ g/ml paraformaldehyde at 4  $^{\circ}$ C  
23 overnight. Tumors were excised and the volume determined using calipers. Tumor sections  
24 were fixed overnight in 4% paraformaldehyde and stained with hematoxylin and eosin or  
25 immunostained for CAXII (Abcam), anti-Pgp (Millipore), Ki67 (mouse, clone KiS5;

1 Millipore), cleaved (Asp175)caspase 3 (rabbit, #9661; Cell Signaling Technology Inc.,  
2 Danvers, MA), followed by a peroxidase-conjugated secondary antibody (Dako, Glostrup,  
3 Denmark). Stained sections were examined with a Leica DC100 microscope. In parallel,  
4 tumor tissue was homogenized for 30 s at 15 Hz, using a TissueLyser II device (Qiagen,  
5 Hilden, Germany) and clarified at 12000×g for 5 minutes. Protein (10 µg) from tumor lysates  
6 were used for the immunoblot analysis of Pgp, as reported above. In a third experimental set,  
7 animals with orthotopic tumors were monitored after the treatment detailed in **Figure 5**.  
8 Animals were euthanized when they showed signs of significantly compromised neurological  
9 function or loss of body weight >20%. Overall survival was defined as the time interval  
10 between tumor implant and euthanasia.

11 Animal care and experimental procedures were approved by the Bio-Ethical Committee of  
12 the Italian Ministry of Health (#122/2015-PR).

13 **Statistical analysis.** All data in the text and figures are provided as means  $\pm$ SD. The results  
14 were analysed by a Student's t-test, using Statistical Package for Social Science (SPSS)  
15 software (IBM SPSS Statistics v.19). The Kaplan-Meier method was used to calculate overall  
16 survival of mice. Log rank test was used to compare the outcome of the treatment groups,  
17 using MedCalc® software (v.17.4).  $p < 0.05$  was considered significant. Data analysis was  
18 performed blinded.

## 19 **Results**

### 20 **Glioblastoma-derived neurospheres co-express CAXII and Pgp**

21 The clinical, genomic and phenotypic data for the three GB patients of this study are provided  
22 in **Table 1** and **Supplementary Table S1**. The *MGMT* promoter status is partially methylated  
23 in patient #1, unmethylated in patient #2 and fully methylated in patient #3 (**Table 1**). We  
24 generated primary cultures from patients #1-#3 and grew them as AC or NS.

1 NS had comparable levels of CAIX and CAXII protein, while only CAIX was detected in AC  
2 (**Figure 1a**). NS had higher levels of CAXII and Pgp on the cell surface than AC (**Figure**  
3 **1b**). CAXII co-immunoprecipitated with Pgp (**Figure 1c**). The results of the PLA  
4 demonstrate that CAXII and Pgp are physically associated in the NS plasma-membrane  
5 (**Figure 1d**). Quantification of CAXII:Pgp co-localization, based on confocal laser-scanning  
6 microscopy, indicated that  $58.67 \pm 1.1$  % of NS Pgp interacted with CAXII in the plasma-  
7 membrane of NS (**Figure 1e**).

8 The expression of Pgp and CAXII was independent of the different culture conditions  
9 between AC and NS (**Supplementary Figure S1**).

#### 10 **The addition of CAXII inhibitors to neurospheres reduces Pgp activity and increases** 11 **retention and cytotoxicity of chemotherapeutic drugs**

12 A compound panel comprising Psammaplin C (**1**), its derivatives (**2-4**) and the non-CAXII  
13 inhibitor control compound (**5**) (**Figure 2a**) was tested for the ability to indirectly reduce Pgp  
14 activity in NS. The more potent the CAXII inhibitor (lower  $K_i$ ; **Supplementary Table S2**),  
15 the higher the reduction of Pgp activity (**Figure 2b**). The Pgp substrate doxorubicin  
16 accumulated to a greater extent (**Figure 2c**) and exhibited greater toxicity (**Figure 2d-e**) in  
17 AC than in NS. NS were refractory to doxorubicin. These characteristics were unchanged by  
18 compounds **1-5** in AC. In NS compounds **1** or **3**, the two most potent CAXII inhibitors,  
19 restored the intracellular doxorubicin concentration to a level comparable to AC (**Figure 2c**),  
20 partially restored the release of LDH induced by doxorubicin (**Figure 2d**) and reduced cell  
21 viability (**Figure 2e**).

22 Comparable effects were observed with the chemotherapeutic drugs etoposide, topotecan and  
23 irinotecan. These drugs are known substrates of Pgp (21) (**Supplementary Figure S2a-f**). As  
24 compound **1** was the most effective in restoring the effects of Pgp substrates in GB NS, it was  
25 selected for further characterization.

