## Dedication

To Linda, my partner in life and business

Our life together is like a really good bottle of wine...  
it gets so much better with age

I am the luckiest person alive because of you!

# Preface

Wow! This is really the fifth edition. This journey started a long time ago in 1998 when the first edition of this book was published. This has been so much fun, I hope that I never have to stop. I was going to say that I am like a bottle of fine wine that keeps getting better with age, but those of you who know me or have bought earlier editions of this book know that I keep getting older. I will leave it for you to decide if I am getting any better with age. In the meantime, since you purchased this book, keep reading.

I have been saying this with every new edition: This is just what we need, another book on business valuation. Years ago, there were only a limited number of books on this topic—mostly finance texts. Today, it is nearly impossible to read everything that is being published in this field unless you have no life. Anyway, for those of you with a limited life, there are definitely some books on this topic that are worth reading. I can no longer list only two or three books that are my favorites because so many good books on this topic have been published over the last decade that the list has grown too much. I have included many references to these books throughout this edition, so you should have no problem figuring out which ones I like.

So, what's new in this edition? A lot. I wrote this fifth edition for several reasons; first, because I need the royalties; second, because I find that there is still a need for this stuff to be explained in plain, uncomplicated English in a manner that helps a valuation analyst apply valuation theory to real-world practice. Please don't get me wrong, I am not claiming to know everything! In fact, I keep finding out that the smarter I get, the less I realize I know. But I have come to accept that there are things in this world we may never understand. Regarding the new stuff in this edition and from the weight of this book, you can tell that there is a lot; I will tell you about it soon.

The purpose of this book is to provide some guidance on the theory, as well as on how to apply the theory in a meaningful fashion. Whether or not I'm successful is up to you. First, some basic ground rules and general information:

1. To get the most out of this book, you must read it, not only in its entirety, but also in the sequence in which it is written. Don't go to the chapter on discount rates without reading the earlier sections of the book. Otherwise, you may feel like you walked into the middle of a movie. It is also important to make sure that you read the exhibits and the appendixes at the time they are referenced. The exhibits have been included as an integral part of this book. If you skip over them or go back to them later, you may miss a valuable point I am trying to make. As for the appendixes, this edition has a new format that I will explain shortly in its own section. Wait until you see what you are getting with this book—it is incredible!
2. In general, I do not think in terms of complex mathematical formulas. My mind does not work that way. I do not like equations with lots of parentheses, nor do I like formulas that have Greek letters in them. Therefore, if you really enjoy mathematical equations, this book is not for you. However, if you are a student and your professor has chosen this book, you're stuck. I am sorry. Believe it or not, my intentions are honorable because I want readers to understand this stuff! In certain sections of this book, you will see some mathematical formulas. You will even see some Greek letters. It is not for a fraternity or sorority. The notation may be different from that found in other books. Concentrate on the concepts, not the letters and symbols used.
3. I am a firm believer in the KISS theory (keep it simple, stupid). This does not mean, however, that business valuations are simple, nor are they stupid. Quite the contrary! If you are at all like me, after reading this book, you will never feel comfortable doing or relying on a business valuation again. This can be an extremely subjective process. For the accountants reading this book, this is not at all like accounting in which the debits have to equal the credits. What you will learn is that there is no black and white answer. There are a million shades of gray. To quote a good friend of mine, the answer to most questions that are asked about business valuation is, "It depends."

4. The concepts discussed in this book cannot be read and applied as if they were in a vacuum. Many of the items discussed will directly or indirectly affect other parts of the valuation process. You must be a big-picture type of person.
5. In some of the exhibits, I cheated. They were so good in the last edition that I decided to merely update the dates to freshen them up. If I messed up because the interest rates are not from that exact period, please forgive me. I am much more concerned with the concepts than the dates. In some instances in which I felt the exhibit was date-sensitive, I did not change the dates. In some cases, I also changed the location of the business to protect the confidentiality of the client, so here, too, if it is a little inconsistent, please forgive me.
6. This book is not intended to present every alternative to every situation. Just because I have included something in this book, please do not rely solely on my writings. There may be facts and circumstances that could negate my opinion. You will find that there is no substitute for common sense in this process.
7. In some instances, I will be illustrating points from the negative. Several of the exhibits contain sections of actual reports critiquing someone else's work. Learn from what they may have done wrong.
8. Please don't shoot the messenger! Throughout this book, several topics will be discussed that may be controversial. Some may not even have a definitive answer, but you must think about these issues when you do or use a business valuation.
9. While reading this book, you are going to be exposed to my own form of humor. This is not intended to insult anyone but, rather, to add a little levity to what can be a very dry and technical topic. The very last thing that I ever want to do is insult anyone. If any of my comments make you feel uncomfortable, please accept my apology in advance. I promise that it was not intended to do so. Although business valuation tends to be extremely complex, let's have some fun while we learn. You just can't take this stuff too seriously, unless of course, you have a mid-term or final exam.
10. And finally, in much of what I am trying to teach, I have made many of the mistakes that I am trying to prevent you from making. Someone once told me I will learn from my mistakes. By now, I am a genius!

With that stuff out of the way, please enjoy my attempt to explain what little I know about business valuation.

# Acknowledgments

I must acknowledge several people for their contributions to this book. These people are not listed in any special order, but they are all very important to me. The first person is admittedly the most important. First and foremost, I have to thank my wife, Linda Trugman, CPA/ABV, MCBA, ASA, MBA, who, as you can see, is much more qualified than I am. She is my business partner of 33 years, past president of the American Society of Appraisers, and I have to thank her for her countless hours in assisting me to make this book more readable, logical, and technically accurate. She also is one heck of an editor. She makes this kid from the Bronx sound like I am from Manhattan while keeping my Bronx accent intact. She is also the primary author of the chapter on estate and gift valuations. This is clearly her area of expertise, and there is no reason to try to produce a chapter on this topic without her significant input.

Next, my special thanks to Mark Zyla, CPA/ABV, CFA, ASA, who was the primary author of the chapter on valuations for financial reporting. This is one of Mark's areas of expertise, and I was delighted to have him participate in this book. I also want to thank Lynn Pierson, CPA, CFA, from Mark's firm, for her edits in this chapter, as well. Finally, I also want to thank William Harris, ASA, CFA, from my firm, for his significant contribution to updating many of the chapters with new content. Another individual who deserves special thanks is Ed Dupke, CPA/ABV, ASA, who provided a complete technical review of the entire book. Another group of folks who deserve a thank you, and I apologize for not listing everyone by name, is the group of individuals who sent me various emails about either corrections that needed to be made to the book or items they felt needed additional clarification. You are the folks who bought this book and actually took the time to go through it and provided comments to make it better. I hope we fixed all the typos and clarifications. In fact, one person actually added up all of the tables in this book and pointed out that there were a few addition errors. Wow, what an attention to detail! All I can say is thank you, thank you, and thank you again.

And one more special thanks to a group of folks I could not have done without—the group at the AICPA who made this book what it is: David Cohen, Whitney Woody, and Annmarie Piacentino. These folks had to put up with my writing style and the many mistakes I made throughout the manuscript. This group of folks is my dream team. I could not have done this without you all!

And finally, one more thank you goes to two different groups of individuals. The first group consists of the many practitioners I have taught with over the years who have taught me so much. This list goes on and on and just keeps getting longer as I get older. You know who you are. The second group of individuals consists of all the students who have attended my classes, participants at past conferences who attended sessions where I spoke, and all my colleagues who have had such flattering things to say to me over the years about my teaching, my writings, and, particularly, the first four editions of this book. I have said this before, and I will repeat it here: It is hard to make me humble, but you have succeeded.

# Introduction

This book has been methodically organized to help you get the most you possibly can out of it. Each chapter contains lots of new stuff since the last edition, and there is even a brand new chapter; therefore, you might want to go through all the chapters in sequence. The chapters are set up as follows:

- Chapter 1 provides background stuff regarding why businesses are valued, who values them, and the various valuation organizations. The intention of this chapter is to provide you with some background about the valuation profession. You want to be aware of the different types of valuation analysts and their standards because you will most likely run across them in your endeavors.
- Chapter 2 consists of an annotation of the AICPA business valuation standard. Other standards are also covered in this chapter. This chapter is so important (and also so long) that I made it into its own chapter.
- Chapter 3 gets you started in the valuation process. In this chapter, I discuss the things that a valuation analyst must know to start an assignment. Chapter 3 includes information about engagement letters, conflicts of interest, internal work programs, and the initial document request.
- Chapter 4 takes you through the basic valuation principles and theory behind the stuff that we are trying to figure out how to do. We will learn that the term *value* has many different meanings in business valuation, and we will discuss some of the more important definitions. Because so much of the valuation work we do involves taxes, this chapter will also point out the influence of the IRS on what we do.
- Chapter 5 includes a discussion of internal and external sources of information that will be gathered by the valuation analyst. Numerous references are provided about where the valuation analyst can locate information. This chapter lists all types of neat websites for doing the required research. However, they change faster than any of us can keep up with.
- Chapter 6 walks you through the process of what the valuation analyst should do with the data that was gathered during the valuation process. This chapter includes a discussion of economic, industry, company, and financial analysis. This is one of the most important chapters in the valuation process. It will help the valuation analyst arrive at the numbers needed to apply to valuation methodologies, as well as help the valuation analyst assess the riskiness of the income stream of the valuation subject.
- Chapter 7 covers statistics for business valuation and economic damages. Don't worry; I kept it relatively basic because I could not make it complex. Keeping it simple is a good thing! If you are going to do this work, don't skip this chapter.
- Chapter 8 addresses forecasts. So much of what we do involves working with forecasts that I decided to dedicate a separate chapter to this topic. The intention is to keep the valuation analyst out of trouble. Various forecasting techniques are discussed.
- Chapter 9 presents the first part of the market approach to valuation. The underlying theory for the market approach is presented in this chapter. The balance of the chapter concentrates on the guideline public company method, including more detail on how to perform the analysis involving publicly traded companies. You will have to read this chapter to find out about size, growth, leverage, performance, turnover, and liquidity. You will also learn how to size-adjust multiples.
- Chapter 10 presents the second half of the market approach. This chapter includes a detailed discussion of the guideline transaction method, including a description of the various databases available to find merger and acquisition information involving closely held businesses. This chapter takes you step by step through the process of using this method, including making you aware of the potential pitfalls. Using internal transactions and rules of thumb are also discussed in this chapter.
- Chapter 11 presents the asset-based approach to valuation. Several methods are also explored here, and there is a discussion of how to find and communicate with other types of appraisers. New to this edition is a detailed discussion about economic obsolescence.
- Chapter 12 presents the income approach to valuation. For small- and medium-sized businesses, this chapter may be one of the most important. Single period and multiperiod models are presented. Forecasting financial information is also included in this chapter because it is the very essence of this approach to valuation.

- Chapter 13 is the chapter everyone will want to turn to! Discount rates and capitalization rates are discussed. Lots of theory and, hopefully, practical guidance have been included in this chapter. This chapter has been significantly changed and expanded from the last edition. An in-depth discussion about the equity risk premium and the small stock premium are included in this chapter. Discussions about several Duff & Phelps publications and their discount rate calculator are included in this chapter. I have also included a discussion about private equity cost of capital. This may cause even the experienced valuation analysts to change the manner in which they do things.
- Chapter 14 includes the first part of my discussion on valuation adjustments, also known as *premiums and discounts*. In this chapter, the valuation analyst will learn when to use different premiums and discounts, as well as how to support his or her opinion. This chapter includes a discussion on valuation premiums and discounts, in general, control premiums, lack of control (minority) discounts and discounts from net asset value.
- Chapter 15 is the second part of my discussion on valuation adjustments. This chapter includes everything that you want to know about discounts for lack of marketability (maybe not). I have a lot of stuff in this chapter, including a separate discussion on quantification techniques of this discount. I have an expanded discussion about the Quantitative Marketability Discount Model and the Stout (formerly FMV Opinions) DLOM Calculator. Other discounts and premiums discussed in this chapter include private company discounts, key person discounts, nonhomogeneous (portfolio) discounts, blockage discounts, and more. I even explain how to apply these discounts.
- Chapter 16 contains an annotated version of Revenue Ruling 59-60. This revenue ruling is so important that it deserves a separate chapter. You can never get enough of a Revenue Ruling that is almost 60 years old but has the makings of being the best writing in business valuation of all time (maybe with the exception of my book).
- Chapter 17 addresses the valuation report. The valuation analyst can learn how to prepare and defend the report and learn some tips regarding presentation techniques. This chapter includes the reporting requirements of the AICPA's business valuation standard.
- Chapter 18 is dedicated to Pass-Through Entities. Besides having a discussion about the tax issues of these types of entities, I have included a discussion about all of the leading models being used to calculate the impact on value. This chapter is a dandy!
- Chapter 19 covers valuations for financial reporting. While it is intended to be basic, if the valuation analyst does valuations for financial reporting purposes, he or she knows that this work is anything but basic. This chapter discusses the basic rules and pronouncements in this area of practice.
- Chapter 20 is a basic chapter on intangible assets. There are several examples to help the valuation analyst learn how to value different types of intangibles. There are some really good reference materials cited in this chapter, as well.
- Chapter 21 addresses valuation assignments that are performed for estate and gift tax purposes. Learn about the Chapter 14 (of the IRC) requirements, the adequate disclosure requirements, and family limited partnership valuations. Also, learn about valuation analyst penalties if you mess up.
- Chapter 22 covers issues involved in divorce valuations. Valuations performed as part of a divorce assignment entail very unique considerations for the valuation analyst.
- Chapter 23 contains a discussion on unique aspects of valuing professional practices. Learn what factors should be considered in valuing different types of professional practices, making these assignments different from valuing an operating company. Also included in this chapter is a detailed analysis on the valuation of work in process for a contingent fee law firm.
- Chapter 24 addresses valuation assignments for ownership disputes, including issues involving the fair value standard of value. There are some new exhibits in this chapter that address very significant issues regarding fair value.
- Chapter 25 is a brand new chapter. This chapter includes a discussion on the valuation of stock options, warrants, preferred stock, debt, and early-stage companies. It also includes a discussion of the backsolve method.
- Chapter 26 contains a discussion about economic damages. There are several new exhibits addressing different types of damages issues in this chapter.
- As a bonus, chapter 25 from the last edition is now included as chapter 27 to this book. It is a discussion of some of my favorite court cases. In fact, the name of this chapter is "My Favorite Court Cases." Pretty catchy, isn't it? This chapter has a few really good court cases that will help you understand some important issues regarding valuation. In many instances, I refer to these cases in other chapters.

And finally, for those of you that bought the last edition of this book, you may recall that there was a CD-ROM containing appendixes, sample reports, bibliography materials, and a bunch of other stuff. Guess what? The CD-ROM is gone. But fear not, see the next section.

## Replacement of the CD-ROM With Downloadable Materials

Because technology changes regularly, the publisher of this book has decided to take advantage of the times. All the appendixes, as well as some reports for you to plagiarize, are included as downloadable materials at [AICPAStore.com/UBV](http://AICPAStore.com/UBV). I only hope that you will give our firm proper attribution. Several new sample reports are included so that you can see the differences among the reports. Also new to this edition is a link to a special website that has been made available to anyone that purchased this book from Business Valuation Resources. This website will allow you to download many of the court cases that are discussed throughout this book. There will also be other stuff added to this special website as time passes. To visit the website, go to [www.bvresources.com/products/understanding-business-valuation](http://www.bvresources.com/products/understanding-business-valuation). Special thanks go out to the folks at Business Valuation Resources that have made this possible.

Although the material in this book is not necessarily unique, it has been organized in a manner that is intended to provide you with a logical analysis of the valuation process. Many of the exhibits contain actual sections of valuation reports to help emphasize the subject matter. Make sure you read them!

## Steps of a Business Valuation

This book proceeds in a sequence that resembles the steps of performing a business valuation. The chapters will address these steps in detail. Because you are probably dying to know what these steps are, I listed them here:

1. Define the valuation engagement.
2. Gather the necessary data to perform the engagement.
3. Analyze the data that you gathered.
4. Estimate the value of the interest being valued.
5. Write the report to communicate the value.

## Notation System Used in This Book

A source of confusion for those trying to understand financial theory and methods is the fact that financial writers have not adopted a standard system of notation. Although I have attempted to follow the most common notation system, I may have deviated along the way. This should not concern you.

Following are the symbols used in this book:

- Value at a point in time:
  - $PV$  = Present value
  - $FV$  = Future value
- Cost of capital and rate of return variables:
  - $k$  = Discount rate (generalized)
  - $k_e$  = Discount rate for common equity capital (cost of common equity capital); unless otherwise stated, it generally is assumed that this discount rate is applicable to the net cash flow available to common equity
  - $k_d$  = Discount rate for debt (*Note:* for complex capital structures, there could be more than one class of capital in any of the preceding categories, in which case, expanded subscripts would be required.)
  - $c$  = Capitalization rate
  - $C^{pt}$  = Capitalization rate for a pretax benefit stream
  - $C^{at}$  = Capitalization rate for an after-tax benefit stream
  - $CP$  = Control premium
  - $t$  = Tax rate (expressed as a percentage of pretax income)

- $R_f$  = Rate of return on a risk-free security
- $\beta$  = Beta (a coefficient, usually used to modify a rate of return variable)
- $(R_m - R_f)$  = Risk premium for the “market” (usually used in the context of a market for equity securities such as NYSE or S&P 500)
- SCA = Specific company adjustment
- SCP = Small company premium
- WACC = Weighted average cost of capital

- Income variables:

- $E$  = Expected economic income (in generalized sense [that is, could be dividends], any of several possible definitions of cash flow, net income, and so on; also called a *benefit stream*)
- EBIT = Earnings before interest and taxes
- EBITDA = Earnings before depreciation, interest, and taxes (“depreciation” in this context usually includes amortization)

- Periods or variables in a series:

- $i$  = The  $i$ th period, or the  $i$ th variable in a series (may be extended to the  $j$ th variable, the  $k$ th variable, and so on)
- $n$  = The number of periods or variables in the series, or the last number in the series
- $\infty$  = Infinity
- $0$  = Period, the base period, usually the latest year immediately preceding the valuation date

- Weightings:

- $W$  = Weight
- $W_e$  = Weight (percentage) of common equity in capital structure
- $W_p$  = Weight (percentage) of preferred equity in capital structure
- $W_d$  = Weight (percentage) of debt in capital structure

*Note:* For purposes of computing a weighted average cost of capital (WACC), it is assumed that the above weightings are at market value.

- Growth:

- $g$  = Rate of growth

- Mathematical functions:

- $\Sigma$  = Sum of (add up all the variables that follow)

# Chapter 1

# Overview of Business Valuation

## Learning Objectives

Business valuation is process-oriented. As such, I thought that I should start the process at the beginning. Therefore, this chapter is designed to do the following:

- Give you a very brief history about the valuation profession
- Explain why businesses are valued
- Provide some background about who values businesses
- Familiarize you with professional valuation organizations

What did you expect at this point, the complicated stuff? Be patient, and we will get there.

## Introduction

Business valuations are performed for companies and interests in companies of all sizes and types. The conceptual principles are the same for companies of different sizes, but very often, the manner in which these principles are applied varies greatly. The quantity and quality of data available for the valuation of small- and mid-sized companies tends to be considerably lower than what is available for larger businesses. Just for the record, having a greater amount of data for larger companies is not always better. Sometimes, the quality of the data is awful, even for larger companies. When there is a lack of data available for the smaller companies, either certain methodologies cannot be used or the result should be considered less reliable. However, there can be a lack of data for larger companies, as well. The valuation analyst<sup>1</sup> must be more careful in circumstances in which less data is available because having less data creates a larger risk of not being able to interpret the existing data properly. The valuation analyst should understand the business valuation process from the large company, more theoretical basis, in order to adapt these concepts properly to its smaller counterparts. This means that the same theory that applies to the valuation of large companies may have to be adapted for the valuation of small companies. However, valuing smaller businesses can be extremely challenging because most of the empirical data that a valuation analyst regularly uses applies to larger companies and only tangentially to smaller ones.

## A Brief Walk Down Memory Lane

Let's take a couple of giant steps to cover this material. If you are looking for a longer history about the profession, buy an earlier edition of this book! Over the last few decades, the business valuation industry has gone through staggering changes. We have seen the following occur:

- 1987—Establishment of the Appraisal Foundation. This organization was set up by seven real estate organizations and the American Society of Appraisers, a multidiscipline body, in response to the growing problems facing the real estate appraisal world. The Appraisal Foundation is the creator of the *Uniform Standards of Professional Appraisal Practice* (USPAP). The provisions of the USPAP include Standards 1 and 2 that pertain to real estate appraisal, Standards 7 and 8 that pertain to personal property appraisal, Standard 6 that pertains to mass appraisals, whether real estate or personal property, and Standards 9 and 10 that pertain to business valuations. Standard 3, Appraisal Review, applies to business valuation as well as real estate and personal property. You are probably wondering about Standards 4 and 5. They used to pertain to real estate, but they are now retired.

<sup>1</sup> In this book, I will be referring to the business or intangible asset appraiser as the *valuation analyst*. This is the wording used in the AICPA Statement on Standards for Valuation Services No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* (AICPA, *Professional Standards*, VS sec. 100) that I will be discussing throughout this book. We might as well be consistent!

- 1989—Passage of the Financial Institutions Reform, Recovery, and Enforcement Act of 1989 (FIRREA). Among other provisions, this law requires all who perform real estate appraisals involving a *federally related transaction* to follow the USPAP. There was quite a bit of confusion when this law was first passed because the business valuation profession thought that it would also be subject to this act. However, it is pretty clear now that it was only real estate appraisers who were subject to the federally related transaction portion of the legislation. Yet, several of the appraisal organizations have encouraged all appraisers to follow the USPAP as a “best practices” technique, although the American Society of Appraisers is the only organization with a business valuation discipline that mandates adherence to these standards.
- 1997—The American Institute of Certified Public Accountants (AICPA) Executive Board passes a specialty designation known as Accredited in Business Valuation (ABV). The first examination was given in November 1997. This designation, especially because it is appended to the CPA (CPA/ABV), gains immediate recognition in the marketplace among all of the credentials available in our field.
- 1998—The AICPA, through great insight and foresight, published the first edition of my book. (Hey, don’t laugh—it could not have been that bad—this is the fifth edition, and you either bought it or it was given to you as a birthday present!)
- 2007—The AICPA’s business valuation standard was approved and passed. It became effective January 1, 2008. This is such an important event in our history that I have devoted a complete chapter to this standard (see chapter 2).
- 2017—The fifth edition of my book gets published. Based on its popularity, it is now being used in the academic market as well as the professional market. That, my friends, is a very cool thing!

## Why Are Businesses Valued?

Business valuation assignments will vary depending on their purpose. Therefore, it is imperative that the valuation analyst understand the purpose of the assignment before the process can begin. More often than not, the purpose will influence the standard of value, the methodologies used, the level of research performed, and possibly the date of the valuation. This does not mean that the valuation analyst takes shortcuts or aims for a high or low value. Examples of how these items can affect the assignment can be demonstrated by understanding that certain types of business valuations are guided by specific sets of rules, such as state statutes, IRS regulations, or Department of Labor (DOL) regulations, or, if a minority interest is being valued, certain adjustments may not be made to the company’s financial statements because the minority interest cannot legally effectuate such adjustments. Valuations performed for divorce purposes may have case law restrictions that must be considered (for example, separating personal or professional goodwill from the goodwill of the enterprise). Business valuations of closely held companies will fall into one of three categories: 1) as part of an arm’s-length, negotiated sale or acquisition of a company, 2) as part of a statutory or legal action, such as a dissenting shareholder suit, fairness opinion, or marital dissolution, and 3) as part of a hypothetical sale, when no actual transaction takes place (such as fair market value for income, gift, and estate tax purposes and fair value reporting for financial reporting purposes). If you have never performed a business valuation, this stuff probably has you wondering what I am talking about. Be patient, this will start to make more sense as we proceed. Box 1.1 explains the variety of reasons that business valuation engagements are performed.

## Mergers, Acquisitions, Reorganizations, Spin-Offs, Liquidations, and Bankruptcy

Business valuations are frequently performed when one company acquires another company, when a company is targeted for an acquisition, when a company’s capital structure is reorganized, when a company splits up, or when a company enters bankruptcy in liquidation or reorganization. The transactions may include entire or partial acquisitions, divestitures, liquidation, or recapitalization. Mergers will generally require both companies to be valued, whereas an acquisition may require only a single valuation. The terms of the transaction generally include cash, notes, stock, or a combination of these forms of payment. Sometimes, the valuation analyst has to calculate the cash equivalent value of the payment terms when the terms include payments in stock or notes that may not reflect market rates. This will be further explained in chapter 10.

In bankruptcy, in addition to the involvement of the different classes of creditors and the owners,<sup>2</sup> the approval of the bankruptcy court is usually required. Closely held companies with two or more definable divisions may be split up or spun off into separate entities. Reasons for doing this can include estate tax considerations, family conflict, or sale of only part of the total business. In the liquidation of a business enterprise, the valuation analyst's allocation of the assets distributed to the owners may be required to substantiate subsequent depreciation and other deductions claimed. Many publicly traded companies have acquired closely held businesses by using restricted stock (Rule 144 stock) as the form of payment. Restricted stock is discussed in chapter 15. The advantage of using stock as a form of payment is that the acquirer does not have to use cash to make the acquisition. Frequently, the transaction can provide the seller with a tax-free transaction under IRC Section 1031. It also provides the seller with the opportunity to take advantage of the tax-deferred appreciation of owning the acquirer's stock. This can be a good or bad thing. This can also create work for the valuation analyst.

**BOX 1.1****Reasons for a Business Valuation Engagement**

- Mergers, acquisitions, reorganizations, spin-offs, liquidations, and bankruptcy
- Allocation of purchase price (tax and financial reporting)
- Estate, gift, and income taxes
- Marital dissolution
- ESOPs
- Buy-sell agreements
- Ownership disputes
- Financing
- Ad valorem taxes
- Incentive stock option (equity) considerations
- Initial public offerings
- Damages litigation
- Insurance claims
- Charitable contributions
- Eminent domain actions
- Fairness opinions

## Allocation of Purchase Price

An allocation of purchase price may be performed for either tax or financial reporting purposes. Each of these assignments will be accomplished based on the applicable set of rules for the intended purpose. The tax rules have been around longer, so I am going to start with them. The financial reporting rules continue to evolve.

Years ago, when a transaction took place, both the purchaser and seller would determine their own values and treat the breakdown of the value of the transferred assets and liabilities differently. The purchaser did not want to buy goodwill because it was not tax deductible, and the seller wanted to sell goodwill because it was subject to lower capital gains tax treatment. This created some very interesting allocations between the buyer and the seller. The all-around loser was Uncle Sam. However, the Tax Reform Act of 1986 changed all of that. IRC Section 1060 requires that when a business is acquired, a valuation must be performed to support the allocation of the total purchase price to the component parts for income tax purposes. The law requires a uniform allocation of the purchase price based on an appraisal of the underlying assets. The IRS pays attention to these transactions to ensure that the purchase price allocation is reasonable and is treated consistently by both the purchaser and the seller. An inappropriate or inconsistent allocation of the purchase price can result in an increased tax liability and, in some instances, penalties.

In 1993, the tax law changed, providing for intangible assets to be amortized over 15 years. This change reduced the necessity for valuation analysts to allocate the purchase price between different classes of intangible assets that had different amortization periods or no amortization period (for example, goodwill) under the old law. In more recent times, an allocation of purchase price for income tax purposes has become important because many sellers are trying to allocate a certain portion of a corporate sale as the personal goodwill of an owner. This is intended to create capital gain treatment for a portion of the sale that might otherwise be subject to ordinary income tax rates (for non-tax people, ordinary tax rates are higher).

<sup>2</sup> In this book, I will be referring to the terms *owner* or *owners* because of the different types of ownership interests that may exist for a business. A sole proprietorship or a single-member limited liability company may only have a single owner; a partnership will have partners, generally two or more; a limited liability company may have anywhere from one to numerous "members" that own the equity of the enterprise; and a corporation will have one or more stockholders (with the possibility of multiple classes of stock) that own the equity of the enterprise. I am going to keep it simple, but the type of owner will depend on the type of entity that is being addressed.

In addition to allocating the purchase price for tax purposes, generally accepted accounting principles (GAAP) also require these types of valuations. The valuation analyst is frequently being called on to provide valuation services with respect to pronouncements made by FASB. They include, but are not necessarily limited to, FASB *Accounting Standards Codification (ASC) 805, Business Combinations*; FASB ASC 350, *Intangibles—Goodwill and Other*; FASB ASC 360, *Property, Plant, and Equipment*; and FASB ASC 820, *Fair Value Measurement*, all of which deal with issues such as the determination of the fair value of assets acquired and impairment of goodwill. These topics will be covered in more detail in chapter 19.

Not all allocations of purchase price are performed for income tax or financial reporting purposes. In some instances, an allocation may be performed when it is necessary to value certain components (assets or liabilities) of a company, rather than the entire equity of an enterprise. This is illustrated in the following situation. A company was sold, and the value of the transaction was known. However, the \$17 million sales price was problematic because the client thought that her husband's business was worth \$5 million. After all, he told her this when they settled their divorce action based on this value. To say the least, she was not happy when she found out that the business was sold for \$17 million, with the transaction closing about two weeks after the divorce was finalized. The court decided that she was entitled to her equitable share of the excess (due to the husband's fraud), but, because the divorce was in a state that did not consider personal goodwill or personal covenants not to compete as part of a marital settlement, she was entitled to the non-personal portion (see chapter 22 for an extensive discussion about personal goodwill).

The valuation analyst representing the husband allocated a large portion of the purchase price to personal goodwill or a personal covenant not to compete, or both. We had to allocate the purchase price to support the value of what our client was entitled to receive. This is an example of a non-tax allocation of purchase price.

## Estate, Gift, and Income Taxes

The valuation of a closely held business or business interest is important to estate planners as they consider the effect of the unified estate and gift tax credit on lifetime transfers of property. Although this is not a tax book, valuation analysts working in this area are urged to consult the appropriate IRC sections and regulations for specifics on the unified estate and gift tax requirements. If you think that finance books on business valuation are fun reading, try the tax code. You will never have so much fun! Chapter 21 of this book contains specific information about estate and gift tax valuations. Also included in that chapter are the rules that pertain to defining a *qualified appraiser*, as well as penalties if the valuation prepared is determined to be substantially outside of the final determined value.

Valuations performed for income tax purposes may include S corporation conversions due to the built-in gains tax issues that arise if a sale occurs before the required holding period established by the IRC. Although these assignments do not occur as often as they did a number of years ago, valuation analysts are still being approached to perform this type of assignment, especially in circumstances in which the client did not listen to its tax accountants when he or she said that the client needed to perform the valuation at the time of the conversion. Clients frequently said, "I have no intention of selling my business during the next few years, so I am not worried about it." Guess what? The built-in gains tax kicked in when the client received an offer to sell that was too good to pass up. Valuation analysts should consult applicable sections of the tax law to properly understand the unique requirements of S corporation valuations performed for a conversion. S corporation and other pass-through entity valuation issues are discussed further in chapter 18.

## Marital Dissolution

In a marital dissolution, most of a couple's assets and liabilities are valued, regardless of whether their state follows equitable distribution or community property rules. Frequently, one of the assets included in the marital estate is an interest in a closely held business. Usually, the business or business interest is not divided between the spouses because that would defeat the idea of them getting divorced. Instead, one spouse keeps the business, and the other receives different assets of equal value. Because marital dissolution laws vary significantly from state to state, the valuation analyst must be aware of the rules of the state in which the

divorce takes place. For example, in some states, goodwill associated with a professional is excludable from distribution, whereas in other states, it is includable. Another item that the valuation analyst must be aware of is the standard of value (covered in chapter 4) used in the jurisdiction of the marital dissolution. Frequently, fair market value is the standard of value discussed, but the application from state to state varies greatly from the definition found in the tax laws. This can be illustrated by reviewing cases from various states. For example, in Florida, fair market value has been interpreted to be the value of the business, assuming that the business owner walks away without a covenant not to compete. In most instances, fair market value assumes a covenant not to compete. Logically, what willing buyer would purchase a business if the seller could open up next door and compete with him or her? In Pennsylvania, fair market value excludes personal goodwill. Clearly, the valuation analyst cannot be expected to know every state's law, but he or she should ask the client's attorney for information before proceeding in a direction that may have his or her report thrown out for failure to comply with the rules of the jurisdiction. Chapter 18 contains specific information about divorce valuations.

## Employee Stock Ownership Plans

An employee stock ownership plan (ESOP) is an incentive ownership arrangement funded by the employer. In general, employer stock is contributed instead of cash. ESOPs provide capital, liquidity, and certain tax advantages for private companies whose owners do not want to go public. An independent valuation analyst must value the employer's securities, at least annually, and must determine the price per share supporting transactions with participants, plan contributions, and allocations within the ESOP. Valuation analysts are urged to become familiar with the rules promulgated by the IRS and the DOL before they begin an ESOP engagement. Although I am not going to spend time on these types of engagements in this book, there are entire books devoted to this topic. If you plan to value an ESOP, I suggest that you track down the appropriate literature before you begin.

## Buy-Sell Agreements

A buy-sell agreement allows an owner in a closely held business to acquire the interest of another owner who withdraws from the business. The agreement may contain a designated price or a formula to determine the price that the remaining owners of the entity will pay to acquire the interest. The price, or the formula, needs to be updated periodically. Payment terms and conditions of sale are also generally provided. A client may ask a valuation analyst to assist in determining which valuation method is appropriate in such an agreement. Buy-sell agreements are also used frequently to establish a value for a transaction between the owners or the entity, or both in the event of death, disability, or retirement. It is common to see different formulas for each event. Unfortunately, there are so many poorly written and outdated agreements that this area of practice has evolved in the litigation arena, where the parties are fighting over the intent of the agreement. It is part of the full-employment act for business valuers.

The valuation analyst must be aware of and understand IRC Section 2703 and its effect on valuations when there is a buy-sell agreement in effect. This is discussed in chapter 21.

In working with the client, the valuation analyst should caution him or her, and possibly the entity's legal counsel, about the use of a single formula. Formulas do not always appropriately consider the economic and financial climate at the valuation date, stand the test of time, or achieve the parties' intentions. Therefore, their usage should be limited. Instead, the basis of a buy-sell agreement should be a valuation. If an extensive valuation is required, it should be performed by a qualified valuation analyst.

## Ownership Disputes

Ownership disputes can range from company breakups resulting from disagreements between owners to ownership dissent relating to mergers, dissolutions, and similar matters. Because many states allow a business enterprise to merge, dissolve, or restructure without unanimous ownership consent, many disputes have arisen over the years because minority owners have felt that the action of the majority had a negative impact on them. Dissenting owners have filed lawsuits to allow their ownership interests to be valued as if the action never took place.

In such cases, the value of the ownership interest is what it was immediately before the change; it does not reflect the impact of the proposed change on the value of the business enterprise. In these instances, the value is generally determined according to the standard of fair value, based on either statute or the case law within the state of incorporation or formation. When a valuation analyst accepts an engagement relating to an ownership action, it is advisable for him or her to request the client's legal counsel to clarify the value definition used in the particular state. The valuation analyst cannot address such issues as control premiums, discounts for lack of control, and discounts for lack of marketability without adequate legal information about the value definition to be used.

Many states also have statutes to protect minority owners from being "oppressed" (abused) by the controlling owner(s). This is another instance in which the valuation analyst must become familiar with the statutes and case law of the jurisdiction where the legal action is pending. Chapter 24 contains some specific information about ownership dispute valuations.

## Financing

A valuation of the business may be necessary to provide lenders or potential investors with information that will help the business enterprise obtain additional funds. Financial statements for an established business present information about that enterprise based on historical amounts, but rarely reflect the current values of the assets and liabilities that are contained in the balance sheet.

For a new business, the traditional balance sheet may closely reflect the estimated current value since the assets and liabilities were recently acquired. However, this is generally not the case for an established business that has developed intangible value over the years. Assets with intangible value (such as special trademarks, patents, customer lists, and goodwill) will most likely not be included in a balance sheet at current value unless it was recently acquired. Furthermore, other assets and liabilities of the business (such as real estate and equipment) may be worth significantly more or less than the book value as recorded under GAAP.

## Ad Valorem Taxes

In some jurisdictions, ad valorem taxes are based on the value of property used in a trade or business. Various entities are subject to ad valorem taxation; therefore, the fair market value of such properties must frequently be determined to ascertain the amount of tax. Regulations and case law differ significantly from jurisdiction to jurisdiction. To determine the appropriate standard of value for these properties, the valuation analyst needs to consult the client's attorney.

## Incentive Stock Option (Equity) Considerations

Many large companies provide fringe benefits in the form of incentive stock option plans that allow their employees to purchase the company's stock at a certain point in time and at a stated price. Even non-corporate entities can have incentive equity plans that work in a similar fashion as the stock plans. Employees pay no taxes when the incentive stock option is granted or when the stock option is exercised. Employees do pay tax, however, when they sell the stock received through the exercise of the option. To qualify as an incentive stock option, a stock's option price must equal or exceed its fair market value when the option is granted. Accordingly, the valuation of a closely held company has a significant effect on its incentive stock option plan.

Stock options have become a major component of employee compensation packages, especially for start-up companies that may not have the cash flow to pay market rates of compensation to its employees. Instead, the employee works for the company for a lower salary but a very generous stock option plan. The computer industry has produced many millionaires as a result of these programs. Maybe I should have considered a different profession!

## Initial Public Offerings

A substantial amount of legal and accounting services must be rendered to bring a private business to the public marketplace. From a financial standpoint, the corporation's accounting records and statements are carefully reviewed and amended, if necessary. The capital structure may need enhancement, and executive benefit plans may need revisions. More important, the corporation's stock is valued for the initial offering.

The underwriter must exercise a great deal of judgment about the price the public may be willing to pay for the stock when it is first offered for sale. Such factors as prior years' earnings, potential earnings, general stock market conditions, and the stock prices of comparable or guideline companies need to be considered to determine the final offering price. The client may ask the valuation analyst to support the offering price by performing a valuation or a fairness opinion.

## Damages Litigation

Many court cases involve economic damages. Some cases relate to compensation sought for patent infringements, illegal price fixing, breaches of contract, lost profits, or lost business opportunities, while others relate to lender liability, discrimination, and wrongful death actions. The valuation analyst may also be asked to perform hypothetical valuations of a company to determine the amount of damages resulting from the loss of business value (that is, diminution of value) to the owners. These types of valuations generally require the valuation analyst to value the company twice. The first valuation determines the value of the company at the present time. The second valuation is based on what the company would have been worth had a certain action taken place or not taken place. The difference is generally a measure of damages.

When you work in this area of practice, you need to be aware of such court decisions as *Daubert*<sup>3</sup> and *Kumho Tire*<sup>4</sup> to ensure that the methodologies employed in these and other types of litigation are generally accepted in the literature. Using methods that are not generally accepted can result in the expert's disqualification from a litigation. This is sure to make for unhappy clients and attorneys. Keep in mind that these cases also apply to more than just damages litigation. They are applicable to all types of litigation assignments. Chapter 26 contains specific information pertaining to economic damages.

## Insurance Claims

Cases involving risk insurance claims focus on the loss of income because of business interruptions and the value of such separate business assets as inventory and equipment. A valuation may be required to support the owner's position or the insurer's position. The loss of income would be determined based on documentable lost profits. The value of individual business assets, such as inventory and equipment, would be based on the replacement cost of these assets.

## Charitable Contributions

Owners of closely held businesses may wish to give all or part of their interest in a business to a favorite charity. Although ownership interests in a closely held business are donated to charity infrequently, this option exists, and the valuation analyst must be aware of the income tax rules concerning the necessary documentation to be included in a valuation report for the deductibility of such gifts. Current tax laws encourage charitable donations by permitting a tax deduction equal to the fair market value of certain appreciated capital gains property. For gifts of property in excess of \$500, the IRS requires that donors provide documentation to support the deduction for the year in which the gift was given. If the amount of the tax deduction warrants the expense, donors can obtain a valuation of the gift. If the value of the gift exceeds \$5,000, a qualified appraisal is required. I will discuss what makes a qualified appraisal in chapter 21.

.....  
<sup>3</sup> *William Daubert, et al. v. Mzw Pharmaceuticals, Inc.*, 509 U.S. 579, 113 S. Ct. 2786, 125 L.Ed.2d 469 (1993).

<sup>4</sup> *Kumho Tire Company, Ltd., et al. v. Patrick Carmichael, et al.*, 119 S. Ct. 1167, 143 L.Ed.2d 238 (1999).

## Eminent Domain Actions

An eminent domain action takes place when the government exercises its right to take over property and must compensate the owner for any resulting reduction in the value of the property. For example, a business may have to forfeit a prime location to accommodate the widening of a street. Although the business can relocate, its value may be adversely affected during the period of the move or as a result of changing locations. An expert opinion on the monetary effect of the condemnation may be necessary to support the business owner's claim or the government's offer. As part of the business valuation, the valuation analyst should become familiar with the demographics of the area and should assess the impact of the change in location. In assessing the impact, the business valuation analyst needs to remember that real estate valuation analysts have often said that the key to a business's success is "location, location, location." Forecasts may be required to calculate the losses. A valuation of the business, both before the condemnation and after the move, may be required. The expenses of the actual move need to be considered in the valuation.

## Fairness Opinions

A service that is very closely related to business valuation is the fairness opinion. A fairness opinion is generally required when a corporation is involved in a merger, acquisition, going private, or other type of transaction in which the board of directors wants to have an independent valuation analyst give its blessing to the transaction. This is a high risk type of service, and it should not be performed by a valuation analyst unless he or she really understands the nuances of preparing a fairness opinion.

This service is frequently provided by investment bankers (with deep pockets). However, many valuation firms also offer this service. After the Sarbanes-Oxley Act of 2002<sup>5</sup> was passed, many smaller publicly traded companies have gone private, requiring fairness opinions. The purpose of the fairness opinion is for the valuation analyst to opine that the transaction is fair to the stockholders from a financial point of view. The valuation analyst does not determine value because there is already an agreed upon price for the transaction. Fairness opinions also arise in the context of an ESOP. Frequently, a valuation firm is asked to opine that an ESOP transaction is fair. This can present an area of danger to the valuation analyst if the analyst is also the consultant to the ESOP who establishes the initial purchase price for the transaction. How can the analyst opine that the transaction that was based on his or her valuation was anything but fair? This is a potential conflict of interest that has apparently been below the radar of the DOL. The question is can the analyst stay lucky for an unlimited amount of time? The valuation analyst should read many other publications, including actual fairness opinions, before even thinking about doing one. Think liability!