1 **CAXII inhibition enhances temozolomide cytotoxicity in neurospheres by reducing Pgp**  
2 **activity**

3 TMZ, a substrate and down-regulator of Pgp (4, 22), decreased Pgp expression in NS (**Figure**  
4 **3a; Supplementary Figure S3a**). TMZ consistently reduced the amount of Pgp that co-  
5 immunoprecipitated with CAXII (**Figure 3b; Supplementary Figure S3b**) and the activity  
6 of Pgp (**Figure 3c**). Pgp expression (**Figure 3a; Supplementary Figure S3a**) and the  
7 interaction of Pgp and CAXII (**Figure 3b; Supplementary Figure S3b**) was unchanged by  
8 compound **1**, however Pgp-ATPase activity was reduced, even more so when in combination  
9 with TMZ (**Figure 3c**). Consequently, in NS compound **1** increased TMZ accumulation  
10 (**Figure 3d**), cell necrosis (**Figure 3e**), apoptosis (**Figure 3f**) and reduced viability in the  
11 presence of TMZ (**Figure 3g**), to the extent observed in *Pgp*-KO NS clones (wherein the  
12 levels of CAXII were unaltered) or in AC (**Figure 3d-g; Supplementary Figure S3c-d**). In  
13 *Pgp*-KO NS clones compound **1** did not enhance the effect of TMZ on reduced cell viability  
14 (**Figure 3g**), suggesting that Pgp is the ultimate – although indirect – target of compound **1**.  
15 The isobologram analysis in NS (**Supplementary Figure S4a-c**) indicated a CI of TMZ and  
16 compound **1** equal to 0.08838 for patient #1, 0.07017 for patient #2 and 0.1775 for patient #3.  
17 *CAXII*-KO NS clones had the same levels of Pgp in whole cell (**Figure 4a; Supplementary**  
18 **Figure S5a**) and plasma-membrane extracts (**Figure 4b; Supplementary Figure S5b**) than  
19 in NS or NS treated with a non-targeting vector. Similarly, the amount of plasma-membrane-  
20 associated Pgp in NS did not change when NS were treated with 10 nM of compound **1**  
21 (**Figure 4b; Supplementary Figure S5b**). However, when plasma-membrane extracts of  
22 *CAXII*-KO NS clones were immuno-precipitated with an anti-CAXII antibody, Pgp was  
23 undetectable in the immunoprecipitated extracts (**Figure 4c; Supplementary Figure S5c**),  
24 confirming a strong and specific interaction between the two proteins. *CAXII*-KO NS clones  
25 had lower Pgp-ATPase activity than wild-type NS (**Figure 4d**) even when the levels of Pgp

1 were the same. TMZ further reduced Pgp-ATPase activity in *CAXII*-KO NS clones (**Figure**  
2 **4d**) and produced the same phenotypic response as in AC, namely TMZ accumulation  
3 (**Figure 4e**) and cytotoxicity (**Figures 4f-h; Supplementary Figure S5d**).

4 **CAXII inhibition restores the efficacy of temozolomide in tumors derived from resistant**  
5 **glioblastoma neurospheres *in vivo***

6 Compound **1** was stable in Balb/c mice plasma (half-life >240 min) (**Supplementary Table**  
7 **S3**) and showed low potential to inhibit major drug metabolizing CYP P450 enzymes  
8 (**Supplementary Table S4**).

9 Following identification of the dosing schedule that maximally reduced the tumor growth of  
10 AC *in vivo* (**Supplementary Figure S6a**) with significantly less effect against NS  
11 (**Supplementary Figure S6b-c**), we co-administered compound **1** in mice bearing patient #2-  
12 derived NS at two dosages, 38 ng/kg and 3800 ng/kg, the former according to the *CAXII*  $K_i$ ;  
13 the latter to limit hematic/lymphatic clearance. Compound **1** did not reduce AC- or NS-  
14 derived tumor growth. When compound **1** was combined with TMZ, TMZ efficacy in AC-  
15 derived tumors was unchanged; however in NS-derived tumors TMZ efficacy was enhanced  
16 in a dose-dependent manner (**Supplementary Figure S6b-c**). Moreover, the combined  
17 treatment did not elevate hematopoiesis, liver, kidney or muscle toxicity compared to TMZ-  
18 only treatment (**Supplementary Table S5**). Consistent with the *in vitro* setting (**Figure 3f**),  
19 the growth of *Pgp*-KO NS-derived tumors was reduced by TMZ, while the growth of  
20 scrambled-transduced tumors was not (**Supplementary Figure S6d**). Compound **1**, at the  
21 dosage of 3800 ng/kg, enhanced the anti-tumor effect of TMZ in animals bearing scrambled-  
22 NS but not in animals bearing *Pgp*-KO NS (**Supplementary Figure S6d**) that lack this  
23 indirect target of compound **1**.

24 In orthotopic GB-NS-PDX neither compound **1** nor TMZ alone reduced tumor growth, with  
25 the exception of tumors derived from patient #3, wherein the genetic profile and clinical

1 history were suggestive of a more favorable response to TMZ (**Table 1**). The combination of  
2 compound **1** and TMZ significantly decreased tumor growth in all three GB-NS-PDX  
3 (**Figure 5a-b**) and increased overall survival (**Figure 5c**). Although TMZ reduced the  
4 expression of Pgp in CAXII-positive tumors (**Figure 5d-f**), it did not reduce intratumor  
5 proliferation or increase apoptosis (**Figure 5d-e**). Compound **1** did not change these  
6 parameters. The combined use of compound **1** and TMZ reduced Pgp expression in tumors  
7 (**Figure 5d-f**) as it did in NS cultured *in vitro* (**Figure 3a**). The combination also rescued the  
8 anti-proliferative and pro-apoptotic effects of TMZ, as demonstrated by the reduced  
9 intratumor positive staining for Ki67 and by the increased activation of caspase 3 (**Figure 5d-**  
10 **e**).

## 11 **Discussion**

12 We analyzed samples from three GB patients that experienced a variable but poor clinical  
13 response to TMZ. The patients had different genetic backgrounds however the NS-derived  
14 from all patients co-expressed CAXII and Pgp, suggesting a relationship that may represent  
15 an ancestral feature of GB SC, independent of genetic alterations or environmental conditions  
16 (such as different culture conditions). Notably, up to 60% of the Pgp in the plasma-membrane  
17 of NS was found to interact with CAXII. This indicates that the enzymatic activity of CAXII  
18 may act to influence the microenvironment pH for the co-localized Pgp. We are currently  
19 investigating the mechanisms of up-regulation of Pgp and CAXII expression in NS and the  
20 nature of interaction between these two proteins. To the best of our knowledge, ours is the  
21 first work showing an increased CAXII expression in GB NS derived from primary tumors.  
22 Until now, there have been no reports on the role of CAXII in the response to chemotherapy  
23 in NS. Based on our previous observations in Pgp-expressing solid cancer cell lines (7,9), we  
24 hypothesized that CAXII inhibitors may reverse the Pgp-mediated drug-resistance in GB NS,  
25 wherein Pgp activity is enhanced by CAXII activity. Even though CAIX is expressed in NS

1 and is important in GB pathogenesis (23), our data indicate no significant role for CAIX in  
2 the chemoresistance of NS.

3 We recently synthesized Psammaplin C (compound **1** in this manuscript), one of the most  
4 potent CAXII inhibitors ever reported (24). We synthesized a panel of related sulfonamides  
5 (**2-4**) and the control compound **5**, which is identical to **1** but lacks the sulfonamide moiety.  
6 This panel enabled the structure-activity relationships (SAR) between CAXII inhibition and  
7 indirect Pgp inhibition to be established. The strongest inhibitor of CAXII, compound **1**, was  
8 the most effective in rescuing the cytotoxicity of all tested Pgp substrates: topoisomerase I/II  
9 inhibitors topotecan, irinotecan, etoposide and doxorubicin. These drugs are under evaluation  
10 in clinical trials as second-line treatments for GB and in GB patients that are refractory to  
11 TMZ (25). Our findings suggest CAXII inhibitors may substantially enhance the efficacy of  
12 these agents, being particularly effective against GB NS, where improvement of current  
13 therapy is desperately sought.

14 Most importantly, compound **1** rescued the efficacy of TMZ, the first-line drug in GB  
15 treatment. TMZ fails to eradicate GB SC, owing to a combination of *MGMT* status, cell  
16 survival/anti-apoptotic pathways driven by *EGFR* amplification, mutations in *IDH1/2* and  
17 *TP53*, hypoxia, niches rich of growth factors (2). The three patient-derived NS analyzed in  
18 this work had slight variation in their *in vitro* and *in vivo* sensitivity and clinical response to  
19 TMZ, likely as a consequence of their different genetic background. In general, however, NS  
20 from all patient samples were more resistant to TMZ than corresponding AC. The co-  
21 administration of compound **1** rescued sensitivity to TMZ, independent of *MGMT* status or  
22 other genetic alterations, suggesting that inhibition of CAXII may overcome Pgp-mediated  
23 resistance to TMZ.