## Who Values Businesses?

There is a considerable amount of competition among business valuers. There is a growing number of full-time valuation analysts in the business, but they are outnumbered by the part-time valuation analysts, who spend much of their time in other areas. It is important to understand who the other players in the field are because it will help you to assess the qualifications of the individual whose report you may be reading. Understanding the strengths and weaknesses of a valuation analyst, particularly in a litigation engagement, will allow you to properly assist the attorney with whom you are working so that he or she can cross-examine the other expert more thoroughly. Among the groups providing business valuation services are the following:

- Business valuation analysts
- Accountants (CPAs)
- Business brokers
- College professors (finance and economics)
- Commercial real estate appraisers
- Investment bankers
- Industry experts
- The Internet (the newest entry into our field!)

.....  
5 Sarbanes-Oxley Act of 2002 (Pub. L. No. 107-204, 116 Stat. 745).

Each group of professionals brings something unique to the practice of business valuation. Each group has its advantages and disadvantages, although the better business valuation analysts have crossed over boundaries and obtained some of the advantages of the other groups. Each of these groups is discussed in the following sections.

## Business Valuation Analysts

Professional business valuation analysts are those individuals who provide business valuation services as the primary area of expertise of their professional practice. They are generally well educated in business valuation, and this includes having an understanding of issues involved in the fields of finance, economics, security analysis, and accounting, among others. Most of these individuals either have received some form of accreditation from a professional valuation organization or are currently pursuing these credentials (credentials are discussed later in this chapter).

Many of these individuals work in an environment in which they are exposed to businesses of a particular type (for example, professional practices, large companies, small companies, or a particular industry). One difficulty that these individuals may encounter is trying to value a company that is not in their area of specialization. For example, a valuation analyst who is accustomed to using public stock market information to value large closely held companies may have a difficult time valuing the small hardware store (not The Home Depot).

## Accountants (CPAs)

Over the past few decades, the number of accountants performing business valuations has grown exponentially. An accountant's background and training provide both advantages and disadvantages with regard to being a business valuation analyst.

Accountants have several advantages in rendering business valuation services. They are educated in financial concepts and terminology, which gives the accountant a distinct advantage in understanding financial statements, and in some cases, tax returns. It also may give the accountant the ability to analyze the financial statements using the same analytical tools (for example, ratio analysis) that he or she employs to perform other types of accounting services.

Working with numbers is another clear advantage for the accountant. We bean counters can count beans better than anyone else. Accountants are also frequently exposed to revenue rulings and tax laws. This can represent a significant advantage over other types of valuation analysts, especially when tax-related appraisals are being performed. To illustrate this point, our firm performed a valuation assignment for the IRS (I know, the so-called "bad guys." They really are not a bad group to work for once you get to know them.) in which the subject of the valuation was a 1.6 percent beneficial interest in a trust. The taxpayer's valuation analyst took a discount for lack of marketability, which we pointed out as being incorrect because of specific IRS regulations that pointed to mortality tables that took this into consideration. Don't try to figure out all the details; suffice it to say that our awareness of the tax laws gave us a distinct advantage over the non-CPA valuation analyst.

However, there are disadvantages as well. Accountants are used to working with financial statements and concepts that are either GAAP-oriented or tax-oriented. These concepts deal with book value, rather than market value. Accountants are also frequently uncomfortable working with operating performance forecasts of the business being valued. Accountants are historians by nature. Financial statements generally report the past, not the future.

Over the years, accountants have been exposed to a large number of malpractice lawsuits, particularly in the audit area, but more recently, in the litigation support area, as well. As a result, accountants tend to be concerned with malpractice exposure because of the subjective nature of business valuation. The debits do not equal the credits; therefore, is the answer correct? Accountants also have to be concerned with potential conflicts of interest (for example, preparing tax returns for the business and then adjusting the officer's compensation in the valuation as being excessive). Even if there is not a conflict of interest, there can be a perceived bias in certain types of assignments.

## Business Brokers

---

Business brokers have a distinct advantage as business valuation analysts because they are involved with actual transactions in the marketplace. Because fair market value comes from the market, the business broker is frequently more familiar with the market for the business being appraised.

However, many business brokers do not complete business valuation training. They are generally salespeople as opposed to valuation analysts. They will tell you that a similar business sold for \$1 million and that the valuation subject is, therefore, also worth \$1 million, but they may not understand the effect on value that the terms of the transaction can have. What if the similar business sold with terms of 20 percent down, with the balance being paid off over 10 years with no interest? The present value of this transaction would be quite a bit less than \$1 million. Business brokers are generally involved in the investment value standard and often have trouble switching to fair market value due to their lack of valuation training.

Business brokers are also very quick to value a business based on “rules of thumb.” Rules of thumb can be dangerous. They are discussed in chapter 10. It has also been my experience that some brokers tend to sell the same type of business for the same multiple of earnings or gross revenues, over and over again, which tends to make them market makers instead of interpreters of the market—which is actually the role of the valuation analyst. Frequently, the business broker also lacks training in financial statement analysis.

## College Professors

---

Another group of valuation analysts who are visible in the field are college professors with backgrounds in economics, finance, and accounting. Many professors are entering this field because they have time after school or as a means to supplement their income (not a bad part-time job). There is no doubt that the vast majority of these individuals understand the theory, but some (not all) demonstrate two shortcomings: First, they try to apply some very complex formulas to simple little businesses, and second, they cannot explain what they did in language that most regular people can understand. Many of these individuals are very strong in their comprehension of financial modeling and formulas. Although the mathematical formula may be correct, the answer may still be wrong.

## Commercial Real Estate Appraisers

---

Every time we see the real estate market suffer, we have seen a growing number of commercial real estate appraisers entering the field of business valuation. Included among the students from past courses that I have taught are members of this profession who are trying to expand their businesses. During the slow times in the real estate world, many real estate appraisers look to fill up their work week with business valuation assignments. And often, the pay is better for business valuation assignments.

Although real estate appraisers understand the valuation process and principles, they often have a difficult time with the accounting aspects of financial reporting. They also have some difficulty making the transition into business valuation, where the ability to verify comparables is not always possible. Finally, although many real estate appraisals involving a capitalization of income use capitalization rates between 7 percent and 12 percent, real estate appraisers have a difficult time understanding the substantially higher capitalization rates used to value small businesses.

## Investment Bankers

---

Investment bankers are frequently employed to perform valuations for a wide variety of assignments, including estate and gift tax valuations, initial public offerings, and going private, as well as for other purposes. More often than not, the investment bankers perform pretty large valuation assignments. They are brought into assignments for reasons that come before the issue of the fee. It is much different from the local hardware store.

## Industry Experts

Industry experts are being called upon more often these days to provide valuation opinions regarding businesses in their industry. Many of these individuals are familiar with what is going on in the industry, but they rarely have the qualifications of a business valuation analyst. However, the courts are paying a lot of attention to these individuals, rightfully or wrongfully, because they are believed to understand the mechanics of the industry. My own experience is that many of these industry experts are more expert from the operational side of the business than from the valuation side. Sometimes, you may want to team up with someone who has the industry know-how to strengthen your valuation.

## The Internet

Did you know that you can get a business valuation done on the Internet? There are websites that allow you to put in your credit card number, some financial data about a company, and out comes a business valuation. Some sites even claim that the report is in compliance with standards. We actually had one prospective client ask us how we differentiate ourselves from an Internet site, particularly because our fee quote was considerably higher. The question just did not deserve an answer. We told the prospect that you get what you pay for. We also told her that she can talk to us and get an answer (rather than talk to the computer and get no response). For that matter, our name does not start with “www.”

There are many websites available to have a business valuation done. Many of them seem to be designed and administered by college professors (or, for all I know, their graduate students). The fees range from as low as \$99 to a high of \$6,000. By the time you finish reading this book and realize how much work you need to do to produce a credible valuation, you may wonder how these fees are possible!

## Professional Valuation Organizations

When one thinks of business valuation, several organizations<sup>6</sup> come to mind, including the following:

- The AICPA
- The American Society of Appraisers
- The National Association of Certified Valuation Analysts/The Institute of Business Appraisers
- The CFA Institute
- The Appraisal Foundation

## The AICPA

The AICPA is not a valuation organization, but its members probably provide the largest percentage of business valuations performed because of their sheer numbers. In 1981, the AICPA established a membership section for CPAs who provide management advisory services, recognizing that AICPA members provide services other than audit and tax. Today, that section is divided into multiple member sections, including the Forensic and Valuation Services (FVS) section. The AICPA recognizes business valuation services as an important component of CPA services.

The ABV designation was approved by the AICPA Council in the fall of 1996, and the first examination was given in November 1997. This has been an area of specialization recognized by the accounting profession. To obtain this accreditation, a candidate must meet the following requirements:

1. Be a member in good standing of the AICPA
2. Hold a valid and unrevoked CPA certificate or license issued by a legally constituted jurisdictional authority (50 states plus 6 territories)
3. Pass a comprehensive business valuation examination
4. Have the appropriate education and experience
5. Pay the required fee

<sup>6</sup> There are also international organizations, such as the Canadian Institute of Chartered Business Valuers (CICBV), our friends to the north, that participate with the American organizations in conferences, standards, education, and so on.

Box 1.2 describes additional requirements that must be completed before the ABV certificate is awarded, but may be completed at any time within 24 months of passing the AICPA ABV examination. The ABV credential is required to be recertified every 3 years. This may seem like a lot, but it can't be that bad. After all, I am an ABV! For more information about obtaining the credential, go to the following website: [www.aicpa.org/Membership/Join/Pages/credentials.aspx](http://www.aicpa.org/Membership/Join/Pages/credentials.aspx).

Because the requirements change from time to time, you should visit this site for the most current requirements.

### BOX 1.2 Additional Requirements to Become an ABV

#### THE BUSINESS EXPERIENCE REQUIREMENT\*

There are two ways an ABV credential candidate may successfully fulfill the business experience requirement:

1. A credential candidate will successfully complete the requirement by serving as a full-time instructor, who has taught at least four accredited college courses covering at least 50 percent of the material included in the business valuation body of knowledge indicated in the ABV Exam Content Specification Outline.
2. A credential candidate will also successfully complete the requirement by completing at least 150 hours of or 6 business valuation engagements in which the valuation analyst must use professional judgment, and the engagement results in the estimation of value, culminating in the expression of either a conclusion of value or a calculated value (see paragraph .21 of Statement on Standards of Valuation Services [SSVS] No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* [AICPA, *Professional Standards*, VS sec. 100]). Examples of methods used on such engagements include, but are not limited to the following:
  - **Cash flow valuation**—Analyze the historical performance of the business; estimate the cost of capital; calculate the value of the cash flow stream; and interpret the results
  - **Specialized valuation skills and training**—Security market options; research techniques and research tools; company, industry, and economic data analysis; valuation calculations and conclusions; engagement reporting; and the AICPA Code of Professional Conduct and AICPA *Professional Standards*
  - **Analysis of financial information**—Linkage between purpose for the valuation, standard of value and ownership, and sources and uses of industry financial and operating data
  - **Financial forecasting**—Statistical techniques: simple and multiple regressions, time series analysis, AICPA Prospective Financial Reporting Guidelines, determining and documenting significant forecast assumptions, company and industry data, and sources and uses of economic data
  - **Estimating cost of capital (discount and capitalization rates)**—Understanding the sources and limitations of data; security market line; market efficiency, theoretical underpinning of discount and capitalization rates—capital asset pricing model (CAPM), multifactor models, difference and similarities of CAPM and the build-up method; sources of small firm risk premiums, firm-specific risk premiums and other adjustments to cost of capital (when and how); Beta—understanding the sources and calculations, R-squared and other potential limitations; estimating Beta for privately owned companies, including guideline companies' levered Beta (bL) and Guideline Companies' Proxy unlevered Beta (bu)
  - **Selecting and evaluating guideline company data**—Screening and selection process; goodness of fit issues; guideline companies; data to use and the proper use of the data; linkages between the Standard of Value, purpose for the valuation, selection of guideline companies and specific data; court cases involving acceptance and rejection of guideline company data
  - **Determining the proper valuation discounts or premiums**—Reasons for discounts and premiums such as marketability and control issues; Standard of Value, purpose for the valuation, ownership issues, and the proper usage of discounts; sources for estimating discounts such as identifying and understanding the empirical research of liquidity and control issues; and methods used to select and apply proper discounts and premiums
  - **Linkages between approaches, standards of value**—Purpose of Valuation and Discounts Income methods; market methods; asset-based methods; liquidity and marketability issues; control and minority ownership positions; fair market value, investment value, and fair value
  - **Entity and specialized industry issues**—ESOP plans; family limited partnerships; medical practices; professional service businesses; other service businesses; start-ups, research and development, or technology-based businesses; initial public offering (IPO) candidates; merger and acquisition valuation engagements; real estate or other holding companies; and specialized industries (construction, retail, restaurants, and so on)
  - **Report preparation and engagement administration**—Awareness of appropriate SSVS No. 1 and USPAP reporting standards, proper documentation of research, presentation of and support for the valuation conclusion, sufficient and competent evidential matter, guidelines for working paper and supporting documentation, and engagement letters and letters of representation
  - **Litigation and dispute resolution services**—Rules of evidence, qualifications of experts, roles of the consulting expert and the testifying expert, and depositions and court testimony

\* [www.aicpa.org/InterestAreas/ForensicAndValuation/Membership/Pages/default.aspx](http://www.aicpa.org/InterestAreas/ForensicAndValuation/Membership/Pages/default.aspx).

**BOX 1.2****Additional Requirements to Become an ABV** *(continued)***THE EDUCATION REQUIREMENT**

An ABV candidate must have a minimum of 75 hours of business valuation-related education. The objectives of the Education component of the program are as follows:

- Maintain competency by requiring timely updates of valuation knowledge and skills
- Provide a mechanism for monitoring maintenance of competency

In order to maintain the ABV credential, ABVs must comply with continuing professional education (CPE) standards issued by the AICPA and NASBA. It is suggested ABV credential candidates and members visit [aicpa.org/cpe](http://aicpa.org/cpe) to become familiar with these standards, the CPE requirements for AICPA members, and the specific CPE requirements for each state board and society.

The following are examples of education related to business valuation:

- **Cash flow valuation**—Analyze the historical performance of the business, forecast future performance, estimate the cost of capital, estimate the continuing value, calculate and interpret the results
- **Specialized valuation skills and training**—Security market options; research techniques and research tools; company, industry, and economic data analysis; valuation calculations and conclusions; engagement reporting; and the AICPA Code of Professional Conduct and AICPA *Professional Standards*
- **Analysis of financial information**—Linkage between purpose for the valuation, standard of value and ownership, characteristics and normalized earnings, normalizing earnings, sources and uses of industry financial and operating data
- **Financial forecasting**—Statistical techniques: simple and multiple regressions, time series analysis, exponential smoothing, AICPA Prospective Financial Reporting Guidelines, determining and documenting significant forecast assumptions, company and industry data, and sources and uses of economic data
- **Estimating cost of capital (discount and capitalization rates)**—Understanding the sources and limitations of data; security market line; market efficiency, theoretical underpinning of discount and capitalization rates—CAPM, multifactor models, difference and similarities of the CAPM and the build-up method; sources of small firm risk premiums, firm-specific risk premiums, and other adjustments to cost of capital (when and how); Beta—understanding the sources and calculations, R-squared and other potential limitations; estimating Beta for privately owned companies, including guideline companies' levered Beta (bL) and Guideline Companies' Proxy unlevered Beta (bu)
- **Selecting and evaluating guideline company data**—Screening and selection process; goodness of fit issues; guideline companies; data to use and the proper use of the data; linkages between the Standard of Value, purpose for the valuation, selection of guideline companies and specific data; court cases involving acceptance and rejection of guideline company data
- **Determining the proper valuation discounts or premiums**—Reasons for discounts and premiums such as marketability and control issues; Standard of Value, purpose for the valuation, ownership issues, and the proper usage of discounts; sources for estimating discounts such as identifying and understanding the empirical research of liquidity and control issues; and methods used to select and apply proper discounts
- **Linkages between approaches, standards of value, purpose of valuation and discounts**—Income methods, market methods, asset-based methods, liquidity and marketability issues, control and minority ownership positions, fair market value, investment value, and fair value
- **Entity and specialized industry issues**—ESOP companies; family limited partnerships; medical practices; professional service business, other service businesses; start-up, research and development, or technology-based businesses; initial public offering (IPO) candidates; merger and acquisition valuation engagements; real estate or other holding companies; and specialized industries (construction, retail, restaurants, and so on)
- **Report preparation and engagement administration**—USPAP reporting standards, proper documentation of research, presentation of and support for the valuation conclusion, sufficient and competent evidential matter, guidelines for working paper and supporting documentation, and engagement letters and letters of representation
- **Litigation and dispute resolution services**—Rules of evidence, qualifications of experts, roles of the consulting expert and the testifying expert, and depositions and court testimony
- **Attendance at annual AICPA conferences and conferences of other professional organizations focusing on valuation-related topics**

## The American Society of Appraisers

The American Society of Appraisers (ASA) is a multidisciplinary organization specializing in all types of appraisals. The organization was founded in 1936, but by 1981, there was a growing need within the organization (which was primarily a real estate dominated professional appraisal organization) to recognize business valuation as a specialty. In 1981, ASA established a business valuation committee after recognizing the business valuation discipline as a separate specialization.

ASA accredits its members by requiring candidates to pass an extensive series of written examinations, usually given at the end of four, three-day training courses. The alternative is to pass an examination that is administered in one day without taking the various training courses. Candidates are also required to submit one valuation report that the International Board of Examiners must approve and that demonstrates knowledge and compliance with valuation theory and standards.

ASA has two levels of accreditation based on the experience of the applicant. First, a designation of Accredited Member (AM) is granted to those individuals who meet the other requirements and have greater than two years, but less than five years, of full-time experience. ASA gives credit for partial years for those applicants who do not perform appraisals on a full-time basis. CPAs are given one year of valuation experience for being a CPA for five years. Financial Analysts (CFAs) are given full-time equivalent experience and are exempt from taking the examinations. Second, those applicants with five or more years of experience are granted the Accredited Senior Appraiser designation.

### The National Association of Certified Valuation Analysts/The Institute of Business Appraisers, Inc.

---

Founded in 1991, the National Association of Certified Valuation Analysts (NACVA) is one of the newer organizations accrediting business appraisers. This organization has one designation. To become a Certified Valuation Analyst (CVA), the applicant must be a member in good standing with NACVA, successfully demonstrate that he or she meets NACVA's experience threshold requirement by completing a sample case study (or submitting an actual and sanitized fair market value report prepared in the last 12 months) for peer review, attend a 5-day training program, submit 3 personal and 3 business references, and pass a comprehensive examination.

Although considered a separate organization, The Institute of Business Appraisers (IBA) is effectively being run as a parallel organization to NACVA. IBA's assets were acquired several years ago, and both organizations are run under one roof. In the past, new and non-certified appraiser candidates for the Certified Business Appraiser (CBA) accreditation must have possessed a four-year college degree or equivalent; successfully completed both the written examination and the submission of two demonstration reports demonstrating a high degree of skill, knowledge, and judgment as a business appraiser; be a member in good standing of the IBA; submit an official CBA application form and fee; and provide four satisfactory references: two personal character references and two references regarding professional competence as a business appraiser.

Candidates for the CBA designation were exempt from the education and examination requirements if they were accredited by ASA, NACVA, the AICPA, the Canadian Institute of Certified Business Valuators, the CFA Institute, or if they hold the IBA's junior accreditation: Accredited by IBA.

IBA also has a Master Certified Business Appraiser (MCBA) designation, which is given to individuals who have held the CBA designation for no less than 10 years and who have 15 years of full-time experience as a business appraiser. That individual must have been endorsed by senior business appraisers as leading contributors to the profession's body of knowledge. I don't know how, but I am an MCBA. However, at the time of the writing of this chapter, NACVA sent out a notice informing the members that they would support existing accredited members, but they were discontinuing all of IBA's accreditations.

### The CFA Institute

---

The CFA Institute is not really a valuation organization. This organization grants the CFA designation after an applicant passes three extensive annual examinations. The CFA designation has more of a public company orientation (mostly portfolio and asset management) than the designations of the valuation organizations that primarily deal with closely held companies. There is no report requirement, and the experience level needed for one to obtain this designation is four years.

## The Appraisal Foundation

Established in 1987, The Appraisal Foundation is not a valuation organization. This organization was set up by seven real estate organizations and ASA, which was the only multidisciplinary organization, in response to a growing problem facing the real estate appraisal world. Real estate appraisers lacked standards to provide consistency in their work product. As a result, relying on these real estate appraisals caused bad bank loans to be made, creating severe problems for lending institutions. Facing some form of regulation in the near future, The Appraisal Foundation promulgated a set of standards relative to appraisals. These standards are the USPAP. Although these were primarily intended to cover real estate appraisals, ASA used its influence to have standards included for its other disciplines as well: personal property and business valuation. The USPAP is discussed in greater detail throughout this book.

## Conclusion

Because this was only the first chapter of the book, you are probably starting to doze off. What did you expect? This is introductory stuff. It gets better. By now, you are at least familiar with some history of the profession, who values businesses, why businesses are valued, and valuation organizations. You also were told many times to consult with an attorney about certain issues. In fact, I said this many, many times. I know the suspense of the next chapter is probably killing you, so let's move on.

## Chapter 2

# Business Valuation Standards

### Learning Objectives

This is an extremely important chapter. Regardless of who you are, whether you provide or use business valuation services, this chapter is sure to have an effect on you. I have dedicated this chapter solely to business valuation standards. Therefore, this chapter is only designed to do the following:

- Familiarize you with the business valuation standards of the AICPA
- Familiarize you with some of the old, but yet required, standards of the AICPA
- Familiarize you with the standards of the other valuation organizations

Whatever you do, do not skip this chapter! Whether you are a practitioner who had the last edition of this book and you think that since you read it the last time you do not need to read it again, or if you are a student reading it for the first time, do not skip this chapter! I know that reading standards is about as exciting as watching paint dry, but if you are going to provide or use business valuation services, you really need to understand these standards to ensure that the services are performed properly. I promise that this stuff will get more exciting soon.

### Introduction

Different organizations have different standards, and so the question that often arises is: What standards should I follow? Anyone who belongs to a professional organization knows that each organization mandates that its members follow its own set of standards. The discussion that follows is intended to give some helpful suggestions, but it is up to each individual to make certain that the proper sets of standards are followed. The following standards are discussed:

- AICPA Statement on Standards for Valuation Services (SSVS) No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* (AICPA, *Professional Standards*, VS sec. 100)
- AICPA Statement on Standards for Consulting Services No. 1, *Consulting Services: Definitions and Standards* (AICPA, *Professional Standards*, CS sec. 100) (and others)
- American Society of Appraisers (ASA) Standards
- *Uniform Standards of Professional Appraisal Practice* (USPAP)
- National Association of Certified Valuation Analysts (NACVA)/Institute of Business Appraisers (IBA) Standards

### AICPA Statement on Standards for Valuation Services No. 1

SSVS No. 1 was issued at the end of June 2007 and is effective for engagements entered into on or after January 1, 2008. Therefore, this standard is currently in place and must be followed by all members of the AICPA. In fact, CPAs who practice in jurisdictions whose boards of accountancy (or equivalent) adopt the AICPA standards must also follow this standard, even if they are not members of the AICPA. Therefore, I am providing you with the entire standard, with my own annotations, so that you can hopefully follow these rules in practice. My annotations are located in the boxes included within the text of the standard.

## Foreword

### Why Issued

Valuations of businesses, business ownership interests, securities, or intangible assets (hereinafter collectively referred to in this foreword as *business valuations*) may be performed for a wide variety of purposes, including the following:

- Transactions (or potential transactions), such as acquisitions, mergers, leveraged buyouts, initial public offerings, employee stock ownership plans and other share-based plans, partner and shareholder buy-ins or buyouts, and stock redemptions.
- Litigation (or pending litigation) relating to matters such as marital dissolution, bankruptcy, contractual disputes, owner disputes, dissenting shareholder and minority ownership oppression cases, and employment and intellectual property disputes.
- Compliance-oriented engagements, including (a) financial reporting and (b) tax matters such as corporate reorganizations; S corporation conversions; income, estate, and gift tax compliance; purchase price allocations; and charitable contributions.
- Planning-oriented engagements for income tax, estate tax, gift tax, mergers and acquisitions, and personal financial planning.

#### Author's Note

Do you think that the authors of the standard read chapter 1 of my book? Many of these items will be discussed throughout the book.

In recent years, the need for business valuations has increased significantly. Performing an engagement to estimate value involves special knowledge and skill.

Given the increasing number of members of the AICPA who are performing business valuation engagements or some aspect thereof, the AICPA Consulting Services Executive Committee has written this standard to improve the consistency and quality of practice among AICPA members performing business valuations. AICPA members will be required to follow this standard when they perform engagements to estimate value that culminate in the expression of a conclusion of value or a calculated value.

#### Author's Note

Notice that they said "AICPA members will be required to follow this standard." This is not optional. However, with that being said, there are many practitioners who are trying to find ways to avoid following the standard. Please don't be one of them.

The Consulting Services Executive Committee is a body designated by AICPA Council to promulgate professional standards under the "General Standards Rule" (ET sec. 1.300.001 and 2.300.001), and the "Compliance with Standards Rule" (ET sec. 1.310.001 and 2.310.001), of the AICPA Code of Professional Conduct (the code).

## Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset

### Introduction and Scope

**.01** This statement establishes standards for AICPA members (hereinafter referred to in this statement as *members*) who are engaged to, or, as part of another engagement, estimate the value of a **business**,<sup>1</sup>

<sup>1</sup> This statement includes two glossaries. Appendix B is the "International Glossary of Business Valuation Terms" (IGBVT). The IGBVT is a verbatim reproduction of the glossary jointly developed by the AICPA, the American Society of Appraisers (ASA), the Canadian Institute of Chartered Business Valuators, the National Association of Certified Valuation Analysts, and the Institute of Business Appraisers. Appendix C, "Glossary of Additional Terms," provides definitions for terms included in this statement, but not defined in the jointly developed glossary. The terms defined in appendix B are in boldface type the first time they appear in this statement; the terms defined in appendix C are in italicized boldface type the first time they appear in this statement.

**business ownership interest, security, or intangible asset** (hereinafter collectively referred to in this statement as **subject interest**). For purposes of this statement, the definition of a business includes not-for-profit entities or activities.

**Author's Note**

Don't go bouncing around looking for the definitions of the terms used in this document. Many of them will be defined in later chapters as I discuss them. This will all make sense by the time you finish this book. As much as I hate to suggest this, you may want to reread this chapter after you have finished the book because it will really make more sense at that point. I thought about putting another chapter at the back of the book with a repeat of the standard, but the accountant in me said that the cost of doing this would raise the price of the book. Although I might get more royalties, you probably would not buy the book. So, just read it again when you are done.

**.02** As described in this statement, the term **engagement to estimate value** refers to an engagement or any part of an engagement (for example, a tax, litigation, or acquisition-related engagement) that involves estimating the value of a subject interest. An engagement to estimate value culminates in the expression of either a **conclusion of value** or a **calculated value** (see paragraph .21). A member who performs an engagement to estimate value is referred to, in this statement, as a **valuation analyst**.

**.03** Valuation analysts should be aware of any governmental regulations and other professional standards applicable to the engagement, including the code and the Statement on Standards for Consulting Services (SSCS) No. 1, *Consulting Services: Definitions and Standards* (AICPA, *Professional Standards*, CS sec. 100), and the extent to which they apply to engagements to estimate value. Compliance is the responsibility of the valuation analyst.

**Author's Note**

It is really ironic that I once heard a CPA testify under pressure that as a CPA, "we have no business valuation standards." However, we certainly do now, and even back then we probably had the most rigorous set of standards of any organization that I know. Although they may not have been labeled as business valuation standards, they clearly relate to the manner in which we conduct ourselves in every assignment that we undertake.

**.04** In the process of estimating value as part of an engagement, the valuation analyst applies **valuation approaches** and **valuation methods**, as described in this statement, and uses professional judgment. The use of professional judgment is an essential component of estimating value.

## Exceptions From This Statement

**.05** This statement is not applicable to a member who participates in estimating the value of a subject interest as part of performing an attest engagement defined by the "Independence Rule" of the code (ET sec. 1.200.001) (for example, as part of an audit, review, or compilation engagement).

**Author's Note**

An attest engagement falls under a completely different set of rules. Those rules have an objective to attest to a firm's representations on its financial statements and have nothing to do with business valuation. Because the purpose of an attest engagement is so much different from a valuation engagement, this is a logical exception.

**.06** This statement is not applicable when the value of a subject interest is provided to the member by the client or a third party, and the member does not apply valuation approaches and methods, as discussed in this statement.

**Author's Note**

This exception relates to the situation, for example, when a client provides the CPA with the value of his or her business for inclusion in a bank loan application, and the CPA does nothing to establish or validate the client's value. It may also apply when the client or another person, such as a real estate appraiser, provides the value for inclusion in an "intangible" tax return.

**.07** This statement is not applicable to internal use assignments from employers to employee members not in public practice, as that term is defined in the code (ET sec. 0.400.42). See also Valuation Interpretation No. 1, "Scope of Applicable Services" (VS sec. 9100), illustrations 24 and 25 (VS sec. 9100 par. .78–.81).

**.08** This statement is not applicable to engagements that are exclusively for the purpose of determining economic damages (for example, lost profits) unless those determinations include an engagement to estimate value. See also Interpretation No. 1, illustrations 1, 2, and 3 (VS sec. 9100 par. .06–.11).

**Author's Note**

Many times, litigation assignments, particularly those calling for the calculation of economic damages, may require either a lost profits component, a lost business value component, or sometimes both. Although the lost profits portion of the assignment is clearly excluded from this standard, a determination of the loss of value pertaining to a business enterprise or part thereof is subject to this standard. Economic damages are discussed in greater detail in chapter 26.

**.09** This statement is not applicable to mechanical computations that do not rise to the level of an engagement to estimate value; that is, when the member does not apply valuation approaches and methods and does not use professional judgment. See Interpretation No. 1, illustration 8 (VS sec. 9100 par. .20–.23).

**Author's Note**

If a CPA determines the value of 100 shares of IBM stock to report on an estate tax return, he or she has made a mechanical calculation because it only involves multiplying the number of shares by the share value, which is easily ascertainable. SSVS No. 1 does not apply to this calculation. As for professional judgment, I have seen too many practitioners who should have used professional judgment in their assignments but failed to do so. You do not get to ignore this standard if you should have, but did not, use professional judgment.

This statement is not applicable when it is not practical or not reasonable to obtain or use relevant information; as a result, the member is unable to apply valuation approaches and methods that are described in this statement.<sup>2</sup>

**Author's Note**

An example of this situation could be when a valuation analyst is hired to provide a valuation of a very small interest in a foreign company for an estate tax return in which the decedent received about \$15 in distributions each year for the last 10 years, and you cannot get any other information about the investment.

## Jurisdictional Exception

**.10** If any part of this statement differs from published governmental, judicial, or accounting authority, or such authority specifies valuation development procedures or valuation reporting procedures, then the valuation analyst should follow the applicable published authority or stated procedures with respect to that part

<sup>2</sup> Unless prohibited by statute or by rule, a member may use the client's estimates for compliance reporting to a third party if the member determines that the estimates are reasonable (based on the facts and circumstances known to the member). See Interpretation No. 1, "Scope of Applicable Services" (VS sec. 9100 par. .01–.89), and Statement for Standards on Tax Services No. 4, *Use of Estimates* (TS sec. 400).

applicable to the valuation in which the member is engaged. The other parts of this statement continue in full force and effect (Interpretation No. 1 [VS sec. 9100 par. .01–.89]).

#### Author's Note

What does this really mean? If someone else makes the rules, and you are playing in their backyard, you have to follow their rules. For example, if you are engaged to value a business for a divorce in a state that excludes personal goodwill from equitable distribution, you cannot hide behind this standard to avoid carving out the personal goodwill piece of the pie. So if you represent the nonbusiness owner-spouse, don't think that you can get away with ignoring personal goodwill to pump up the value. Besides the fact that this is unethical (because advocacy for a client should never be done as an expert witness), the law of the land supercedes this standard. However, all other provisions of this standard will still apply.

## Overall Engagement Considerations

### Professional Competence

**.11** The “General Standards Rule” of the code (ET sec. 1.300.001 and 2.300.001) states that a member shall “undertake only those *professional services* that the *member* or the *member's firm* can reasonably expect to be completed with professional competence.” Performing a valuation engagement with professional competence involves special knowledge and skill. A valuation analyst should possess a level of knowledge of valuation principles and theory and a level of skill in the application of such principles that will enable him or her to identify, gather, and analyze data, consider and apply appropriate valuation approaches and methods, and use professional judgment in developing the estimate of value (whether a single amount or a range). An in-depth discussion of valuation theory and principles, and how and when to apply them, is not within the scope of this statement.

#### Author's Note

Lucky for you that even though “an in-depth discussion of valuation theory and principles, and how and when to apply them, is not within the scope of this statement,” it is covered throughout this book. Once you have read this book, you should have a much better understanding of your own level of competence to perform business valuations. Buying this book was your first step to becoming competent!

One of the most humbling experiences that we all have, as professionals, is knowing when to admit that we are really not competent to perform a particular assignment. I learned a long time ago that **CPA** does not stand for **Can Perform Anything**. There are certain types of assignments that I pass on regularly because I know that it is not in the best interest of the prospective client to have me perform the assignment because I don't have as much expertise in this area, and there may be people out there who are much more qualified to do a certain job. I also know that my malpractice carrier is much happier with me for not doing jobs that will get my firm sued.

- .12** In determining whether he or she can reasonably expect to complete the valuation engagement with professional competence, the valuation analyst should consider, at a minimum, the following:
- a. Subject entity and its industry
  - b. Subject interest
  - c. **Valuation date**
  - d. Scope of the valuation engagement
    - i. Purpose of the valuation engagement
    - ii. **Assumptions and limiting conditions** expected to apply to the valuation engagement (see paragraph .18)
    - iii. Applicable **standard of value** (for example, **fair value** or **fair market value**), and the applicable **premise of value** (for example, going concern)
    - iv. Type of valuation report to be issued (see paragraph .48), intended use and users of the report, and restrictions on the use of the report
  - e. Governmental regulations or other professional standards that apply to the subject interest or to the valuation engagement

**Author's Note**

Although many of these items seem to be common sense, valuation analysts get themselves in trouble by not truly understanding the many considerations that must enter into the process of accepting an engagement. Many of the terms that are used in the preceding section will be discussed in great detail in the next chapter, when I discuss engagement considerations. Be patient, and I will get there soon.

## Nature and Risks of the Valuation Services and Expectations of the Client

**.13** In understanding the nature and risks of the **valuation services** to be provided, and the expectations of the client, the valuation analyst should consider the matters in paragraph .12, and in addition, at a minimum, the following:

- a. The proposed terms of the valuation engagement
- b. The identity of the client
- c. The nature of the interest and ownership rights in the business, business interest, security, or intangible asset being valued, including control characteristics and the degree of **marketability** of the interest
- d. The procedural requirements of a valuation engagement and the extent, if any, to which procedures will be limited by either the client or circumstances beyond the client's or the valuation analyst's control
- e. The use of and limitations of the report, and the conclusion or calculated value
- f. Any obligation to update the valuation

## Objectivity and Conflict of Interest

**.14** The code requires objectivity in the performance of all professional services, including valuation engagements. Objectivity is a state of mind. The principle of objectivity imposes the obligation to be impartial, intellectually honest, disinterested, and free from conflicts of interest. If necessary, where a potential conflict of interest may exist, a valuation analyst should make the disclosures and obtain consent as required by the "Conflicts of Interest" interpretation (ET sec. 1.110.010 and 2.110.010) under the "Integrity and Objectivity Rule" (ET sec. 1.100.001 and 2.100.001).

**Author's Note**

I am going to address conflicts of interest in the next chapter. This is another way that valuation analysts, and more specifically, CPA valuation analysts, can get themselves in trouble.

## Independence and Valuation

**.15** If valuation services are performed for a client for which the valuation analyst or valuation analyst's firm also performs an attest engagement (defined by the "Independence Rule" of the code), the valuation analyst should meet the requirements included in the interpretations of the "Nonattest Services" subtopic (ET sec. 1.295) under the "Independence Rule" (ET sec. 1.200.001) so as not to impair the member's independence with respect to the client.

**Author's Note**

In other words, you cannot be everything to every client. The term independence is a term of art in the accounting profession. AICPA standards and state board of accountancy laws require CPAs to be independent when they perform attest services for a client. Performing a valuation for an attest client could impair the CPA's independence for the attest engagement. A CPA firm might need to decline a valuation engagement for an attest client and refer the work to someone else. Sometimes it pays to refer that client to someone else who can do a competent job so that you can continue to service the client in other areas. This is a great way to form relationships with your colleagues. You refer to them, and they will refer to you. Client sharing—what a wonderful thing!

## Establishing an Understanding With the Client

**.16** The valuation analyst should establish an understanding with the client, preferably in writing, regarding the engagement to be performed. If the understanding is oral, the valuation analyst should document that understanding by appropriate memoranda or notations in the working papers. (If the engagement is being performed for an attest client, the “General Requirements for Performing Nonattest Services” interpretation [ET sec. 1.295.040] of the “Independence Rule” [ET sec. 1.200.001] requires the engagement understanding to be in writing.) Regardless of whether the understanding is written or oral, the valuation analyst should modify the understanding if he or she encounters circumstances during the engagement that make it appropriate to modify that understanding.

### Author's Note

I have to be honest with you. You have to be nuts to perform an assignment without a written engagement letter. Although the standards allow an oral agreement, the money you save by not having your attorney draft your engagement letter should be used for your psychiatrist. Engagement letters are discussed in great detail in the next chapter.

**.17** The understanding with the client reduces the possibility that either the valuation analyst or the client may misinterpret the needs or expectations of the other party. The understanding should include, at a minimum, the nature, purpose, and objective of the valuation engagement, the client's responsibilities, the valuation analyst's responsibilities, the applicable assumptions and limiting conditions, the type of report to be issued, and the standard of value to be used.

## Assumptions and Limiting Conditions

**.18** Assumptions and limiting conditions are common to valuation engagements. Examples of typical assumptions and limiting conditions for a business valuation are provided in appendix A, “Illustrative List of Assumptions and Limiting Conditions for a Business Valuation” (par. .80). The assumptions and limiting conditions should be disclosed in the valuation report (see paragraphs .52l, .68g, and .71m).

### Author's Note

Best practices, and my attorney, say that the assumptions and limiting conditions, where appropriate, should also be part of your engagement letter to put your client on notice at the inception of the engagement. This will be discussed in more detail in the next chapter.

## Scope Restrictions or Limitations

**.19** A restriction or limitation on the scope of the valuation analyst's work, or the data available for analysis, may be present and known to the valuation analyst at the outset of the valuation engagement or may arise during the course of a valuation engagement. Such a restriction or limitation should be disclosed in the valuation report (see paragraphs .52m, .68e, and .71n).

## Using the Work of Specialists in the Engagement to Estimate Value

**.20** In performing an engagement to estimate value, the valuation analyst may rely on the work of a third party specialist (for example, a real estate or equipment appraiser). The valuation analyst should note in the assumptions and limiting conditions the level of responsibility, if any, being assumed by the valuation analyst for the work of the third party specialist. At the option of the valuation analyst, the written report of the third party specialist may be included in the valuation analyst's report.

**Author's Note**

As a valuation analyst, we are regularly faced with using other appraisers to accomplish our assignments. The standard states that using other appraisers is okay as long as we disclose the level of responsibility in the report. However, if you know that the work of the third party is wrong or does not meet professional standards, it would be foolish, and very dangerous, to try to stick your head in the sand and ignore the bad work that you will be relying upon. We had an assignment that required us to rely on a real estate appraiser to determine the underlying value of the real estate for a family limited partnership. The real estate appraisal was so bad that my partner had to tell the client's attorney that we could not use this value in our analysis. Another real estate appraiser was hired, and the job went fine thereafter. The worst that could have happened is that we would have been fired from the assignment. I would much rather have that happen than to rely on what we know is bad work.

**Development****Types of Engagement**

**.21** There are two types of engagements to estimate value—a **valuation engagement** and a **calculation engagement**. The valuation engagement requires more procedures and consideration of more information than does the calculation engagement. The valuation engagement results in a conclusion of value. The calculation engagement results in a calculated value. The type of engagement is established in the understanding with the client (see paragraphs .16 and .17):

- a. *Valuation engagement*—A valuation analyst performs a valuation engagement when (1) the engagement calls for the valuation analyst to estimate the value of a subject interest and (2) the valuation analyst estimates the value (as outlined in paragraphs .23–.45) and is free to apply the valuation approaches and methods he or she deems appropriate in the circumstances. The valuation analyst expresses the results of the valuation as a conclusion of value; the conclusion may be either a single amount or a range.
- b. *Calculation engagement*—A valuation analyst performs a calculation engagement when (1) the valuation analyst and the client agree on the valuation approaches and methods the valuation analyst will use and the extent of procedures the valuation analyst will perform in the process of calculating the value of a subject interest (these procedures will be more limited than those of a valuation engagement) and (2) the valuation analyst calculates the value in compliance with the agreement. The valuation analyst expresses the results of these procedures as a calculated value. The calculated value is expressed as a range or as a single amount. A calculation engagement does not include all of the procedures required for a valuation engagement (see paragraph .46).

**Author's Note**

Once again, you really need to apply some common sense about which type of engagement will be right for a particular circumstance. SSVS No. 1 is identifying valuation engagement and calculation engagement as terms of art, just as audit, review, and compilation are terms of art in accounting literature. Although I will discuss this in more detail in a later chapter, it is important enough for me to put it here also. On many occasions, a client does not need a comprehensive analysis; a limited analysis will suffice. The standard is flexible enough to accommodate a variety of client needs. Clients frequently suffer from sticker shock when they hear the fee for performing a valuation engagement. Therefore, they may ask for less. The valuation analyst, as the professional, must exercise good judgment to determine if performing a lesser assignment will suffice for the client's situation. The analyst should discuss this with the client. For example, the valuation analyst may be asked to quote a fee for a valuation for estate tax purposes. After hearing the fee, the client may want less, possibly a calculation engagement instead of a valuation engagement. The valuation analyst should be aware that the tax law requires an appraisal (valuation) to be done and not a calculation. The valuation analyst should advise the client that a calculation is not the proper service level required for this type of engagement.

*(Box continued)*

**Author's Note (continued)**

The valuation analyst also needs to consider how he or she and the client will come out of an assignment if less than a comprehensive analysis is done. When engaged by a client in a divorce litigation, the valuation analyst may be asked to provide calculations for mediation. If the mediation does not result in a settlement, the valuation analyst may then be asked to testify to the calculations. The one that may be hurt the most on cross-examination is the valuation analyst, when the testimony is that a comprehensive valuation analysis was not done. The judge may only hear that the valuation analyst did not do a thorough job. The fact that the client did not want to pay to have the valuation analyst perform a full valuation engagement may be forgotten, especially if the other expert did one. The valuation analyst should try to properly guide the client about the best assignment under the circumstances. If the client does not want to listen, the valuation analyst should speak with the attorney. At the end of the day, the valuation analyst should consider what is best for himself or herself and the firm and possibly turn down the assignment. The valuation analyst may also run into a problem while sitting on the witness stand, and he or she cannot provide an expert opinion (or “conclusion” as it is called in the standard) of value to a reasonable degree of certainty (the legal standard) because the valuation analyst did not perform a valuation engagement. The valuation analyst cannot provide a conclusion of value in a calculation engagement. The valuation analyst's opinion may be thrown out of court, which will lead to a very unhappy client.

## Hypothetical Conditions

**.22** Hypothetical conditions affecting the subject interest may be required in some circumstances. When a valuation analyst uses hypothetical conditions during a valuation or calculation engagement, he or she should indicate the purpose for including the hypothetical conditions and disclose these conditions in the valuation or calculation report (see paragraphs .52*n*, .71*o*, and .74).

## Valuation Engagement

**.23** In performing a valuation engagement, the valuation analyst should do the following:

- Analyze the subject interest (paragraphs .25–.30)
- Consider and apply appropriate valuation approaches and methods (paragraphs .31–.42)
- Prepare and maintain appropriate documentation (paragraphs .44–.45)

**Author's Note**

These topics are covered throughout this book. Analyzing the subject interest is covered in chapter 6. The valuation approaches and methods appear in chapters 9–12. Documentation is taught to every accountant on earth. Even if you are not an accountant, documenting your work is like motherhood and apple pie. The valuation analyst's file should contain adequate documentation (in accounting speak, we call it “sufficient relevant data”) to support the work that was done and the manner in which the valuation analyst determined the conclusion of value. The best way to avoid a problem is to make certain that the file is plastered with the appropriate documentation to support the analysis and conclusions.

**.24** Even though the list in paragraph .23 and some requirements and guidance in this statement are presented in a manner that suggests a sequential valuation process, valuations involve an ongoing process of gathering, updating, and analyzing information. Accordingly, the sequence of the requirements and guidance in this statement may be implemented differently at the option of the valuation analyst.

## Analysis of the Subject Interest

**.25** The analysis of the subject interest will assist the valuation analyst in considering, evaluating, and applying the various valuation approaches and methods to the subject interest. The nature and extent of the information needed to perform the analysis will depend on, at a minimum, the following:

- Nature of the subject interest
- Scope of the valuation engagement
- Valuation date
- Intended use of the valuation
- Applicable standard of value
- Applicable **premise of value**
- Assumptions and limiting conditions
- Applicable governmental regulations or other professional standards

**.26** In analyzing the subject interest, the valuation analyst should consider financial and nonfinancial information. The type, availability, and significance of such information vary with the subject interest.

#### Author's Note

Gathering information, both financial and nonfinancial, is discussed in several of the following chapters. Document checklists are discussed in chapter 4, gathering economic and industry information is discussed in chapter 5, gathering benchmark data is discussed in chapter 6, gathering guideline company data is discussed in chapter 9, and so forth. Notice how many times the standard tells us to “analyze” something. This does not mean buy some research and put it in a file or as an appendix to the report. This means analyze. Too many of the reports that I review are superficial when it comes to analysis. Analyze means analyze!

## Nonfinancial Information

**.27** The valuation analyst should, as available and applicable to the valuation engagement, obtain sufficient nonfinancial information to enable him or her to understand the subject entity, including the following:

- Nature, background, and history
- Facilities
- Organizational structure
- Management team (which may include officers, directors, and key employees)
- Classes of **equity** ownership interests and rights attached thereto
- Products or services, or both
- Economic environment
- Geographical markets
- Industry markets
- Key customers and suppliers
- Competition
- **Business risks**
- Strategy and future plans
- Governmental or regulatory environment

#### Author's Note

Think about this list of items that the standard suggests the valuation analyst should gather. How can the valuation analyst possibly understand anything about the subject company without this information? We will discuss this in much more detail in subsequent chapters, but this is also a pretty good time to introduce you to IRS Revenue Ruling 59-60, which also provides a discussion on factors to consider in valuing a closely held business. The nature and history of the business is the first item covered. We will discuss the revenue ruling in much greater detail. In fact, Chapter 16 includes an annotated version of this important ruling.

## Ownership Information

**.28** The valuation analyst should obtain, where applicable and available, ownership information regarding the subject interest to enable him or her to

- determine the type of ownership interest being valued and ascertain whether that interest exhibits control characteristics.
- analyze the different ownership interests of other owners and assess the potential effect on the value of the subject interest.
- understand the classes of equity ownership interests and rights attached thereto.
- understand the rights included in, or excluded from, each intangible asset.
- understand other matters that may affect the value of the subject interest, such as the following:
  - *For a business, business ownership interest, or security:* Shareholder agreements, partnership agreements, operating agreements, voting trust agreements, buy-sell agreements, loan covenants, restrictions, and other contractual obligations or restrictions affecting the owners and the subject interest.
  - *For an intangible asset:* Legal rights, licensing agreements, sublicense agreements, nondisclosure agreements, development rights, commercialization or exploitation rights, and other contractual obligations.

## Financial Information

**.29** The valuation analyst should obtain, where applicable and available, financial information on the subject entity such as the following:

- Historical financial information (including annual and interim financial statements and key financial statement ratios and statistics) for an appropriate number of years
- Prospective financial information (for example, budgets, forecasts, and projections)
- Comparative summaries of financial statements or information covering a relevant time period
- Comparative common size financial statements for the subject entity for an appropriate number of years
- Comparative common size industry financial information for a relevant time period
- Income tax returns for an appropriate number of years
- Information on compensation for owners including benefits and personal expenses
- Information on key man or officers' life insurance
- Management's response to inquiry regarding the following:
  - Advantageous or disadvantageous contracts
  - Contingent or off-balance-sheet assets or liabilities
  - Information on prior sales of company stock

### Author's Note

If you think about it, this information is a great start for a checklist of items to ask for in either the initial document request or the management interview. I will discuss these items in greater detail in the upcoming chapters. This is also a good time to introduce another important point about gathering financial information. Frequently, a valuation analyst uses the subject company's general ledger to prepare financial statements for a business valuation report, particularly when the company does not have financial statements. See the following question and answer from the AICPA Forensic and Valuation Services Executive Committee for more information:

**Q1.** If the valuation analyst uses a subject company's general ledger and prepares financial statements that will be presented as part of the business valuation report, does the valuation analyst or his/her firm have to comply with Statements on Standards for Accounting and Review Services (SSARSs), including the performance and reporting requirements for a compilation engagement with respect to those financial statements?

**A1.** Yes. Paragraph .01 of AR section 80, *Compilation of Financial Statements* states that the accountant is required to comply with the provisions of AR section 80 whenever he or she submits financial statements to a client or to third parties.

Paragraph .04 of AR section 60, *Framework for Performing and Reporting on Compilation and Review Engagements* defines submission of financial statements as "presenting to management financial statements that the accountant has prepared."<sup>3</sup>

Furthermore, SSARS No. 21, *Statements on Standards for Accounting and Review Services: Clarification and Recodification* (AICPA, *Professional Standards*), issued in October 2014, now distinguishes between an engagement to prepare client financial statements and an engagement to report on them. The engagement letter will make that determination. If the engagement letter says a CPA is being hired to prepare the financials, there is no longer an obligation to report on them. However, if the engagement letter says the CPA is retained to review or compile the financials, then there is an obligation to report on them. SSARS No. 21 is effective for financial statements ending after December 15, 2015.

This essentially means that if you are a CPA, you have to pay additional attention to other standards promulgated by the AICPA while doing business valuation assignments.

**.30** The valuation analyst should read and evaluate the information to determine that it is reasonable for the purposes of the engagement.

<sup>3</sup> AICPA, FVS News (October 5, 2011).

**Author's Note**

Although this seems to be common sense, you would be amazed at how often I have seen valuation analysts ask for a boatload of documents and never bother to look at them. The idea is to ask for relevant information for the valuation, and then review the information received to make certain that not only is it what was requested, but it is also useable. For example, in doing a valuation as of June 15, 2016, the valuation analyst may ask for an accounts receivable aging as of that date. If it is not available, the client may either send the aging for May 31, 2016, or June 30, 2016. In some cases, the schedule sent may not even be close to these time frames. The valuation analyst should review the document to make certain that it is relevant for the valuation. If June 15 data is unavailable, May 31 may be perfectly acceptable as long as the analyst inquires about any large transactions that may have occurred between June 1 and June 15. However, June 30 data may not work because, in most instances, the valuation is supposed to be based on information that is “known or knowable” as of the valuation date. Using subsequent information may be improper in many circumstances. I will discuss this point in more detail later.

## Valuation Approaches and Methods

**.31** In developing the valuation, the valuation analyst should consider the three most common valuation approaches:

- **Income (income-based) approach**
- **Asset (asset-based) approach** (used for businesses, business ownership interests, and securities) or **cost approach** (used for intangible assets)
- **Market (market-based) approach**

**Author's Note**

These are the three main approaches to business valuation. They are discussed in detail in chapters 9–12. Intangible assets are discussed in chapter 20.

**.32** The valuation analyst should use the valuation approaches and methods that are appropriate for the valuation engagement. General guidance on the use of approaches and methods appears in paragraphs .33–.41, but detailed guidance on specific valuation approaches and methods and their applicability is outside the scope of this statement.

**Author's Note**

Once again, you made the right choice by purchasing this book. Detailed guidance on specific approaches and methods and their applicability may be outside the scope of this standard, but it is included in unbelievable detail throughout this book.

**.33** *Income Approach.* Two frequently used valuation methods under the income approach include the **capitalization of benefits method** (for example, earnings or cash flows) and the **discounted future benefits method** (for example, earnings or cash flows). When applying these methods, the valuation analyst should consider a variety of factors, including but not limited to, the following:

- a. *Capitalization of benefits (for example, earnings or cash flows) method.* The valuation analyst should consider the following:
  - i. **Normalization** adjustments
  - ii. Nonrecurring revenue and expense items
  - iii. Taxes
  - iv. Capital structure and financing costs
  - v. Appropriate capital investments
  - vi. Noncash items

- vii. Qualitative judgments for risks used to compute discount and **capitalization rates**
- viii. Expected changes (growth or decline) in future benefits (for example, earnings or cash flows)
- b. *Discounted future benefits method (for example, earnings or cash flows)*. In addition to the items in item a above, the valuation analyst should consider the following:
  - i. Forecast or projection assumptions
  - ii. Forecast or projected earnings or cash flows
  - iii. **Terminal value**
- c. For an intangible asset, the valuation analyst should also consider, when relevant, the following:
  - i. Remaining useful life
  - ii. Current and anticipated future use of the intangible asset
  - iii. Rights attributable to the intangible asset
  - iv. Position of intangible asset in its life cycle
  - v. Appropriate discount rate for the intangible asset
  - vi. Appropriate **capital or contributory asset charge**, if any
  - vii. Research and development or marketing expense needed to support the intangible asset in its existing state
  - viii. Allocation of income (for example, **incremental income**, **residual income**, or **profit split income**) to intangible asset
  - ix. Whether any tax amortization benefit would be included in the analysis
  - x. Discounted multi-year excess earnings
  - xi. Market royalties
  - xii. Relief from royalty

#### Author's Note

The income approach, and its related methods, is covered in chapter 12. Discount rates and capitalization rates are covered in chapter 13. Although intangible assets are covered in chapter 20, this book is not really intended to cover this group of assets in as much detail as it deserves. This could be the subject of another entire book. In fact, there are books dedicated solely to intangible assets and intellectual property. Five of the books<sup>4</sup> in my library include *Guide to Intangible Asset Valuation*, *Intellectual Property: Valuation, Exploitation, and Infringement Damages*, *Valuing Intangible Assets*, *Valuation for Financial Reporting*, *Fair Value Measurements and Reporting*, *Intangible Assets, Goodwill and Impairments*, and *Fair Value Measurements: Practical Guidance and Implementation*.

## Asset Approach and Cost Approach

**.34** A frequently used method under the asset approach is the adjusted net asset method. When using the adjusted net asset method in valuing a business, business ownership interest, or security, the valuation analyst should consider, as appropriate, the following information related to the premise of value:

- Identification of the assets and liabilities
- Value of the assets and liabilities (individually or in the aggregate)
- Liquidation costs (if applicable)

#### Author's Note

The asset-based approach is covered in chapter 11. Identification of assets, valuation, and liquidation methods are discussed in detail.

4 See the bibliography included in appendix 15 for the complete references for these publications.

**.35** When using methods under the cost approach to value intangible assets, the valuation analyst should consider the type of cost to be used (for example, reproduction cost or replacement cost), and, where applicable, the appropriate forms of depreciation and obsolescence and the remaining useful life of the intangible asset.

#### Author's Note

Terms such as reproduction cost and replacement cost will be defined by me in the appropriate chapter. Be patient, and we will get there eventually.

## Market Approach

**.36** Three frequently used valuation methods under the market approach for valuing a business, business ownership interest, or security are as follows:

- **Guideline public company method**
- **Guideline company transactions method**
- Guideline sales of interests in the subject entity, such as business ownership interests or securities

Three frequently used market approach valuation methods for intangible assets are as follows:

- Comparable uncontrolled transactions method (which is based on arm's-length sales or licenses of guideline intangible assets)
- Comparable profit margin method (which is based on comparison of the profit margin earned by the subject entity that owns or operates the intangible asset to profit margins earned by guideline companies)
- **Relief from royalty method** (which is based on the royalty rate, often expressed as a percentage of revenue that the subject entity that owns or operates the intangible asset would be obligated to pay to a hypothetical third-party licensor for the use of that intangible asset).

For the methods involving guideline intangible assets (for example, the comparable profit margin method), the valuation analyst should consider the subject intangible asset's remaining useful life relative to the remaining useful life of the guideline intangible assets, if available.

**.37** In applying the methods listed in paragraph .36 or other methods to determine valuation pricing multiples or metrics, the valuation analyst should consider the following:

- Qualitative and quantitative comparisons
- Arm's-length transactions and prices
- The dates and, consequently, the relevance of the market data

#### Author's Note

Not sure what this means? Don't worry, neither do I. All kidding aside, these items will all be discussed in chapters 9 and 10 (and possibly elsewhere).

**.38** The valuation analyst should set forth in the report the rationale and support for the valuation methods used (see paragraph .47).

**.39 Rules of Thumb.** Although technically not a valuation method, some valuation analysts use rules of thumb or industry benchmark indicators (hereinafter, collectively referred to as **rules of thumb**) in a valuation engagement. A rule of thumb is typically a reasonableness check against other methods used and should generally not be used as the only method to estimate the value of the subject interest.

**Author's Note**

I am going to state this again later, but rules of thumb are so badly misused that I am going to state it here also. A rule of thumb is nothing more than a sanity check for the many hours that the valuation analyst will spend performing a valuation assignment. It should never, and I mean never, be used as a standalone method of valuation. Depending on whom you speak with, many businesses have multiple rules of thumb. For example, the older versions of the *Business Reference Guide*<sup>5</sup> listed as many as 31 different rules of thumb for restaurants, based on the type of restaurant, and that excludes franchise operations. Even the authors realized that it was silly to have so many rules of thumb for the same category. Now, they just list every different franchise restaurant and type so that the reader does not see 31 different rules of thumb in the same place.

**Valuation Adjustments**

**.40** During the course of a valuation engagement, the valuation analyst should consider whether valuation adjustments (discounts or premiums) should be made to a **pre-adjustment** value. Examples of valuation adjustments for valuation of a business, business ownership interest, or security include a **discount for lack of marketability or liquidity** and a **discount for lack of control**. An example of a valuation adjustment for valuation of an intangible asset is obsolescence.

**Author's Note**

Valuation adjustments (premiums and discounts) are discussed in chapters 14 and 15.

**.41** When valuing a controlling ownership interest under the income approach, the value of any **non-operating assets**, non-operating liabilities, or **excess or deficient operating assets** should be excluded from the computation of the value based on the operating assets and should be added to or deleted from the value of the operating entity. When valuing a non-controlling ownership interest under the income approach, the value of any non-operating assets, non-operating liabilities, or excess or deficient operating assets may or may not be used to adjust the value of the operating entity depending on the valuation analyst's assessment of the influence exercisable by the non-controlling interest. In the asset-based or cost approach, it may not be necessary to separately consider non-operating assets, non-operating liabilities, or excess or deficient operating assets.

**Author's Note**

Topics such as controlling or non-controlling ownership interests, non-operating assets and liabilities, as well as excess or deficient operating assets are also discussed in this book. These topics will make much more sense once you have had the opportunity to read about them.

**Conclusion of Value**

**.42** In arriving at a conclusion of value, the valuation analyst should

- a. correlate and reconcile the results obtained under the different approaches and methods used.
- b. assess the reliability of the results under the different approaches and methods using the information gathered during the valuation engagement.
- c. determine, based on items *a* and *b*, whether the conclusion of value should reflect
  - i. the results of one valuation approach and method, or
  - ii. a combination of the results of more than one valuation approach and method.

**Subsequent Events**

**.43** The valuation date is the specific date at which the valuation analyst estimates the value of the subject interest and concludes on his or her estimation of value. Generally, the valuation analyst should consider only circumstances existing at the valuation date and events occurring up to the valuation date. An event

<sup>5</sup> See the bibliography included in appendix 18 for the complete reference for this publication.

that could affect the value may occur subsequent to the valuation date; such an occurrence is referred to as a **subsequent event**. Subsequent events are indicative of conditions that were not known or knowable at the valuation date, including conditions that arose subsequent to the valuation date. The valuation would not be updated to reflect those events or conditions. Moreover, the valuation report would typically not include a discussion of those events or conditions because a valuation is performed as of a point in time—the valuation date—and the events described in this subparagraph, occurring subsequent to that date, are not relevant to the value determined as of that date. In situations in which a valuation is meaningful to the intended user beyond the valuation date, the events may be of such nature and significance as to warrant disclosure (at the option of the valuation analyst) in a separate section of the report in order to keep users informed (see paragraphs .52*p*, .71*r*, and .74). Such disclosure should clearly indicate that information regarding the events is provided for informational purposes only and does not affect the determination of value as of the specified valuation date.

#### Author's Note

This gets back to the concept of using information that is “known or knowable.” The standard is saying that it is okay to disclose this item, but it should not affect your value conclusion. For example, I once valued a bicycle shop for a divorce as of December 31, 1997. On January 3, 1998, there was a fire that destroyed the business. Because a fire was not known or knowable on December 31, 1997, it would not have affected my valuation. However, if I was representing a prospective purchaser of the business, wouldn't common sense dictate that I disclose to my client the fact that the business burned down? Even in a divorce, wouldn't the judge who has to determine equitable distribution want to know that an asset has been destroyed? This is an instance in which a subsequent event needs to be disclosed. By the way, in this situation, the spouse of the business owner torched the place, was convicted of arson, and my client received the full value of the bicycle shop in equitable distribution as of December 31, 1997. The insurance proceeds were sufficient to restore and probably increase the value of the shop. But with that said, sometimes subsequent information is used to corroborate value indications that should have been “known or knowable” as of the valuation date. The subsequent information is merely confirming the fact that value existed at the valuation date. USPAP Frequently Asked Question 142 states the following regarding retrospective value opinions:

A retrospective appraisal is complicated by the fact that the appraiser already knows what occurred in the market after the effective date of the appraisal. Data subsequent to the effective date may be considered in developing a retrospective value as a confirmation of trends that would reasonably be considered by a buyer or seller as of that date... [emphasis added].<sup>6</sup>

Various other valuation treatises discuss the use of subsequent data, as well. Box 1 contains excerpts from these publications. Box 2 contains a list of relevant court cases that should also be considered.

#### BOX 1

#### Excerpts From Various Treatises About Subsequent Events

- David Laro and Shannon P. Pratt, *Business Valuation and Taxes: Procedure, Law and Perspective*, 2nd ed. (Hoboken, NJ: John Wiley & Sons, Inc., 2011): 27.
  - “Subsequent events are used as evidence of value rather than as factors affecting value.”
- Jay E. Fishman, Shannon P. Pratt, and William J. Morrison, *Standards of Value: Theory and Applications* (Hoboken, NJ: John Wiley & Sons, Inc., 2013): 65.
  - “Subsequent events that were foreseeable at the valuation date may be considered in a valuation.”
- Shannon Pratt and Alina V. Niculita, *The Lawyer's Business Valuation Handbook: Understanding Financial Statements, Appraisal Reports and Expert Testimony*, 2nd ed. (Chicago: American Bar Association, 2010): 280.
  - “Readers should be put on notice that the Tax Court frequently relies on subsequent sales as evidence of value. The court distinguishes between subsequent sales that affected the value and those that are merely evidence of value.”
- James R. Hitchner, *Financial Valuation: Applications and Models*, 3rd ed. (Hoboken, NJ: John Wiley & Sons, Inc., 2011): 41.
  - “...events that are reasonably foreseeable at the date of valuation should be considered.”

See appendix 15 for a complete bibliography.

## Author's Note

**BOX 2** Court Cases Addressing Subsequent Events *(continued)*

Date	Jurisdiction	Refers to Case(s)	Reference to Use of Subsequent Information
1956	United States Court of Appeals, Eighth Circuit	FITTS' Estate v. Commissioner, 237 F.2d 729 (8th Cir. 1956)	It was determined in this case that actual sales made in reasonable amounts in arm's-length transactions, in the normal course of business, within a reasonable time frame after or before the date of value, are the best criteria of market value.
1975	United States Supreme Court	LOWE v. Commissioner (4236 U.S. 827 (1975))	Sales after the valuation date "may be used to corroborate the ultimate determination of value."
1983	United States Tax Court	Estate of JEPHSO v. Commissioner (81 TCM 999)	The tax court ruled that "...subsequent events may be considered for the limited purpose of substantiating reasonable expectations." (emphasis added)
1987	United States Tax Court	Estate of Saul R. GILFORD (88 TCM 38)	In this case, the price of decedent's stock was determined by the price it was sold for in a merger six months after the date of death.
1992	United States Tax Court	Estate of Bessie I. MUELLER (63 TCM (CCH) 3027)	In this case, subsequent events, which occurred 67 days after the date of death, were admissible by the tax court and allowed to set the value of the shares of stock in question at the date of death on the premise that merger negotiations were initiated prior to the date of death.
1993	United States Tax Court	Estate of JUNG v. Commissioner (101 TCM 412 (1993))	A common argument as evidenced by this case is that a subsequent sale does not affect the value on an earlier valuation date; rather, it is evidence to that value.
1995	United States Federal District Court, Seventh Circuit	The FIRST NATIONAL BANK OF KENOSHA v. U.S. (763 F.2d 891)	In this case, the estate had been approached 15 months after the valuation date about a purchase of the property. The court allowed the postmortem event into evidence, thus, affecting the jury's determination of value.
1996	United States Tax Court	Estate of Arthur G. SCANLAN v. Commissioner (TCM 1996-331 (July 25, 1996))	Decedent died in July 1991. The court relied on an offer to buy the entire company in March 1993 (resulting in a sale consummated in January 1994) and discounted the sale price by 30 percent to account for both a marketability and a minority discount, as well as the change in setting from the date of the decedent's death.

*(Box continued)*

Author's Note (continued)

**BOX 2** Court Cases Addressing Subsequent Events (continued)

Date	Jurisdiction	Refers to Case(s)	Reference to Use of Subsequent Information
1997	United States Tax Court	Nathan and Geraldine MORTON v. Commissioner (TCM 1997-166 (April 1, 1997))	The tax court stated "...Subsequent events which merely provide evidence of the value of the property on the valuation date can be taken into account regardless of whether they are foreseeable on the valuation date."
1997	U.S. Court of Appeals, First District	Ansin et. al. v. River Oaks Furniture, Inc., et al.	Anticipated IPO considered in determining fair value.
1999	New Jersey Supreme Court	Lawson Mardon Wheaton, Inc. v. Smith (II)	Merger price in 1996 was considered in the determination of the fair value of the dissenters stock on December 5, 1991.
2005	United States Tax Court	Estate of Helen M. Noble, et al. v. Commissioner (TCM 2005-2 (2005))	IRS's estate tax valuation of decedent's stock interest in closely held bank based on post-death outside sale price was upheld, as adjusted for inflation: post-death sale, occurring a little over one year after death, was sufficiently contemporaneous and most relevant transaction for evaluating stock's price because that sale involved decedent's actual interest and was effected in arm's length transaction, whereas pre-death transfers involved relatively small number of shares and were sold at prices well below appraised value.

## Documentation

**.44** Documentation is the principal record of information obtained and analyzed, procedures performed, valuation approaches and methods considered and used, and the conclusion of value. The quantity, type, and content of documentation are matters of the valuation analyst's professional judgment. Documentation may include the following:

- Information gathered and analyzed to obtain an understanding of matters that may affect the value of the subject interest (paragraphs .25–.30)
- Assumptions and limiting conditions (paragraph .18)
- Any restriction or limitation on the scope of the valuation analyst's work or the data available for analysis (paragraph .19)
- Basis for using any **valuation assumption** during the valuation engagement
- Valuation approaches and methods considered
- Valuation approaches and methods used including the rationale and support for their use

- If applicable, information relating to subsequent events considered by the valuation analyst (paragraph .43)
  - For any rule of thumb used in the valuation, source(s) of data used, and how the rule of thumb was applied (paragraph .39)
  - Other documentation considered relevant to the engagement by the valuation analyst
- .45** The valuation analyst should retain the documentation for a period of time sufficient to meet the needs of applicable legal, regulatory, or other professional requirements for records retention.

## Calculation Engagement

**.46** In performing a calculation engagement, the valuation analyst should consider, at a minimum, the following:

- a. Identity of the client
- b. Identity of the subject interest
- c. Whether or not a business interest has ownership control characteristics and its degree of marketability
- d. Purpose and intended use of the calculated value
- e. Intended users of the report and the limitations on its use
- f. Valuation date
- g. Applicable premise of value
- h. Applicable standard of value
- i. Sources of information used in the calculation engagement
- j. Valuation approaches or valuation methods agreed upon with the client
- k. Subsequent events, if applicable (paragraph .43)

In addition, the valuation analyst should comply with the documentation requirements listed in paragraphs .44 and .45. The quantity, type, and content of documentation are matters of the valuation analyst's professional judgment.

### Author's Note

I have said it before, and I will say it again—the valuation analyst needs to make sure that the client does not influence him or her to provide a calculation engagement in which a valuation engagement is required. The client wants cheap! If the analyst is required to provide a conclusion of value (as in a court of law, also known as an “expert opinion” to a reasonable degree of certainty), he or she cannot get away with a calculation engagement. This does not rise to the level of allowing the analyst to provide a conclusion of value. If the client cannot afford the fees for a valuation engagement, he will find a lawyer on a contingent fee basis to sue the analyst for malpractice when the court rejects his or her opinion. It is not worth the analyst trying to save the client a few dollars while putting his or her reputation on the line.

## The Valuation Report

**.47** A valuation report is a written or oral communication to the client containing the conclusion of value or the calculated value of the subject interest. Reports issued for purposes of certain controversy proceedings are exempt from this reporting standard (see paragraph .50).

**.48** The three types of written reports that a valuation analyst may use to communicate the results of an engagement to estimate value are as follows: either a detailed report or a summary report for a valuation engagement and a calculation report for a calculation engagement:

- a. *Valuation engagement—detailed report.* This report may be used only to communicate the results of a valuation engagement (conclusion of value); it should not be used to communicate the results of a calculation engagement (calculated value) (paragraph .51).
- b. *Valuation engagement—summary report.* This report may be used only to communicate the results of a valuation engagement (conclusion of value); it should not be used to communicate the results of a calculation engagement (calculated value) (paragraph .71). For a valuation engagement, the determination of whether to prepare a detailed report or a summary report is based on the level of reporting detail agreed to by the valuation analyst and the client.

c. *Calculation engagement—calculation report.* This type of report should be used only to communicate the results of a calculation engagement (calculated value); it should not be used to communicate the results of a valuation engagement (conclusion of value) (see paragraph .73).

**.49** The valuation analyst should indicate in the valuation report the restrictions on the use of the report (which may include restrictions on the users of the report, the uses of the report by such users, or both) (paragraph .65d).

#### Author's Note

The detailed report, referred to previously, is a more formal or comprehensive report than the summary report. Over the years, detailed reports have been called formal, comprehensive, self-contained, and who knows what else depending on the set of standards or the textbook that you were looking at. Regardless of what it is called, the detailed report is detailed. It should contain what an uninformed user of the report needs to know and explain it clearly. Paragraph .51 of SSVS No. 1, as well as chapter 17 of this book, describes what should be included in a detailed report. A sample detailed report is included in the downloadable ancillary material.

A summary report has less detail than a detailed report. Previously, you may have seen this also called a “letter report” or an “informal report.” A sample summary report is also provided in the ancillaries. Someone once asked me what the difference was between a detailed report and a summary report. My response was about \$3,000. All kidding aside, the difference is the amount of time it might take to write a 100-page report versus a 15-page report. You still must do all the work required to provide a supportable conclusion of value. It is only the document that changes.

A calculation report has also been included in the ancillaries. With all three reports being included, you really got your money's worth for this book!

## Reporting Exemption for Certain Controversy Proceedings

**.50** A valuation performed for a matter before a court, an arbitrator, a mediator or other facilitator, or a matter in a governmental or administrative proceeding, is exempt from the reporting provisions of this statement. The reporting exemption applies whether the matter proceeds to trial or settles. The exemption applies only to the reporting provisions of this statement (see paragraphs .47–.49 and .51–.78). The developmental provisions of the statement (see paragraphs .21–.46) still apply whenever the valuation analyst expresses a conclusion of value or a calculated value (Interpretation No. 1 [VS sec. 9100 par. .01–.89]).

#### Author's Note

This is an important paragraph. What it basically states is that if the valuation analyst is doing the job as part of a litigation, arbitration, mediation, or the like, the reporting requirements of this standard do not have to be followed. This means that because the valuation analyst may be subject to testimony, including cross-examination, the analyst and the client's attorney must determine how much (or how little) to put into a report, if you do a report at all. Be aware, however, that there are certain rules, such as Rule 26 of the Rules of Federal Civil Procedure that might require certain inclusions in the report. Also, reports that are to be used in the U.S. Tax Court become your direct testimony. Therefore, if it is not in the report, the court will not consider it. The valuation analyst does not get a second bite of the apple if it was left out of the report. Despite the type of report, the valuation analyst still must follow all of the developmental provisions of the standard. Essentially, the valuation analyst still must do the proper job. The valuation analyst should make sure that the client's attorney is consulted regarding how much detail should be in the report. This is not a judgment call that a valuation analyst should make without input from legal counsel.

## Detailed Report

**.51** The *detailed report* is structured to provide sufficient information to permit intended users to understand the data, reasoning, and analyses underlying the valuation analyst's conclusion of value. A detailed report should include, as applicable, the following sections titled using wording similar in content to that shown:

- Letter of transmittal
- Table of contents
- Introduction

- Sources of information
- Analysis of the subject entity and related nonfinancial information
- Financial statement or financial information analysis
- Valuation approaches and methods considered
- Valuation approaches and methods used
- Valuation adjustments
- Non-operating assets, non-operating liabilities, and excess or deficient operating assets (if any)
- Representation of the valuation analyst
- Reconciliation of estimates and conclusion of value
- Qualifications of the valuation analyst
- Appendixes and exhibits

The report sections previously listed and the detailed information within the sections described in the following paragraphs .52–.77 may be positioned in the body of the report or elsewhere in the report at the discretion of the valuation analyst.

## Introduction

**.52** This section should provide an overall description of the valuation engagement. The information in the section should be sufficient to enable the intended user of the report to understand the nature and scope of the valuation engagement, as well as the work performed. The introduction section may include, among other things, the following information:

- a. Identity of the client
- b. Purpose and intended use of the valuation
- c. Intended users of the valuation
- d. Identity of the subject entity
- e. Description of the subject interest
- f. Whether the business interest has ownership control characteristics and its degree of marketability
- g. Valuation date
- h. Report date
- i. Type of report issued (namely, a detailed report) (paragraph .51)
- j. Applicable premise of value
- k. Applicable standard of value
- l. Assumptions and limiting conditions (alternatively, these often appear in an appendix) (paragraph .18)
- m. Any restrictions or limitations in the scope of work or data available for analysis (paragraph .19)
- n. Any hypothetical conditions used in the valuation engagement, including the basis for their use (paragraph .22)
- o. If the work of a specialist was used in the valuation engagement, a description of how the specialist's work was relied upon (paragraph .20)
- p. Disclosure of subsequent events in certain circumstances (paragraph .43)
- q. Any application of the jurisdictional exception (paragraph .10)
- r. Any additional information the valuation analyst deems useful to enable the user(s) of the report to understand the work performed

If the items previously listed are not included in the introduction, they should be included elsewhere in the valuation report.

### Author's Note

Keep in mind that this list is not meant to be all inclusive, and the order is flexible and at the discretion of the valuation analyst.

## Sources of Information

**.53** This section of the report should identify the relevant sources of information used in performing the valuation engagement. It may include, among other things, the following:

- a. For valuation of a business, business ownership interest, or security, whether and to what extent the subject entity's facilities were visited

- b. For valuation of an intangible asset, whether the legal registration, contractual documentation, or other tangible evidence of the asset was inspected
- c. Names, positions, and titles of persons interviewed and their relationships to the subject interest
- d. Financial information (paragraphs .54 and .56)
- e. Tax information (paragraph .55)
- f. Industry data
- g. Market data
- h. Economic data
- i. Other empirical information
- j. Relevant documents and other sources of information provided by or related to the entity

**.54** If the financial information includes financial statements that were reported on (audit, review, compilation, or attest engagement performed under the Statements on Standards for Attestation Engagements [SSAEs] [AT section 20–701]) by the valuation analyst’s firm, the valuation report should disclose this fact and the type of report issued. If the valuation analyst or the valuation analyst’s firm did not audit, review, compile, or attest under the SSAEs (AT sec. 20–701) to the financial information, the valuation analyst should so state and should also state that the valuation analyst assumes no responsibility for the financial information.

#### Author’s Note

The vast majority of valuations that are performed will generally include a limiting condition in the report that the financial statements were accepted, without independent verification and are being accepted as is. This is especially important for CPAs because many clients will use “CPA” and “auditor” as being synonymous. The valuation analyst wants to make sure that the reader of the report is very clear on what was and was not done as part of the assignment.

**.55** The financial information may be derived from, or may include information derived from, tax returns. With regard to such derived information and other tax information (see paragraph .53e), the valuation analyst should identify the tax returns used and any existing relationship between the valuation analyst and the tax preparer. If the valuation analyst or the valuation analyst’s firm did not audit, review, compile, or attest under the SSAEs (AT section 20–701) to any financial information derived from tax returns that is used during the valuation engagement, the valuation analyst should so state and should also state that the valuation analyst assumes no responsibility for that derived information.

#### Author’s Note

According to the Forensic and Valuation Services Executive Committee, using tax returns to present comparative financial information in a valuation assignment does not fall under the same rules that I discussed before regarding using general ledgers. Also, do not forget about SSARS No. 21. A report is not necessary if the information comes from tax returns. It is still considered to be a “best practice” to have a limiting condition stating that you are accepting the information without independent verification, list the source of the financial data as being from the tax returns, and that it is being presented only in the context of the business valuation report.

**.56** If the financial information used was derived from financial statements prepared by management that were not the subject of an audit, review, compilation, or attest engagement performed under the SSAEs, the valuation report should do the following:

- Identify the financial statements
- State that, as part of the valuation engagement, the valuation analyst did not audit, review, compile, or attest under the SSAEs (AT sec. 20–710) to the financial information and assumes no responsibility for that information

## Analysis of the Subject Entity and Related Nonfinancial Information

**.57** The valuation analyst should include a description of the relevant nonfinancial information listed and discussed in paragraph .27.

## Financial Statement or Financial Information Analysis

**.58** This section should include a description of the relevant information listed in paragraph .29. Such description may include the following:

- a. The rationale underlying any normalization or **control adjustments** to financial information
- b. Comparison of current performance with historical performance
- c. Comparison of performance with industry trends and norms, where available

## Valuation Approaches and Methods Considered

**.59** This section should state that the valuation analyst has considered the valuation approaches discussed in paragraph .31.

## Valuation Approaches and Methods Used

**.60** In this section, the valuation analyst should identify the valuation methods used under each valuation approach and the rationale for their use.

**.61** This section should also identify the following for each of the three approaches (if used):

- a. Income approach:
  - Composition of the representative benefit stream
  - Method(s) used, and a summary of the most relevant risk factors considered in selecting the appropriate **discount rate**, the capitalization rate, or both
  - Other factors as discussed in paragraph .33
- b. Asset-based approach or cost approach:
  - *Asset-based approach*: Any adjustments made by the valuation analyst to the relevant balance sheet data
  - *Cost approach*: The type of cost used, how this cost was estimated, and, if applicable, the forms of and costs associated with depreciation and obsolescence used under the approach and how those costs were estimated
- c. Market approach:
  - For the guideline public company method:
    - The selected guideline companies and the process used in their selection
    - The pricing multiples used, how they were used, and the rationale for their selection. If the pricing multiples were adjusted, the rationale for such adjustments
  - For the guideline company transactions method, the sales transactions and pricing multiples used, how they were used, and the rationale for their selection; if the pricing multiples were adjusted, the rationale for such adjustments
  - For the guideline sales of interests in the subject entity method, the sales transactions used, how they were used, and the rationale for determining that these sales are representative of arm's length transactions

**.62** When a rule of thumb is used in combination with other methods, the valuation report should disclose the source(s) of data used and how the rule of thumb was applied (see paragraph .39).

## Valuation Adjustments

**.63** This section should (a) identify each valuation adjustment considered and determined to be applicable, for example, discount for lack of marketability, (b) describe the rationale for using the adjustment and the factors considered in selecting the amount or percentage used, and (c) describe the pre-adjustment value to which the adjustment was applied (see paragraph .40).

## Non-Operating Assets and Excess Operating Assets

**.64** When the subject interest is a business, business ownership interest, or security, the valuation report should identify any related non-operating assets, non-operating liabilities, or excess or deficient operating assets and their effect on the valuation (see paragraph .41).

## Representation of the Valuation Analyst

**.65** Each written report should contain the representation of the valuation analyst. The representation is the section of the report wherein the valuation analyst summarizes the factors that guided his or her work during the engagement. Examples of these factors include the following:

- a. The analyses, opinions, and conclusion of value included in the valuation report are subject to the specified assumptions and limiting conditions (see paragraph .18), and they are the personal analyses, opinions, and conclusion of value of the valuation analyst.
- b. The economic and industry data included in the valuation report have been obtained from various printed or electronic reference sources that the valuation analyst believes to be reliable (any exceptions should be noted). The valuation analyst has not performed any corroborating procedures to substantiate that data.
- c. The valuation engagement was performed in accordance with the American Institute of Certified Public Accountants Statement on Standards for Valuation Services.
- d. The parties for which the information and use of the valuation report is restricted are identified; the valuation report is not intended to be and should not be used by anyone other than such parties (see paragraph .49).
- e. The analyst's compensation is fee-based or is contingent on the outcome of the valuation.
- f. The valuation analyst used the work of one or more outside specialists to assist during the valuation engagement. (An outside specialist is a specialist other than those employed in the valuation analyst's firm.) If the work of such a specialist was used, the specialist should be identified. The valuation report should include a statement identifying the level of responsibility, if any, the valuation analyst is assuming for the specialist's work.
- g. The valuation analyst has no obligation to update the report or the opinion of value for information that comes to his or her attention after the date of the report.
- h. The valuation analyst and the person(s) assuming responsibility for the valuation should sign the representation in their own name(s). The names of those providing significant professional assistance should be identified.

### Author's Note

Under the various other sets of standards, this section is frequently called "appraiser's certification." The accounting profession does not like the word "certification" because the reader may get confused because the auditor certifies financial statements. Certify and certification are terms of art in the accounting profession, so the AICPA valuation standard avoids these terms. Therefore, it is called a "representation." If it looks like a duck, quacks like a duck. . . . Just be clear that you did not do an audit or even appear to do an audit.

## Representations Regarding Information Provided to the Valuation Analyst

**.66** It may be appropriate for the valuation analyst to obtain written representations regarding information that the subject entity's management provides to the valuation analyst for purposes of his or her performing the valuation engagement. The decision whether to obtain a representation letter is a matter of judgment for the valuation analyst.

**Author's Note**

Representation letters are considered to be risk management tools within the accounting profession. However, although I am clearly risk adverse, I do not like to get representation letters when I perform valuation services because I believe that it is a procedure that is covered under the attestation standards. I do not want anyone to misconstrue the service that I am providing to look like an audit or review. However, there are many CPAs who feel more comfortable getting a representation letter from the client. This is clearly a professional preference. Many of my friends think that I am nuts. Maybe I am, but that does not change the way I feel. For those accountants who are reading this book with a few gray hairs, like me, I used to work for Max Rothenberg & Company CPAs (look up in your old auditing textbook the matter referred to as 1136 Tenants Cooperative v. Max Rothenberg & Company CPAs). That firm got clobbered in a malpractice suit for providing services that appeared to be an audit even though the firm was not engaged to do an audit. My general feeling is that if the client does not give me good information, the end result will be a bad valuation. I will be covering myself with documentation, memos to the file, and, where appropriate, sending sections of my report (for example, history of the business) to the client to verify the accuracy. Do what you believe is right for your circumstances. Don't just follow what I say because I said it.

**Qualifications of the Valuation Analyst**

**.67** The report should contain information regarding the qualifications of the valuation analyst.

**Author's Note**

This is the part of the report where you get to tell the reader how great you are. Just be careful not to exaggerate your experience or credentials. Let the reader know that you are qualified, but puffery is both unethical and likely to get you sued. If you received a credential in business valuation from one of the organizations that I discussed in the last chapter, congratulations! However, if you do not have a lot of experience performing business valuation assignments, be careful not to make your client think that you are very experienced. If the assignment ends up with you being on the wrong side of a malpractice verdict, you will probably be held to a higher standard because you are credentialed. There are several organizations that credential people with little to no experience. All the people have to do is show up to a course. If you are one of those folks, be careful.

**Conclusion of Value**

**.68** This section should present a reconciliation of the valuation analyst's estimate or various estimates of the value of the subject interest. In addition to a discussion of the rationale underlying the conclusion of value, this section should include the following or similar statements:

- a. A valuation engagement was performed, including the subject interest and the valuation date.
- b. The analysis was performed solely for the purpose described in this report, and the resulting estimate of value should not be used for any other purpose.
- c. The valuation engagement was conducted in accordance with the Statement(s) on Standards for Valuation Services of the American Institute of Certified Public Accountants.
- d. A statement that the estimate of value resulting from a valuation engagement is expressed as a conclusion of value.
- e. The scope of work or data available for analysis is explained, including any restrictions or limitations (see paragraph .19).
- f. A statement describing the conclusion of value, either a single amount or a range.
- g. The conclusion of value is subject to the assumptions and limiting conditions (see paragraph .18) and to the valuation analyst's representation (see paragraph .65).
- h. The report is signed in the name of the valuation analyst or the valuation analyst's firm.
- i. The date of the valuation report is included.
- j. The valuation analyst has no obligation to update the report or the conclusion of value for information that comes to his or her attention after the date of the report.