24 Our findings in *Pgp*-KO and *CAXII*-KO NS support the hypotheses that i) in addition to the  
25 *MGMT* methylation status and other known genetic alterations determining resistance to

1 TMZ, the presence of Pgp plays a pivotal role in NS resistance to chemotherapy; ii) CAXII  
2 inhibition overcomes this resistance by reducing Pgp activity. It is probable that the  
3 interaction of CAXII with Pgp sustains the activity of Pgp, and that interfering with CAXII  
4 by treatment with either compound **1** or genetic knockout significantly reduces ATPase  
5 activity. Notably, this genetic or pharmacological inhibition did not alter the amount of  
6 surface Pgp. As Pgp mediates TMZ efflux (4), targeting CAXII increases the intracellular  
7 retention of TMZ to restore its cytotoxic effects.

8 The strong synergism observed with TMZ and compound **1** further enforces the hypothesis  
9 that they are involved in the same pathway leading to inhibition of Pgp efflux activity. The  
10 ability of compound **1** to reduce Pgp activity together with its potency and selectivity for  
11 CAXII over other CAs, contribute to making compound **1** highly effective against GB NS.  
12 Furthermore, CAXII has minimal expression in healthy cells  
13 (<https://www.proteinatlas.org/ENSG00000074410-CA12/tissue>). This is a major advantage  
14 as targeting CAXII to indirectly reduce Pgp activity provides a selective GB SC-targeting  
15 tool and avoids the *in vivo* toxicity associated with using direct Pgp inhibitors (5).  
16 Furthermore, the *in vitro* results obtained from treatment of GB-SC with a combination of  
17 compound **1** and second-line chemotherapeutic drugs (all substrates of Pgp) may open the  
18 way for new combination therapies with the potential to lower the chemotherapy dose  
19 required to achieve significant GB reduction.

20 In line with the TMZ resistance observed in NS cultures and the clinical response of the  
21 corresponding patient to TMZ, two of the three GB-NS-PDX were refractory to TMZ. The  
22 third xenograft - generated from the patient with the most favorable genetic profile toward  
23 TMZ sensitivity, longest time to recurrence after TMZ treatment and longest overall survival  
24 - was partially sensitive to TMZ. In accordance with the *in vitro* findings tumor growth in  
25 compound **1** only treated GB-NS-PDX was not reduced, however compound **1** in

1 combination with TMZ significantly improved the anti-tumor activity over the TMZ-only  
2 cohort and increased the overall survival, likely as a consequence of the co-expression of  
3 CAXII and Pgp in these NS-derived tumors. Furthermore, the combination of TMZ and  
4 compound **1** reduced the intratumor level of Pgp, and recapitulated the same cytotoxic events  
5 observed in NS cultures.

6 Recently the combination of the CAIX/CAXII inhibitor SLC-0111 (100 mg/kg, daily over 14  
7 days) with TMZ (100 mg/kg once every 7 days over 14 days) reduced GB growth compared  
8 to TMZ only. The authors speculate that the mechanism of SLC-0111 may be mediated by  
9 CAIX together with increased DNA damage (26). This study did not however have the  
10 benefit of the inactive probe/active compound combination (compound **5** and **1** in our study)  
11 to contribute evidence to support the hypothesis that CAIX was the predominant target of  
12 SLC-0111. Our work may provide an additional explanation for the effect of SLC-0111,  
13 correlating its efficacy with CAXII inhibition causing indirect inhibition of Pgp and increased  
14 intratumor retention of TMZ. Of note, compound **1** was effective at a substantially lower  
15 dosage than SLC-0111. Additionally, compound **1** was devoid of toxicity and did not  
16 exacerbate TMZ side-effects, suggesting an appropriate efficacy and safety window with this  
17 combination treatment.

18 In summary, we have investigated for the first time the expression and therapeutic  
19 implication of CAXII in the highly chemorefractory GB SC-component of GB. We propose  
20 that CAXII and Pgp co-expression is a new hallmark of chemoresistance in GB NS. This  
21 relationship represents a previously unknown mechanism of TMZ resistance in GB-derived  
22 NS, wherein CAXII contributes to the Pgp-mediated resistance to TMZ and topoisomerase  
23 I/II inhibitors in patient-derived GB NS. The detection of CAXII in primary GB samples by  
24 routine immunohistochemistry techniques may be difficult however as CAXII is restricted to  
25 the SC-component that represents only a small portion of tumor bulk. This restricted

1 distribution may limit the potential use of CAXII as a predictive marker of low TMZ-  
2 response. CAXII may however represent an exciting new therapeutic target in GB patients  
3 resistant to TMZ and with a significant component of SC identified by pathology analysis.  
4 Pharmacological inhibition of CAXII rescues the efficacy of TMZ, independently of genetic  
5 alterations commonly associated with TMZ-resistance. Our results may form a basis to  
6 warrant clinical validation of a new combinatorial therapy, based on a CAXII-inhibitor with  
7 TMZ and/or topoisomerase I/II inhibitor, as more effective treatments to eliminate GB SC  
8 compared to current treatment options.

1 **Table 1. Patient clinical, pathological and genetic data**

	Patient #1	Patient #2	Patient #3
Age at diagnosis	57	53	61
Sex	M	F	M
Histological grade	IV	IV	IV
Therapy	Surgery + radiotherapy + chemotherapy	Surgery + radiotherapy + chemotherapy	Surgery + radiotherapy + chemotherapy
Time to recurrence (months)	7	6	9
Post-recurrence therapy	Re-resection + radiotherapy	Radiotherapy	Radiotherapy+ chemotherapy
Overall survival (months)	12	9	18
MGMT status	Partially methylated	Fully unmethylated	Fully methylated
EGFR status	Not amplified	Not amplified	Amplified
IDH1 status	Mutated (395G>A)	Mutated (395G>A)	Wild-type
IDH2 status	Wild-type	Wild-type	Wild-type
TP53	Wild-type	Mutated (380C>T)	Wild-type
1p/19q co-deletion	Present	Absent	Absent

2 Anagraphical, pathological, clinical and genetic data of patients of samples were used in the  
3 study. Radiotherapy: 60 Gy (30 fractions). Chemotherapy: 75 mg/m<sup>2</sup> temozolomide (TMZ),  
4 *per os*, daily, concurrently to radiotherapy, followed by 200 mg/m<sup>2</sup> TMZ, *per os*, days 1-5,  
5 every 28 days, 6 cycles. Post-recurrence therapy: radiotherapy: 60 Gy (30 fractions);  
6 chemotherapy: 80 mg/m<sup>2</sup> carmustine (BCNU), days 1-3, every 8 weeks, 3 cycles. Time to  
7 recurrence: time between the surgery and the appearance of tumor relapse at magnetic  
8 resonance imaging (MRI). Overall survival: time between diagnosis and patient death.  
9 MGMT: O<sup>6</sup>-methylguanine-DNA methyltransferase. Fully methylated: promoter methylation  
10 of both alleles; partially methylated: promoter methylation of one allele. EGFR: epithelial

- 1 growth factor receptor. Amplified: > 2 copies of EGFR genes; not amplified: < 2 copies of
- 2 EGFR gene. IDH: isocitrate dehydrogenase.

21 **Figure 3. CAXII pharmacological inhibition restores temozolomide cytotoxicity in**  
22 **glioblastoma-derived neurospheres**

23 NS were grown for 48 h (panels **a-f**) or 72 h (panel **g**) in fresh medium (-) or in medium  
24 containing 50 µM temozolomide (T) or 10 nM compound **1**, alone or in association. Panels **b,**  
25 **c, d, f:** pooled data of patients #1, #2 and #3 are presented as means±SD (n=4 independent

1 experiments for each patient). Violet, orange and blue circles represent the mean of technical  
2 replicates of #1, #2 and #3. AC were included as control of cells with undetectable CAXII  
3 levels. **a.** Patient #2 NS were lysed and immunoblotted for Pgp and CAXII. The figure is  
4 representative of one out of three experiments. **b.** Plasma-membrane extracts were  
5 immunoprecipitated (IP) with an anti-CAXII antibody, then immunoblotted (IB) with an anti-  
6 Pgp antibody. no Ab: sample immuno-precipitated without antibody. An aliquot of the  
7 extracts before the immunoprecipitation was loaded and probed with an anti-pancadherin  
8 antibody, as control of equal protein loading. The figure is representative of one out of three  
9 experiments. **c.** Spectrophotometric measure of Pgp ATPase, detected in triplicates in NS.  
10 \* $p < 0.01$ : T-treated vs. untreated (-) cells; \*\*  $p < 0.01$ : **1**-treated vs. untreated (-) cells;  
11 \*\*\* $p < 0.001$ : T+**1**-treated vs. untreated (-) cells; # $p < 0.05$ : T+**1**-treated vs. T-treated cells  
12 (Student's t-test ). **d.** Intracellular content of temozolomide (TMZ), measured in duplicates  
13 after cell radiolabelling. NS clones knocked out for Pgp (KO#1, KO#2) and AC were  
14 included as control of cells with undetectable expression of Pgp. \*\*\* $p < 0.001$ : all  
15 experimental conditions vs. untreated (-) NS (Student's t-test ). **e.** LDH release, measured  
16 spectrophotometrically in duplicates. \*\*\* $p < 0.001$ : all experimental conditions vs. untreated (-  
17 ) AC/NS; ### $p < 0.001$ : T+**1**-treated, T+KO1/KO2 cells vs. T-treated cells; §§§ $p < 0.001$ :  
18 T+KO1/KO2 cells vs. KO1/KO2 cells (Student's t-test ). **f.** Patient #2 NS, incubated as  
19 reported in **a** and/or knocked out for Pgp, were lysed and immunoblotted for procaspase and  
20 cleaved caspase 3. The figure is representative of one out of three experiments. **g.** Cell  
21 viability measured by a chemiluminescence-based assay in quadruplicates. \*\*\* $p < 0.001$ : all  
22 experimental conditions vs. untreated (-) AC/NS; ## $p < 0.005$ : T+**1**-treated vs. T-treated cells;  
23 ### $p < 0.001$ : T+KO1/KO2 or T+**1**+ KO1/KO2 cells vs. T-treated cells; §§§ $p < 0.001$ :  
24 T+KO1/KO2 or T+**1**+ KO1/KO2 cells vs. KO1/KO2 cells (Student's t-test).