**Author's Note**

What is important to remember about this section of the standard is that we are being provided with the information that should be contained in a good valuation report. The task force that wrote this standard really bent over backwards to provide all of us with guidance in this document, eliminating much of the guess work regarding what are the true meanings behind the standard. They are not telling us that we must make our reports look like cookie cutters, but, rather, that each valuation report must contain an appropriate level of information to allow the intended reader to understand not only what the valuation analysis is all about but also what steps we perform in rendering our services.

**.69** The following is an example of report language that could be used, but is not required, when reporting the results of a valuation engagement:

We have performed a *valuation engagement*, as that term is defined in the Statement on Standards for Valuation Services (SSVS) of the American Institute of Certified Public Accountants, of [DEF Company, GHI business ownership interest of DEF Company, GHI security of DEF Company, or GHI intangible asset of DEF Company] as of [valuation date]. This valuation was performed solely to assist in the matter of [purpose of the valuation]; the resulting estimate of value should not be used for any other purpose or by any other party for any purpose. This valuation engagement was conducted in accordance with the SSVS. The estimate of value that results from a valuation engagement is expressed as a conclusion of value.

[If applicable] We were restricted or limited in the scope of our work or data available for analysis as follows: [describe restrictions or limitations].

Based on our analysis, as described in this valuation report, the estimate of value of [DEF Company, GHI business ownership interest of DEF Company, GHI security of DEF Company, or GHI intangible asset of DEF Company] as of [valuation date] was [value, either a single amount or a range]. This conclusion is subject to the Statement of Assumptions and Limiting Conditions found in [reference to applicable section of valuation report] and to the Valuation Analyst's Representation found in [reference to applicable section of valuation report]. We have no obligation to update this report or our conclusion of value for information that comes to our attention after the date of this report.

[Date]

## Appendixes and Exhibits

**.70** Appendixes or exhibits may be used for required information or information that supplements the detailed report. Often, the assumptions and limiting conditions and the valuation analyst's representation are provided in appendixes to the detailed report.

## Summary Report

**.71** A summary report is structured to provide an abridged version of the information that would be provided in a detailed report, and therefore, need not contain the same level of detail as a detailed report. However, a summary report should, at a minimum, include the following:

- a. Identity of the client
- b. Purpose and intended use of the valuation
- c. Intended users of the valuation
- d. Identity of the subject entity
- e. Description of the subject interest
- f. The business interest's ownership control characteristics, if any, and its degree of marketability
- g. Valuation date
- h. Valuation report date

- i.* Type of report issued (namely, a summary report) (paragraph .48)
- j.* Applicable premise of value
- k.* Applicable standard of value
- l.* Sources of information used in the valuation engagement
- m.* Assumptions and limiting conditions of the valuation engagement (paragraph .18)
- n.* The scope of work or data available for analysis including any restrictions or limitations (paragraph .19)
- o.* Any hypothetical conditions used in the valuation engagement, including the basis for their use (paragraph .22)
- p.* If the work of a specialist was used in the valuation (paragraph .20), a description of how the specialist's work was used, and the level of responsibility, if any, the valuation analyst is assuming for the specialist's work
- q.* The valuation approaches and methods used
- r.* Disclosure of subsequent events in certain circumstances (paragraph .43)
- s.* Any application of the jurisdictional exception (paragraph .10)
- t.* Representation of the valuation analyst (paragraph .65)
- u.* The report is signed in the name of the valuation analyst or the valuation analyst's firm
- v.* A section summarizing the reconciliation of the estimates and the conclusion of value as discussed in paragraphs .68 and .69
- w.* A statement that the valuation analyst has no obligation to update the report or the calculation of value for information that comes to his or her attention after the date of the valuation report

**.72** Appendixes or exhibits may be used for required information (see paragraph .70) or information that supplements the summary report. Often, the assumptions, limiting conditions, and the valuation analyst's representation are provided in appendixes to the summary report.

## Calculation Report

**.73** As indicated in paragraph .48, a calculation report is the only report that should be used to report the results of a calculation engagement. The report should state that it is a calculation report. The calculation report should include the representation of the valuation analyst similar to that in paragraph .65, but adapted for a calculation engagement.

**.74** The calculation report should identify any hypothetical conditions used in the calculation engagement, including the basis for their use (paragraph .22), any application of the jurisdictional exception (paragraph .10), and any assumptions and limiting conditions applicable to the engagement (paragraph .18). If the valuation analyst used the work of a specialist (paragraph .20), the valuation analyst should describe in the calculation report how the specialist's work was used and the level of responsibility, if any, the valuation analyst is assuming for the specialist's work. The calculation report may also include a disclosure of subsequent events in certain circumstances (paragraph .43).

**.75** Appendixes or exhibits may be used for required information (paragraph .72) or information that supplements the calculation report. Often, the assumptions and limiting conditions and the valuation analyst's representation are provided in appendixes to the calculation report.

**.76** The calculation report should include a section summarizing the calculated value. This section should include the following (or similar) statements:

- a.* Certain calculation procedures were performed; include the identity of the subject interest and the calculation date.
- b.* Describe the calculation procedures and the scope of work performed or reference the section(s) of the calculation report in which the calculation procedures and scope of work are described.
- c.* Describe the purpose of the calculation procedures, including that the calculation procedures were performed solely for that purpose and that the resulting calculated value should not be used for any other purpose or by any other party for any purpose.
- d.* The calculation engagement was conducted in accordance with the Statement on Standards for Valuation Services of the American Institute of Certified Public Accountants.

- e. A description of the business interest's characteristics, including whether the subject interest exhibits control characteristics, and a statement about the marketability of the subject interest.
- f. The estimate of value resulting from a calculation engagement is expressed as a calculated value. A general description of a calculation engagement is given, including that
  - i. a calculation engagement does not include all of the procedures required for a valuation engagement and
  - ii. had a valuation engagement been performed, the results may have been different.
- g. The calculated value, either a single amount or a range, is described.
- h. The report is signed in the name of the valuation analyst or the valuation analyst's firm.
- i. The date of the valuation report is given.
- j. The valuation analyst has no obligation to update the report or the calculation of value for information that comes to his or her attention after the date of the report.

**.77** The following is an example of report language that could be used, but is not required, in reporting a calculation engagement:

We have performed a *calculation engagement*, as that term is defined in the Statement on Standards for Valuation Services (SSVS) of the American Institute of Certified Public Accountants. We performed certain calculation procedures on [DEF Company, GHI business ownership interest of DEF Company, GHI security of DEF Company, or GHI intangible asset of DEF Company] as of [calculation date]. The specific calculation procedures are detailed in paragraphs [reference to paragraph numbers] of our calculation report. The calculation procedures were performed solely to assist in the matter of [purpose of valuation procedures], and the resulting calculation of value should not be used for any other purpose or by any other party for any purpose. This calculation engagement was conducted in accordance with the SSVS. The estimate of value that results from a calculation engagement is expressed as a calculated value.

In a calculation engagement, the valuation analyst and the client agree on the specific valuation approaches and valuation methods the valuation analyst will use and the extent of valuation procedures the valuation analyst will perform to estimate the value of the subject interest. A calculation engagement does not include all of the procedures required in a *valuation engagement*, as that term is defined in the SSVS. Had a valuation engagement been performed, the results might have been different.

Based on our calculations, as described in this report, which are based solely on the procedures agreed upon as referred to above, the resulting calculated value of [DEF Company, GHI business ownership interest of DEF Company, GHI security of DEF Company, or GHI intangible asset of DEF Company] as of [valuation date] was [calculated value, either a single amount or a range]. This calculated value is subject to the Statement of Assumptions and Limiting Conditions found in [reference to applicable section of valuation report] and to the Valuation Analyst's Representation found in [reference to applicable section of valuation report]. We have no obligation to update this report or our calculation of value for information that comes to our attention after the date of this report.

## Oral Report

**.78** An oral report may be used in a valuation engagement or a calculation engagement. An oral report should include all information the valuation analyst believes necessary to relate the scope, assumptions, limitations, and the results of the engagement so as to limit any misunderstandings between the analyst and the recipient of the oral report. The member should document in the working papers the substance of the oral report communicated to the client.

**Author's Note**

I was going to include an oral report on the downloadable materials that came with this book, but then I realized that this was not a book-on-tape. Use your imagination, and read one of the sample reports aloud; that should suffice.

**Effective Date**

**.79** This statement applies to engagements to estimate value accepted on or after January 1, 2008. Earlier application is encouraged.

**Author's Note**

This standard has been effective for a long time by now. The valuation analyst needs to follow these rules if he or she belongs to the AICPA or if licensed in a state that follows the AICPA rules. If the analyst is not an accountant, these rules are a good guide to performing valuation services. The analyst probably will be following most of these rules anyway because the different appraisal organizations have similar rules.

This standard includes several appendixes that are also important. However, it is not yet time to read each one individually. Appendix A is an "Illustrative List of Assumptions and Limiting Conditions for a Business Valuation." This will be covered in chapter 17 when I discuss reports. Appendix B is the "International Glossary of Business Valuation Terms." I already have this as appendix 2 in this book, so I am not going to repeat it here. Appendix C is a "Glossary of Additional Terms." I have included this as appendix 3 in this book.

**Author's Note**

Now, just when you thought that we were done with this AICPA standard, here comes what I consider to be the bonus that was included with the standard: Interpretation No. 1-01, "Scope of Applicable Services," of SSVS No. 1. This is an important part of the document because it explains many of the areas that CPAs who perform valuation services only occasionally are concerned with. It also contains sections that pertain to business valuers, so don't stop reading yet!

## **VS Section 9100, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset: Valuation Services Interpretations of Section 100***

### **1. Scope of Applicable Services**

#### **Background**

**.01** The Statement on Standards for Valuation Services (SSVS) No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* [VS section 100] establishes standards of performance and reporting for all AICPA members performing those valuation services that are within the scope of the Statement. When originally proposed on March 30, 2005, the Exposure Draft contained a list of questions and answers (Appendix A of the March 30, 2005 Exposure Draft) that were intended to assist members in determining if an engagement, particularly with regard to litigation or tax engagements, fell within the scope of the Statement. Through the Exposure Draft process, it was determined that the questions and answers were an integral part of the Statement and should be made authoritative. This Interpretation is part of the AICPA's continuing efforts at self-regulation of its members in valuation practice, and its desire to provide guidance to members when providing valuation services. The Interpretation does not change or elevate any level of conduct prescribed by any standard. Its goal is to clarify existing standards.

### General Interpretation

**.02** The SSVSs apply to an engagement to estimate value if, as all or as part of another engagement, a member determines the value of a business, business ownership interest, security, or intangible asset (SSVS No. 1, paragraphs 1 and 2 [VS section 100.01–.02]). In the process of estimating value, professional judgment is used to apply valuation approaches and valuation methods as described in the SSVS No. 1, paragraph 4 [VS section 100.04].

**.03** In determining whether a particular service falls within the scope of the Statement, a member should consider those services that are specifically excluded:

- Audit, review, and compilation engagements (SSVS No. 1, paragraph 5 [VS section 100.05])
- Use of values provided by the client or a third party (SSVS No. 1, paragraph 6 [VS section 100.06])
- Internal use assignments from employers to employee members not in the *practice of public accounting* (SSVS No. 1, paragraph 7 [VS section 100.07])
- Engagements that are exclusively for the purpose of determining economic damages (for example, lost profits) and that do not include an engagement to estimate value (SSVS No. 1, paragraph 8 [VS section 100.08])
- Mechanical computations that do not rise to the level of an engagement to estimate value (SSVS No. 1, paragraph 9(a) [VS section 100.09a])
- Engagements where it is not practical or reasonable to obtain or use relevant information and, therefore, the member is unable to apply valuation approaches and methods described in this Statement. (SSVS No. 1, paragraph 9(b) [VS section 100.09b])
- Engagements meeting the jurisdictional exception (SSVS No. 1, paragraph 10 [VS section 100.10])

**.04** A member should be diligent in determining if an engagement falls within the scope of the Statement. Unless specifically excluded by the SSVS, if the engagement requires a member to apply valuation approaches and methods, and use professional judgment in applying those approaches and methods, the SSVS would apply. In determining the scope and requirements of the engagement, a member should consider the client's needs, or the requirements of a third party for which the valuation is intended, including governmental, judicial, and accounting authorities. In addition, a member should consider other professional standards that might apply.

### Specific Illustrations

**.05** The following illustrations address general fact patterns. Accordingly, the application of the guidance discussed in the “General Interpretation” section to variations in general facts, or to particular facts and circumstances, may lead to different conclusions. In each illustration, there is no authority other than that indicated.

#### Illustrations Relating to Litigation Engagements and Certain Controversy Proceedings

**.06** *Illustration 1.* Do lost profits damage computations fall within the scope of the Statement?

**.07** *Conclusion.* No, unless the computations are undertaken as part of an engagement to estimate value (SSVS No. 1, paragraphs 1, 2, and 8 [VS section 100.01, .02, and .08]).

#### Author's Note

This means that if the valuation analyst, who would otherwise be subject to this standard, performs litigation support services in the form of lost profit analysis, the service performed is excluded from this standard. However, the valuation analyst probably wants to make sure that he or she follows the guidance in the other applicable AICPA standards and practice aids. Let's face it, we probably have rules for just about everything!

**.08** *Illustration 2.* Is an economic damages computation that incorporates a terminal value within the scope of the Statement?

**.09** *Conclusion.* The use of a terminal value exclusively for the determination of lost profits is not within the scope of this statement unless that determination will be used as part of an engagement to estimate value (*Illustration 1*).

**Author's Note**

If you do not know what a terminal value is, you probably should not be doing this type of work until you meet the competency provisions of the AICPA standards. However, do not worry. I will be discussing terminal values in chapter 12 as part of the income approach. After you read that chapter, you can start doing the work. (Only kidding!)

**.10 Illustration 3.** If a start-up business is destroyed, is the economic damages computation within the scope of the Statement?

**.11 Conclusion.** There are two common measures of damages: lost profits and loss of value. If a valuation analyst performs an engagement to estimate value to determine the loss of value of a business or intangible asset, the Statement applies. Otherwise, the Statement does not apply (*Illustration 1*). In order to determine whether the Statement applies, a member acting as an expert witness should evaluate whether the particular damages calculation constitutes an engagement to estimate value with respect to the business, business interest, security, or intangible asset or whether it constitutes a lost profits computation.

**Author's Note**

If you perform this type of work, do not let the standard determine whether you choose between a lost profits analysis or a business valuation. The case law of the presiding jurisdiction, as well as the facts and circumstances of the case, must be the determining factors. Speak with legal counsel to get the answer. If it is lost business value, then follow the standards.

**.12 Illustration 4.** Does the Statement include any exceptions relating to litigation or controversy proceedings?

**.13 Conclusion.** Yes, the Statement includes a reporting exemption for certain controversy proceedings (SSVS No. 1, paragraph 50 [VS section 100.50]); however, there is no litigation or controversy proceeding exemption from the developmental provisions of the Statement (SSVS No. 1, paragraphs 21–46 [VS section 100.21–.46]) in circumstances in which an engagement to estimate value is performed (*Illustration 1*).

**Author's Note**

Notice that this is only a reporting exemption. It is not an exemption to allow the valuation analyst to ignore the standards. This means that the valuation analyst still has to do everything necessary to develop a conclusion of value. The valuation analyst only has flexibility regarding how much or how little is put in the report. The valuation analyst should make sure to speak with the attorney handling the litigation before deciding what to exclude from the report. Certain jurisdictions require everything to be included in the report and do not care about the AICPA's litigation reporting exemption.

**.14 Illustration 5.** Is the Statement's reporting exemption for litigation or controversy proceedings (see SSVS No. 1, paragraph 50 [VS section 100.50]) the same as the "litigation exemption" in the AICPA attestation standards?

**.15 Conclusion.** No, the so-called "litigation exemption" is provided for in the AICPA attestation standards and is further discussed in the attestation interpretations. The attestation standards do not apply to engagements in which a practitioner is engaged to testify as an expert witness in accounting, auditing, taxation, or other matters, given certain stipulated facts. This is clarified in the attestation interpretation, which states, in part, that the attestation standards do not apply to litigation services engagements when (among other requirements) the practitioner "has not been engaged to issue and does not issue an examination, a review, or an agreed upon procedures report on the subject matter, or an assertion about the subject matter that is the responsibility of another party." (Interpretation No. 3, "Applicability of Attestation Standards to Litigation Services," of chapter 1, "Attest Engagements," of Statement on Standards for Attestation Engagements No. 10, *Attestation Standards: Revision and Recodification*, as revised [AT section 9101.34–.42].) However, unlike

the AICPA attestation standards, which do not apply in any capacity to litigation or controversy proceeding situations, as discussed above, the Statement's exemption for litigation or certain controversy proceedings is an exemption from the reporting provisions of the Statement (SSVS No. 1, paragraphs 47–78 [VS section 100.47–.78]).

### Illustrations Relating to Tax Engagements

**.16 Illustration 6.** When does the Statement apply to members who determine values related to tax reporting and planning engagements?

**.17 Conclusion.** The Statement applies when the member is engaged to estimate the value of a business, business ownership interest, security, or intangible asset (SSVS No. 1, paragraph 1 [VS section 100.01]). The application of valuation approaches and methods and the use of professional judgment (SSVS No. 1, paragraph 4 [VS section 100.04]) are required, unless an exception applies (SSVS No. 1, paragraphs 5–10 [VS section 100.05–.10]).

#### Author's Note

Tax practitioners, like business valuers, who are members of the AICPA are subject to this standard if the services rendered fall within the services covered by this standard. This is similar to the fact that if I prepare a tax return, there are rules that I must follow. The first rule is “Go to a psychiatrist because I must be going nuts!” I do not even do my own tax return. My wife does ours. I'm an innocent spouse!

However, if a tax practitioner is engaged to determine a value for estate or gift tax purposes, the same standards need to be followed whether the tax practitioner performs the service or a valuation analyst does it. It would make no sense to have different sets of standards for the same organization depending on the section that the member practices under.

What about the tax practitioner who is going to prepare an intangibles tax return for the client and needs the value of the business for inclusion in the return? If the client does not want to pay for a valuation engagement, let the client estimate the value and provide it to the tax practitioner for inclusion in the tax return. Just make sure to get it in writing from the client and have them sign an engagement letter indicating use of the value they provide.

**.18 Illustration 7.** If the sole purpose of an engagement is reporting a value in a tax return and the Statement applies to this engagement, are any separate reports (specifically, valuation reports) required to be issued? To whom are those reports required to be provided? Is a report required to be attached to the tax return? Are any specific disclosures required?

**.19 Conclusion.** The Statement requires the preparation of a written or oral valuation report (SSVS No. 1, paragraphs 47–78 [VS section 100.47–.78]) that is communicated to the client (SSVS No. 1, paragraph 47 [VS section 100.47]) but does not require that any report be attached to the tax return or mandate any other tax-specific disclosures. In limited circumstances, a taxing authority may require its own report, which would obviate the need for a separate valuation report (SSVS No. 1, paragraph 10 [VS section 100.10] and *Illustration 18*). There is also a reporting exemption for certain controversy proceedings (SSVS No. 1, paragraph 50 [VS section 100.50] and *Illustration 4*).

**.20 Illustration 8.** Are mechanical computations of value, for example, computations using actuarial tables, excluded from the Statement?

**.21 Conclusion.** Mechanical computations of value are excluded from the Statement if they do not rise to the level of an engagement to estimate value, that is, if the member does not apply valuation approaches and methods, and does not use professional judgment, as described in the Statement (SSVS No. 1, paragraph 9(a) [VS section 100.09a]).

**.22** Examples of services that do not rise to the level of an engagement to estimate value include:  
(a) computations of a remainder interest under a grantor retained annuity trust (GRAT) using actuarial tables;

(b) determining the value of relatively small blocks (relative to the total amount of corporate stock outstanding) of publicly traded stock whose per share price is readily ascertainable; (c) preparing a tax return using the valuation of a business that was provided by a third-party appraiser, or by the client (SSVS No. 1, paragraph 6 [VS section 100.06]); and (d) calculating cash “hold back” requirements for tax contingencies (SSVS No. 1, paragraphs 1, 4, and 9(a) [VS section 100.01, .04, and .09a]).

**.23** Examples of services that rise to the level of an engagement to estimate value include: (a) valuing a block of publicly traded stock, if the analysis includes consideration of a discount for blockage, lock-up, or other contractual or market restrictions such that valuation approaches and methods are applied, and professional judgment is used to determine the fair value, fair market value, or other applicable standard of value; (b) valuing stock that is not publicly traded; and (c) computing the fair market value of assets in a charitable remainder trust (CRT), if the engagement requires the application of valuation approaches and methods, and the use of professional judgment to estimate the fair market value.

**.24** *Illustration 9.* Does the “jurisdictional exception” (SSVS No. 1, paragraph 10 [VS section 100.10]) provide that an engagement to estimate value is not subject to the Statement if a member determines and reports values using procedures mandated or allowed by the Internal Revenue Code (IRC), Internal Revenue Service (IRS) regulations, court cases, or other published guidance and other sources of federal, state, and local law solely for purposes of tax return preparation and other tax services using these methods?

**.25** *Conclusion.* No, the “jurisdictional exception” would not exempt the engagement from this Statement, even if the engagement’s sole purpose was to value a subject interest (SSVS No. 1, paragraph 1 [VS section 100.01]) for tax reporting purposes. Only the portion of the Statement that differs from the published governmental or judicial authority is superseded for purposes of the engagement. The remainder of the Statement applies to the engagement.

#### Author's Note

So what the standard is really saying is that if all you are doing is opening up The Wall Street Journal and multiplying the number of shares times the share price, then that is a mechanical calculation not covered by the standard. However, if you plan to take a discount, for example, blockage (discussed in chapter 15), you just became subject to the standard. If you have to think, rather than merely use your calculator, you are subject to the standard.

**.26** *Illustration 10.* Is an interest in a publicly traded partnership whose shares are frequently traded considered a “security” under the Statement? Is an interest in a family limited partnership (FLP), or in another non-traded partnership, considered a “security” under the Statement?

**.27** *Conclusion.* Whether interest constitutes a “security” is a legal determination. However, where the value of a security is readily ascertainable, a valuation analyst does not need to apply valuation approaches and methods and use professional judgment. Accordingly, the valuation of such an interest would not be subject to the Statement (SSVS No. 1, paragraphs 1 and 9(a) [VS section 100.01 and .097]). An interest in a non-publicly traded partnership, such as an FLP, whether considered a security or not, is a business ownership interest. The valuation of such nonpublicly traded interest requires the application of valuation approaches and methods and the use of professional judgment, and, accordingly, would be subject to the Statement (SSVS No. 1, paragraphs 1, 4, [VS section 100.01 and .04], and Illustration 6), unless the exception under SSVS No. 1, paragraph 9(b) [VS section 100.09b] applies (*Illustration 13e*). If the engagement requires the valuation analyst to consider and apply adjustments, for example, valuation discounts or premiums, then the engagement would be subject to the Statement.

**.28** *Illustration 11.* A client engages a member to provide advice for planning purposes (such as estate planning, personal financial planning, or merger and acquisitions planning). The client holds an ownership interest in a family business being operated as a limited liability company, an interest in a private real estate limited partnership, publicly traded stock, a personal residence, and a retirement account (not an IRA). Is this a valuation engagement subject to the Statement?

**.29 Conclusion.** It depends. Providing technical advice, without reference to values for the various assets, is not subject to the Statement. However, if a member calculates a value to illustrate various planning options, he or she may fall under the Statement with regard to various assets. If one or more of the assets for which value is to be determined for purposes of the plan illustrations is a business, business ownership interest, security, or intangible asset, and the client or a third party does not provide the values for these assets, or the member does not use assumed or hypothetical values as part of the overall engagement, the member performing the valuation(s) is subject to the Statement with regard to these assets (SSVS No. 1, paragraph 1 [VS section 100.01] and *Illustration 6*). In this example, if the member applies valuation approaches and methods and uses professional judgment to determine the value of the ownership interest in the family business or the interest in the private real estate limited partnership in order to provide planning advice, the Statement would apply. In contrast, if the client or a third party provides the values for these assets, or the member uses assumed or hypothetical values, the Statement would not apply because the member would not be applying valuation approaches and methods and using professional judgment. In addition, the exception under SSVS No. 1, paragraph 9(b), [VS section 100.09b] where it is not practical or reasonable to obtain or use relevant information, could apply (see *Illustration 13e*). The computation of the “estimated estate tax” or other taxes once the values have been determined, assumed, or provided is not subject to the Statement, as the computation is a tax computation but would be subject to the Statement on Standards for Tax Services [TS sections 100–900] (*Illustration 10* at paragraph .27 of this interpretation).

**.30 Illustration 12.** There are many instances where a tax engagement involves the need for a member to estimate value. The estimation of value may not be the primary purpose of the engagement, but rather a necessary task to perform or item to consider, when making a tax determination concerning the reporting of a transaction on a tax return. Consider the following practice situations:

**.31 Illustration 12a.** A member has been engaged to determine the deductibility of interest on a nonrecourse loan. Under applicable regulations, interest on a nonrecourse loan cannot be deducted if it is clear that the company will be unable to service the debt. For purposes of tax reporting, a conclusion must be reached concerning the ability of the company to service the debt. Is this considered a valuation engagement subject to the Statement?

**.32 Conclusion.** This is not a valuation engagement covered by the Statement because it is not the valuation of a subject interest (SSVS No. 1, paragraph 1 [VS section 100.01]). This example is a debt service analysis.

**.33 Illustration 12b.** There are compliance filings that require an estimate of the value of a company. For example, the “market value” of “intangible personal property,” as defined by a state’s taxing authority may need to be reported annually on an intangible personal property tax return. A client has a subject interest that is considered intangible personal property for purposes of the return. The member has been engaged to prepare the tax return. Is this a valuation engagement subject to the Statement?

**.34 Conclusion.** It depends. If the state requires an estimation of the value of a subject interest, and the estimation of value requires the application of valuation approaches and methods and the use of professional judgment (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]), the Statement applies. If, however, the client or a third-party appraiser provides the value of the subject interest to the member, the Statement does not apply (SSVS No. 1, paragraphs 1 and 6 [VS section 100.01 and .06]). In addition, the exception under SSVS No. 1, paragraph 9(b), [VS section 100.09b] where it is not practical or reasonable to obtain or use relevant information, could apply (*Illustration 13e*). Alternatively, if the state follows more informal rules where the application of valuation approaches or valuation methods are not necessary, the Statement does not apply (SSVS No. 1, paragraph 4 [VS section 100.04]).

#### Author's Note

I told you so! Get the value from the client, and you can skate!

**.35 Illustration 12c.** There are times when a member must allocate value among various assets. For example, IRC sections 1060 and 338 require the allocation to assets, based on relative values, of consideration paid. In partnership taxation, there may be allocations under IRC sections 754, 743, and 734 and special tax basis adjustments for partnerships (sales or exchanges and transfers at or upon death) may require an allocation of value among various partnership assets. Are these types of allocations engagements to estimate value subject to the Statement?

**.36 Conclusion.** It depends. If one or more of the assets to which value is to be allocated is a subject interest (that is, a business, business ownership interest, security, or intangible asset), and the client or a third party did not provide the member with a value for those assets, then the member performing the allocation would be subject to the Statement, and the member is required to apply valuation approaches and methods, and use professional judgment to value those assets (SSVS No. 1, paragraphs 1, 4, [VS section 100.01 and .04] and *Illustration 6*), unless an exception applies (SSVS No. 1, paragraphs 5–10 [VS section 100.05–.10]). For example, in an IRC section 1060 allocation, after the allocation of purchase price to cash, receivables, inventory, and depreciable tangible assets, there is a residual amount of value allocable to goodwill or going concern. The mechanical assignment of the residual amount to goodwill or going concern is not subject to the Statement. However, if the member allocates this residual amount to specific intangible assets (such as to various customer-based and supplier-based intangibles), such allocation is based on the assets' relative values. Because the member applies valuation approaches and methods and uses professional judgment to value those specific intangible assets, the Statement applies.

#### Author's Note

Time for a pop quiz. Can you tell me how many times the answer to any of the preceding questions is “It depends?” Welcome to my world. The correct answer most of the time is that it depends. You will really know that you are starting to understand this stuff when you know what it depends on.

**.37 Illustration 12d.** If the member does not apply any discount and simply computes the fair market value of an interest in a FLP for tax purposes, is this a valuation engagement subject to the Statement?

**.38 Conclusion.** Yes, the Statement applies if the member determines the value of the FLP or an interest in an FLP. The application of valuation approaches and methods, and the use of professional judgment are required, unless an exception applies (SSVS No. 1, paragraphs 5–10 [VS section 100.05–.10]). The fact that the member does not apply a discount does not exempt the engagement from the Statement (SSVS No. 1, paragraphs 1–4 and 9(a) [VS section 100.01–.04 and .09a]).

**.39 Illustration 12e.** Would the Statement apply to the computation of the fair market value of assets in, or the computation of the required distribution of, a charitable remainder trust (CRT)?

**.40 Conclusion.** It depends on the underlying assets held by the CRT. The Statement would apply only if the member determines the value of a business, business ownership interest, security, or intangible asset (SSVS No. 1, paragraph 1 [VS section 100.01]). To the extent that the CRT holds assets that, to be valued, require the application of valuation approaches and methods, and the use of professional judgment, such as an interest in a limited liability corporation (LLC), the Statement would apply. However, if the CRT only holds publicly traded stock with a readily ascertainable value, the Statement would not apply because valuation approaches and methods and professional judgment would not be needed in the computation (SSVS No. 1, paragraphs 1 and 4, [VS section 100.01 and .04] and *Illustration 6*).

**.41 Illustration 12f.** In circumstances in which the value of assets contributed by partners to a partnership differ from their cost basis, each difference must be tracked for tax purposes under IRC section 704(c) so that amounts of gain or loss can be properly assigned to the contributing partners. Are these types of asset value assignments valuation engagements subject to the Statement?

**.42 Conclusion.** It depends. If one or more of the assets for which value is relevant under IRC section 704(c) is a subject interest, that is, a business, business ownership interest, security, or intangible asset, and the client or a third party does not provide the valuation, and the member applies valuation approaches and methods and uses professional judgment to value these assets for IRC section 704(c) tax purposes, then the Statement applies (SSVS No. 1, paragraphs 1 and 6, [VS section 100.01 and .06 and *Illustration 6*]).

**.43 Illustration 12g.** A member has been engaged to perform a cost segregation study. The study involves an analysis of the costs of building a structure and the allocation of such costs to the real and personal property components of the structure so that depreciation of those components may be properly computed. Is this a valuation engagement subject to the Statement?

**.44 Conclusion.** No, none of the assets constitutes a subject interest (SSVS No. 1, paragraph 1 [VS section 100.01]).

**.45 Illustration 12h.** A member has been engaged to provide advice to a company regarding the tax planning for income from discharge of indebtedness under IRC section 108. The company has advised the member that the company will be able to negotiate a settlement in complete satisfaction of an obligation at 30 cents on the dollar. Is this a valuation engagement subject to the Statement?

**.46 Conclusion.** It depends. Under IRC section 108(a), gross income of the company excludes income from discharge of indebtedness only under certain circumstances. One of those circumstances is the insolvency of the company. Under IRC section 108(d)(3), insolvency results from an excess of liabilities over the fair market value of assets. If (a) the company must rely on the insolvency provisions of IRC section 108; (b) one or more of the assets for which value is relevant under IRC section 108 is a subject interest (that is, a business, business ownership interest, security, or intangible asset); (c) the company or a third party does not provide the valuation; and (d) the member applies valuation approaches and methods, and uses professional judgment to value the subject interest(s) for purposes of the IRC section 108(d)(3) insolvency determination, the Statement applies.

**.47 Illustration 13.** An executor has engaged a member to prepare an estate tax return, which requires determining values for the following estate assets: (a) shares in a publicly traded company, “TI Corporation,” whose shares are infrequently traded; (b) a large block of stock in “LB Corporation,” a publicly traded company; (c) a brokerage account consisting of shares in various publicly traded companies; (d) “CHB Corporation,” a closely held business owned by the decedent and the decedent’s family; and (e) a 5 percent interest in “RP,” a privately held rental real estate partnership. Does the Statement apply to any of the following assets owned by the estate? (See *Illustration 10* at paragraph .27 of this Interpretation regarding the valuation of a security.)

#### Author's Note

By now, you should realize that this standard does not apply where the value of a security is readily ascertainable; a valuation analyst does not need to apply valuation approaches and methods and use professional judgment. Accordingly, the valuation of such an interest would not be subject to the standard (SSVS No. 1, paragraphs 1 and 9a). An interest in a non-publicly-traded partnership, such as a family limited partnership, whether considered a security or not, is a business ownership interest. The valuation of such non-publicly-traded interest requires the application of valuation approaches and methods and the use of professional judgment in the application of valuation approaches and methods and, accordingly, would be subject to the standard (SSVS No. 1, paragraphs 1, 4, and *Illustration 6*), unless the exception under SSVS No. 1, paragraph 9b applies (*Illustration 13e*). This does not apply to professional judgment in, for example, applying the tax law. If the engagement requires the valuation analyst to consider and apply adjustments, for example, valuation discounts or premiums, then the engagement would be subject to the standard. Don't bother to look back at paragraph .27—I just gave it to you.

**.48 Illustration 13a.** Does the Statement apply to shares in a publicly traded company, “TI Corporation,” whose shares are traded infrequently?

**.49 Conclusion.** It depends; although the price of a share of publicly traded stock is ascertainable from published sources, there are no definitive criteria that would indicate when the Statement applies to shares that are infrequently traded. A key consideration is the average daily trading volume of TI Corporation stock on or around the valuation date. The concept of fair market value incorporates the notions that (1) cash could have been received for the stock at the valuation date, and (2) the share price of an infrequently traded stock could decrease if a relatively large block of the stock were to be put on the market on that date. If the subject shares held by the estate do not represent a significant percentage of the daily trading volume of TI stock on or around the valuation date, and the price of a share of the stock is readily ascertainable on the valuation date, then the resulting value (the quoted share price times the number of shares owned) represents a cash price that could have been received at the valuation date for the block, and the Statement does not apply because the calculation of value is mechanical (SSVS No. 1, paragraph 9(a) [VS section 100.09a]). If, however, the subject shares held by the estate represent a large percentage of the average daily trading volume of the stock, the quoted market price for a share may not be adequate for purposes of determining the fair market value of the block of shares on the valuation date. In that case, the Statement applies because valuation approaches and methods need to be applied, and professional judgment needs to be used in determining the value of the block (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]) (See *Illustration 10* at paragraph .27 of this interpretation regarding the valuation of a security.)

**Author's Note**

What is actually being said here is that if the public company stock is thinly traded, the market price of the stock may not be reflective of its fair market value. If you have to determine a different value, you would be subject to this standard. I just said it in a lot less words!

**.50 Illustration 13b.** Does the Statement apply to a large block of stock in “LB Corporation,” a publicly traded company?

**.51 Conclusion.** The answer depends on the amount of shares to be valued in relation to the average daily trading volume in LB Corporation on or around the valuation date. There are no definitive criteria that would indicate when the Statement applies to the valuation of a large block of publicly traded stock. The concept of fair market value incorporates the notion that cash could have been received from a sale of the block on the valuation date. A large block could decrease the share price if sold on the valuation date. The Statement would typically not apply to the valuation of a large block (for example, 200,000 shares) of a large and actively traded public company. Even though the value of the estate’s stock may be large in absolute terms, the daily trading volume in such stock on the valuation date may be sufficiently high that a sale of the block on the valuation date would not affect the market price of a company’s shares. In such a case, the quoted market price of a share times the number of shares held by the estate may be considered to reflect the fair market value of the subject block of stock, and because it would not be the case that valuation approaches and methods would need to be applied and professional judgment used, the Statement would not apply. If, however, the large block of publicly traded shares represents a significant percentage of the daily trading volume, the Statement would apply because valuation approaches and methods would need to be applied and professional judgment used to determine the value (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]).

**Author's Note**

That is a lot of words to say that because a blockage discount may need to be applied, the valuation analyst would be subject to the standard. Blockage is discussed in chapter 15.

**.52 Illustration 13c.** Does the Statement apply to a brokerage account consisting of shares in various publicly traded companies?

**.53 Conclusion.** The Statement would not apply to the determination of the value of a brokerage account consisting of publicly traded securities, except as discussed in paragraphs .49 and .51 of this interpretation. Absent certain scenarios involving infrequently traded securities or large blocks of stock, the application of valuation approaches and methods and the use of professional judgment are not necessary in that determination (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]).

**.54 Illustration 13d.** Does the Statement apply to “CHB Corporation,” a closely held business owned by the decedent and the decedent’s family?

**.55 Conclusion.** The Statement would apply to the determination of value of CHB Corporation because valuation approaches and methods need to be applied, and professional judgment needs to be used to determine the fair market value of the ownership interest in CHB (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]).

**.56 Illustration 13e.** Does the Statement apply to a 5 percent interest in a privately held rental real estate partnership (RP)?

**.57 Conclusion.** The Statement would apply to the determination of value of the 5 percent interest in rental real estate partnership (RP) because valuation approaches and methods need to be applied and professional judgment needs to be used to determine the fair market value of the ownership of a fractional interest in a privately held partnership (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]). However, where it is not practical or not reasonable to obtain or use relevant information and, therefore, the member is unable to apply valuation approaches and methods, the Statement would not apply. For example, the member has requested from RP’s general partner financial information the member needs in order to apply valuation approaches and methods. The general partner is not responsive to the member’s requests, and the due date for filing the estate tax return is near. Given the small ownership interest, and given that RP is likely a relatively small percent of the total estate, unless prohibited by statute or by rule, the member may then use the taxpayer’s estimates if the member determines that the estimates are reasonable (based on the facts and circumstances known to the member) (SSVS No. 1, paragraph 9(b) [VS section 100.09b]).

#### Author’s Note

This is an interesting example. Very often, we are asked to value things that probably have little to no value, but we cannot get the cooperation that we need to do our jobs. For an estate tax return, I agree with the notion that if the client provides something that is reasonable, and the effect is relatively minor (remember materiality?), then we can go ahead and perform the job and not be concerned with this standard. However, be careful if this is your problem in a litigation assignment. If you are impeached on a small item, the judge may start to doubt you on the larger ones. Keep this interpretation in perspective for the tax practitioners for whom it is intended.

**.58 Illustration 14.** Would the answers to *Illustration 13* change if the values were provided by the client or a client-engaged third party?

**.59 Conclusion.** The Statement would not apply if the values were provided by the client or by a client-engaged third party because the member is not applying valuation approaches and methods and using professional judgment to determine value (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]). However, the member would be subject to Statement on Standards for Tax Services No. 3, *Certain Procedural Aspects of Preparing Returns* [TS section 300], in providing appropriate due diligence with respect to the values provided to the member. It is also recommended that the understanding between member and client in these circumstances include documentation of the fact that the member is not determining but rather is being provided with the value of the subject interest.

**.60 Illustration 15.** Would the answers to *Illustration 13* change if the values were provided by an outside third-party specialist hired by the member?

**.61 Conclusion.** If the member engages an outside third-party specialist to assist with the member's work, and it is the member expressing a conclusion or calculated value, the member will be applying valuation approaches and methods and using professional judgment; thus, the Statement would apply (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]; SSVS No. 1, paragraph 20, "Using the Work of Specialists in the Valuation Engagement" [VS section 100.20]). If, however, the third-party specialist is determining the value in his or her own name and providing that value to the client, and the member will not be applying valuation approaches and methods or using professional judgment (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04], and *Illustration 6*), the Statement would not apply, but the member would be subject to Statement on Standards for Tax Services No. 3, *Certain Procedural Aspects of Preparing Returns* [TS section 300] in providing appropriate due diligence with respect to the values provided.

**.62 Illustration 16.** The client and the member agree that the member will value a partnership interest and then apply an "average" discount that the member is to determine (based on the results of various studies and case law). Does the Statement apply? If so, is this a valuation engagement or a calculation engagement?

**.63 Conclusion.** Yes, the Statement applies because the member determined the value of the partnership interest by applying valuation approaches and valuation methods and using professional judgment. This would be considered a calculation engagement because the member and the client have agreed on the specific valuation approaches or valuation methods the valuation analyst will use and the extent of valuation procedures the valuation analyst will perform (SSVS No. 1, paragraph 21(b) [VS section 100.21b] and *Illustration 6*).

#### Author's Note

A calculation engagement is conceptually similar to an agreed upon procedures engagement in the AICPA's attestation standards, where the valuation analyst and the client agree that certain procedures will be applied. Anything less than an engagement that allows the valuation analyst complete discretion over the methods and procedures to be applied is considered to be a calculation engagement.

**.64 Illustration 17.** Would the Statement apply if a member has an informal conversation or communicates in writing with a client regarding the alternative tax consequences of gifting versus selling a business using a presumption of a specific value of the business?

**.65 Conclusion.** No, the Statement would not apply. The member is providing tax advice using an assumed or hypothetical value of a business and is not determining value, applying valuation approaches and methods, and using professional judgment to value a business (SSVS No. 1, paragraphs 1 and 4, [VS section 100.01 and .04] and *Illustration 6*).

**.66 Illustration 18.** Would the Statement apply to a transfer pricing study (IRC section 482) that involves the use of specific methodologies, data, terminology, and documentation requirements that are provided in the IRS regulations and procedures, and whose methodologies and documentation requirements differ from those contained in the Statement?

**.67 Conclusion.** No. To the extent that the transfer pricing study applies, for example, to the valuation of inventory or services, the Statement would not apply (see SSVS No. 1, paragraph 1 [VS section 100.01] and *Illustration 6*). To the extent that the transfer pricing study applies to the valuation of intangible assets, the Statement would normally apply. However, because the IRS regulations require that the taxpayer reasonably calculate an arm's-length price according to the best method that is determined using third-party comparable data under explicit IRS rules and documentation procedures, and to the extent these IRS rules and procedures differ from the Statement, the jurisdictional exception (SSVS No. 1, paragraph 10 [VS section 100.10]) would exempt the valuation of the intangible assets from the developmental provisions of the Statement (SSVS No. 1, paragraphs 25–48 [VS section 100.25-.48]). In addition, to the extent that the IRS regulations (such as IRS regulation section 1.6662-6(d) (2) (iii)) and procedures provide specific documentation requirements for avoiding potential penalties, and if a transfer pricing report is provided to a client according to such IRS documentation requirements, the jurisdictional exception would apply to the reporting provisions of the Statement (SSVS No. 1, paragraphs 50–78 [VS section 100.50-.78]) and thus a valuation report would not be necessary.