1 **Figure 4. CAXII knocking-out restores sensitivity to temozolomide in glioblastoma-**  
2 **derived neurospheres**

3 NS were grown for 48 h (panels **a-g**) or 72 h (panel **h**) in fresh medium (-) or in medium  
4 containing 50  $\mu$ M temozolomide (T) or 10 nM compound **1**, alone or in association. Panels **d**,  
5 **e, f, h**: pooled data of patients #1, #2 and #3 are presented as means $\pm$ SD (n=4 independent  
6 experiments for each patient). Violet, orange and blue circles represent the mean of technical  
7 replicates of #1, #2 and #3. AC were included as control of cells with undetectable CAXII  
8 levels. **a**. Patient #2 NS were growth in fresh medium (-), transduced with a non-targeting  
9 vector (scrambled vector; scr) or with two CRISPR pCas *CAXII*-targeting vectors (KO#1,  
10 KO#2), lysed and immunoblotted with the indicated antibodies. The figure is representative  
11 of one out of three experiments. **b**. Plasma-membrane extracts were probed with an anti-Pgp  
12 antibody, or an anti-pancadherin antibody, as control of equal protein loading. The figure is  
13 representative of one out of three experiments. **c**. Plasma-membrane extracts from patient #2  
14 *CAXII*-KO NS clones were immunoprecipitated (IP) with an anti-CAXII antibody and  
15 immunoblotted (IP) with an anti-Pgp antibody. no Ab: sample immuno-precipitated without  
16 antibody. An aliquot of the extract before the immunoprecipitation was loaded and probed  
17 with an anti-pancadherin antibody, as control of equal protein loading. The figure is  
18 representative of one out of three experiments. **d**. Spectrophotometric measure of Pgp  
19 ATPase, detected in triplicates in NS. \*p<0.05: T-treated vs. scrambled-treated (-) cells;  
20 \*\*\*p<0.001: KO1/KO2 or T+KO1/KO2 cells vs. scrambled-treated (-) cells; ###p<0.001:  
21 T+KO1/KO2 cells vs. T-treated cells; §§p<0.01: T+KO1/KO2 cells vs. KO1/KO2 cells  
22 (Student's t-test ). **e**. Intracellular content of temozolomide (TMZ), measured in duplicates  
23 after cell radiolabelling. \*\*\*p<0.001: all experimental conditions vs. untreated (-) NS  
24 (Student's t-test ). **f**. LDH release, measured spectrophotometrically in duplicates.  
25 \*\*\*p<0.001: all experimental conditions vs. untreated (-) AC/NS; ###p<0.001: T+**1**-treated,