**Author's Note**

My sincere apologies to the non-CPAs reading this part of the book. I would not have started with IRS regulation section numbers, but the accountant-types put it in the interpretation. Boy, I forgot how ugly code and regulation sections are! The bottom line is that if the IRS regulations tell us what to do and how to do it, as well as how to report it, the jurisdictional exception applies, and the standard does not.

**.68 Illustration 19.** In a situation where the Statement applies to members who determine value as part of tax engagements, would the member also be required to be in compliance with the Statements on Standards for Tax Services (SSTs) [TS sections 100–900]?

**.69 Conclusion.** Yes, the Statement would apply only to the valuation determination and reporting aspects of the engagement, but the SSTs would apply to all aspects of the engagement. For example, even though the Statement would govern the determination of value of an applicable asset reported on a tax return, the member would also have to be in compliance with SSTs No. 1, *Tax Return Positions*, [TS section 100] for that valuation.

**.70 Illustration 20.** Do settlements or negotiations of value in offers-in-compromise or tax disputes fall under the Statement? (Appears as *Illustration 21* in original publication.)

**.71 Conclusion.** No, settlements or negotiations of value in offers-in-compromise or tax disputes are part of a tax process. However, if a member prepares a valuation in preparation for a settlement or negotiation of value, and the valuation involves the application of valuation approaches and methods and the use of professional judgment, the valuation would fall under the developmental aspects of the Statement. The settlement or negotiation process itself is not a valuation and would not fall under the Statement. In addition, the Statement's reporting exemption for certain controversy proceedings would apply as the valuation was performed specifically for the administrative matter (SSVS No. 1, paragraph 50 [VS section 100.50]).

**Illustrations Relating to Other Engagements**

**.72 Illustration 21.** Does determining the value of accounts receivable fall under the Statement? (Appears as *Illustration 20* in original publication.)

**.73 Conclusion.** No, accounts receivable constitute **tangible assets** under the Statement (SSVS No. 1, Appendix B [VS section 100.81]), and do not constitute a subject interest (SSVS No. 1, paragraph 1 [VS section 100.01]).

**.74 Illustration 22.** In the course of performing a valuation under the Statement, if a valuation analyst prepares prospective financial information (for example, as part of a discounted cash flow or discounted earnings analysis within the income approach), does this require the valuation analyst to examine or compile such information in accordance with the Statements on Standards for Attestation Engagements (SSAEs) [AT sections 20–701]?

**.75 Conclusion.** No, chapter 1, “Attest Engagements,” of SSAE No. 10, *Attestation Standards: Revision and Recodification*, as amended [AT section 101.01] states that the attestation standards apply when a practitioner is “engaged to issue or does issue an examination, a review, or an agreed-upon procedures report on subject matter, or an assertion about the subject matter..., that is the responsibility of another party.” If the valuation analyst has not been engaged to examine, compile, assemble, review, or apply agreed upon procedures to prospective financial information, and does not issue an examination, compilation, assembly, or agreed upon report on prospective financial information, the SSAEs [AT sections 20–701] do not apply (SSARS No. 14 AR section 120)).

**Author's Note**

Notice that the wording in this illustration states “if a valuation analyst prepares prospective financial information...” This means that the valuation analyst can prepare prospective information. I will discuss this later in chapters 8 and 12 under forecasts and the discounted future benefits method. Many accountants (and some valuation analysts) try to hide behind the fact that if management does not give them prospective financial statements, they cannot use this method. That is a bunch of nonsense!

**.76 Illustration 23.** Under a valuation engagement, a valuation analyst is free to select any and all valuation approaches and methods the valuation analyst deems appropriate in the circumstances. Under a calculation engagement, the valuation analyst and the client agree to the specific approaches or methods the valuation analyst will use or the extent of calculation procedures the valuation analyst will perform. (SSVS No. 1, paragraph 21 [VS section 100.21].) Under SSVS No. 1, paragraph 18 [VS section 100.18], a restriction or limitation on the scope of the valuation analyst’s work, or the data available for analysis may be present and known to the valuation analyst at the outset of the engagement, or may arise during the course of an engagement (and such restriction or limitation should be disclosed in the report). Is it possible to have a restriction or limitation that is of such a degree that a valuation analyst engaged to perform a valuation engagement should propose altering the engagement to be a calculation engagement?

**.77 Conclusion.** Although the two engagements represent two different types of service performed by valuation analysts, the possibility exists. If, in the course of a valuation engagement, restrictions, or limitations on the scope of the valuation analyst’s work or the data available for analysis are so significant that the valuation analyst believes that he or she cannot, even with disclosure in the valuation report of the restrictions or limitations, adequately perform a valuation engagement leading to a conclusion of value, the valuation analyst should determine whether he or she has the ability to adequately complete the engagement as a calculation engagement or should consider resigning from the engagement.

**.78 Illustration 24.** If a member employed in industry, government, or education “moonlights” doing engagements to estimate value, do the standards apply?

**.79 Conclusion.** Yes, the standard applies. By moonlighting, the member is holding him or herself out as a certified public accountant and as being in public practice. The standard would apply just as it would to any other member in public practice unless one of the exceptions applies.

**.80 Illustration 25.** Does the Statement apply to an assignment from an employer to an employee member not in public practice to prepare a valuation for internal financial reporting purposes?

**.81 Conclusion.** No, SSVS No. 1, paragraph 7 [VS section 100.07] exempts internal use assignments from an employer to an employee member not in the practice of public accounting. However, if the valuation is to be used for financial reporting purposes, the employer and the employee may wish to consider whether the work will be accepted by the employer’s outside auditors if the Statement is not followed.

### Illustrations for PFP-Specific Engagements

*These illustrations assume the member has not been engaged to perform a business valuation.*

**.82 Illustration 26.** When does the Statement apply to members who determine values related to personal financial planning engagements?

**.83 Conclusion.** The Statement applies to personal financial planning engagements when the member determines the value of a business, business ownership interest, security, or intangible asset (SSVS No. 1, paragraph 1 [VS section 100.01]) and in the process of determining the value applies valuation approaches and methods and uses professional judgment (SSVS No. 1, paragraph 4 [VS section 100.04]) unless an exception applies (SSVS No. 1, paragraphs 5–10 [VS section 100.05–.10]).

**Author's Note**

Gee. What a surprise! If this standard is going to apply to tax practitioners, moonlighting professionals, and business valuers, why wouldn't it apply to personal financial planners as well? Bottom line—when ANY AICPA member determines the value of a business, business ownership interest, security, or intangible asset and in the process of determining the value applies valuation approaches and methods and uses professional judgment, this standard applies, unless an exception applies.

**.84 Illustration 27.** If a member is engaged to provide personal financial planning services to a client and, in the course of the engagement, estimates the proceeds from a hypothetical future sale of the client's business interest, does the Statement apply?

**.85 Conclusion.** No. The Statement does not apply because estimate of future sales proceeds does not in itself constitute a valuation engagement (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]).

**.86 Illustration 28.** A member is engaged to provide personal financial planning services to a client and, in the course of the engagement, estimates the proceeds from a hypothetical future sale of the client's business interest. As part of that engagement, the member shares general industry knowledge to assist the client in estimating the current value of the business interest. Does the Statement apply?

**.87 Conclusion:**

- a. If, in the process of determining the current value from which the member estimates future sales proceeds, the member applies valuation approaches and methods and uses professional judgment, the Statement applies to the determination of the current value (SSVS No. 1, paragraph 4 [VS section 100.04]). However, the Statement does not apply when the member shares general industry knowledge with the client instead of applying professional judgment.
- b. If the client or another party provides the current value, and the member does not apply valuation approaches and methods, the Statement does not apply (SSVS No. 1, paragraphs 4 and 6 [VS section 100.04 and .06]).
- c. If the member uses a hypothetical or assumed value as the starting point for the calculation of future sales proceeds and does not apply valuation approaches and methods, the Statement does not apply (SSVS No. 1, paragraphs 1 and 4 [VS section 100.01 and .04]). The Statement does not apply to a general discussion with the client of valuation concepts or industry price multiples based on the member's industry knowledge, which assists the client in determining a hypothetical or assumed value (SSVS No. 1, paragraphs 4 and 6 [VS section 100.04 and .06]).

**.88 Illustration 29.** The client has asked the member to prepare a personal financial plan that includes an estimate of future proceeds from a sale of the business interest at retirement. The member estimates the future proceeds based on an estimate of the business' current value by applying a rule of thumb for the business' industry, but the member does not consider the risk factors of the subject interest or exercise other professional judgment in applying the multiple. Does the Statement apply?

**.89 Conclusion.** No, the Statement does not apply because the member did not use professional judgment (SSVS No. 1, paragraph 4 [VS section 100.04]). If the member considers specific risk factors of the business interest in applying the price multiple, the Statement applies.

*This Statement titled Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset was unanimously adopted by the assenting votes of the AICPA Consulting Services Executive Committee.*

**Author's Note**

By now, you are probably sick of standards. However, we only have a little bit more to go. Please hang in there, and we will be finished shortly. The good news is that we are done with the most important standard in this book (particularly if you are a member or a future member of the AICPA). For the rest of this chapter, I am going to minimize these boxes around what I have to say. You will know if I am quoting the other standards.

## AICPA Statement on Standards for Consulting Services

The AICPA promulgated Statement on Standards for Consulting Services No. 1, *Consulting Services: Definitions and Standards* (AICPA, *Professional Standards*, CS section 100), to cover a broad range of consulting services that its members provide, not just business valuations. Therefore, this standard is extremely general and deals with a wide variety of issues, such as due care and proper staffing for consulting engagements. This standard follows the format of other accounting-oriented standards but cannot be used to provide guidance or direction, other than on a superficial level. This standard is reproduced in appendix 1.

Besides these standards, there are other standards that should guide AICPA members to perform these assignments properly. Although they are not all-inclusive, some of the more important standards include the following:

### AICPA Code of Professional Conduct

CPAs are required to follow the Code of Professional Conduct when performing any service for a client, including business valuations and litigation work. The AICPA Code of Professional Conduct (the code) was rewritten and reissued effective December 15, 2014. A copy of the AICPA Code of Professional Conduct is available at [www.aicpa.org](http://www.aicpa.org).

The code covers ethical considerations (integrity and objectivity). It requires that in the performance of any professional service a member shall maintain objectivity and integrity, shall be free of conflicts of interest, and shall not knowingly misrepresent facts or subordinate his or her judgment to others. This is important because valuation analysts should understand the differences between the responsibility of the attorney and the accountant related to conflicts of interest—the attorney is an advocate for the client, whereas the valuation analyst (accountant) is only an advocate for his or her opinion.

### Professional Competence

As stated in the AICPA Consulting Services Practice Aid 93-3, *Conducting a Valuation of a Closely Held Business*, which I have modified to bring the references to the current literature, (written by yours truly, but unfortunately no longer in print, although I still have some copies in my library that I am willing to sell you):

In performing business valuation engagements, practitioners are advised to determine whether the competency provisions of the preface to the AICPA Code of Professional Conduct, found in Section 0.300.060 are met. Although accountants have a thorough understanding of financial statements and related matters, they also need to be proficient in the area of appraisals to competently complete an engagement. Usually, being proficient requires an in-depth knowledge of finance, economics, and security analysis and an understanding of appraisal principles and methods.

As described in Section 0.300.060.03 of the AICPA Code of Professional Conduct, in order for the practitioner to obtain competency required to accept a business valuation engagement, appropriate education is required.

Professional competence is also covered in SSVS No. 1. About 14 years later, and competence is still important! Who would have thought?

### Select Components of the Code

In 2003, The AICPA issued *Consulting Services Special Report 03-1, Litigation Services and Applicable Professional Standards*. Although this publication has been retired, the concepts covered in it have not been. Many of the sections that are discussed in this publication stem from the AICPA Code of Professional Conduct. The following discussion is an adaptation of that really good publication. Too bad it was retired.

The AICPA Code of Professional Conduct applies to all services rendered by AICPA members. The following sections of the code have particular applicability to the practice of litigation services:

- The “Integrity and Objectivity Rule” (ET section 1.100.001)
- The “Compliance With Standards Rule” (ET section 1.310.001)
- Principles and Rules of Conduct (ET section 0.100.010)
- The definition of “confidential client information” (ET section 0.400.09)
- The “Contingent Fees Rule” (ET section 1.510.001)
- The “Acts Discreditable Rule” (ET section 1.400.001)

In some instances, the following also apply:

- The “Independence Rule” (ET section 1.200.001)
- The “Accounting Principles Rule” (ET section 1.320.001)

An understanding and appreciation of the importance of all rules contained in the code will assist valuation analysts in their efforts to provide opinions that are relevant and reliable, and that assist the trier of fact (judge or jury).

### The “Independence Rule” (ET section 1.200.001)

Independence, as set forth in the AICPA Code of Professional Conduct, is ordinarily not required when performing litigation service engagements. As a result of the Sarbanes-Oxley Act of 2002, the valuation analyst should be aware that, in some instances, if the valuation analyst or the valuation analyst’s firm provides audit services, statutes may preclude the provision of litigation services.

Lack of independence from the client may be used to question the valuation analyst’s credibility and objectivity. The valuation analyst should carefully consider the potential difficulties inherent in serving as an expert witness for a party. If the valuation analyst lacks independence, or could appear to lack independence in relation to that party, the analyst should discuss these issues with the client or the client’s attorney, or both, before accepting an engagement. In addition, independence notwithstanding, the valuation analyst’s working paper files relating to other engagements for the same client may be subject to the discovery process.

### “The Integrity and Objectivity Rule” (ET section 1.100.001)

To maintain integrity is to adhere to an ethical code and be free from corrupting influences and motives. Service and public trust should not be subordinated to personal gain and advantage.

The roles of valuation analysts differ from attorneys in the litigation process, which is an adversarial proceeding in which the best case for each party is put before the trier of fact. The litigating attorney is the client’s advocate.

The valuation analyst does not serve as an advocate for the client’s position and, therefore, should not subordinate his or her judgment to the client. The valuation analyst, who is hired as an expert, is engaged as someone who has specialized knowledge, skills, training, and experience in a particular area and presents conclusions and judgments with integrity and objectivity. The expert’s function is to assist the trier of fact in understanding complex or unfamiliar concepts after having applied reliable principles and methods to sufficient relevant data.

### Principles and Rules of Conduct (ET section 0.100.010)

The Principles of Professional Conduct (ET section 0.300.010), applies to litigation services as well as to all other services rendered by CPAs to their clients. The principles cover a preamble, professional responsibilities, the public interest, integrity, objectivity and independence, due care, and the scope and nature of services.

### Due Care (ET section 0.300.060)

Valuation analysts should undertake only those litigation services that they reasonably can expect to complete with professional competence. Consequently, valuation analysts may be unprepared to meet client needs adequately in every area and in every phase of litigation engagements. To comply with this standard in providing litigation services, practitioners may need the assistance of other individuals with the required education and experience.

Professional competence includes, among other things, identifying client needs. The valuation analyst should be aware that, in some instances, if the valuation analyst's firm provides audit services, statutes or other such rules may preclude the provision of litigation services.

As a result of *Daubert v. Merrill Dow Pharmaceuticals, Inc.*, 509 U.S. 579 (1993), and *Kumho Tire Company, Ltd. v. Patrick Carmichael*, 526 U.S. 137 (1999), the valuation analyst should consider that the reliability and relevance of the expected testimony is likely to be subjected to careful judicial scrutiny before it will be allowed to be presented at trial. When deciding whether to accept a litigation services engagement, the valuation analyst should consider whether it is likely that he or she has the knowledge and skills necessary to provide a reasonable basis to present relevant and reliable testimony on the issues to be presented in the particular case.

A valuation analyst exercises due professional care in the performance of professional services. Due care requires diligence and critical analysis of all work performed. It also requires that all work be completed in accordance with the provisions of the applicable professional standards of the AICPA, including the code.

In a litigation engagement, valuation professionals are often the only professionals capable of quantifying the impact of the events that led to the dispute. Therefore, their work product is important in the litigation process. Each party to the proceedings may retain professionals to quantify and analyze the economic impact of events. Valuation analysts need to be able to evaluate and challenge the assumptions and calculations of other professionals as well as defend their own assumptions and calculations under rigorous cross-examination.

## Planning and Supervision

A valuation analyst adequately plans and supervises the performance of professional services. Planning is essential in a litigation engagement. Planning consists of developing engagement objectives and translating them into the activities necessary for the CPA to form an opinion. Planning guides the conduct, supervision, control, and completion of the engagement.

The facts and circumstances of each litigation engagement are unique. Planning is essential to ensure the quality of the performance of professional services in each engagement. Planning includes obtaining information from the counsel of the client. Plans continually change in a litigation engagement and usually are not written because the litigation process is dynamic.

As with any professional services, the supervision of assistants helps to ensure quality performance. The extent of the supervision will vary according to the number of assistants, their experience, and the complexity of the engagement. Ultimately, the valuation analyst, as the potential expert witness or consultant, is responsible for the work performed.

## Sufficient Relevant Data

A valuation analyst attempts to obtain relevant data that is sufficient to provide a reasonable basis for conclusions or recommendations for any professional services performed. In litigation, data are usually obtained through discovery, including depositions, interrogatories, and document production motions. In addition, the data-gathering process may include a review of relevant documents, research and analysis, and interviews. The nature and extent of the data will vary with each engagement and may include the valuation analyst's computations and analysis and other information-supporting conclusions.

The expert needs to base his or her conclusions and judgments on sufficient relevant data. The expert should rely on the attorney to comply with the applicable rules of evidence.

- a. *Legal evidence.* The courts have established rules for the determination of admissible evidence and expert testimony.

The expert can generally rely on documents that have been authenticated by the parties to the proceeding or that are acceptable to the court under the various rules of evidence. Each legal jurisdiction may have different rules governing what the expert may and must rely on. It is important to communicate to the attorney what evidence is necessary to properly support the expert's conclusions and

judgments. Different rules of evidence may apply in different jurisdictions, and the valuation analyst is not expected to be a legal expert.

- b. *Assumptions.* Experts can base opinion testimony on either facts or assumptions. Experts may base assumptions on facts, presumptions from facts, or assumptions provided by the client, other experts, or counsel. For example, some analyses require the use of assumptions about what would have happened if certain behavior or activities had been different. Counsel may provide the expert assumptions that may be proven from other evidence. In any case, the expert should identify the source of the information. The valuation analyst should consider analyzing key assumptions to determine whether they are reasonable. In several recent cases, experts had their testimony excluded because their opinions were based on assumptions that were deemed not reasonable. Ultimately, the trier of fact will determine the reasonableness of the assumptions.
- c. *Documentation.* The valuation analyst should prepare and maintain documentation, the form and content of which should be designed to meet the circumstances of the particular engagement. Results of research and working paper documentation (including electronic mail, spreadsheets, and correspondence) are the principal records of the procedures applied, information obtained, and the conclusions reached by the valuation analyst in the engagement. The quantity, type, and content of documentation are determined by several factors, including the valuation analyst's professional judgment, the nature of the engagement, and the directives of counsel.

The expert should understand that his or her conclusions and judgments are subject to discovery and cross-examination by the opposing counsel and evaluation by the trier of fact. The expert may have to defend these conclusions and judgments and in so doing maintain objectivity and integrity. Documentation that is fundamental to the expert's conclusions and judgments should be retained.

The valuation analyst should adopt a policy on the retention of records in litigation matters; the existence of subpoenas or agreements between litigant parties may affect the valuation analyst's retention policy.

### The “Compliance With Standards Rule” (ET section 1.310.001)

This Rule requires all CPAs to comply with standards promulgated by bodies designated by the AICPA Council. For valuation analysts, that body is the Consulting Services Executive Committee. This committee issued SSCS No. 1, *Consulting Services: Definition and Standards* (AICPA, *Professional Standards*, CS sec. 100), and all valuation analysts are required to adhere to its standards.

### The “Accounting Principles Rule” (ET section 1.320.001)

To the extent that generally accepted accounting principles are applicable in a litigation services engagement, the valuation analyst shall apply the appropriate accounting principles.

### Definition of “Confidential Client Information” (ET section 0.400.09)

The valuation analyst may not disclose confidential client information without the client's consent. Due to the ethical obligation to preserve client confidences, valuation analysts may be confronted with the risk of breaching client confidentiality.

The expert brings to the courtroom prior experience and knowledge of clients and their practices, operations, and trade secrets. Although such experiences may enable the expert to render expert opinions, confidential client information obtained in prior engagements for nonparty clients must be protected. Thus, the expert has the dual responsibility to be both truthful and honest while preserving past and present nonparty client confidences. If the expert relies on specific information obtained in an unrelated prior engagement and uses that information as the basis for his or her opinion, the trier of fact may require the expert to disclose the source. If the expert refuses, the trier of fact may preclude the testimony because discovery could not be taken as the basis of the expert's opinion. So, the expert should consider such a circumstance and either obtain the consent of the nonparty client to reveal its confidences or abandon any effort to use such information as the basis of his or her opinions.

The valuation analyst should evaluate any prior or existing relationship with the parties to a litigation matter before accepting the engagement. Assuming there is no conflict, the valuation analyst is free to be retained.

There may be circumstances in which the very fact of a prior relationship may be confidential; the valuation analyst may be forced to reject an engagement without giving the attorney a specific reason because he or she may not disclose information gained from another client. The valuation analyst is required to adhere to the profession's confidentiality standards and confidentiality agreements executed during the course of an engagement. During the course of an engagement, there is the potential for an unknown party to become an opposing party, so continuing sensitivity to newly arising conflicts is necessary, particularly in engagements that are lengthy or involve many parties.

If you have not figured it out yet, because so many valuation analysts perform their services in a litigation environment, all of the standards previously mentioned come into play for CPAs. The item that I run into on a regular basis is *Sufficient Relevant Data*. Frequently, we have trouble getting enough documentation from the opposing party in a litigation assignment to allow us to feel comfortable providing a conclusion of value about the subject company. In those instances, we speak with our client's attorney so that The Court can be petitioned to get those missing documents, we have to include an extraordinary limiting condition, or we may even be forced to withdraw from the engagement.

## Consulting Standards

In addition to the general standards, specific consulting standards apply to the consulting process and are established by SSCS No. 1 under the "Compliance With Standards Rule" (AICPA, *Professional Standards*, ET sec. 1.310.001). These standards include serving the client's interest, entering into an understanding with the client, and communicating with the client.

The general standards are related to the quality of the performance of any professional service. The consulting standards apply specifically to the consulting process to guide valuation analysts in their relationships with consulting clients.

## Defining the Client

Each of the consulting standards refers to the client. The valuation analyst needs to have an understanding of who the client is to comply with the consulting standards. The code (ET section 0.400.07) defines a *client* as "any person or entity, other than the member's employer, that engages a member or a member's firm to perform professional services and, if different, the person or entity with respect to which professional services are performed."

The client in a litigation services engagement may be the attorney, the attorney's client (litigant), or both. It is important to define who the client is in a litigation services engagement depending on the issue(s), given the requirements of SSCS No. 1 that the valuation analyst (a) define the client, (b) serve the client interest, (c) establish an understanding with the client, and (d) communicate with the client (footnote omitted). For example:

- a. In determining conflicts and client interests, the litigant is generally deemed to be the client, although relationships with the attorneys for each party should be considered.
- b. The party with whom the valuation analyst obtains an understanding is dependent upon an assessment of the facts and circumstances of the engagement. This often leads to an understanding with either the attorney or the litigant, or both. In addition, if the valuation analyst is to protect his or her status as a consultant to counsel, the analyst should consider discussing with counsel how the understanding should be secured in order to protect any privilege that may be asserted.
- c. The valuation analyst's responsibility to communicate with the client is generally viewed to extend only to the attorney. SSCS No. 1 is not intended to cause the valuation analyst to pierce the attorney-client relationship. In many litigation services engagements, the valuation analyst's contact with the litigant is minimal or nonexistent. To clarify the communication responsibility, the valuation analyst may determine that it is appropriate to advise the attorney that any communication with the attorney will be deemed communication with the litigant. The valuation analyst may also consider having the attorney's client co-sign the engagement letter.
- d. SSCS No. 1 calls for the valuation analyst to communicate significant engagement findings and events to the client. As noted previously, the professional standards do not intend this to cause the valuation analyst to interfere with the unique attorney-client relationship. Therefore, the expert's communication with the client, unless otherwise required by the terms of the engagement, should be with

the attorney. This is even more important when acting in a consulting capacity if there is usually a desire to maintain a privilege between the attorney-consultant communications.

## Understanding With the Client

The valuation analyst should establish a written or an oral understanding with the client, who may be the attorney representing the litigant, about the responsibilities of the parties and the nature of the services to be performed. The understanding (written or oral) could encompass the following:

- a. The attorney's client
- b. The attorney for the retaining litigant
- c. The title of the litigation including the litigants' names and the court
- d. A description of the nature of the litigation services to be provided or a statement that the services will be as the attorney may direct
- e. The expert witness or the willingness of the person who will be the expert witness, if necessary
- f. The absence of conflicts of interest
- g. Restrictions on the use of the valuation analyst's work
- h. The valuation analyst's right to withdraw from and terminate the engagement in certain circumstances
- i. Administration and fee matters, including a description of fees, the fact that these are not contingent upon the successful resolution of the matter, and billing arrangements
- j. A description of the valuation analyst's records retention policy

The valuation analyst should check with his or her own firm's legal counsel to determine what should be put into the understanding with the client (also known as the *engagement letter*).

If circumstances require a significant change during the engagement, the understanding, whether written or oral, should be modified accordingly.

## Communication With the Client

In compliance with the "Conflicts of Interest for Members in Public Practice" interpretation (AICPA, *Professional Standards*, ET sec. 1.110.010) .010 of the code and interpretations thereof, the valuation analyst informs the client of any conflicts of interest. A conflict of interest may occur if a significant relationship could be viewed as impairing the valuation analyst's objectivity in the performance of a professional service. The valuation analyst should carefully evaluate each engagement request with sensitivity to the possibility of such conflicts.

A conflict of interest might arise in the performance of litigation services if the valuation analyst has a relationship with one of the parties to the dispute, the court, attorneys, or witnesses, and, thus, may not be an impartial expert. The responsibility of the valuation analyst is to decline litigation engagements that involve a conflict of interest; otherwise, the valuation analyst might disclose confidential client information in the litigation process through discovery or testimony.

When the conflict is uncertain, the valuation analyst should disclose the possible conflict of interest, which allows the prospective client or counsel to consider the potential impact on the litigation. Nothing in the professional standards requires a valuation analyst to accept any engagement, so the valuation analyst can, without stating specific reasons, refuse an engagement for any reason. On the other hand, a valuation analyst who wishes to accept an engagement, but is concerned about possible conflicts, should evaluate those possibilities before acceptance.

In addition to assessing possible conflicts of interest, valuation analysts consider whether it is otherwise in their best interest to accept the engagement. The goals and objectives of their practice might conflict with the performance of services in the proposed engagement. Although there may be no conflict with the attorneys or parties to the litigation, the issues in dispute may be areas that the valuation analysts are uncomfortable about pursuing or that may conflict with their philosophy, practice, or business interest.

Consistent with SSCS No. 1, before accepting the engagement or during the engagement, the valuation analyst should communicate to the client any serious reservations concerning the scope or benefits of the engagement. During the performance of the engagement, communications, ordinarily oral, should include significant engagement findings and events.

**Author's Note**

We are going to discuss engagement letters in the next chapter. Therefore, I am not going to elaborate on this very important section at this point.

## ASA Standards

The most recent version of the ASA Standards can be obtained from their website ([www.appraisers.org](http://www.appraisers.org)). They are a well-thought-out set of standards that must be followed by members of ASA. These standards do not provide the same level of guidance that is included in the AICPA standards, but they are essentially the same. A similar group of individuals, appraisers, CPAs, and brokers strongly influenced the creation of these standards. ASA also has one other requirement imposed on its members that the AICPA does not have. Because ASA is a sponsoring member of The Appraisal Foundation, all of its members must comply with the USPAP in all appraisals. Fortunately, the USPAP and the ASA standards do not contradict each other. All ASA members must take a comprehensive, 15-hour USPAP course and pass a USPAP examination to become a candidate member of ASA. Afterwards, there are requirements to take additional USPAP courses every five years. International members have to follow the rules of either their own country or the International Valuation Standards, which are beyond the scope of this book.

## Uniform Standards of Professional Appraisal Practice

The 2016–17 USPAP publication is approximately 378 pages long. This entire publication used to be under 150 pages. The price at the time this book was published was \$75. If you wish to obtain a copy (and every valuation analyst should), this amount should be sent to:

The Appraisal Foundation  
Distribution Center  
P.O. Box 381  
Annapolis Junction, Maryland 20701-0381

Don't forget to tell them what you want! If you want to order it online, go to [www.appraisalfoundation.org](http://www.appraisalfoundation.org). In my opinion, if you are considering business valuation assignments, you should not only be familiar with the USPAP, but you should also attempt to follow these standards in all your assignments. By following the other sets of standards, you will also be complying with most of the provisions of the USPAP.

Standards 9 and 10, as well as Standard 3 and all of the prefatory materials, pertain to business valuations. Various other sections of the USPAP also apply. The essence of Standards 9 and 10 is to do your job in a competent manner and communicate it properly. Several government agencies have adopted provisions requiring the USPAP to be followed for all appraisals performed for their agencies. More and more courts are also becoming familiar with the USPAP. Also, the IRS has specifically mentioned the USPAP in Notice 2006-96, which was issued as a result of the Pension Protection Act of 2006 to provide guidance regarding the definition of a qualified appraiser and a qualified appraisal. As a result, business valuation analysts are advised to follow these standards.

## NACVA/IBA Standards

NACVA has its own set of standards, which have been greatly expanded over the years. Most of these standards come from the AICPA and are the very standards that I referred to previously. Take the time to read them. These standards are available on their website ([www.nacva.com](http://www.nacva.com)). The IBA uses the same standards, and you can get them from the same website.

## Glossary of Business Valuation Terms

In an attempt to assist users of valuation services at being better able to understand the terminology used by our profession, various organizations came together to form a committee whose purpose was to establish a single set of terminology that is recommended for use by its members. These organizations include the AICPA, IBA, ASA, NACVA, and the Canadian Institute of Chartered Business Valuators. The glossary is reproduced as appendix 2.

This is the appendix that is part of the AICPA standards.

## Conclusion

By now, you are probably at your wit's end. Imagine, this is only chapter 2. Standards make our profession better, and if you have not figured it out yet, standards will also provide you with the necessary guidance to make sure that you do a good job and stay out of trouble. Obviously, I have spent a great deal of time on the AICPA standards. What did you expect? The AICPA is the publisher of this book. Truthfully, my hat comes off to the various individuals who drafted this standard and put it in its final form. This is one heck of a document, and I believe that it adds a tremendous amount to the standards in our field. To demonstrate what a great job was done on the business valuation standard, the only changes that have been made since its release have been purely cosmetic in nature. It just goes to show how much thought went into the process of getting it done correctly the first time. Although certain sections clearly apply only to accountants, I believe that anyone who performs business valuation assignments will benefit by following the guidance provided in this document. Time to get off my soapbox and move on.

# Chapter 3

## Getting Started

### Learning Objectives

In this chapter, I will attempt to explain the following:

- Learning about the engagement
- Deciding whether to accept the engagement
- Defining the engagement
- Writing engagement letters
- Creating the initial document request

### Introduction

Before we can get to the good stuff, it is important to get some of the preliminary items out of the way. Let's start off with some items that should be addressed at the beginning of this process.

### Learning About the Engagement

After the telephone rings, and after the caller tells you that he or she needs the services of a good valuation analyst, what should you do? Should the valuation analyst find out more about the assignment, automatically accept it, or recommend a good valuation analyst? Believe it or not, these are serious considerations that the valuation analyst must be taken into account. If you have read chapter 2, you have seen that professional standards address many issues that the valuation analyst must consider before just saying yes to every assignment that comes through the door. The beginning of the assignment, or should I say the pre-beginning of the assignment, is the most important part of the valuation process for several reasons.

First and foremost, the valuation analyst needs to properly understand the nature of the assignment to determine if he or she is competent to perform it. The analyst must take a step back and ask if the assignment can be completed with competence. We all like to think that we are competent to do every assignment that comes through the door, but, truthfully, we are not. The analyst cannot possibly possess the competence to take on every assignment that comes his or her. If the proper level of competence can be obtained, the analyst can accept the assignment. All of the valuation organizations (and especially the AICPA) have competency standards for their members.

Furthermore, the *Uniform Standards of Professional Appraisal Practice* (USPAP) requires the valuation analyst to disclose any deficiencies to the client in his or her level of competence, as well as what he or she will do to compensate for it. Imagine telling the client, "Although I am incompetent, I really want to do this job for you." If the client hires that valuation analyst, the client deserves what he or she gets. However, full disclosure to the client is essential. At that point, it is up to the client to decide if he or she is comfortable with the valuation analyst handling the assignment.

After the client has decided to go forward with the valuation analyst, and assuming that the analyst does a good job, there should be no reason for the client to have the opportunity at a later date to question why the analyst didn't tell him or her something. Can you imagine the client, sitting in a courtroom on the witness stand, stating that "the valuation analyst never told me that this was the first valuation he had ever done?" If you are new to this business, do not feel intimidated because of your inexperience. We all have to start

somewhere. Unfortunately, we are in a more litigious society than we were in when I got started, and, as a result, we have to be especially careful not to find ourselves as a party to a lawsuit. I prefer to be the expert in a litigation, rather than the defendant.

If the client is not comfortable with the valuation analyst or the analyst's experience level at the start, the worst mistake that the valuation analyst can make is to oversell his qualifications to get the assignment. If anything can go wrong, it probably will; as a result, the analyst is staring a malpractice suit in the eyes. The worst thing an analyst can do is to try to boost his level of experience to impress a potential client. Doing so raises serious ethical considerations that go far beyond just the assignment.

## Deciding Whether to Accept the Engagement

Before a valuation analyst accepts an assignment, considerations include, but should not be limited to, the following:

- The possibility of a conflict of interest or the appearance of a conflict of interest
- The purpose and function of the engagement
- The amount of time required to do the job
- The scope of the assignment, including the possibility of giving expert testimony
- The type of report to be issued

These items will be addressed over and over again throughout this book, and they must be understood at the start of the assignment, especially because many of these issues will affect the ability to accept the engagement. You can tell from the last chapter that many of these items are discussed in the standards. Clearly, they are important!

### Conflicts of Interest

The telephone rings, and the valuation analyst is asked to do a business valuation for a litigation that is pending. The attorney asks the analyst to perform a conflict check to determine if the analyst knows any of the parties. The analyst says no. Does this mean only the valuation analyst, or does it mean someone in the valuation analyst's firm, on staff, the firm's partners, or the analyst's cousin or great uncle? The valuation analyst better check for conflicts! Conflicts are a great way to get sued. Sometimes, the conflict is immediately apparent. Other times, conflicts are well hidden. The first step in avoiding a problem is to make certain that the valuation analyst's firm employs some form of conflict of interest verification form for use in all assignments. Trugman Valuation Associates' form is reproduced as exhibit 3.1.

First of all, let me give attribution where it belongs. Our forms (and many of the other forms that you may see in this book) have been adapted from Thomson PPC's *Guide to Business Valuations*.<sup>1</sup> There is no reason to start from scratch when we have good tools that we can use as a jumping-off point. They should be customized for the valuation analyst's firm.

In addition to checking with all professional staff, it is a good idea to make certain that nonprofessional staff do not present a problem. What if one of the parties is the valuation analyst's administrative assistant's next door neighbor? Or what if it is the assistant's child's godfather?

Let's stick with conflicts of interest for a little longer. Checking with all staff becomes critically important, especially when you have multiple offices. Imagine your staff in New York being hired against your staff in Chicago. Or, what happens when you are asked to represent an existing client? I even encountered one situation in which two firms merged, and they were on opposite sides of a divorce engagement and had to refund a large fee and get out of the case completely.

The appearance of impropriety is almost as bad as the act itself. Litigation services is an area that the SEC has suggested may impair an auditor's independence. Think about the cross-examining attorney who is in front of the valuation analyst, almost salivating, asking him or her the following questions:

.....

<sup>1</sup> Fishman, J. et al.: *Guide to Business Valuations*. Fort Worth: Thomson Practitioner's Publishing Co., updated annually.

- You receive current income from this client for accounting services, don't you?
- This company has been your firm's client for the last 10 years?
- Isn't it true that they paid you about \$80,000 in fees last year?
- Do you consider them a good client?
- You wouldn't want to lose this client, would you?
- Do you expect this jury to believe that you can sit on this witness stand and be objective with respect to this client when your opinion in this matter may hurt your client?

**EXHIBIT 3.1 Trugman Valuation Associates, Inc. Business Valuation Engagement Acceptance Form: Conflict of Interest Verification**

**INSTRUCTIONS:** This form should be completed for a prospective new client and sent to ALL staff for confirmation that there are no conflicts of interest with any of the parties or entities involved in this matter. If the referral source, attorneys, CPAs or others associated with these individuals/entities are known, list them also for conflict verification. ALL staff must immediately respond via e-mail to the sender of the original e-mail.

TRUGMAN VALUATION ASSOCIATES, INC. has been requested to perform services with respect to the following individuals and/or entities:

---

---

---

---

---

---

	Yes	No
1. Do you know any of these individuals/entities?		
2. Do you have any personal knowledge about these individuals/entities that would cause our firm to have information that another firm would not readily have?		
3. Are we doing any work for any of these individuals/entities currently?		
4. Have we done any work for them in the past?		
5. Have we been approached by any of these individuals/entities to do work for them in the past?		
6. Do you know of any reason that we should not do this assignment?		

If you answered yes to any of these questions, please explain and give details.

(Adapted from *PPC's Guide to Business Valuations*, Copyright © 2017 Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit [tax.thomsonreuters.com](http://tax.thomsonreuters.com).)

Even if the valuation analyst can be objective, he or she is dead in the water. No juror will believe that the analyst is not acting as an advocate for the client. It is often difficult to prove that as a paid expert we are objective, even when we are truly independent from the client. The burden becomes that much more difficult when the valuation analyst is the client's accountant. Even in non-litigation jobs (for example, estate tax valuation), a perceived conflict can arise. Imagine being the tax return preparer taking a deduction on a return for officer's compensation of \$1 million and then adjusting it in the valuation to reflect reasonable compensation of \$250,000. Even though the standard for deductible compensation for income tax purposes is very different from the concept of a replacement salary on a prospective basis for valuation purposes, the valuation analyst

needs to think about the reader of the report who does not know better. If the valuation analyst thinks that he or she will educate the reader, think again.

Let's discuss one more conflict that is sure to get the valuation analyst in trouble. As past chairman of the ethics committee of two of the valuation organizations, I saw this example more often than you can imagine. An accountant's business client is going through a divorce. The accounting firm prepares the corporate tax returns. The accounting firm also prepares the personal tax returns for the stockholders. The accounting firm has been preparing joint income tax returns for the clients, who are about to get divorced. The business client turns to the partner in the firm who handles this account, the trusted business adviser, to perform various divorce-related services, perhaps even a business valuation. Because the partner expects the firm to remain the company's accountant, and because the owner is a good client, the partner says, "Sure, we'll do it." Guess what? What about the spouse? The accounting firm has also been the spouse's accountant because the couple has been filing joint income tax returns. The accounting firm cannot suddenly say, "Sorry, but we are no longer going to be your accountant, so that we can represent your soon-to-be ex-spouse against you in the divorce."

There is no easy way to avoid appearances of conflict other than to stick with my motto: "Perception is reality." If it can, in any way, be perceived to be a conflict, you probably want to protect yourself. Protection can come in many different forms. First, stay away from the engagement. Second, stay away from the engagement. Third, if you decide not to stay away from the engagement, have the client(s) sign a waiver acknowledging that there may be a conflict and that they have been made aware of it, and, despite that, they still want you to proceed.

Let me give you a real example of how to protect yourself. We were retained by a former accounting client (back in the days when we performed traditional tax and accounting services) to assist him as his expert in a litigation in which he was being accused of fraud relating to the sale of a laundromat (a cash business—imagine that!). I was afraid not only of the appearance of a conflict of interest, but also that I could be asked on the witness stand why his tax returns had different amounts than the current information sheet he had put together for prospective purchasers (like many clients, he got honest when he went about selling the business). In our retainer agreement (and we will discuss these agreements in much more detail soon), we put in the following language:

The client also acknowledges that a discussion took place between himself and Gary Trugman regarding the possible appearance of a conflict of interest. The client, by signing this agreement, acknowledges that Gary Trugman has expressed his concern about the appearance of conflict of interest, and despite this, the client has expressed his desire to have Trugman Valuation Associates, Inc. perform services in this matter. The client agrees to completely indemnify Trugman Valuation Associates, Inc., its officers, its directors, and its shareholders, as well as Trugman & Company CPAs (a partnership) and its partners, Gary and Linda Trugman, from any liability that may arise out of the client's request to these parties or firms involved as a result of this litigation engagement.

Fortunately, the case settled before we had to go to court. But do not expect to be so lucky—protect yourself.

Sometimes, something as simple as an engagement letter signed by two parties will help. We are often hired as a mutual valuation analyst by both sides of a litigation. We use the retainer agreement (engagement letter) in exhibit 3.2 on the following page, which we have each party sign individually.

Let me share one more conflict that actually happened to me just to demonstrate how well hidden they can be at times. I am based out of our Florida office but had an assignment in Pennsylvania. I was allowed to interview the management of the company at their attorney's office in Philadelphia. I was representing a shareholder who sued the company to be bought out. I was conducting the management interview, and we took a quick break. While we were waiting for the other side's attorney to come back into the room, I was chatting with the father and son management team that I was interviewing. We were not talking about anything that would require the attorney to be in the room.

### EXHIBIT 3.2 Mutually Retained Business Valuation Retainer Agreement

The undersigned clients (The Clients) acknowledge this engagement of Trugman Valuation Associates, Inc. (The Valuation Analyst) to perform a business valuation of <<DEFINE THE PROPERTY TO BE VALUED>> as of <<VALUATION DATE(S)>> to be used <<PURPOSE OF VALUATION>>. Our conclusion of value will be communicated to you in a <<DETAILED OR SUMMARY>> report.

All of the undersigned clients, by signing this agreement, acknowledge the mutual retention of The Valuation Analyst to perform this assignment. This means that the clients waive any and all potential conflict of interest claims against The Valuation Analyst, its owners, directors, principals, and employees. It is further recognized that The Valuation Analyst cannot represent any one client more than the other, and therefore, no services will be rendered as part of this assignment that would place The Valuation Analyst in a position of a conflict of interest.

#### PARAGRAPH TO BE INCLUDED IF LESS THAN A DETAILED REPORT TO BE ISSUED

Since The Clients have requested that the conclusion of value be communicated in less than a detailed report, valuation standards that must be adhered to by The Valuation Analyst require that this report be restricted in its distribution. A summary report can easily be misunderstood by individuals who are not well-informed about the subject property, and therefore, valuation standards require that this type of report not be distributed to anyone other than The Clients for their own use. **THIS REPORT IS FOR OUR CLIENT'S EYES ONLY.** Distribution to any other party is expressly prohibited.

The standard of value for this assignment shall be fair market value. Said fair market value is defined as a value at which a willing seller and willing buyer, both being informed of the relevant facts about the business, could reasonably conduct a transaction, neither party acting under any compulsion to do so.

The standard of value is frequently determined by law. For example, the Internal Revenue Code requires fair market value to be used for all valuation assignments for tax purposes. In some instances, the standard of value may be determined by state statute, and in other instances, it may be subject to the interpretation of case law. As such, since The Valuation Analyst is not authorized to practice law, the standard of value should be determined by your legal advisor. The Valuation Analyst assumes no liability as a result of the incorrect standard of value being used in this assignment. Before signing this retainer agreement, consult your legal advisor.

Furthermore, the valuation date is also frequently subject to legal interpretation. Therefore, it is essential that The Clients also make sure that the correct valuation date(s) is used in this retainer agreement for the performance of this assignment. The Valuation Analyst will be valuing the subject property based on whichever date(s) appear in this retainer agreement without any consideration as to the correctness of this date. The Valuation Analyst assumes no liability if incorrect dates are used as long as The Valuation Analyst uses the date(s) provided in this retainer agreement.

It is understood that Trugman Valuation Associates, Inc. is not being engaged to perform an audit as defined by the AICPA, but rather, the necessary tests of the accounting records that will be performed for the purpose of issuing a valuation report, and not a statement regarding the fairness of presentation of the financial statements of the above business.

Certain values, derived from reports of others, and which are so designated, will be included in our report. The Valuation Analyst takes no responsibility for those items. Nor does the Valuation Analyst take responsibility to update the report or disclose any events or circumstances occurring after the date of the report.

It is the responsibility of The Clients to provide the necessary documentation that will be requested by The Valuation Analyst to perform this assignment. This documentation must be provided on a timely basis in order for The Valuation Analyst to conduct the assignment in an efficient manner. Additional fees could result from delays in receiving requested information. If this assignment is part of a litigation where the clients do not control the books and records of the company that is the subject of the valuation, it is The Clients' responsibility to ensure that legal counsel obtains the necessary documentation requested by The Valuation Analyst for The Valuation Analyst to feel that it has satisfied its compliance with valuation standards with regard to "sufficient relevant data." In the event sufficient records and/or documentation cannot be supplied to The Valuation Analyst, no such valuation report will be issued. The Valuation Analyst assumes no liability for not issuing a report on a timely basis if The Valuation Analyst believes that it would be in violation of valuation standards to issue a report where The Valuation Analyst cannot meet the "sufficient relevant data" standard.

*(continued)*

**EXHIBIT 3.2 Mutually Retained Business Valuation Retainer Agreement** *(continued)*

This valuation will be subject to, at least, the following contingent and limiting conditions, which will be included in the report as an appendix:

1. The conclusion of value arrived at herein is valid only for the stated purpose as of the date of the valuation.
2. Financial statements and other related information provided by the business or its representatives, in the course of this engagement, have been accepted without any verification as fully and correctly reflecting the enterprise's business conditions and operating results for the respective periods, except as specifically noted herein. The Valuation Analyst has not audited, reviewed, or compiled the financial information provided to us and, accordingly, we express no audit opinion or any other form of assurance on this information.
3. Public information and industry and statistical information have been obtained from sources we believe to be reliable. However, we make no representation as to the accuracy or completeness of such information and have performed no procedures to corroborate the information.
4. We do not provide assurance on the achievability of the results forecasted by or for the subject company because events and circumstances frequently do not occur as expected; differences between actual and expected results may be material; and achievement of the forecasted results is dependent on actions, plans, and assumptions of management.
5. The conclusion of value arrived at herein is based on the assumption that the current level of management expertise and effectiveness would continue to be maintained, and that the character and integrity of the enterprise through any sale, reorganization, exchange, or diminution of the owners' participation would not be materially or significantly changed.
6. This report and the conclusion of value arrived at herein are for the exclusive use of The Clients for the sole and specific purposes as noted herein. They may not be used for any other purpose or by any other party for any purpose. Furthermore, the report and conclusion of value are not intended by the author and should not be construed by the reader to be investment advice in any manner whatsoever. The conclusion of value represents the considered opinion of The Valuation Analyst, based on information furnished to them by the subject company and other sources.
7. Neither all nor any part of the contents of this report (especially the conclusion of value, the identity of any valuation specialist(s), or the firm with which such valuation specialists are connected or any reference to any of their professional designations) should be disseminated to the public through advertising media, public relations, news media, sales media, mail, direct transmittal, or any other means of communication without the prior written consent and approval of The Valuation Analyst.
8. Future services regarding the subject matter of this report, including, but not limited to testimony or attendance in court, shall not be required of The Valuation Analyst unless previous arrangements have been made in writing.
9. The Valuation Analyst is not an environmental consultant or auditor, and it takes no responsibility for any actual or potential environmental liabilities. Any person entitled to rely on this report, wishing to know whether such liabilities exist, or the scope and their effect on the value of the property, is encouraged to obtain a professional environmental assessment. The Valuation Analyst does not conduct or provide environmental assessments and has not performed one for the subject property.
10. The Valuation Analyst has not determined independently whether the subject company is subject to any present or future liability relating to environmental matters (including, but not limited to CERCLA/Superfund liability) nor the scope of any such liabilities. The Valuation Analyst's valuation takes no such liabilities into account, except as they have been reported to The Valuation Analyst by the subject company or by an environmental consultant working for the subject company, and then only to the extent that the liability was reported to us in an actual or estimated dollar amount. Such matters, if any, are noted in the report. To the extent such information has been reported to us, The Valuation Analyst has relied on it without verification and offers no warranty or representation as to its accuracy or completeness.
11. The Valuation Analyst has not made a specific compliance survey or analysis of the subject property to determine whether it is subject to, or in compliance with, the American Disabilities Act of 1990, and this valuation does not consider the effect, if any, of noncompliance.
12. No change of any item in this appraisal report shall be made by anyone other than The Valuation Analyst, and we shall have no responsibility for any such unauthorized change.
13. Unless otherwise stated, no effort has been made to determine the possible effect, if any, on the subject business due to future federal, state, or local legislation, including any environmental or ecological matters or interpretations thereof.
14. We have conducted interviews with the current management of the subject company concerning the past, present, and prospective operating results of the company. Except as noted, we have relied on the representations of these individuals.
15. Except as noted, we have relied on the representations of the owners, management, and other third parties concerning the value and useful condition of all equipment, real estate, investments used in the business, and any other assets or liabilities, except as specifically stated to the contrary in this report. We have not attempted to confirm whether or not all assets of the business are free and clear of liens and encumbrances or that the entity has good title to all assets.

### EXHIBIT 3.2 Mutually Retained Business Valuation Retainer Agreement

16. All facts and data set forth in the report are true and accurate to the best of the Valuation Analyst's knowledge and belief. We have not knowingly withheld or omitted anything from our report affecting our value estimate.
17. Possession of this report, or a copy thereof, does not carry with it the right of publication of all or part of it, nor may it be used for any purpose without the previous written consent of the Valuation Analyst, and in any event only with proper authorization. Authorized copies of this report will be signed in blue ink by a principal of The Valuation Analyst. Unsigned copies, or copies not signed in blue ink, should be considered to be incomplete.
18. Unless otherwise provided for in writing and agreed to by both parties in advance, the extent of the liability for the completeness or accuracy of the data, opinions, comments, recommendations, and conclusions shall not exceed the amount paid to the Valuation Analysts for professional fees and, then, only to the party(s) for whom this report was originally prepared.
19. The conclusion reached in this report is based on the standard of value as stated and defined in the body of the report. An actual transaction in the business or business interest may be concluded at a higher value or lower value, depending on the circumstances surrounding the company, the appraised business interest, and the motivations and knowledge of both the buyers and sellers at that time. The Valuation Analyst makes no guarantees as to what values individual buyers and sellers may reach in an actual transaction.
20. No opinion is intended to be expressed for matters that require legal or other specialized expertise, investigation, or knowledge beyond that customarily employed by the Valuation Analysts valuing businesses.

It is possible that additional contingent and limiting conditions will be required, and The Clients agree that all conditions disclosed by The Valuation Analyst will be accepted as incorporated into the Valuation Analyst's report.

For all business valuation assignments that are being used as part of a litigation assignment, particularly where testimony is expected to be provided by The Valuation Analyst, The Clients acknowledge that The Valuation Analyst will not be held responsible if a court excludes the testimony of The Valuation Analyst for circumstances that are beyond the control of The Valuation Analyst. For example, a court may exclude The Valuation Analyst as a result of not being an industry expert in the subject company's industry. While we are valuation experts, we do not hold ourselves out to be industry experts except in our own industry.

For non-litigation assignments, The Clients acknowledge that The Valuation Analyst will not be held responsible for a finding by another party, such as a taxing authority, based on a difference of opinion as to the value conclusion reached or a negotiated value. Since The Valuation Analyst is generally not part of negotiations between the taxing authority and The Clients, we cannot assume any liability when we are not part of that process.

**BY SIGNING THIS RETAINER AGREEMENT, THE CLIENTS ACKNOWLEDGE THAT THE VALUATION ANALYST WILL NOT BE EXPECTED TO TESTIFY IN ANY LEGAL PROCEEDING WHERE THE CLIENTS HAVE ADVERSE INTERESTS. FOR EXAMPLE (AND FOR EXAMPLE ONLY), IF ONE CLIENT DOES NOT AGREE WITH THE OPINIONS OF THE VALUATION ANALYST, THE OTHER PARTY CANNOT HIRE THE VALUATION ANALYST TO TESTIFY AGAINST A PARTY TO THIS AGREEMENT. THEREFORE, NO TESTIMONY SHALL BE RENDERED AS PART OF THIS ENGAGEMENT UNLESS THE VALUATION ANALYST'S TESTIMONY SHALL BE ON BEHALF OF ALL CLIENTS SIGNING THIS AGREEMENT.**

The Valuation Analyst's goal is to be as fair as possible in its billing practices with respect to this assignment. It is our intention to perform this engagement as quickly and affordably as possible, but these services take a reasonable amount of time to render. We will make certain that the appropriate personnel in our firm render those services that will comply with the level of expertise required by this engagement. In that regard, hourly rates will be charged based on the billing rates in effect at the time that the services are rendered. Currently those hourly rates range from \$XXX to \$YYY per hour depending on the level of staff performing the assignment.

While The Valuation Analyst does its best to estimate fees in these types of assignments, there will be times that the fees may be greater than the range estimated. This is especially true in litigation assignments where The Valuation Analyst has a difficult time obtaining records, or where it takes a long time to get those records requiring The Valuation Analyst to constantly pick up and put down the file. This is not the only reason for assignments to go over budget. If The Valuation Analyst believes that the fees will exceed an estimated range, we will try to notify The Clients as soon as practical to discuss the overage. However, when The Valuation Analyst sends an invoice to The Clients, unless the clients question said invoice within 14 days of the date of the invoice, The Valuation Analyst assumes that The Clients have accepted the invoice as being reasonable and expects it to be paid in accordance with this retainer agreement.

*(continued)*

### EXHIBIT 3.2 Mutually Retained Business Valuation Retainer Agreement *(continued)*

Hourly rates are charged portal to portal from our Plantation, Florida office. In addition to these hourly rates, the following charges may be applicable:

- a. Fees for appearance at depositions and/or trial testimony shall be charged based on our standard billing rates. Although payment for deposition testimony is usually the responsibility of the adverse party in a litigation, the undersigned clients guarantee payment of the same to The Valuation Analyst.
- b. Any out-of-pocket expenses relating to this valuation. It is expected that we will perform research through computer databases, and that we may be required to purchase research materials relating to this engagement. These and other such costs will be billed to you at our cost. Regardless of which office this assignment is billed from, there is an expectation that only normal travel expenses will be incurred by The Valuation Analyst. Any additional expenses that are incurred by The Valuation Analyst will be billed to The Clients. For example, higher than normal fares due to last minute travel or change fees due to changes to travel that were not initiated by The Valuation Analyst will be billed at our cost to you. These costs also assume a limited number of trips to the business, court, an attorney's office, etc. We want to be fair with our clients but we also expect that our clients will be fair with us and not expect abnormally high expenses to be incurred by The Valuation Analyst.

Payment terms shall be as follows:

\$<<RETAINER AMOUNT>> due in advance as a retainer. **This retainer shall be allocated against the final payment** that will be due to The Valuation Analyst. All amounts shall be billed regularly. The Valuation Analyst reserves the right to request additional retainers pertaining to this assignment at any time, particularly if the clients do not pay our invoices in accordance with the terms of this agreement.

Since it is considered unethical for us to perform these services on a contingency basis, it is important to us that our fees are paid promptly. The appearance of independence is of considerable importance for our firm to maintain our credibility, and therefore, we reserve the right to stop providing services at any time that there is a balance due our firm. In the event that we continue to provide services, we do not waive our right to stop at a later date. Furthermore, in order to ensure that our fees are not misconstrued to be on a contingency basis, **we will require all fees that are outstanding at the time of trial to be paid before we testify. We will also require a sufficient retainer to cover all anticipated time and expenses relating to a trial so that all fees are paid prior to our testifying.** Any unused retainer will be refunded to the clients once our involvement has been considered to be finished.

**The Valuation Analyst requires that all fees be paid before we release our report.** This is our regular practice and we request that our clients understand this practice before we are retained. This is not a personal reflection of The Client, but it is a practice that avoids a discriminatory collection practice. Chasing clients for fees is not our intention, and we believe that this practice assists us in providing our services in a manner that prevents concern about our ability to remain independent due to unpaid fees.

The Clients must understand that professional business valuation services are not inexpensive and unless other arrangements are made, in writing, with our firm, services rendered by our firm will be invoiced regularly, and are due upon presentation of our invoice to you. Balances outstanding beyond 30 days will have a service charge added at the rate of 1-1/2 percent per month or part thereof.

In the event that The Valuation Analyst must turn collection of fees over to an attorney, the undersigned will be responsible for all reasonable costs and fees associated with the collection action. Reasonable fees will be deemed to be up to 33 percent of the amount collected. Any collection action that is required due to nonpayment of fees shall be venued in Broward County, Florida.

The undersigned clients agree to indemnify The Valuation Analyst from any legal expenses incurred as a result of this engagement, other than those relating to the conduct of this assignment. This would include, but not be limited to, any legal expenses required to protect the confidentiality of this or any other client who becomes an issue in this matter.

The final report is copyrighted by The Valuation Analyst. It shall remain the property of The Valuation Analyst and no copies or reproductions shall be allowed without the written consent of The Valuation Analyst until such time as any outstanding balance is paid.

The Valuation Analyst reserves the right to withdraw from this engagement at any time. It is not our intention to withdraw. All workpapers created by The Valuation Analyst will remain in the possession of The Valuation Analyst. In the event of a withdrawal, we would only be liable to return those materials and documents supplied by The Clients and the unused portion of the retainer.

### EXHIBIT 3.2 Mutually Retained Business Valuation Retainer Agreement

The undersigned gives The Valuation Analyst the right to discuss this matter with the clients' attorney, accountant, other individuals so designated by The Clients and any professional colleagues of The Valuation Analyst from whom professional information is sought.

If this is acceptable, please sign the acknowledgment below and return a signed copy of this retainer agreement with your check in the amount of \$<<RETAINER AMOUNT>> to our office.

TRUGMAN VALUATION ASSOCIATES, INC.

**THIS BUSINESS VALUATION RETAINER AGREEMENT CONSISTS OF SEVEN (7) PAGES INCLUDING THIS ONE. ALL SEVEN (7) PAGES MUST BE RETURNED TO TRUGMAN VALUATION ASSOCIATES, INC. AFTER EXECUTION OF THIS DOCUMENT WITH THE REQUESTED RETAINER IN ORDER TO RETAIN OUR FIRM. IF THIS DOCUMENT IS NOT RECEIVED BY TRUGMAN VALUATION ASSOCIATES, INC. FULLY EXECUTED BY THE CLIENT WITH THE REQUESTED RETAINER BY <<DATE>>, TRUGMAN VALUATION ASSOCIATES, INC. RESERVES THE RIGHT TO DEEM THE TERMS OF THIS AGREEMENT AND THE OFFER TO PERFORM BUSINESS VALUATION SERVICES NULL AND VOID.**

During the conversation, the father says to me "I have a son who is an attorney in Miami. Maybe you know him? His name is John Smith." Two things immediately went through my head. First, one of the defendants in this lawsuit was a trust for the benefit of John Smith (the son). Second, I was currently working with John Smith on a case in Florida where John Smith retained me as the expert to maintain the work-product privilege of a client and attorney. At that point, realizing that John Smith was a client of mine and a small defendant in the pending matter, I stopped the interview. I immediately disclosed to the parties at the interview that I had a conflict, and I would have to resign from the assignment. I told my client that I would refund, all fees paid to our firm in full, and I would assist him in getting a new expert.

The next day, when I was back in Florida, I called John Smith to disclose what had happened. Ironically, he had already spoken with his father and knew about it. Both attorneys talked, and it was agreed that both sides felt that it was in the best interest of the case to ignore the conflict of interest and for me to continue the job. My client was comfortable with the fact that I could continue to do my job without any bias attributable to the other assignment in which John Smith was my client. John Smith actually convinced them that they were better off with me as the expert for the defendant's side because John knew that I would be impartial and

call it the way I saw it. Everybody signed (both sides and John Smith) a conflict waiver that I had my attorney prepare. The case settled with a happy ending for all.

This is just one more situation in which a conflict can come up. Who would have put together an attorney in Miami with a trust for the benefit of a child of the principal shareholder of a business in Pennsylvania? The moral of this story is: Just be careful.

## Purpose and Function of the Engagement

When the valuation analyst is first approached about a valuation assignment, it is important for the individual to gain a clear understanding of the purpose and function of the engagement. In simple terms: What is the valuation analyst going to be doing, and how will the analysis or report be used? This also raises the question what is going to be valued? Very often, an entire company will be valued; this is frequently referred to as the *equity* of the company. There are other times when the valuation analyst may be asked to value the entire capital structure of the business; this is referred to as the *invested capital* of the company (this will be discussed in more detail later).

There will also be times when only a portion of the equity will be valued. This may involve valuing a fractional interest in the company (less than 100 percent) or valuing only certain assets and liabilities. For example, the valuation analyst may be approached to value a 40 percent interest in the company. This is not as simple as taking 40 percent of the value of the entire company. A minority interest may be worth less than a pro rata share of the entire company. This will also be discussed later.

Another alternative might be that the valuation analyst is asked to value a company for a sale in which the owner will be keeping certain assets, such as a company car or cash in the bank. Many, if not most, small businesses are sold as *asset sales* as opposed to *stock sales*. This means that the purchaser will generally transfer the assets—and possibly liabilities—that were part of the deal to a new entity. There are several reasons why this is done, but this book is not the forum for that discussion. A proper understanding of the valuation subject is essential if the valuation analyst is going to do a good job.

Another important consideration is the intended use of the valuation. The intended use can affect the manner in which the job is performed. For example, if the valuation assignment is for a divorce litigation in a jurisdiction that does not recognize goodwill, the valuation analyst will have to conduct the valuation in a manner that would meet the requirements of that jurisdiction. However, if the same company is being valued for a sale, the methodologies employed in the valuation will most likely be different. Because goodwill is part of the sales price of the company, the valuation result would be different. After all, one includes goodwill and the other does not.

The intended use is also important to know so that the valuation analyst can perform the appropriate assignment. For example, I would not perform a calculation engagement for a litigation. I believe that a valuation engagement is more appropriate.

## Amount of Time Required to Do the Job

Knowing how much time is required to do the job properly is an important part of the planning stage for the assignment. Understanding the assignment will provide the valuation analyst with the ability to budget staff time and meet any deadlines that are imposed on the assignment. The client will also want to know how much the valuation will cost. Unfortunately, an answer such as “How high is up?” is generally unacceptable. Sometimes, budgeting time is probably more difficult than the valuation assignment itself because you never know what type of research problems or document production problems you may run into, particularly in litigation assignments. In chapter 5, I will discuss data gathering and expand on the research portion of the assignment.

## The Scope of the Assignment

Understanding the scope of the assignment, including the possibility of giving expert testimony, will help the valuation analyst determine whether he or she can accept the assignment. If a client tells the valuation analyst at the beginning that he or she will have severe scope restrictions but is expected to testify in court, the valuation analyst may want to think twice about taking the assignment. The valuation analyst may end up on the short end of the stick if he or she allows the client to limit the scope. Clients frequently look to save money and will often ask the valuation analyst to streamline the process. If expert testimony is anticipated, the judge or jury will remember only that the valuation analyst did not do a complete job. Regardless of whether the valuation analyst qualifies the conclusion of value because of the client's scope restrictions, the valuation analyst's reputation will be the most damaged element in the litigation. I had one case in which the client did not want me to perform a piece of analysis that I thought was important, and I was foolish enough to not do it because the client did not want to pay me to do it. When the judge asked me about the analysis and I said that I did not do it, he looked at me and said, "Am I supposed to do it? You're the expert." That case did not end very well. Be selective when you allow scope limitations.

Exhibit 3.3 contains a business valuation engagement acceptance form, which may make your life a whole lot easier.

### EXHIBIT 3.3 Trugman Valuation Associates, Inc. Business Valuation Engagement Acceptance Form

Prospective Client: \_\_\_\_\_

Completed by: \_\_\_\_\_ Date: \_\_\_\_\_

**INSTRUCTIONS:** This form should be completed for a prospective new client or a prospective engagement for an existing client. The person completing this checklist need only complete those parts of the form that apply to the proposed engagement.

#### I. PROSPECTIVE CLIENT DATA

[The following data should be obtained for the prospective client (the person or company that will be engaging our firm). That client may not be the actual entity being valued. Accordingly, a separate section of the form is designed for documenting information about the entity being valued.]

Prospective Client's Name: \_\_\_\_\_ Phone No.: \_\_\_\_\_

Fax No.: \_\_\_\_\_

Business Address: \_\_\_\_\_

Referral Source: \_\_\_\_\_

Is the prospective client the same entity that is to be valued?

\_\_\_\_\_ Yes Proceed to Section II of this form (Entity to Be Valued). The remaining portion of Section I does not need to be completed.

\_\_\_\_\_ No Complete the remaining portion of Section I before proceeding to Section II.

Briefly explain the prospective client's relationship to the entity to be valued (for example, the client's ownership interest in the entity, if any; whether the entity is a proposed acquisition candidate of the entity, among others).

(continued)

### EXHIBIT 3.3 Trugman Valuation Associates, Inc. Business Valuation Engagement Acceptance Form *(continued)*

#### II. ENTITY TO BE VALUED

(If the prospective client and the entity to be valued are the same, it is not necessary to repeat the data obtained in the preceding section of this form.)

Name of Entity to Be Valued: \_\_\_\_\_

Type of Legal Entity (Corp., S Corp., Partnership, or Proprietorship): \_\_\_\_\_

Business Address: \_\_\_\_\_

Phone No.: \_\_\_\_\_ Fax No.: \_\_\_\_\_

Contacts at the entity with whom we would work (state name and title): \_\_\_\_\_

Brief description of the entity's business: \_\_\_\_\_

Entity's Accounting Firm: \_\_\_\_\_

Address: \_\_\_\_\_

Phone No: \_\_\_\_\_

Contact: \_\_\_\_\_

Entity's Primary Attorney: \_\_\_\_\_

Address: \_\_\_\_\_

Phone No: \_\_\_\_\_

Contact: \_\_\_\_\_

Other Contact: \_\_\_\_\_

Address: \_\_\_\_\_

Phone No: \_\_\_\_\_

#### III. SCOPE OF THE ENGAGEMENT

Briefly describe the purpose of the engagement (for example, determination of a party's interest in a divorce proceeding, valuation of a company for a proposed sale or acquisition, or determination of a value for an estate tax return).

Describe the interest to be valued (that is, the ownership percentage being valued and whether it is a controlling or minority interest).

Valuation Date(s): \_\_\_\_\_ Proposed Deadline: \_\_\_\_\_

Describe any obvious difficulties that may be associated with the valuation date (for example, the date may be at an interim period when no financials are available). \_\_\_\_\_

Does there appear to be enough historical financial statements and tax returns to assess the financial background and trend of the company? Yes \_\_\_\_\_ No \_\_\_\_\_

(Adapted from *PPC's Guide to Business Valuations*, Copyright © 2017 Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit [tax.thomsonreuters.com](http://tax.thomsonreuters.com).)

**EXHIBIT 3.3 Trugman Valuation Associates, Inc. Business Valuation Engagement Acceptance Form**

If the answer to the preceding question is “No,” explain how this absence will affect the scope of the engagement. \_\_\_\_\_

How are the valuation conclusions to be communicated? (Check one.)

\_\_\_\_ Oral report    \_\_\_\_ Detail report    \_\_\_\_ Summary report

What is the intended distribution of a written report? (Check one.)

\_\_\_\_ It will be restricted to internal use or to use solely by a court of law.

\_\_\_\_ It will be distributed to third parties.

Based on your knowledge of the company to be valued, what valuation methods appear to be appropriate for the engagement? \_\_\_\_\_

Will an asset appraiser be needed? Yes \_\_\_\_\_ No \_\_\_\_\_

Is it likely that we will be asked to provide expert witness testimony? Yes \_\_\_\_\_ No \_\_\_\_\_

What will our role be on this proposed engagement? (Check one.)

\_\_\_\_ We will be objective, third-party valuation analysts.

\_\_\_\_ We will be client advisors and, accordingly, will not be able to render an independent valuation conclusion or act as expert witnesses.

**IV. ACCEPTANCE CONSIDERATIONS**

**Yes**

**No**

- |   |       |       |
|---|-------|-------|
| 1. Are we aware of any independence problems or conflicts of interest?  | _____ | _____ |
| 2. Are we aware of any potential fee collection problems?   | _____ | _____ |
| 3. Is the professional competence (expertise) necessary to perform the engagement beyond our capabilities?  | _____ | _____ |
| 4. Is the staffing commitment required by the engagement beyond our capabilities?   | _____ | _____ |
| 5. Do the terms of the proposed engagement, including fee arrangements, violate applicable professional standards?  | _____ | _____ |
| 6. Is the fee arrangement unacceptable given the scope of the engagement?   | _____ | _____ |
| 7. Is there anything about the engagement that subjects us to undue legal risk or causes us to be uncomfortable about being associated with the engagement? | _____ | _____ |

**COMMENTS**—A “Yes” answer does not necessarily indicate that the prospective engagement should be rejected. However, for any “Yes” answer, explain the steps that we plan to take to mitigate the situation (for example, closer supervision, a substantial fee deposit before work can start, renegotiation of the fee, or use of specialists).

**V. CONCLUSION**

We should accept \_\_\_\_\_ not accept \_\_\_\_\_ the engagement.

Approved by: \_\_\_\_\_ Date: \_\_\_\_\_

**Note: If “Yes” was answered to any question in Section IV, an officer other than the original contact must approve acceptance.**

## The Type of Report to Be Issued

Knowing the type of report that is expected to be issued is important for several reasons. First, long narrative reports take a considerable amount of time to write. This affects not only the fee to be charged, but also your time budget for meeting deadlines. In chapter 17, I will discuss different types of reports (including the suggested content of each type), as well as their applicability to various types of assignments. The standards in the previous chapter should have already whet your appetite.

## Engagement Letters

Always—and I mean *always*—have the client sign an engagement letter (sometimes called a *retainer agreement*) in order to avoid any potential misunderstanding between the valuation analyst and the client. I cannot emphasize strongly enough the need for a good engagement letter. Exhibits 3.4 and 3.5 contain sample engagement letters for use in valuation and calculation engagements. These can be changed to meet the specific needs of each business valuation or calculation engagement. A well-constructed engagement letter should be perceived to be the contract that it is. Any modifications to the agreement should be in writing and agreed to by both parties. It may also be a good idea to have an attorney review the engagement letter so that the valuation analyst and the firm are legally protected in the jurisdiction in which the firm operates. Our standard engagement letter is six pages long. If you think that it is long, you're right. We had an attorney draft it for us, and he charged us by the word! An engagement letter is a written contract between the valuation analyst's firm and the client. As with any legal contract, it should be taken seriously. The valuation analyst should be clear about what will be done for the client, and in some cases, what the client is expected to do for the valuation analyst. When we have a very tight deadline, we generally will include language that outlines that the client is responsible for getting us the requested information by a certain date, or we cannot be held responsible for a missed deadline. Missed deadlines can have your report excluded from a litigation, they can cause an estate tax return to be filed late, generating penalty and interest, and they can get the valuation analyst sued.

If the engagement is to include forensic accounting work, this should be properly explained in the engagement letter. If the assignment does not include forensics, make sure that it is clear that the valuation analyst will be relying on the information that is provided. The assumptions and limiting conditions in the report should be clear about what the valuation analyst did or did not do. This book is not intended to cover forensic accounting issues, but I need to make just one point: In litigation assignments, be very careful not to blindly accept information from a client without performing the necessary forensics to verify the information. Because forensics can be so very broad, I cannot begin to do it justice in this book.

This is probably a good time to discuss assumptions and limiting conditions. Exhibits 3.4 and 3.5 contain the limiting conditions included in the AICPA business valuation standard (appendix A). There are a few modifications that we made as well. The AICPA's recommended list from the standard is included in exhibit 3.6.

The assumptions and limiting conditions included in the exhibits may not be applicable to every engagement. Our assumption and limiting conditions include a few other items that are not included here.

It is generally advisable to have the assumptions and limiting conditions included in your engagement letter. There are certain items that will be standard for all assignments. That can become part of your boilerplate. We include a statement in our engagement letter that states, "It is possible that additional contingent and limiting conditions will be required, and the client agrees that all conditions disclosed by The Valuation Analyst will be accepted as incorporated into The Valuation Analyst's report." This will allow you to add any additional items that may become necessary as the engagement proceeds.

There will be times that a special limiting condition may be necessary in the report, but the valuation analyst cannot anticipate it for the engagement letter. We had the following special limiting condition on page 1 of a report that we did for a litigation engagement:

### SPECIAL LIMITING CONDITION OF THIS REPORT

Despite requesting a considerable amount of information required to properly analyze the valuation subject, we were not provided with much of the data. As far as we can tell, there were two main reasons for this, namely:

- I. The Court largely denied our request for data that we deemed necessary to perform this valuation in accordance with professional valuation standards, and
- II. XYZ Company, Inc. failed to provide requested documentation that would support its operations.

Appendix 2, at the back of this report, includes a complete list of those items that were requested and the reason that we requested them.

We consider this lack of documentation to rise to the level of a “Scope Restriction” in accordance with our professional standards. Had we received the requested information, our conclusion of value may have been different.

Accepting the financial information without independent verification does not mean that we will not perform the necessary due diligence required as a valuation analyst. We look for the items that may require adjustments in the valuation process, but we certainly are not going to try to find unreported income as part of the assignment unless it is spelled out. Be careful here also because if you are mutually retained by both parties, trying to find unreported income may cause you to be working more as an advocate for one of the clients because any finding may assist the other client in furthering his or her position.

### EXHIBIT 3.4 Business Valuation Retainer Agreement

The undersigned client (The Client) acknowledges this engagement of Trugman Valuation Associates, Inc. (The Valuation Analyst) to perform a business valuation of <<DEFINE THE PROPERTY TO BE VALUED>> as of <<VALUATION DATE(S)>> to be used <<PURPOSE OF VALUATION>>. Our conclusion of value will be communicated to you in a <<DETAILED OR SUMMARY>> report.

#### PARAGRAPH TO BE INCLUDED IF LESS THAN A DETAILED REPORT TO BE ISSUED

Since The Client has requested that the conclusion of value be communicated in less than a detailed report, valuation standards that must be adhered to by The Valuation Analyst require that this report be restricted in its distribution. A summary report can easily be misunderstood by individuals who are not well-informed about the subject property, and therefore, valuation standards required that this type of report not be distributed to anyone other than The Client for his/her own use. **THIS REPORT IS FOR OUR CLIENT’S EYES ONLY.** Distribution to any other party is expressly prohibited.

The standard of value for this assignment shall be fair market value. Said fair market value is defined to be a value at which a willing seller and willing buyer, both being informed of the relevant facts about the business, could reasonably conduct a transaction, neither party acting under any compulsion to do so.

The standard of value is frequently determined by law. For example, the Internal Revenue Code requires fair market value to be used for all valuation assignments for tax purposes. In some instances, the standard of value may be determined by state statute, and in other instances, it may be subject to the interpretation of case law. As such, since The Valuation Analyst is not authorized to practice law, the standard of value should be determined by your legal advisor. The Valuation Analyst assumes no liability as a result of the incorrect standard of value being used in this assignment. Before signing this retainer agreement, consult your legal advisor.

Furthermore, the valuation date is also frequently subject to legal interpretation. Therefore, it is essential that The Client also makes sure that the correct valuation date(s) is used in this retainer agreement for the performance of this assignment. The Valuation Analyst will be valuing the subject property based on whichever date(s) appear in this retainer agreement without any consideration as to the correctness of this date. The Valuation Analyst assumes no liability if incorrect dates are used as long as we use the date(s) provided in this retainer agreement.

*(continued)*

**EXHIBIT 3.4 Business Valuation Retainer Agreement** *(continued)*

It is understood that The Valuation Analyst is not being engaged to perform an audit as defined by the AICPA, but, rather, the necessary tests of the accounting records that will be performed for the purpose of issuing a valuation report and not a statement regarding the fairness of presentation of the financial statements of the above business.

Certain values, derived from reports of others, and which are so designated, will be included in our report. We take no responsibility for those items. Nor do we take responsibility to update the report or disclose any events or circumstances occurring after the date of the report.

It is the responsibility of The Client to provide the necessary documentation that will be requested by The Valuation Analyst to perform this assignment. This documentation must be provided on a timely basis in order for The Valuation Analyst to conduct the assignment in an efficient manner. Additional fees could result from delays in receiving requested information. If this assignment is part of a litigation where The Client does not control the books and records of the company that is the subject of the valuation, it is The Client's responsibility to ensure that legal counsel obtains the necessary documentation requested by The Valuation Analyst for The Valuation Analyst to feel that it has satisfied its compliance with valuation standards with regards to "sufficient relevant data." In the event sufficient records and/or documentation cannot be supplied to The Valuation Analyst, no such valuation report will be issued. The Valuation Analyst assumes no liability for not issuing a report on a timely basis if The Valuation Analyst believes that it would be in violation of valuation standards for issuing a report where it cannot meet the "sufficient relevant data" standard.

This valuation will be subject to, at least, the following contingent and limiting conditions, which will be included in the report as an appendix:

1. The conclusion of value arrived at herein is valid only for the stated purpose as of the date of the valuation.
2. Financial statements and other related information provided by the business or its representatives, in the course of this engagement, have been accepted without any verification as fully and correctly reflecting the enterprise's business conditions and operating results for the respective periods, except as specifically noted herein. The Valuation Analyst has not audited, reviewed, or compiled the financial information provided to us and, accordingly, we express no audit opinion or any other form of assurance on this information.
3. Public information and industry and statistical information have been obtained from sources we believe to be reliable. However, we make no representation as to the accuracy or completeness of such information and have performed no procedures to corroborate the information.
4. We do not provide assurance on the achievability of the results forecasted by or for the subject company because events and circumstances frequently do not occur as expected; differences between actual and expected results may be material; and achievement of the forecasted results is dependent on actions, plans, and assumptions of management.
5. The conclusion of value arrived at herein is based on the assumption that the current level of management expertise and effectiveness would continue to be maintained, and that the character and integrity of the enterprise through any sale, reorganization, exchange, or diminution of the owners' participation would not be materially or significantly changed.
6. This report and the conclusion of value arrived at herein are for the exclusive use of our client for the sole and specific purposes as noted herein. They may not be used for any other purpose or by any other party for any purpose. Furthermore, the report and conclusion of value are not intended by the author and should not be construed by the reader to be investment advice in any manner whatsoever. The conclusion of value represents the considered opinion of The Valuation Analyst, based on information furnished to them by the subject company and other sources.
7. Neither all nor any part of the contents of this report (especially the conclusion of value, the identity of any valuation specialist(s), or the firm with which such valuation specialists are connected or any reference to any of their professional designations) should be disseminated to the public through advertising media, public relations, news media, sales media, mail, direct transmittal, or any other means of communication without the prior written consent and approval of The Valuation Analyst.
8. Future services regarding the subject matter of this report, including, but not limited to, testimony or attendance in court, shall not be required of The Valuation Analyst unless previous arrangements have been made in writing.
9. The Valuation Analyst is not an environmental consultant or auditor, and it takes no responsibility for any actual or potential environmental liabilities. Any person entitled to rely on this report, wishing to know whether such liabilities exist, or the scope and their effect on the value of the property, is encouraged to obtain a professional environmental assessment. The Valuation Analyst does not conduct or provide environmental assessments and has not performed one for the subject property.

**EXHIBIT 3.4 Business Valuation Retainer Agreement**

10. The Valuation Analyst has not determined independently whether the subject company is subject to any present or future liability relating to environmental matters (including, but not limited to CER-CLA/Superfund liability) nor the scope of any such liabilities. The Valuation Analyst's valuation takes no such liabilities into account, except as they have been reported to The Valuation Analyst by the subject company or by an environmental consultant working for the subject company, and then only to the extent that the liability was reported to us in an actual or estimated dollar amount. Such matters, if any, are noted in the report. To the extent such information has been reported to us, The Valuation Analyst has relied on it without verification and offers no warranty or representation as to its accuracy or completeness.
11. The Valuation Analyst has not made a specific compliance survey or analysis of the subject property to determine whether it is subject to, or in compliance with, the American Disabilities Act of 1990, and this valuation does not consider the effect, if any, of noncompliance.
12. No change of any item in this valuation report shall be made by anyone other than The Valuation Analyst, and we shall have no responsibility for any such unauthorized change.
13. Unless otherwise stated, no effort has been made to determine the possible effect, if any, on the subject business due to future federal, state, or local legislation, including any environmental or ecological matters or interpretations thereof.
14. We have conducted interviews with the current management of the subject company concerning the past, present, and prospective operating results of the company. Except as noted, we have relied on the representations of these individuals.
15. Except as noted, we have relied on the representations of the owners, management, and other third parties concerning the value and useful condition of all equipment, real estate, investments used in the business, and any other assets or liabilities, except as specifically stated to the contrary in this report. We have not attempted to confirm whether or not all assets of the business are free and clear of liens and encumbrances or that the entity has good title to all assets.
16. All facts and data set forth in the report are true and accurate to the best of the Valuation Analyst's knowledge and belief. We have not knowingly withheld or omitted anything from our report affecting our value estimate.
17. Possession of this report, or a copy thereof, does not carry with it the right of publication of all or part of it, nor may it be used for any purpose without the previous written consent of The Valuation Analyst, and in any event, only with proper authorization. Authorized copies of this report will be signed in blue ink by a principal of The Valuation Analyst. Unsigned copies, or copies not signed in blue ink, should be considered to be incomplete.
18. Unless otherwise provided for in writing and agreed to by both parties in advance, the extent of the liability for the completeness or accuracy of the data, opinions, comments, recommendations, and conclusions shall not exceed the amount paid to the Valuation Analysts for professional fees and, then, only to the party(s) for whom this report was originally prepared.
19. The conclusion reached in this report is based on the standard of value as stated and defined in the body of the report. An actual transaction in the business or business interest may be concluded at a higher value or lower value, depending on the circumstances surrounding the company, the appraised business interest, and the motivations and knowledge of both the buyers and sellers at that time. The Valuation Analyst makes no guarantees as to what values individual buyers and sellers may reach in an actual transaction.
20. No opinion is intended to be expressed for matters that require legal or other specialized expertise, investigation, or knowledge beyond that customarily employed by Valuation Analysts valuing businesses.

It is possible that additional contingent and limiting conditions will be required, and the client agrees that all conditions disclosed by the Valuation Analyst will be accepted as incorporated into the Valuation Analyst's report.

For all business valuation assignments that are being used as part of a litigation assignment, particularly where testimony is expected to be provided by The Valuation Analyst, The Client acknowledges that The Valuation Analyst will not be held responsible if a court excludes the testimony of The Valuation Analyst for circumstances that are beyond the control of The Valuation Analyst. For example, a court may exclude The Valuation Analyst as a result of not being an industry expert in the subject company's industry. We are valuation experts, we do not hold ourselves out to be industry experts except in our own industry.

For non-litigation assignments, The Client acknowledges that The Valuation Analyst will not be held responsible for a finding by another party, such as a taxing authority, based on a difference of opinion as to the value conclusion reached or a negotiated value. The Valuation Analyst is generally not part of negotiations between the taxing authority and The Client, we cannot assume any liability when we are not part of that process.

*(continued)*

### EXHIBIT 3.4 Business Valuation Retainer Agreement *(continued)*

The Valuation Analyst's goal is to be as fair as possible in its billing practices with respect to this assignment. It is our intention to perform this engagement as quickly and affordably as possible, but these services take a reasonable amount of time to render. We will make certain that the appropriate personnel in our firm render those services that will comply with the level of expertise required by this engagement. In that regard, hourly rates will be charged based on the billing rates in effect at the time that the services are rendered. Currently those hourly rates range from \$XXX to \$YYY per hour depending on the level of staff performing the assignment.

While The Valuation Analyst does its best to estimate fees in these types of assignments, there will be times that the fees may be greater than the range estimated. This is especially true in litigation assignments where The Valuation Analyst has a difficult time obtaining records, or where it takes a long time to get those records requiring The Valuation Analyst to constantly pick up and put down the file. This is not the only reason for assignments to go over budget. If The Valuation Analyst believes that the fees will exceed an estimated range, we will try to notify The Client as soon as practical to discuss the overage. However, when The Valuation Analyst sends an invoice to The Client, unless the client questions said invoice within 14 days of the date of the invoice, The Valuation Analyst assumes that The Client has accepted the invoice as being reasonable and expects it to be paid in accordance with this retainer agreement.