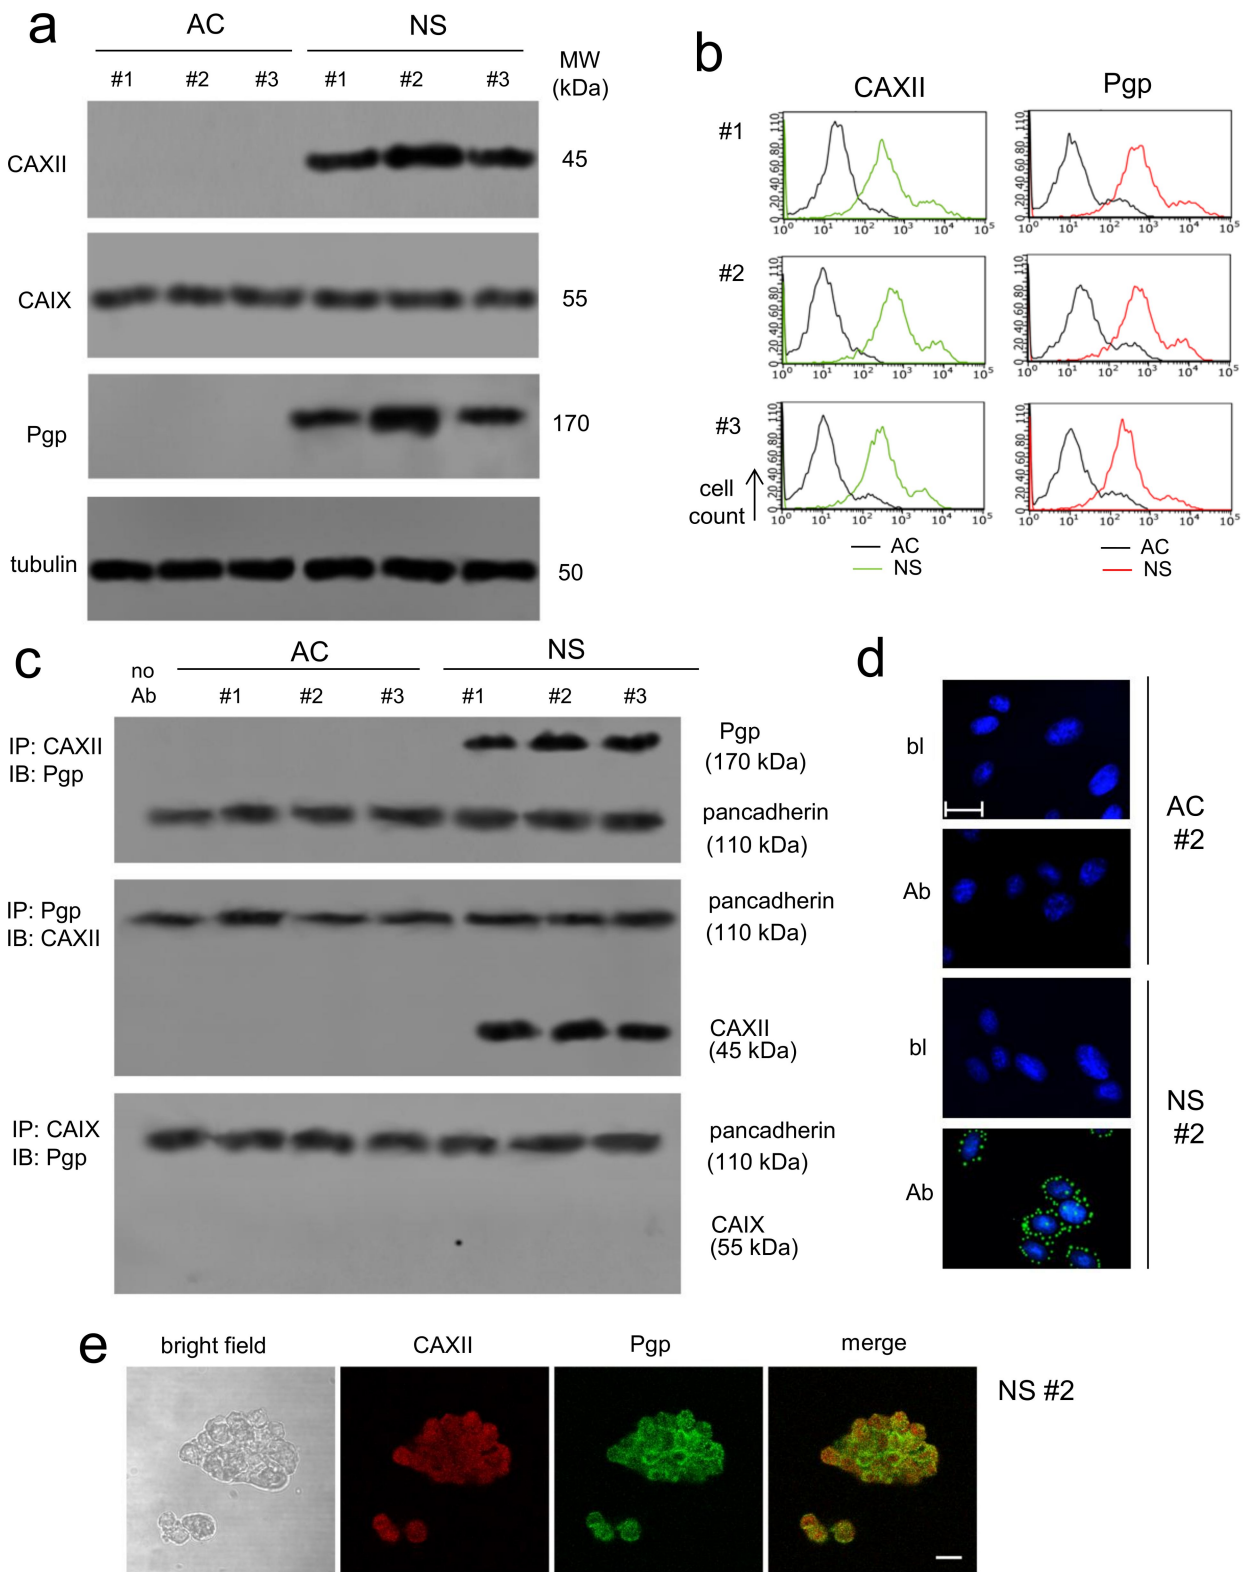

1 T+KO1/KO2 cells vs. T-treated cells;  $^{\text{§§§}}p<0.001$ : T+KO1/KO2 cells vs. KO1/KO2 cells  
2 (Student's t-test ). **g.** Patient #2 NS were lysed and immunoblotted for procaspase and  
3 cleaved caspase 3. The figure is representative of one out of three experiments. **h.** Cell  
4 viability measured by a chemiluminescence-based assay in quadruplicates.  $^{\text{***}}p<0.001$ : all  
5 experimental conditions vs. untreated (-) AC/NS;  $^{\text{###}}p<0.001$ : T+1-treated, T+KO1/KO2 cells  
6 vs. T-treated cells;  $^{\text{§§§}}p<0.001$ : T+KO1/KO2 cells vs. KO1/KO2 cells (Student's t-test).

7 **Figure 5. Compound 1 improves temozolomide efficacy against orthotopically**  
8 **implanted glioblastoma neurosphere-derived tumors**

9 **a.** Representative *in vivo* bioluminescence imaging of orthotopically implanted patient #2 NS,  
10 in animals treated with vehicle (ctrl), compound **1** and temozolomide (TMZ), as follows: 1)  
11 control group, treated with 0.2 ml saline solution intravenously (i.v.); 2) **1** group, treated with  
12 3800 ng/kg compound **1** i.v.; 3) TMZ group, treated with 50 mg/kg TMZ *per os* (p.o.); 4)  
13 TMZ+**1** group, treated with 50 mg/kg TMZ p.o.+3800 ng/kg compound **1** i.v. (6  
14 animals/group). **b.** Quantification of patient #1-3 NS-derived bioluminescence, taken as index  
15 of tumor growth. Data are presented as means $\pm$ SD (6 animals/group). At day 24:  $^{\text{**}}p<0.005$ ,  
16  $^{\text{***}}p<0.001$ : TMZ+**1** group vs. all the other groups of treatment;  $^{\text{°°}}p<0.005$ ,  $^{\text{°°°}}p<0.01$ :  