Hourly rates are charged portal to portal from our Plantation, Florida office. In addition to these hourly rates, the following charges may be applicable:

- a. Fees for appearance at depositions and/or trial testimony shall be charged based on our standard billing rates. Although payment for deposition testimony is usually the responsibility of the adverse party in a litigation, the undersigned client guarantees payment of the same to The Valuation Analyst.
- b. Any out-of-pocket expenses relating to this valuation. It is expected that we will perform research through computer databases, and that we may be required to purchase research materials relating to this engagement. These and other such costs will be billed to you at our cost. Regardless of which office this assignment is billed from, there is an expectation that only normal travel expenses will be incurred by The Valuation Analyst. Any additional expenses that are incurred by The Valuation Analyst will be billed to The Client. For example, higher than normal airfares due to last minute travel or change fees due to changes to travel that were not initiated by The Valuation Analyst will be billed at our cost to you. These costs also assume a limited number of trips to the business, court, an attorney's office, etc. We want to be fair with our clients, but we also expect that our clients will be fair with us and not expect abnormally high expenses to be incurred by The Valuation Analyst.

Payment terms shall be as follows:

\$<<RETAINER AMOUNT>> due in advance as a retainer. **This retainer shall be allocated against the final payment** that will be due to The Valuation Analyst. All amounts shall be billed regularly. The Valuation Analyst reserves the right to request additional retainers pertaining to this assignment at any time, particularly if the client does not pay our invoices in accordance with the terms of this agreement.

Since it is considered unethical for us to perform these services on a contingency basis, it is important to us that our fees are paid promptly. The appearance of independence is of considerable importance for our firm to maintain our credibility, and therefore, we reserve the right to stop providing services at any time that there is a balance due our firm. In the event that we continue to provide services, we do not waive our right to stop at a later date. Furthermore, in order to ensure that our fees are not misconstrued to be on a contingent basis, **we will require all fees that are outstanding at the time of trial to be paid before we testify. We will also require a sufficient retainer to cover all anticipated time and expenses relating to a trial so that all fees are paid prior to our testifying.** Any unused retainer will be refunded to the client once our involvement has been considered to be finished.

**The Valuation Analyst requires that all fees be paid before we release our report.** This is our regular practice, and we request that our clients understand this practice before we are retained. This is not a personal reflection of The Client, but it is a practice that avoids a discriminatory collection practice. Chasing clients for fees is not our intention, and we believe that this practice assists us in providing our services in a manner that prevents concern about our ability to remain independent due to unpaid fees.

**EXHIBIT 3.4 Business Valuation Retainer Agreement**

The client must understand that professional business valuation services are not inexpensive and unless other arrangements are made, in writing, with our firm, services rendered by our firm will be invoiced regularly and are due upon presentation of our invoice to you. Balances outstanding beyond 30 days will have a service charge added at the rate of 1½ percent per month or part thereof.

In the event that The Valuation Analyst must turn collection of fees over to an attorney, the undersigned will be responsible for all reasonable costs and fees associated with the collection action. Reasonable fees will be deemed to be up to 33½ percent of the amount collected. Any collection action that is required due to nonpayment of fees shall be venued in Broward County, Florida.

The undersigned client agrees to indemnify The Valuation Analyst from any legal expenses incurred as a result of this engagement, other than those relating to the conduct of this assignment. This would include, but not be limited to, any legal expenses required to protect the confidentiality of this or any other client who becomes an issue in this matter.

The final report is copyrighted by The Valuation Analyst. It shall remain the property of The Valuation Analyst, and no copies or reproductions shall be allowed without the written consent of The Valuation Analyst until such time as any outstanding balance is paid.

The Valuation Analyst reserves the right to withdraw from this engagement at any time. It is not our intention to withdraw. All workpapers created by The Valuation Analyst will remain in the possession of The Valuation Analyst. In the event of a withdrawal, we would only be liable to return those materials and documents supplied by the client and the unused portion of the retainer.

The undersigned gives The Valuation Analyst the right to discuss this matter with The Client's attorney, accountant, other individuals so designated by The Client, and any professional colleagues of The Valuation Analyst from whom professional information is sought.

If this is acceptable, please sign the acknowledgment below and return a signed copy of this retainer agreement with your check in the amount of \$<<RETAINER AMOUNT>> to our office.

THIS BUSINESS VALUATION RETAINER AGREEMENT CONSISTS OF SEVEN (7) PAGES INCLUDING THIS ONE. ALL SEVEN (7) PAGES MUST BE RETURNED TO TRUGMAN VALUATION ASSOCIATES, INC. AFTER EXECUTION OF THIS DOCUMENT WITH THE REQUESTED RETAINER IN ORDER TO RETAIN OUR FIRM. IF THIS DOCUMENT IS NOT RECEIVED BY TRUGMAN VALUATION ASSOCIATES, INC. FULLY EXECUTED BY THE CLIENT WITH THE REQUESTED RETAINER BY <<DATE>>, TRUGMAN VALUATION ASSOCIATES, INC. RESERVES THE RIGHT TO DEEM THE TERMS OF THIS AGREEMENT AND THE OFFER TO PERFORM BUSINESS VALUATION SERVICES NULL AND VOID.

### EXHIBIT 3.5 Business Valuation Calculation Agreement

The undersigned acknowledges this engagement of Trugman Valuation Associates, Inc. (The Valuation Analyst) to perform limited business valuation services of <<DEFINE THE PROPERTY TO BE VALUED>> as of <<VALUATION DATE(S)>> to be used <<PURPOSE OF CALCULATION>>. These services are described in the Statement on Standards for Valuation Services No. 1, as promulgated by the AICPA. This type of service is explained in this standard as follows:

Calculation Engagement—A valuation analyst performs a calculation engagement when (1) the valuation analyst and the client agree on the valuation approaches and methods the valuation analyst will use and the extent of procedures the valuation analyst will perform in the process of calculating the value of a subject interest (these procedures will be more limited than those of a valuation engagement) and (2) the valuation analyst calculates the value in compliance with the agreement. The valuation analyst expresses the results of these procedures as a calculated value. The calculated value is expressed as a range or as a single amount. A calculation engagement does not include all of the procedures required for a valuation engagement.

Our calculation of value will be communicated to you in a calculation report. A calculation report will contain less information than would be included in a detailed report under a valuation engagement. Our standard does not permit a detailed report to be used for this type of engagement, and therefore, this report is only appropriate for the client's review. This limited report may be misunderstood by those who are not familiar with all of the facts surrounding this engagement.

Unless otherwise noted in this agreement, this calculation engagement is expected to be performed by The Valuation Analyst considering an income approach methodology and a market approach methodology, if sufficient relevant data can be located using the transaction databases that we subscribe to. We will not be performing a site visit, nor will we be performing independent research regarding the industry of the subject company. We will utilize our knowledge of the subject company's industry without gathering additional data beyond our current level of it.

Although the purpose of this calculation engagement is to determine the reasonable value of the subject property, the client has requested only limited analyses to be performed. Based on these limitations, The Valuation Analyst will also not be rendering a conclusion (opinion) of value based on the standards established by the Uniform Standards of Appraisal Practice, the American Society of Appraisers, or The Institute of Business Appraisers.

The Valuation Analyst will perform limited analyses to estimate the negotiable price that can be used by the client in lieu of the more definitive estimate of fair market value of the subject property. Said fair market value is defined to be a value at which a willing seller and willing buyer, both being informed of the relevant facts about the business, could reasonably conduct a transaction, neither party acting under any compulsion to do so.

**It is understood that as a result of this assignment, no expert testimony shall be provided. Any required expert testimony shall be the subject of a different retainer agreement.**

It is also understood that The Valuation Analyst is not being engaged to perform an audit as defined by the AICPA, but, rather, the necessary analysis of only those records deemed necessary to perform this calculation engagement.

In the event sufficient records and/or documentation cannot be supplied to The Valuation Analyst, no such calculation report will be issued.

Certain values, derived from reports of others, and which are so designated, will be included in our report. We take no responsibility for those items. Nor do we take responsibility to update the report or disclose any events or circumstances occurring after the date of the report.

This calculation engagement will be subject to, at least, the following contingent and limiting conditions, which will be included in the report as an appendix:

1. The calculation of value arrived at herein is valid only for the stated purpose as of the effective date of the calculations.

**EXHIBIT 3.5 Business Valuation Calculation Agreement**

2. Financial statements and other related information provided by the business or its representatives, in the course of this engagement, have been accepted without any verification as fully and correctly reflecting the enterprise's business conditions and operating results for the respective periods, except as specifically noted herein. The Valuation Analyst has not audited, reviewed, or compiled the financial information provided to us and, accordingly, we express no audit opinion or any other form of assurance on this information.
3. Public information and industry and statistical information have been obtained from sources we believe to be reliable. However, we make no representation as to the accuracy or completeness of such information and have performed no procedures to corroborate the information.
4. We do not provide assurance on the achievability of the results forecasted by or for the subject company because events and circumstances frequently do not occur as expected; differences between actual and expected results may be material; and achievement of the forecasted results is dependent on actions, plans, and assumptions of management.
5. The calculation of value arrived at herein is based on the assumption that the current level of management expertise and effectiveness would continue to be maintained, and that the character and integrity of the enterprise through any sale, reorganization, exchange, or diminution of the owners' participation would not be materially or significantly changed.
6. This report and the calculation of value arrived at herein are for the exclusive use of our client for the sole and specific purposes as noted herein. They may not be used for any other purpose or by any other party for any purpose. Furthermore, the report and calculation of value are not intended by the author and should not be construed by the reader to be investment advice in any manner whatsoever. The calculation of value represents the considered opinion of The Valuation Analyst, based on limited information furnished to them by the subject company and other sources.
7. Neither all nor any part of the contents of this report (especially the calculation of value, the identity of any valuation specialist(s), or the firm with which such valuation specialists are connected or any reference to any of their professional designations) should be disseminated to the public through advertising media, public relations, news media, sales media, mail, direct transmittal, or any other means of communication without the prior written consent and approval of The Valuation Analyst.
8. Future services regarding the subject matter of this report, including, but not limited to, testimony or attendance in court shall not be required of The Valuation Analyst as a result of this engagement.
9. The Valuation Analyst is not an environmental consultant or auditor, and it takes no responsibility for any actual or potential environmental liabilities. Any person entitled to rely on this report, wishing to know whether such liabilities exist, or the scope and their effect on the value of the property, is encouraged to obtain a professional environmental assessment. The Valuation Analyst does not conduct or provide environmental assessments and has not performed one for the subject property.
10. The Valuation Analyst has not determined independently whether the subject company is subject to any present or future liability relating to environmental matters (including, but not limited to, CER-CLA or Superfund liability) nor the scope of any such liabilities. The Valuation Analyst's calculation takes no such liabilities into account, except as they have been reported to The Valuation Analyst by the subject company or by an environmental consultant working for the subject company, and then only to the extent that the liability was reported to us in an actual or estimated dollar amount. Such matters, if any, are noted in the report. To the extent such information has been reported to us, The Valuation Analyst has relied on it without verification and offers no warranty or representation as to its accuracy or completeness.
11. The Valuation Analyst has not made a specific compliance survey or analysis of the subject property to determine whether it is subject to, or in compliance with, the American Disabilities Act of 1990, and this valuation does not consider the effect, if any, of noncompliance.
12. No change of any item in this calculation report shall be made by anyone other than The Valuation Analyst and we shall have no responsibility for any such unauthorized change.
13. Unless otherwise stated, no effort has been made to determine the possible effect, if any, on the subject business due to future federal, state, or local legislation, including any environmental or ecological matters or interpretations thereof.
14. We have conducted limited interviews by telephone with the current management of the subject company concerning the past, present, and prospective operating results of the company. Except as noted, we have relied on the representations of these individuals.

*(continued)*

**EXHIBIT 3.5 Business Valuation Calculation Agreement** *(continued)*

15. Except as noted, we have relied on the representations of the owners, management, and other third parties concerning the value and useful condition of all equipment, real estate, investments used in the business, and any other assets or liabilities, except as specifically stated to the contrary in this report. We have not attempted to confirm whether or not all assets of the business are free and clear of liens and encumbrances or that the entity has good title to all assets.
16. Possession of this report, or a copy thereof, does not carry with it the right of publication of all or part of it, nor may it be used for any purpose without the previous written consent of the Valuation Analyst, and in any event, only with proper authorization. Authorized copies of this report will be signed in blue ink by a director of The Valuation Analyst. Unsigned copies, or copies not signed in blue ink, should be considered to be incomplete.

It is possible that additional contingent and limiting conditions will be required, and the client agrees that all conditions disclosed by the valuation analyst will be accepted as incorporated into the analyst's report.

It is our intention to perform this engagement as quickly and affordably as possible, but these services take a reasonable amount of time to render. We will make certain that the appropriate personnel in our firm render those services that will comply with the level of expertise required by this engagement. In that regard, hourly rates will be charged based on the billing rates in effect at the time that the services are rendered. Currently those hourly rates range from \$xxx to \$xxx per hour depending on the level of staff performing the assignment.

In addition to these hourly rates, any out of pocket expenses relating to this assignment will be billed to you at our cost. It is expected that we will perform some research through computer databases, and that we may be required to purchase research materials relating to this engagement. We will do everything possible to minimize these expenses, but the client is advised that they most likely will exist.

Payment terms shall be as follows:

\$x,xxx due in advance as a retainer. **This retainer shall be allocated against the final payment that will be due to The Valuation Analyst.** All amounts shall be billed regularly. Since it is considered unethical for us to perform these services on a contingency basis, it is important to us that our fees are paid promptly. The appearance of independence is of considerable importance for our firm to maintain our credibility, and therefore, we reserve the right to stop providing services at any time that there is a balance due our firm. In the event that we continue to provide services, we do not waive our right to stop at a later date.

The client must understand that professional services are not inexpensive and unless other arrangements are made, in writing, with our firm, services rendered by our firm will be invoiced regularly and are due upon presentation of our invoice to you. Balances outstanding beyond 30 days will have a service charge added at the rate of one and a half percent per month or part thereof.

**The Valuation Analyst requires that all fees be paid before we release our report.** This is our regular practice, and we request that our clients understand this practice before we are retained. This is not a personal reflection of this client, but it is a practice that avoids a discriminatory collection practice. Chasing clients for fees is not our intention, and we believe that this practice assists us in providing our services in a manner that prevents concern about our ability to remain independent due to unpaid fees.

In the event that The Valuation Analyst must turn collection of fees over to an attorney, the undersigned will be responsible for all reasonable costs and fees associated with the collection action. Reasonable fees will be deemed to be up to 33.33 percent of the amount collected. Any collection action that is required due to nonpayment of fees shall be venued in Broward County, Florida.

The undersigned client agrees to indemnify The Valuation Analyst from any legal expenses incurred as a result of this engagement other than those relating to the conduct of this assignment. This would include, but not be limited to, any legal expenses required to protect the confidentiality of this or any other client who becomes an issue in this matter.

**EXHIBIT 3.5 Business Valuation Calculation Agreement** *(continued)*

The Valuation Analyst has estimated the cost of this assignment to approximate \$x,xxx to \$x,xxx plus out-of-pocket costs. Although we cannot guarantee the exact fee, we will do everything reasonably possible to minimize this expense without jeopardizing the quality of the services rendered. In the event that it appears that the fee will deviate upwards by more than 20 percent, we will call it to your attention as soon as we become aware of the extra time required to complete the assignment.

The Valuation Analyst reserves the right to withdraw from this engagement at any time. It is not our intention to withdraw. All working papers created by The Valuation Analyst will remain in the possession of The Valuation Analyst. In the event of a withdrawal, we would only be liable to return those materials and documents supplied by the client and the unused portion of the retainer.

The undersigned gives The Valuation Analyst the right to discuss this matter with the client's attorney, accountant, other individuals so designated by the client, and any professional colleagues of the Valuation Analyst from whom professional information is sought.

If this is acceptable, please sign the acknowledgment below and return a signed copy of this retainer agreement with your check in the amount of \$x,xxx to our office.

### EXHIBIT 3.6 Statement on Standards for Valuation Services No. 1— Appendix A

The valuation report or calculation report should include a list of assumptions and limiting conditions under which the engagement was performed. This appendix includes an illustrative list of assumptions and limiting conditions that may apply to a business valuation.

#### ILLUSTRATIVE LIST OF ASSUMPTIONS AND LIMITING CONDITIONS

1. The conclusion of value arrived at herein is valid only for the stated purpose as of the date of the valuation.
2. Financial statements and other related information provided by [ABC Company] or its representatives, in the course of this engagement, have been accepted without any verification as fully and correctly reflecting the enterprise's business conditions and operating results for the respective periods, except as specifically noted herein. [Valuation Firm] has not audited, reviewed, or compiled the financial information provided to us, and, accordingly, we express no audit opinion or any other form of assurance on this information.
3. Public information and industry and statistical information have been obtained from sources we believe to be reliable. However, we make no representation as to the accuracy or completeness of such information and have performed no procedures to corroborate the information.
4. We do not provide assurance on the achievability of the results forecasted by [ABC Company] because events and circumstances frequently do not occur as expected; differences between actual and expected results may be material; and achievement of the forecasted results is dependent on actions, plans, and assumptions of management.
5. The conclusion of value arrived at herein is based on the assumption that the current level of management expertise and effectiveness would continue to be maintained, and that the character and integrity of the enterprise through any sale, reorganization, exchange, or diminution of the owners' participation would not be materially or significantly changed.
6. This report and the conclusion of value arrived at herein are for the exclusive use of our client for the sole and specific purposes as noted herein. They may not be used for any other purpose or by any other party for any purpose. Furthermore, the report and conclusion of value are not intended by the author and should not be construed by the reader to be investment advice in any manner whatsoever. The conclusion of value represents the considered opinion of [Valuation Firm], based on information furnished to them by [ABC Company] and other sources.
7. Neither all nor any part of the contents of this report (especially the conclusion of value, the identity of any valuation specialist(s), or the firm with which such valuation specialists are connected or any reference to any of their professional designations) should be disseminated to the public through advertising media, public relations, news media, sales media, mail, direct transmittal, or any other means of communication without the prior written consent and approval of [Valuation Firm].
8. Future services regarding the subject matter of this report, including, but not limited to, testimony or attendance in court, shall not be required of [Valuation Firm] unless previous arrangements have been made in writing.
9. [Valuation Firm] is not an environmental consultant or auditor, and it takes no responsibility for any actual or potential environmental liabilities. Any person entitled to rely on this report, wishing to know whether such liabilities exist, or the scope and their effect on the value of the property, is encouraged to obtain a professional environmental assessment. [Valuation Firm] does not conduct or provide environmental assessments and has not performed one for the subject property.
10. [Valuation Firm] has not determined independently whether [ABC Company] is subject to any present or future liability relating to environmental matters (including, but not limited to, CER-CLA or Superfund liability) nor the scope of any such liabilities. [Valuation Firm]'s valuation takes no such liabilities into account, except as they have been reported to [Valuation Firm] by [ABC Company] or by an environmental consultant working for [ABC Company], and then only to the extent that the liability was reported to us in an actual or estimated dollar amount. Such matters, if any, are noted in the report. To the extent such information has been reported to us, [Valuation Firm] has relied on it without verification and offers no warranty or representation as to its accuracy or completeness.
11. [Valuation Firm] has not made a specific compliance survey or analysis of the subject property to determine whether it is subject to, or in compliance with, the American Disabilities Act of 1990, and this valuation does not consider the effect, if any, of noncompliance.
12. [Sample wording for use if the jurisdictional exception is invoked.] The conclusion of value (or the calculated value) in this report deviates from Statement on Standards for Valuation Services No. 1 as a result of published governmental, judicial, or accounting authority.
13. No change of any item in this appraisal report shall be made by anyone other than [Valuation Firm], and we shall have no responsibility for any such unauthorized change.

### EXHIBIT 3.6 Statement on Standards for Valuation Services No. 1— Appendix A

14. Unless otherwise stated, no effort has been made to determine the possible effect, if any, on the subject business due to future federal, state, or local legislation, including any environmental or ecological matters or interpretations thereof.
15. If prospective financial information approved by management has been used in our work, we have not examined or compiled the prospective financial information, and therefore, do not express an audit opinion or any other form of assurance on the prospective financial information or the related assumptions. Events and circumstances frequently do not occur as expected, and there will usually be differences between prospective financial information and actual results, and those differences may be material.
16. We have conducted interviews with the current management of [ABC Company] concerning the past, present, and prospective operating results of the company.
17. Except as noted, we have relied on the representations of the owners, management, and other third parties concerning the value and useful condition of all equipment, real estate, investments used in the business, and any other assets or liabilities, except as specifically stated to the contrary in this report. We have not attempted to confirm whether or not all assets of the business are free and clear of liens and encumbrances or that the entity has good title to all assets.

The easiest trap to fall into in a valuation engagement is when the attorney asks the valuation analyst for a ballpark opinion. Next thing the analyst knows, the so-called “ballpark” becomes an expert report without the analyst even realizing that it has been submitted to the other side in a litigation. If the engagement letter and report are not crystal clear regarding what the valuation analyst will and will not do and what restrictions are placed on the use of the report, the valuation analyst is looking for trouble. The valuation analyst’s reputation will be the most impaired part of the litigation. How many times have I now said this? When the valuation analyst finds himself in court trying to explain that this report was not intended to be used for the litigation, the only thing that everyone will remember is that the expert did a poor job. The valuation analyst does not want to find himself doing a calculation engagement when a valuation engagement is called for. Who needs the grief?

The engagement letter should also include the “as of” date for the valuation. The valuation analyst does not want to start doing research and analysis as of a certain date, have the client’s attorney tell the analyst that he or she should be using a different date, and then not be able to collect fees from the client because the analyst did the work twice. In some states, valuations for certain types of litigation can be a moving target. For example, in Connecticut, a divorce valuation starts out at the current date but will frequently be updated at the time of the trial. This can cause several valuations to be done as part of the same engagement. The engagement letter should clearly spell out that the valuation assignment may require additional dates to be used and that the client acknowledges and gives the valuation analyst his or her permission to do whatever needs to be done.

The engagement letter should be updated every so often as needed. We changed parts of our engagement letter since the last edition of this book to spell out the fact that standards of value and valuation dates, particularly in a litigation setting, are determined legally and not by the valuation analyst. Note the language in the engagement letter telling the client to check certain things with the attorney before signing the engagement letter. We merely want to protect ourselves from being provided incorrect information.

Another way to fall into a trap is the engagement to critique the other side’s report without being hired to give a separate opinion of value because the client does not want to spend the money to have the valuation analyst do a full valuation. Besides having the assignment spelled out in the engagement letter—for example, “we are being retained only to critique the report of XYZ Valuation Firm, and we are not being hired to provide a conclusion of value of the company”—some of the language that goes into our report may look like this:

Dear Ms. Smith:

Pursuant to your request, I have reviewed the valuation report of Roberts, Green & Co., CPAs, regarding your interest in Smith Jones & Associates, P.A. The purpose of my review was to determine if I could find any glaring errors in the valuation report. I have not performed a valuation of your interest, and accordingly, I am not offering a conclusion of value in this critique.

Other items that should be spelled out in the engagement letter include the standard of value, payment terms, dispute resolution, and indemnification provisions. The standard of value is as important as the date of the valuation. Is the valuation analyst being hired to determine fair market value or fair value? This stuff is discussed in chapter 4. The valuation analyst needs the client's attorney to tell him or her which standard of value the analyst should be using for the valuation. Though we all want to be helpful, some of these items require legal decisions. As an accountant or valuation analyst, one is generally not qualified (by education and training) to provide legal determinations about standards of value. Though we know that fair market value will be used for estate tax issues, different states have different standards of value for ownership disputes. Sometimes, even within the same standard of value there can be many different jurisdictional interpretations. This is the kind of stuff that can get the analyst in trouble. Imagine the judge knocking out the valuation analyst's report because he or she used the wrong standard of value. Hello, lawsuit!

Do not forget to put payment terms in the engagement letter, unless you like to work for free. I like to choose what pro bono (free) work our firm does. I try not to let the client decide that we should work for free. Get a retainer. In fact, it is becoming more common to consider the retainer as a *back-end retainer*. This means that it is applied at the end of the job, rather than at the beginning. Our retainer agreements also contain a provision that says, "An additional invoice will be rendered once the valuation analyst has completed the valuation report. Payment in full is due prior to the release of said report to the client." This means we get paid before we release the report. I do not like to chase fees. In fact, my insurance carrier would probably prefer that I do not chase fees. They say that one of the biggest reasons that clients sue their accountants for malpractice is because the clients are counter-suing due to a collection dispute. The valuation analyst should get paid before he or she gets sued!

Let me point out some other important stuff about the engagement letter. In the first paragraph, the name of the valuation firm—not the valuation analyst—should appear because it is the firm and not the individual being engaged. This will allow the staffing to be determined by the firm. This will also allow someone else in the firm to step into the assignment if the valuation analyst is unable to complete it. In addition, a good engagement letter at a minimum should include the following:

- A description of the scope of the assignment
- A detailed description of the valuation subject
- The standard of value that will be used, including the definition of that standard
- The effective date(s) of the valuation
- The type of report that will be issued to communicate the value estimate
- The responsibilities of the client, in particular, to provide requested documentation on a timely basis

## Description of the Scope of the Assignment

This section of the engagement letter describes the purpose and function of the valuation assignment. The best way to differentiate between the purpose and function of the valuation is as follows:

Purpose = Type of value (standard of value)

Function = How the valuation will be used

This is probably a good time to introduce another concept that fits into this section. It is called the *highest and best use* of the business. We also call this the *premise of value*. Whenever you pick up a real estate appraisal, the real estate appraiser discusses the concept of highest and best use. This is described as follows:

### Highest and Best Use

This section of the report must be complete and thorough. It should begin with a proper definition of *highest and best use* and include the source of the definition.

Two separate studies are mandatory for this section:

- A highest and best use analysis of the site as vacant
- A highest and best use analysis of the property as improved

### Highest and Best Use of the Land as Vacant

This analysis must address four criteria. The highest and best use must be

- physically possible,
- legally permissible,
- financially feasible, and
- maximally productive.

This analysis should end with a conclusion on the ideal improvement, which would represent the highest and best use of the land if it were vacant.

### Highest and Best Use of the Property as Improved

Through an analysis of the four criteria for highest and best use, this discussion should establish which use is maximally productive. This analysis should reach a highest and best use conclusion that includes curing any curable deficiencies, making repairs, or renovating the structures. A comparison of the existing improvements with the ideal improvements should identify functional obsolescence, which is shown in the cost approach. Any deficiencies must also be considered in the sales comparison and income approaches.<sup>2</sup>

The concept is to value the property in the manner in which it would generate the greatest return to the owner of the property. Logically, if a land purchaser wanted to maximize the return on his or her investment in a vacant lot, the maximum return would be to build an office building, rather than a single family house, assuming that the zoning (what is legally permissible) allows it to be built. The land becomes worth more because of its allowed usage.

The business valuation analyst should determine the highest and best use of the business enterprise in a manner similar to how the concept is used in real estate appraisal. This is not to say that a hardware store should become a manufacturer of plastics, but, rather, the question to be considered is "Should the business be valued as a going concern or as if it were in liquidation?" Some businesses are clearly worth more dead than alive and, therefore, should be valued based on their highest and best use in order to provide the maximum return to the investors. For example, if a business is losing money each year and there is no turnaround in sight, the owner of the business would maximize his or her return by liquidating the company, rather than losing equity each year by going forward. This assumes, however, that the interest being valued has the ability to control the direction of the business. A minority interest usually cannot. I have a really good example of this concept in chapter 11.

The scope section of the engagement letter should also describe the level of service, as well as (in some instances) whatever the valuation analyst will not be doing. In most instances, the analyst will be performing a valuation or a calculation engagement. The non-accountants may be doing an appraisal, a limited appraisal, or a calculation, which will soon be defined. For accountants and valuation analysts, language relating to financial statement opinions should be included pursuant to Statement on Standards for Valuation Services (SSVS) No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* (AICPA, *Professional Standards*, VS sec. 100). Non-CPAs who are reading this book do not need to include the section that discusses audits and the AICPA in their engagement letter. Yours truly has those CPA letters after my name, so I worry a little bit more than the typical valuation analyst that my work is not being misconstrued as an accounting type of service. For CPAs, better to be safe than sorry!

<sup>2</sup> Appraisal Institute: *A Guide to Demonstration Appraisal Reporting: Residential*, January 2005.

There will be times when the valuation analyst will be requested to do less than a valuation engagement. Considering the fact that we need to make a living, and that the spirit of the standards is to allow us to do less than valuation engagements under certain circumstances, it seems acceptable to do less than valuation engagements when applicable. What does that mean? The valuation analyst should never do less than a valuation engagement if the end result will be misleading or prone to error.

SSVS No. 1 distinguishes between a valuation engagement and a calculation engagement. The writers of this standard considered another category called a *limited engagement*, but there was more confusion about this than it was worth. Nobody could answer the question that was raised regarding what the difference was between a limited engagement and a *calculation engagement*. Think about it—how much less does the scope of work have to be for each of these categories? It was decided that there should only be two types of engagements in the standards.

For members of the American Society of Appraisers, there are three levels of service that are defined as follows:

The nature and scope of the assignment must be adequately defined. Acceptable scopes of work would generally be of three types as delineated below. Other scopes of work should be explained and described.

1. Appraisal

- a. The objective of an appraisal is to express an unambiguous opinion as to the value of the business, business ownership interest, or security, which is supported by all procedures that the appraiser deems to be relevant to the valuation.
- b. An appraisal has the following qualities:
  - (1) It is expressed as a single dollar amount or as a range.
  - (2) It considers all relevant information as of the appraisal date available to the appraiser at the time of performance of the valuation.
  - (3) The appraiser conducts appropriate procedures to collect and analyze all information expected to be relevant to the valuation.
  - (4) The valuation is based upon consideration of all conceptual approaches deemed to be relevant by the appraiser.

2. Limited Appraisal

- a. The objective of a limited appraisal is to express an estimate as to the value of a business, business ownership interest, or security, which lacks the performance of additional procedures that are required in an appraisal.
- b. A limited appraisal has the following qualities:
  - (1) It is expressed as a single dollar amount or as a range.
  - (2) It is based upon consideration of limited relevant information.
  - (3) The appraiser conducts only limited procedures to collect and analyze the information, which such an appraiser considers necessary to support the conclusion presented.
  - (4) The valuation is based upon the conceptual approach(es) deemed by the appraiser to be most appropriate.

3. Calculations

- a. The objective of calculations is to provide an approximate indication of value based upon the performance of limited procedures agreed upon by the appraiser and the client.
- b. Calculations have the following qualities:
  - (1) They may be expressed as a single dollar amount or as a range.
  - (2) They may be based upon consideration of only limited relevant information.
  - (3) The appraiser performs limited information collection and analysis procedures.
  - (4) The calculations may be based upon conceptual approaches as agreed upon with the client.<sup>3</sup>

<sup>3</sup> American Society of Appraisers Standards. "BVS-I, General Requirements for Developing a Business Valuation," in Business Valuation Standards, (Herndon, VA: American Society of Appraisers, 2009), Sec. II.B.

This information should be clearly spelled out in an engagement letter with the client. For the accountants, remember that there is no such thing as a limited engagement in SSVS No. 1. Rather, it is a calculation engagement.

## Detailed Description of the Valuation Subject

To avoid confusion, a detailed description of the valuation subject should be included in the engagement letter whenever possible. Stating that the valuation analyst is valuing XYZ Corporation is very ambiguous. Is the valuation analyst valuing the common stock of the company? Maybe he or she is valuing only those assets that will be sold as part of an asset sale. Maybe certain liabilities are supposed to be transferred as well. As you can see, a good description is essential for the reader to understand the valuation report. Putting the description in the engagement letter not only requires the valuation analyst to get a proper understanding of the assignment early in the process, but also prevents the client or the client's attorney from changing the nature of the assignment, which changes the amount of time for which the valuation analyst will have to bill.

Defining the property to be valued includes being very specific about the valuation subject. If the entity being valued (in whole or in part) is a corporation, the valuation analyst must be precise about what the valuation subject is. Is it the common stock, preferred stock, specific assets, specific liabilities, or the invested capital? The valuation analyst must also know if 100 percent of the stock or a fractional interest is being valued. The valuation process will depend on the property being valued. For partnerships, LLCs, and proprietorships, the valuation analyst will need to know whether he or she is valuing total capital, specific assets, specific liabilities, or a combination of these.

Good guidance can be obtained from the valuation standards. These standards tell us what we should consider and what should be included in a valuation report.

## Standard of Value That Will Be Used, Including the Definition of That Standard

One of the advantages of being the author of this book is that I get to choose when we cover each topic. Because I do not want to cover standards of value until chapter 4, all I will say at this point is that you need to determine the appropriate standard of value with the guidance of the client's legal counsel as part of defining the assignment if it is to be used in a litigation assignment. For non-litigation assignments, the valuation analyst should still try to make sure that he or she is not the one to choose which standard of value should be used for the job. Either have the client make the determination or have the client get one of its advisers to assist in the process. This standard, as well as its definition, should be spelled out in the engagement letter. It is also a good idea to reference where the definition comes from. Be patient. We will discuss everything in due time.

## Effective Date(s) of the Valuation

Business valuations are similar to balance sheets in that they are as of a specific point in time. Both internal and external factors affect the value of a company; therefore, the valuation date is a critical component of the valuation process. Changing values are easily illustrated in the public stock market. The constant movement of the price of a share of stock illustrates the potential volatility of the value of the stock. Think about what happened to the stock market on a single day: September 11, 2001. What a difference a day makes!

## Type of Report That Will Be Issued to Communicate the Value Estimate

The engagement letter should also include what type of report the valuation analyst is expected to issue. Our firm's policy is to issue a detailed report as part of our standard engagement letter. If the client requests something less, we will include the lower level of reporting in our engagement letter. We are particularly concerned when a client wants a lower level of service to save money, but the end result may be less than what is required for those circumstances.

This is probably a good time to discuss the difference between the scope of work and the level of reporting. The *scope of work*, regardless of whether the valuation analyst is a CPA, is the assignment at hand. Will it be a detailed valuation, a calculation engagement, or something else? The *level of reporting* relates to the deliverable. The valuation analyst may be asked to do a detailed valuation engagement and provide only an oral report. However, the various standards discuss what must be included in the working papers if the valuation analyst provides an oral report.

## Client Responsibilities

There is nothing worse than a client who does not cooperate with his or her own valuation analyst in providing the requested documentation on a timely basis. The attorney calls the valuation analyst and tells him or her that the report is due in 2 weeks. The valuation analyst asks the client for the information, and it is delivered to his or her office at 5 p.m. on the 13th day. To prevent this from happening, the valuation analyst may need to put some language in the engagement letter requiring the client to respond to the information requests by a certain date, especially when the turnaround is short.

In a litigation engagement, the valuation analyst's problem may be getting the other side to provide vital information for the analyst to do the job properly. Although this problem can take up a book by itself, we are not going to discuss it in any great detail. Make sure the engagement letter includes language stating that if the valuation analyst does not get the information requested, there will be no obligation to issue a report.

## Method of Determining Fees and the Terms of Payment

Don't forget this stuff. We are not charitable organizations. The manner in which the valuation analyst will be billing the client should be clearly spelled out in the engagement letter. Some of the alternatives that I have seen include the following:

- Straight hourly rates
- Flat fees
- Hourly rates with a ceiling
- Hourly rates with a floor

Regardless of the manner in which the billing takes place, it is customary for out-of-pocket costs to be added to these rates. Furthermore, requesting a retainer of approximately 50 percent of the estimated fee is quite normal. This way, the out-of-pocket costs (and then some) are in the bank. For many litigation assignments, the valuation analyst may want to keep a replenishing retainer so that the client does not end up behind in paying fees. A smarter alternative is to have a back end retainer. I would much rather refund the excess at the end of an assignment than chase the client for the balance after they no longer need me!

## The Five Steps of a Valuation Assignment

As you can tell from our engagement letter, the initial part of the valuation process is not to be taken lightly. In the introduction, we outlined the five steps of a valuation assignment. Many of the items for defining the valuation assignment are required before the valuation analyst begins the job so that he or she can include this important stuff in the engagement letter.

## Engagement Letter Considerations for Litigation Reports

The previous discussion addressed engagement letters for any type of engagement. Those readers who are CPAs are probably more familiar with engagement letters than any other professional group. In a business valuation litigation engagement, it is important that the engagement letter clearly defines the type of report that will be expected from the valuation analyst. The different types of reports are discussed in chapter 17. A detailed report is a very time-consuming document to create, and, consequently, the client should acknowledge the fact that the valuation analyst is being engaged to render these services.

Many times, a client does not want to spend the money to have the valuation analyst render a long report, and he or she may be asked to provide a summary report. These types of reports are not always appropriate.

A summary report that is used in Tax Court may be tossed out by the judge for not complying with the *Federal Rules of Civil Procedure*.<sup>4</sup> If this is the case, the valuation analyst can count on having a very unhappy client. The client may even sue for malpractice! The valuation analyst should protect himself or herself by using the engagement letter to avoid this problem.

In our practice, because we also follow the USPAP, we issue either an appraisal report (the full detailed version) or a restricted use appraisal report (anything less than a detailed report is restricted in its circulation). Our engagement letter will expressly prohibit the client from using the summary report as an expert report. When the valuation analyst steps into the courtroom, the only thing that the judge will remember is a poor report. The valuation analyst will not be given time to explain that the client was too cheap to allow the valuation analyst to do the job the right way. Our engagement letter will advise the client that in the event of a litigation, we will have to expand our report so that it will qualify with the appropriate standards. This is generally a good compromise for the client because he or she does not have to pay for the detailed report if it is not needed. This entire subject matter could fill up a full chapter, and many of the readers would be bored silly, so I am not going to do that. Just make sure that the valuation report that is produced is consistent with the rules that the attorney should advise the valuation analyst about.

## The Initial Document Request

Once the valuation analyst has been retained, the next step is to request information from the client. There are several schools of thought regarding the document request. Many valuation analysts send out a general request for information, such as the one that appears in exhibit 3.7. They also might include a document such as the one that appears in exhibit 3.8. Other valuation analysts make the initial request much smaller. Depending on the facts of the situation, all of these methodologies make sense.

### EXHIBIT 3.7 General Document Request

#### ABC Manufacturing Company Business Valuation Valuation Date: November 30, 2016

In order for Trugman Valuation Associates, Inc. to render a meaningful opinion relating to the estimate of value of ABC Manufacturing Company, it is important that as much of the following information be supplied as may be available. In the event certain information is not available as of the valuation date, please provide this information for the time period as close to the valuation date as possible.

#### FINANCIAL STATEMENTS

1. Annual financial statements for the years ended December 31, 2011–2015
2. Interim financial statements for the most recent and the previous 11 months
3. A balance sheet as of November 30, 2016 (if not available, as close as possible)
4. Federal income tax returns for the years ended December 31, 2011–2015; state income tax returns, if applicable
5. Copies of any forecasts or projections prepared by or for the company within the last three years and, in particular, a forecast or projection for the five-year period beginning at the valuation date
6. List of subsidiaries or other businesses in which the subject company has an ownership interest, together with their financial statements.

(continued)

4 The Committee on the Judiciary House of Representatives. *Federal Rules of Civil Procedure*. Washington, D.C.: U.S. Government Printing Office, 2011.

**EXHIBIT 3.7 General Document Request** *(continued)***OTHER FINANCIAL DATA**

7. Accounts receivable listing as of the valuation date, preferably aged
8. List of items comprising inventory (quantity, description, and cost) and information on inventory accounting policies as of the valuation date
9. Fixed asset register or depreciation schedule, or both, including real estate and equipment lists, date of acquisition, cost, depreciation method, useful life, and accumulated depreciation that corresponds to the financial statements and tax returns requested above
10. List of items comprising significant other asset balances as of the valuation date
11. Accounts payable listing as of the valuation date, preferably aged
12. Analyses of significant accrued liabilities as of the valuation date
13. List of notes payable and other interest-bearing debt as of the valuation date
14. List of items comprising significant other liability balances as of the valuation date
15. Copies of sales, capital, or operating budgets for at least the next fiscal year
16. Copies of any business plans prepared within the last five years that may continue to be applicable at the valuation date
17. Schedule of officers' or owners' compensation, or both, corresponding to the financial statements and tax returns requested previously
18. Schedule of key man life insurance
19. Reports of other professionals:
  - a. Appraisals on specific assets
  - b. Reports of other consultants

**OTHER OPERATING DATA**

20. Brochures, price lists, catalogs, or other product information
21. List of shareholders showing the number of shares owned by each person
22. Organization chart for the company at the valuation date
23. List of five largest customers over the past three years and the total amount of sales to each customer in each year
24. List of five largest suppliers over the past three years and the total amount purchased from each supplier in each year
25. Details of transactions with related parties

**LEGAL DOCUMENTS**

26. Copies of significant leases or loans, including notes receivable and notes payable
27. Copies of shareholder agreements
28. Minutes of board of directors' meetings
29. Copies of any buy-sell agreements or written offers, or both, to purchase the entire company or any portion thereof
30. Copies of key managers' employment contracts
31. Copies of any major sale or purchase contracts
32. Details of any litigation, including pending or threatened lawsuits
33. Details of any employee benefit plans, including pension plans, profit sharing plans, and employee stock option plans
34. Collective bargaining agreement
35. Reports of examination issued by government agencies such as the Environmental Protection Agency, Occupational Safety and Health Administration, IRS, and Equal Employment Opportunity Commission

**OTHER COMPANY DATA**

36. List of any of the following: patents, copyrights, trademarks, or other similar intangibles
37. Details of any contingent liabilities (such as guarantees or warranties) or off-balance-sheet financing (such as letters of credit) as of the valuation date
38. Resumes or a summary of the background and experience of all key personnel
39. Copies of other value indicators, such as property tax appraisals

(Adapted from *PPC's Guide to Business Valuations*, Copyright © 2017, Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit [tax.thomsonreuters.com](http://tax.thomsonreuters.com).)

### EXHIBIT 3.7 General Document Request

#### INDUSTRY DATA

40. List of trade associations
41. List of trade publications
42. Standard industrial classification code or North American industry classification code
43. Copies of any surveys received as part of a membership in a trade association

#### MISCELLANEOUS

44. Any other information that is deemed to be pertinent in order for us to fairly express our opinion of value

There may be additional information requested during the appraisal process. In addition to the information above, we will want access to all books of original entry, including but not limited to, cash receipts journals, cash disbursements journals, payroll journals, sales journals, general journals, general ledgers, bank statements, cancelled checks, deposit tickets, and other records that may exist.

(Adapted from *PPC's Guide to Business Valuations*, Copyright © 2017, Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit [tax.thomsonreuters.com](http://tax.thomsonreuters.com).)