17 TMZ+**1** group vs. TMZ-group (Student's t-test ). **c.** Overall survival probability was  
18 calculated using the Kaplan-Meier method. Patient #1 NS:  $p<0.02$ : TMZ+**1**-group vs. all the  
19 other groups of treatment. Patient #2 NS:  $p<0.002$ : TMZ+**1**-group vs. all the other groups of  
20 treatment. Patient #3 NS:  $p<0.001$ : TMZ+**1**-group vs. ctrl and **1**-group;  $p<0.05$ : TMZ+**1**  
21 group vs. TMZ-group;  $p<0.01$ : TMZ-group vs. ctrl and **1**-group (log rank test; not reported in  
22 the figure). **d.** Representative intratumor staining with hematoxylin and eosin (HE) or the  
23 indicated antibodies, from patient #2 NS-derived tumors. The photographs are representative  
24 of sections from 5 tumors/group of treatment. Bar=10  $\mu\text{m}$  (10 $\times$  ocular lens, 20 $\times$  objective). **e.**  
25 Quantification of immuno-histochemical images, performed on sections with 111-94

1 nuclei/field. The percentage of proliferating cells was determined by the ratio Ki67-positive  
2 nuclei/total number (hematoxylin-positive) of nuclei using ImageJ software. The ctrl group  
3 percentage was considered 100%. The percentage of CAXII, Pgp and caspase 3-positive cells  
4 was determined by Photoshop program. Data are presented as means $\pm$ SD. \*\*\*p<0.001:  
5 TMZ+1 group vs. all the other groups of treatment; °°°p<0.001 TMZ+1 group vs. TMZ-  
6 group; ##p<0.005: TMZ vs. ctrl group (Student's t-test ). **f.** Immunoblot analysis of the  
7 indicated proteins from tumor extracts of patient #2 NS (3 animals/group of treatment).