### EXHIBIT 3.8 Business History Checklist

- I. Background
  - a. Brief description of the business' purpose
  - b. Discuss significant events from inception to the valuation date
- II. Products and Services
  - a. Listing of products and services with a brief discussion of each.
  - b. Breakdown of sales by product line.
  - c. Proprietary products (for example, distribution rights, patents, and trademarks)
  - d. Discuss product seasonality or cyclicalities.
  - e. Are sales dependent on any specific economic factors?
- III. Customers
  - a. Describe the target market and how the business fits in the market (for example, size or market share).
  - b. Is the business in a niche market?
  - c. Is the market growing or shrinking?
  - d. List the business' five largest customers and discuss the evolution of each customer, including relationship and primary contact, among others.
  - e. Discuss dependence on key customers (would the loss of any customer dramatically affect continuing operations?).
- IV. Competition
  - a. Discuss the business' direct and indirect competition.
  - b. List the business' largest competitors with a description, including location, products, and services.
  - c. Discuss barriers to entry into this market.
- V. Marketing
  - a. How are products and services sold?
  - b. Discuss the business' marketing activities (for example, advertising, word of mouth, and direct sales).
- VI. Suppliers
  - a. What does the business need to supply its services?
  - b. Have there been any problems obtaining the products and services that the business needs?
  - c. How much does price volatility of inputs affect sales and profit margins?
- VII. Facilities
  - a. List all locations, including intended use and square footage.
  - b. Are there any planned capital expenditures?
  - c. Discuss the condition of the existing facilities.
  - d. Is there sufficient capacity at the existing facilities to support continuing operations?

(continued)

**EXHIBIT 3.8 Business History Checklist** *(continued)*

- VIII. Personnel
- a. Discuss the business' personnel (for example, unskilled, skilled, or union).
  - b. List number of employees.
  - c. Provide organizational chart.
  - d. Discuss depth and competence of management.
  - e. Are there employment contracts with any personnel?
  - f. Are there any key employees (loss of a key employee would have a material effect on operations)?
  - g. Has the business had any difficulty hiring and retaining personnel?
- IX. Financial Information
- a. Discuss the capital structure of the business (debt and equity or ownership structure).
  - b. List all types of securities issued by the business (for example, debt, preferred stock, and common stock).
  - c. Discuss the business' dividend-paying history.
  - d. Discuss any historic stock sales or offers to purchase the business' stock.
- X. Related Parties
- a. Discuss any related parties, including subsidiaries, affiliates, business partners, or family members.
  - b. What effect do these related parties have on operations?
- XI. Strengths and Weaknesses
- List and discuss the business' strengths and weaknesses. This should include specific items that differentiate the business from its competition (for example, strength—the business has proprietary processes that allow it to make its products less expensively than its competition; weakness—the business has not been able to retain skilled employees).
- XII. Other
- Describe any other important issues that may affect the valuation of this business (for example, technology, research and design, contingent litigation, nonrecurring events, accounting changes, acquisitions, credit problems, expected changes in the business' market or changes in federal, state, or municipal legislation that may affect sales). As previously discussed, these examples are illustrative and are not exhaustive. Please include any topics that may be important to the valuation.
- XIII. Conclusion
- Summarize the business history, including forward-looking statements indicating the expected performance of the business.

**Using a Standard Checklist**

Using a standard checklist is an easy way to request all of the things that the valuation analyst might need to perform a business valuation. However, several problems are associated with standard checklists. The valuation analyst frequently does not know much about the company that is being valued. Sending out a standard checklist may demonstrate a lack of interest on the part of the valuation analyst if he or she asks for many items that are totally irrelevant to the assignment. Think about how the client might feel if the valuation analyst asks for stockholder agreements when the analyst was told that the business is a partnership or sole proprietorship. These entities do not have stockholders.

Using this type of document in a litigation may also prove to be dangerous. I learned the hard way when an attorney went down my checklist and asked me whether I had received each requested item that was included in my document request. This particular assignment was so small that much of the information either did not exist or did not matter. After I said that I had not received about 70 percent of the items on my checklist, he had to ask me only two questions to embarrass me while I was on the witness stand. This is what happened:

*Attorney:* Mr. Trugman, you must think these items are important in performing a valuation engagement if you ask for them as a general rule, do you not?

*Trugman:* Yes, sir, I do.

*Attorney:* Well then, Mr. Trugman, if you consider these items important to your valuation, and you did not receive them from my client, how can you expect this court to believe that you did a credible job when you were missing about 70 percent of what you asked for?

*Trugman:* Gulp!

We all make mistakes. The idea is to learn from them. In fact, if I learned from all of my mistakes, I would now be a genius! And I keep getting smarter every day. Asking for too much information can prove to be as dangerous as not asking for enough. It is important to analyze each situation and act accordingly for that assignment. If the valuation analyst tries to standardize this process too much, he or she is doomed.

As an alternative to sending out a massive document request at the beginning of the assignment, some valuation analysts prefer to send out an initial request for tax returns and financial statements only. This allows the valuation analyst to review these documents and get a feel for the financial side of the company. If the company's revenues are \$80,000, a massive document request may be overkill. However, do not let the small valuations fool you. Sometimes, as much work goes into these types of assignments as the big ones. Other times, a company with no revenues can be quite big. We valued a thinly traded public company with a market capitalization of \$1.8 billion that had no revenues.

After the valuation analyst has a feel for the company, a second document request might make sense. Before the valuation analyst sends out this request, however, he or she may want to perform a site inspection and interview the management (the management interview is discussed further in chapter 6). Either the valuation analyst's fieldwork may streamline the document request or the analyst may find that additional documentation is required because something came to his or her attention during the interview.

## Setting Up Multiple Checklists

As long as the valuation analyst remembers to customize each checklist for the particular assignment, he or she may find it to be a time saver to have multiple checklists set up on his or her word processor for those types of jobs that are done over and over again. These can be set up to request common items for a particular type of valuation assignment. For example, the valuation analyst may want to request unbilled work in process for a CPA or law firm, medical supplies and drugs for a medical practice, and so forth. Separate lists keep you from having to modify a generic request every time you get a new engagement. By the way, chapter 23 includes a discussion of the valuation of professional practices.

## Conclusion

By now, you should have more of an idea about how the valuation analyst gets the job started. Please do not underestimate the importance of the contents of an engagement letter. It is more important to the valuation analyst than the valuation report. You should also have an idea of the type of information that will be requested in the initial stages of the valuation assignment.

# Chapter 4

## Valuation Principles and Theory

### Learning Objectives

In this chapter, I will attempt to do the following:

- Explain the principles of valuation
- Explain various standards of value
- Explain how the purpose of the valuation influences the standard of value
- Discuss the concept of subsequent events (items that are known or knowable)
- Discuss the IRS's influence on business valuations and expose the reader to many of the key revenue rulings

### Introduction

Before a valuation analyst can proceed with a business valuation assignment, there are certain items that are important to consider so that the analyst can get the job done properly. Understanding valuation principles is critical to having an understanding of what the valuation analyst is trying to accomplish. Making sure that the correct standard of value is being used is as important as understanding when to use a golf club versus a baseball bat. These very important concepts will be discussed as we move along.

### Principles of Valuation

Three main valuation principles constitute the foundation of valuation theory. Each of these principles is as important to valuation as the law of supply and demand is to economics. These very important principles are (1) the principle of alternatives, (2) the principle of substitution, and (3) the principle of future benefits.

#### Principle of Alternatives

The principle of alternatives states that in any contemplated transaction, each party has alternatives to consummating the transaction.<sup>1</sup> This indicates that there are generally alternatives to the investment. This concept is relatively simple and does not need to be belabored. Assume that I want to sell my boat. I have alternatives for whether I sell the boat, how much I sell it for, and to whom I sell it. In *Basic Business Appraisal*, Miles points out

Because it is one of the fundamental principles that form the basis of almost all appraisals, including those under circumstances that do not actually involve a contemplated sale or other transaction, the appraiser needs to be aware of its existence.<sup>2</sup>

#### Principle of Substitution

The principle of substitution is a presupposition of appraisal practice, expressing a generalized prediction concerning behavior related to an event involving economic choices and values. It predicts how people will

<sup>1</sup> Raymond C. Miles, *Basic Business Appraisal* (Boynton Beach, FL: Institute of Business Appraisers, 1989).

<sup>2</sup> *Ibid.*, 22.

normally choose among comparable properties when prices vary.<sup>3</sup> In English, prudent individuals will not pay more for something than they would pay for an equally desirable substitute. To illustrate how the principle of substitution operates to determine value, assume that an individual wants to purchase a paint store. That person begins looking at various stores that are for sale and narrows down the choice to two of these stores. Both have good inventory, geographic location, and profits and are equally acceptable as purchase alternatives. One is listed for sale for \$800,000, and the other is listed for \$900,000. Which one do you think that person will most likely try to buy? This stuff is not rocket science!

The principle of substitution, in essence, states that nobody will pay more for something than he or she would pay for an equally desirable substitute. Logically, if two items are identical except for the price, a willing buyer will gravitate to the item with the lower price.

This is also illustrated in the investment field. If two investments have equal risk, an investor will invest in the item that will provide the greatest return on investment. Try to remember this stuff. It will be really important in chapter 13.

## Application of the Principle of Substitution

There are three approaches to value (market, asset-based, and income) that should be considered when one performs a business valuation. These were discussed in the standards discussed in chapter 2. Each of these approaches, when applied, illustrates the principle of substitution.

The market approach estimates the value of the business being valued from information derived from the market about prices actually paid for other similar businesses. The asset-based approach simulates the starting of an equivalent business from scratch. In this approach, the value of the business being valued is determined from the estimated cost of replacing (duplicating) the business asset by asset, liability by liability.

The income approach looks to financial equivalents (not necessarily a business) to estimate the value of the subject business or business interest. The value of the business being valued is estimated by either capitalizing a single-period benefit stream or discounting a multi-period benefit stream. The rates used to capitalize or discount the benefit stream are determined from alternative investments based on the risk factors attributable to the stream being capitalized or discounted. This will begin to make more sense in a little while.

## Principle of Future Benefits

The principle of future benefits is the third valuation principle that is fundamental to the valuation process. This principle states that “economic value reflects anticipated future benefits.”<sup>4</sup> This valuation principle can best be illustrated by assuming that someone wants to buy a particular business. Would historic earnings be as important as prospective earnings in determining value? Probably not. The valuation analyst would not care what the business generated for the prior owner as much as what it can generate for the purchaser.

There are only three economic reasons that investors will invest in a certain stock: (1) dividends (future cash flows to the investor), (2) capital appreciation (future cash flows to the investor upon sale), or (3) a combination of the two (future cash flows). Remember: Valuation is based on the future outlook of the business.

This is the foundation for making any financial investment. I will soon discuss standards of value and the approaches to value, but the bottom line is that regardless of how the valuation analyst approaches it, economic value should be determined based on the anticipated future cash flow that is expected from an investment. This means that the discounted cash flow methodology that I will discuss in chapter 12 is theoretically the most sound method, because it measures the present value of the future cash flows to the investor. Unfortunately, as will be shown, it is really easy to make a mistake in the application of this method if the valuation analyst is not careful.

<sup>3</sup> Richard Rickert, “Appraisal and Valuation: An Interdisciplinary Approach” (unpublished textbook from my graduate school days at Lindenwood College, St. Charles, Missouri).

<sup>4</sup> Miles, *Basic Business Appraisal*, 27.

## Standards of Value

A good place to start in any book on valuation is to define what is meant by a valuation. A valuation is a supportable opinion about the worth of something. In this book, and in much of the valuation literature, the term *valuation* is used synonymously with the term *appraisal*. Therefore, a business valuation is the same as a business appraisal.

It is not enough to state that the valuation analyst will determine the *value* of what is being valued. The term *value* has many different meanings in the valuation field. One of the first lessons to be learned relates to what are called *standards of value*. These are also called *definitions of value*. Before an assignment can be started, it is imperative that the standard of value that will be used in the assignment is clearly defined. In chapter 3, I recommended that the standard of value, including a definition, be included in the engagement letter. In addition to discussing standards of value, a valuation analyst must also consider the ownership characteristics of the valuation subject and the premise of value that will be used.

The ownership characteristics refer to whether the valuation will be conducted using the actual buyer and seller versus some hypothetical buyer and seller. Believe it or not, this makes a really big difference. There have been many court battles over this stuff. Using real or hypothetical individuals changes the standard of value.

The premise of value relates to the concept of highest and best use, which I mentioned earlier. Will the valuation analyst be valuing the company as a going concern or as if in liquidation? This, too, is an important concept because there are instances when a business that can be sold for its parts may be worth more than a business that is up and running. Let me give you a quick example. Assume that the valuation analyst has a client that delivers home heating oil. The company has been losing money for the last seven years with no turnaround in sight. The industry has changed, and small independent dealers are struggling because they have these really big trucks that they are sending out to customers, half-full due to the lack of volume. The big players in the industry are purchasing the customer lists for substantial multiples of revenue because they feel that they can fill up their trucks and have their drivers stop at a few more customers on the route, and the incremental sales will only cost them the price of the fuel oil. If the client sells the customer list, in addition to all the other assets of the business, the money from the sale, after satisfying the liabilities, could be invested at a profit. This would provide a greater return than running the business at a loss each year. This is the concept of highest and best use.

According to Merriam-Webster's Dictionary, the definition of *value* is "a fair return or equivalent in goods, services, or money for something exchanged." In business valuation, the following standards of value are the most frequently used:

- Fair market value
- Fair value
- Investment value
- Intrinsic value

This stuff is important. In fact, there is an entire book, *Standards of Value: Theory and Applications*,<sup>5</sup> that addresses it. This book only covers standards of value. So, is this important?

### Fair Market Value

Probably the most commonly used standard of value is fair market value. Revenue Ruling 59-60, a very important tax ruling issued by the Treasury Department in 1959, defines *fair market value* as "[t]he amount at which the property would change hands between a willing buyer and a willing seller, when the former is not under any compulsion to buy, and the latter is not under any compulsion to sell, both parties having reasonable knowledge of relevant facts."

<sup>5</sup> Jay E. Fishman, Shannon P. Pratt, and William J. Morrison, *Standards of Value: Theory and Applications*, 2nd ed. (Hoboken: John Wiley & Sons, Inc., 2013).

This definition implies that the value is the most probable price in cash or cash equivalent that would be paid if the property were placed on the open market for a reasonable period and, in all likelihood, assumes the existence of a covenant not to compete. If it did not assume a covenant not to compete, why would a buyer pay for any portion of a business that could be taken by the seller, who could then open a competing business across the street? Usually, the price is allocated for income tax purposes after each party to the transaction agrees to the negotiated figure. In certain jurisdictions, and for certain types of valuation assignments, this definition assumes the highest price, rather than the most probable price. The valuation analyst needs to make sure that the correct definition is used.

The concept of fair market value is frequently misunderstood; therefore, the inexperienced valuation analyst commits many errors trying to estimate the fair market value of the valuation subject. First and foremost, the definition of fair market value considers the *hypothetical* willing buyer and the *hypothetical* willing seller as opposed to *actual* buyers and sellers. In addition to these hypothetical players being willing, they must also be able to consummate the particular transaction. This will be discussed more throughout this book. To illustrate the concept of fair market value, a real-life example can be used. A number of years ago, I was engaged in a matrimonial matter to determine to what extent an offer to purchase a business, made during the course of negotiating a settlement, was to be considered the fair market value of the business. What rendered this situation especially interesting and unusual was that the offer was made by the wife for the husband's business.

The court had appointed an accountant to value the husband's car wash business. After the accountant arrived at a value, the wife put together a group of potential investors and, during the negotiations, offered the husband \$200,000 more than what was, in the court-appointed accountant's opinion, the fair market value of the car wash. The question was whether this offer should have been considered bona fide and representative of the fair market value of the business.

The answers to these questions lay in the definition of fair market value. In the specific facts and context of this case, I concluded that fair market value would probably not be represented by the wife's offer. I say "probably" because I was not asked to determine the fair market value of the car wash per se, only whether the wife's offer could constitute fair market value. I really did not know what the value of the business was because I did not value it.

Working from expert reports, courts frequently use fair market value as the basis for property distribution in marital dissolution cases. The most frequently used definition of fair market value is the one I cited previously. A similar definition can be found in Miles's *Basic Business Appraisal*:

Fair market value is the price, in cash or equivalent, that a buyer could reasonably be expected to pay and a seller could reasonably be expected to accept, if the property were exposed for sale on the open market for a reasonable period of time with buyer and seller being in possession of the pertinent facts, and neither being under any compulsion to act.<sup>6</sup>

Both of these definitions are regularly accepted by the valuation profession and used interchangeably. These definitions contain the following components: (1) cash or equivalent, (2) exposure for sale on the open market, and (3) neither party under compulsion to act. The concept of fair market value will be understood better through an analysis of these components.

## Cash or Equivalent

The valuation analyst's assignment is to determine the equivalent of cash that would be paid for the item being valued as of the valuation date. Often, a property may be sold with the seller holding a mortgage at a rate of interest below the market rate to induce the buyer to enter into the transaction. This situation requires a present-value calculation because some of the value will not be received until a future date. Valuation theory is founded on the principle of future benefits, with the value of any property constituted by the sum of the benefits that will be obtained by its owner in the future. No one will buy property if there will be no future benefits, whether in the form of income or the appreciation to be realized upon subsequent resale of the property.

.....  
<sup>6</sup> *Ibid.*, 43.

Present-value theory can be illustrated by comparing the sale of two businesses, each for \$100,000—one with a five-year payout and the other a seven-year payout. The value of these businesses can be determined using the present-value formula:

$$PV = \frac{FV}{(1 + k)^n}$$

$PV$  = Present value

$FV$  = Future value

$k$  = Rate of return (sometimes called “discount rate”)

$n$  = Number of periods into the future for which the discounting is being computed

A discount rate of 10 percent would yield the following present values:

<b>Business 1</b>	<b>Business 2</b>
$PV = \frac{FV}{(1 + k)^n}$	$PV = \frac{FV}{(1 + k)}$
$PV = \frac{\$100,000}{(1 + 0.10)^5}$	$PV = \frac{\$100,000}{(1 + 0.10)^7}$
$PV = \$62,092$	$PV = \$51,316$

The example illustrates that the cash equivalent of these two businesses are quite different in today's dollars. This part of the definition of fair market value is frequently overlooked. For a value to be representative of fair market value, it must be reasonable. Simply put, an offer to buy or sell will not represent fair market value if both parties do not feel that the offer is fair. Obviously, a unilateral offer cannot represent the true value of an asset.

The willing buyer and willing seller are hypothetical persons dealing at arm's length, rather than any particular buyer or seller. In other words, a price would not be considered representative of fair market value if influenced by special motivations not characteristic of a typical buyer or seller.<sup>7</sup>

## Exposure for Sale on the Open Market

The concept of *market* is extremely important to the definition of fair market value. In many situations, the valuation subject is not for sale. This is usually the case when property is valued as part of a divorce proceeding. To estimate fair market value, the valuation analyst must assume that the property has been placed on the open market.

The valuation analyst also assumes that a number of similar properties are available in the open market under the principle of substitution. This principle, as previously discussed, is based on the theory that no person will pay more for a property than he or she would have to pay for an equally desirable substitute.

This principle can be illustrated by the following scenario. Let's assume that the wife wants to purchase a car wash. In addition to the one that is owned by the husband, five other car washes are for sale in the general area. All of these car washes have similar revenues, similar locations, and the same overall characteristics. The principle of substitution dictates that the wife would purchase the one that is offered for the lowest price. Let's also assume a number of prospective buyers. The interaction of the buyers with the sellers of these car washes will eventually establish the fair market value for this type of business. However, for the price offered to be representative of fair market value, all the other attributes of fair market value must be present.

<sup>7</sup> Shannon P. Pratt, and Alina V. Niculita, *Valuing a Business*, 5th ed. (New York: McGraw Hill, Inc., 2008-0): 42.

The term *open market* must also be explored. The market for a \$30 billion business would be very small because there would be few buyers who are willing and able to make such a purchase. There would also be very few “equally desirable substitutes.” However, the size of the market does not prevent the valuation analyst from assuming an “open market.” Although limited, the valuation analyst’s environment is the hypothetical market, the price at which the property would change ownership if it actually was offered for sale.

The definition of fair market value also assumes that the subject property would be exposed on the open market for a reasonable amount of time. This means that the property should be made available for a time period long enough for all potential purchasers to be aware of its availability, rather than be offered to a select group of prospective purchasers. The property should remain on the market “for a sufficient length of time to allow the action of market forces to have full effect,” according to Miles, who adds that this may even be “in contrast to some actual situations in which the property may be on the market only a short time before it is sold, possibly even being sold to the first potential buyer who makes an offer, at a price that may very well be lower than its actual open market value.”<sup>8</sup>

### Neither Party Under Compulsion to Act

If a seller is under compulsion to sell a business, he or she may accept an offer that represents a *distress sale*. Similarly, if, because of over-indebtedness, the only way a transaction could occur is if the seller finds a buyer willing to pay more than fair market value for the business, the buyer may also be “under compulsion to act” if he or she needs to acquire a business to earn a living. Under these circumstances, a buyer may overpay.

Returning to the original car wash example, the wife’s offer cannot be considered fair market value. Although her offer does constitute value, it is what Pratt refers to as *investment value* or “the specific value of an investment to a particular investor or class of investors based on individual investment requirements; distinguished from market value, which is impersonal and detached.”<sup>9</sup> Her offer would establish a *price* for this business but would not reflect the value of the business.

The distinction between price and value is crucial. These terms are also to be distinguished from cost. Value will vary depending on the perceived value to a specific type of investor. There are strategic buyers, financial buyers, distress buyers, ego buyers, and so on. The intangible assets being purchased probably have a different value to each of them. The value of any financial asset is equal to the net present value of the expected future cash flows derived from the asset, discounted at the required rate of return, which is also referred to as the *discount rate*. The required rate of return will vary depending on the type of buyer.

*Price* is a term that is used differently in varying situations. Common variations of this term include *offering price*, *market price*, *dealer’s price*, and *fair market value price*. Offering price simply represents a number that a seller is asking for an asset. This can be illustrated by a sticker price on a new automobile or a store price tag on a garment. The unsophisticated layperson believes that if there is a wide enough gap between the asking price and the cost that she will actually pay (in effect, a discount), she is receiving value. So, just remember, when you go to a department store and see a shirt that is marked down from \$295 to \$250, this is a deal. Two hundred fifty dollars for a shirt? Not in my lifetime! (Too many books to sell to get that much in royalties.) In the business valuation world, price is most commonly thought of as the value received as adjusted for the terms of the transaction. For example, Owner A sells his company for \$2 million cash, and Owner B sells his business for \$2 million on a noninterest-bearing note for 10 equal annual payments of \$200,000. Both owners paid the same price, but the underlying value is different. This is simple present-value theory. A dollar is worth more today than in the future.

Next, we get to deal with the concept of *cost*. One viable perspective on the concept of cost is the fact that it simply represents a historical fact. The fact that you paid X dollars for an asset one day, one year, or one decade ago has little, if any, relationship to its current value. Several examples of this are real estate appreciation or new car depreciation one minute after driving it off the sales lot. In a business context, the balance sheet simply represents a historical tracking of costs incurred to acquire certain assets. Some people correctly consider the book value of the stockholders’ equity account to be a misnomer. “Book cost” would be the more accurate title.

<sup>8</sup> Miles, *Basic Business Appraisal*, 44.

<sup>9</sup> Pratt et al., *Valuing a Business*, 43.

So, in the real world, businesses are bought and sold for a price. The valuation analyst's role is to estimate value. The accountants record the purchase at cost. Compared to the valuation environment required by the definition of fair market value, the conditions that exist in the real world often influence price without affecting value. According to The Institute of Business Appraisers, "Price is what you pay; value is what you hope to get."<sup>10</sup>

The determination of fair market value is a process in which the valuation analyst is frequently forced to make a determination of fair market value, but to whom? An excellent lesson can be learned from court cases dealing with this issue. In chapter 27, I have included a discussion about one of my favorite court cases, *Estate of Samuel B. Newhouse*,<sup>11</sup> which illustrates that fair market value can result in different values to different classes of investors. This is a really good case that should be read.

## Fair Value

Fair value has several distinct meanings in the valuation field. For financial reporting, fair value guidance was provided from the AICPA's website, as follows:

FASB ASC 820-10-20 defines *fair value* as the price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date. FASB ASC 820-10-35-5 states that a fair value measurement assumes that the transaction to sell the asset or transfer the liability either occurs in the principal market for the asset or liability or, in the absence of a principal market, the most advantageous market for the asset or liability. The FASB ASC glossary defines the *principal market* as the market in which the reporting entity would sell the asset or transfer the liability with the greatest volume and level of activity for the asset or liability. The principal or most advantageous market (and thus, market participants) should be considered from the perspective of the reporting entity, thereby allowing for differences between and among entities with different activities.

FASB ASC 820-10-35-3 and 820-10-30-2 provide that the hypothetical transaction to sell the asset or transfer the liability is considered from the perspective of a market participant that holds the asset or owes the liability. Therefore, the objective of a fair value measurement focuses on the price that would be received to sell the asset or paid to transfer the liability (an exit price), not the price that would be paid to acquire the asset or received to assume the liability (an entry price). Conceptually, entry prices and exit prices are different. However, FASB ASC 820-10-30-3 explains that, in many cases, at initial recognition a transaction price (entry price) will equal the exit price and, therefore, will represent the fair value of the asset or liability. In determining whether a transaction price represents the fair value of the asset or liability at initial recognition, the reporting entity should consider facts specific to the transaction and the asset or liability.

Paragraphs 7–8 of FASB ASC 820-10-35 explain that the price should not be adjusted for transaction costs. However, if location is an attribute of the asset or liability (as might be the case for a commodity), the price in the principal (or most advantageous) market used to measure the fair value of the asset or liability should be adjusted for the costs, if any, that would be incurred to transport the asset or liability to (or from) its principal (or most advantageous) market.

The other arena where we see the term *fair value* used is in corporate, limited liability company, and partnership dissolution statutes and ownership disputes. However, the definition of fair value in this context varies from state to state. The definition has been developed from case law, primarily in dissenting and oppressed stockholder actions. The Delaware Chancery Court probably hears more dissenting shareholder cases than any other jurisdiction. In fact, many jurisdictions cite Delaware case law in its own case law. However, the valuation analyst should not make the broad assumption that this will be followed in the jurisdiction of the litigation that the valuation analyst is dealing with. This concept is also used in many corporate dissolution statutes, but here also, the definition is an enigma. The valuation analyst should obtain the definition of value from the client's legal counsel based on the corporate statutes and case law in the jurisdiction where the litigation will take place. It is a very bad practice to try to get this definition from a textbook because it is very difficult for any

<sup>10</sup> Institute of Business Valuation Appraisers Inc. newsletter, January 1986.

<sup>11</sup> *Estate of Samuel I. Newhouse v. IRS Commissioner*, 94 T.C. 193 (1990).

book to address this in more than general terms. I have seen many inexperienced valuation analysts quote one of the leading valuing books to define fair value as “fair market value with no discounts.” If the valuation analyst does this, he or she will be wrong more often than right.

The American Law Institute’s concept of fair value as explained in the *Principles of Corporate Governance* (1992), under the “Appraisal Remedy” section, defines fair value as

... the value of the eligible holder’s proportionate interest in the corporation, without any discount for minority status or, absent extraordinary circumstances, lack of marketability...fair value should be determined using the customary valuation concepts and techniques generally employed in the relevant securities and financial markets for similar businesses in the context of the transaction giving rise to appraisal.<sup>12</sup>

Now don’t get too excited about seeing this definition. Not all jurisdictions follow it. The valuation analyst really needs to check with the client’s legal counsel to make certain that the appropriate definition is being used. What we do know is that one of the fundamental differences between fair value and fair market value is that in a litigation setting, there is rarely a willing seller in a fair value appraisal. Most courts are concerned with the concept of fairness, and as a result, the valuation is intended to be equitable for the disadvantaged party. We also see certain jurisdictions placing much more emphasis on the discounted future benefits method (income approach), rather than the guideline public company method (market approach) in the determination of fair value. Some of the differences between fair value and fair market value are illustrated in box 4.1.

#### BOX 4.1 Differences Between Fair Market Value and Fair Value

##### Fair Market Value

1. Willing buyer
2. Willing seller
3. Neither under compulsion
4. Assumes a typical hypothetical buyer and seller
5. A price equitable to both buyer and seller
6. Assumes buyer and seller have equal knowledge
7. Assumes reasonable knowledge of both parties
8. Applicable to controlling interests or minority blocks
9. Applies to all federal tax valuations

##### Fair Value

1. Not always a willing buyer
2. Not a willing seller
3. Buyer not always compelled; seller under compulsion
4. The impact of the proposed transaction not considered; the concept of fairness to the seller a possible consideration
5. A concept of fairness to the seller, considering the inability to keep the stock
6. No such assumption
7. No such assumption
8. Applicable to minority blocks
9. The most common value standard in state dissenting and oppressed shareholder statutes

The concept of fair value is driven by case law, and it is ever-evolving. The valuation analyst should never take it upon himself or herself to take the legal positions regarding the interpretation of the standard or the case law. However, the valuation analyst needs to be aware of when not to use a standard of value that is incorrect. A great example of this was when I was approached to do a valuation for gift tax purposes using a fair value standard. My question to the attorney was “when did the law change?” He thought about it for a minute and said “I guess fair market value is built into the Internal Revenue Code.” Duh! He was looking for a valuation of

<sup>12</sup> The American Law Institute, *Principles of Corporate Governance: Analysis and Recommendations*, vol. 1 and 2, (Washington, D.C., May 13, 1992): 315.

a minority interest without discounts. If the valuation analyst is not sure about the standard of value, I cannot emphasize strongly enough the need to get advice from legal counsel. There are times when even qualified valuation analysts are given incorrect marching orders. That is what engagement letters are for. See, here it is again, the need for a good understanding in the engagement letter. This is why I added language to our engagement letters telling the client that the standard of value is a legal determination that should be verified with the client's attorney. Chapter 24 covers additional issues regarding ownership disputes.

## Investment Value

The investment value of a closely held company is the value to a particular buyer, as compared with the population of willing buyers, as is the case in fair market value. This is one of those instances when the valuation analyst will determine the value to a particular person or entity, instead of the hypothetical person or entity. This value definition would be applicable when an investor has specific investment criteria that must be fulfilled in an acquisition. For example, a purchaser may decide that, as owner-manager, his or her compensation must be at least \$95,000 per year. In addition, the business must have the ability to pay any indebtedness resulting from the purchase from operating cash flow over a period of no longer than five years.

A valuation analyst will frequently use this standard of value when he or she represents a buyer who wants to know, "how much is the business worth to me?" The fact that the buyer is specific about the business value to him or her changes the standard of value to investment value, as opposed to fair market value, which may be the value to everyone else.

Another manner in which to think about this standard of value is to think that every transaction that takes place is specific to the actual buyer and seller, who have specific criteria that cause both of them to consummate the deal. If there are many transactions taking place at about the same time, there is a market. If there are many transactions, it is assumed that a normal distribution will take place for the price that these similar transactions are consummated at. We will discuss statistics in chapter 7, but, for now, the assumption is that in an active market, any special motivations of the individual buyers or sellers would be eliminated as outliers, allowing the price to reach a normative state that would represent fair market value. The market value would cluster around the same point, at a particular moment in time, creating what we consider to be the fair market value of the property. Now, with that being said, market value will change with time because of the mix of buyers and sellers in the marketplace. For example, if all the buyers in the marketplace are synergistic buyers, meaning that making the purchase would enhance their value because of the synergies between the target and the acquirer, the prices paid by this group of buyers would be greater than the price to the financial buyers. This creates greater investment value for the buyers and results in upward pressure on the prices paid in the marketplace for similar properties. This should sound very much like the law of supply and demand that we learned in Economics 101.

Investment value is being examined more closely by many family courts as the standard of value that is appropriate in divorce situations. In a divorce, the elements of fair market value are rarely present; the owner is not a willing seller, nor will there be a sale. We frequently hear the concept of the *value to the owner* used as an alternative to fair market value. Essentially, value to the owner is the investment value to that individual. The valuation analyst should consult with the client's attorney before using this standard of value. Virginia may be the only state whose case law definitively addresses this issue at the current time, but others have discussed aspects of it. These concepts are discussed in much more detail in chapter 22, which addresses valuations for divorces.

## Intrinsic Value

If you have ever heard the expression "Beauty is in the eye of the beholder," you will probably understand the term *intrinsic value*. This term is frequently used by financial analysts. The intrinsic value of a stock is generally considered to be the value based on all the facts and circumstances (sometimes considered to be based on a technical analysis) of the business or the investment. Financial analysts in brokerage firms often ignore the fluctuations of the stock market in determining the intrinsic value of a specific stock. When you watch CNBC and the analyst makes a statement such as "IBM is currently selling at \$80 per share, but we believe that its intrinsic value is \$95," the analyst is basically telling the audience that in the opinion of the analyst, the shares of IBM are being underpriced by the market, and they are really worth more. This is considered a buying opportunity by the particular analyst.

Although I knew what intrinsic value meant, it was not until recently that this definition became more important to a valuation assignment than ever before. The issue was the determination of fair value of a client's interest in a family owned business. Using the market approach, based on public companies, we estimated the value of the company to be about \$75 million. Using the income approach, we estimated the value of the company at about \$125 million. After spending a considerable amount of time trying to reconcile these values, we realized that the publicly traded companies were selling at very low multiples, despite having solid growth expectations. The market was undervaluing these companies. In fact, the investment banking firms that followed this industry had strong buy recommendations for most of the public comparables that we used in our analysis. This means that the intrinsic value of the public companies was greater than the market value. While we were doing a critique of the opposing side's valuation (who only used the market approach to value the business), we reread *Valuing a Business*.

It is truly amazing how much we learn by rereading books that we read on a regular basis. Pratt et al. discuss intrinsic value. On page 44, they explain the following about intrinsic or fundamental value.<sup>13</sup>

*Intrinsic Value.* The amount that an investor considers, on the basis of an evaluation of available fact, to be the “true” or “real” worth of an item, usually an *equity security*. The value that will become the market value when other investors reach the same conclusions. The various approaches to determining intrinsic value of the finance literature are based on expectations and discounted cash flows.

As can be seen from the preceding definition, Pratt et al. indicate that “the various approaches to determining intrinsic value in the finance literature are based on expectations and discounted cash flows.” Clearly, expected earnings are of critical importance, but other variables such as dividends, capital structure, management quality, and so on, are also considered in a fundamental analysis. What is striking is that Pratt et al. state, “If the market value is below what the analyst concludes is the intrinsic value, the analyst considers the stock a ‘buy.’” This is exactly what takes place when an investment banking firm gives a strong buy recommendation on a company's stock. If the market price of this stock is low enough to warrant this type of recommendation, using multiples (discussed in chapter 7), without proper adjustment, may undervalue the subject company.

## How the Purpose of the Valuation Influences the Standard of Value

There should be little doubt that the purpose and function of a valuation will have a dramatic influence on the standards of value that may be applicable in a particular assignment. Table 4.1 highlights how the purpose and standard of value relate to each other.

**TABLE 4.1 Valuation Purpose and Standard of Value Relationships**

Valuation Purpose		Applicable Standard of Value
Estate and gift taxes	☞	Fair market value
Inheritance taxes	☞	Fair market value
Ad valorem taxes	☞	Fair market value
Employee stock ownership plans (ESOPs)	☞	Fair market value
Financial acquisitions	☞	Fair market value
Stockholder disputes	☞	Fair value (in most states)
Corporate or partnership dissolutions	☞	Fair value (in most states)

(Table continued)

<sup>13</sup> Pratt, et al., *Valuing A Business*, 5th ed.

**TABLE 4.1 Valuation Purpose and Standard of Value Relationships**  
(continued)

Valuation Purpose		Applicable Standard of Value
Going private	☞	Fair value (in most states)
Strategic acquisitions	☞	Investment value
Buy-sell agreements	☞	Whatever the parties agree to
Marital dissolutions (divorce)	☞	No specific standard in most states; look to case law
Financial reporting	☞	Fair value

#### Author's Note

Throughout this book, unless otherwise noted, fair market value will be the standard of value applicable to the valuation methodologies discussed.

## Subsequent Events (Known or Knowable)

The issue of subsequent events comes up so often that I decided to include a section about this topic in this book. According to Statement on Standards for Valuation Services (SSVS) No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* (AICPA, *Professional Standards*, VS sec. 100):

### Subsequent Events

**.43** The valuation date is the specific date at which the valuation analyst estimates the value of the subject interest and concludes on his or her estimation of value. Generally, the valuation analyst should consider only circumstances existing at the valuation date and events occurring up to the valuation date. An event that could affect the value may occur subsequent to the valuation date; such an occurrence is referred to as a *subsequent event*. Subsequent events are indicative of conditions that were not known or knowable at the valuation date, including conditions that arose subsequent to the valuation date. The valuation would not be updated to reflect those events or conditions. Moreover, the valuation report would typically not include a discussion of those events or conditions because a valuation is performed as of a point in time—the valuation date—and the events described in this subparagraph, occurring subsequent to that date, are not relevant to the value determined as of that date. In situations in which a valuation is meaningful to the intended user beyond the valuation date, the events may be of such nature and significance as to warrant disclosure (at the option of the valuation analyst) in a separate section of the report in order to keep users informed (paragraphs .52*p*, .71*r*, and .74). Such disclosure should clearly indicate that information regarding the events is provided for informational purposes only and does not affect the determination of value as of the specified valuation date.

This is an important concept that should not be overlooked. The concept is really quite simple. Only information that was *known* or *reasonably knowable* should be considered in the development of the valuation analyst's conclusion of value. Keep in mind that many valuations that valuation analysts perform are retrospective in nature. As a result, time has gone by since the valuation date and it would be very tempting to use the knowledge of what really happened to influence the conclusion of value. However, cheating is not allowed. Let me give you some illustrations to help point you in the right direction. Assume that we are performing a valuation as of December 31, 2016. You are actually doing the work in June 2017. You run into several documents that you want to use in developing your valuation, such as the following:

1. Economic data about the area discussing 2016, but published in March 2017
2. An industry report based on data through December 31, 2016, published in May 2017
3. Public company data included in the 2016 Form 10-K but filed on March 15, 2017
4. Subject company financial statements as of December 31, 2016, issued in March 2017
5. Several emails that were provided to you dated October 2016 through June 2017 discussing an offer to purchase part of the subject company that was ultimately rejected by the company as being too low

Under normal circumstances, you would think that this is easy to understand. However, there is a considerable amount of debate about which items from the preceding list could be used for the ongoing valuation. Let me apologize in advance because if you are looking for absolute guidance in this area, you are probably not going to like this discussion.

The economic data can technically be used only if the data was available from another source as of the valuation date. There are purists in this world that would suggest you not use that source because it was published after the valuation date. The government generally has a lag regarding when information about the economy is released. The non-purists will tell you that it is usable because it was close to the valuation date, and regular forecasts are being published that can get you very close to that date. However, with that being said, where does the valuation analyst draw the line regarding what constitutes being close to the valuation date: one month, two months, six months, a year? Personally, I think it depends on the purpose and function of the valuation. I would be more reluctant to use subsequent data for an estate tax valuation than I would for a valuation for an acquisition. The former valuation is as of a certain date, and, if I use information past that date, I believe I am opening the doors for the IRS to do the same. For an acquisition, I would hate to see my client buy the business after ignoring something that may have happened recently that could affect the value.

Most valuation analysts would agree to not use the industry report because that information would not have been available until the report was published. The valuation analyst might have been able to get some advanced sheets from the publication, but I doubt that the publisher would release them many months before the publication date unless the analyst was a regular subscriber.

The public company filing should technically be off limits because it was not available until March 2017, but many valuation analysts use it anyway based on the premise that public company financial information is never more than three months away (based on Form 10-Q filings), and the analysts on Wall Street generally have good information about earnings estimates before year-end. The valuation analyst has to decide this one on his or her own.

The subject company financial statements will generally be used. Now, the valuation analyst may think that this is a contradiction to the public company data, but technically, if he or she went into the subject company with a SWAT team of accountants with their pencils drawn, the analyst could put a financial statement together between the close of business on December 31, 2016, and the end of the day. The valuation analyst would certainly get close enough for military work!

The emails about a possible deal are another issue that can be argued. However, notice that the first emails were sent before the valuation date. The question is whether the information in these emails is required to value the company, or if the information is used to confirm the value. *Uniform Standards of Professional Appraisal Practice* FAQ 142 states the following regarding retrospective value opinions:

A retrospective appraisal is complicated by the fact that the appraiser already knows what occurred in the market after the effective date of the appraisal. Data subsequent to the effective date may be considered in developing a retrospective value as a confirmation of trends that would reasonably be considered by a buyer or seller as of that date...<sup>14</sup>

.....  
 14 *Uniform Standards of Professional Appraisal Practice*, 2016–17 edition, FAQ 142, 276.

Pratt and Laro indicate that “Some courts find certain later events, transactions, and circumstances relevant to the valuation if they were reasonably foreseeable as of the valuation date (footnoting the *Estate of Spruill v. Comm’r*, 88 T.C. 1197 [1987]) (subsequent events “could not have been reasonably foreseen at the time of the decedent’s death”).”<sup>15</sup> Pratt, Fishman, and Morrison state that “Subsequent events that were foreseeable at the valuation date may be considered in a valuation.”<sup>16</sup> Pratt and Niculita state that “Readers should be put on notice that the Tax Court frequently relies on subsequent sales as evidence of value. The court distinguishes between subsequent sales that *affected* the value and those that are merely *evidence of value*.”<sup>17</sup>

Other quotes were provided in chapter 2, but I felt that a reminder would not hurt. I would argue, and I have argued, that the emails are evidence of value and not information that affected value. This situation actually occurred in a litigation assignment that I was involved in. My client was thrown out of the business and obtained emails that went back and forth between his brother, who was the controlling stockholder, and a possible buyer for a portion of the business. Based on the emails, it was apparent that the brother and the company’s accountant had put together their own forecasts and discounted cash flow analysis of the value of that portion of the business. What a surprise when we learned that they did not share this information with us for our valuation. The other side argued that the forecasts and calculations were not known or knowable at the valuation date and should not be considered. Our argument was that the company put these forecasts together during the negotiations, and they certainly could have done the same forecasts at the valuation date. The company’s own calculations indicated to us that management knew that this portion of the business was very valuable, and they were able to value it. We made a couple of technical corrections to the calculations and used this information as an indication of value.

So, as can be seen, this known or knowable stuff is controversial. There are many court cases that address this issue. In the *Estate of Jung v. Commissioner* (101 TCM 412 [1993]), the Tax Court used a transaction that was years after the valuation date to support what should have been known or knowable. See box 2 in chapter 2 for a list of some of the court cases addressing subsequent events. The actual cases make great reading if you are an insomniac!

## IRS Influence on Business Valuations

When most people think about the IRS, they think of April 15. Believe it or not, the IRS does more than just pick our pockets at tax time. Because so many valuations are performed for tax-related matters, the IRS is actively involved in business valuations. Many valuations are performed that may ultimately be used to defend a position before the IRS. Valuation analysts need to be familiar with the various IRS promulgations that may also be applicable, by reference, to other types of valuations.

The following summary of the key IRS revenue rulings and procedures is intentionally brief because the important stuff will be highlighted throughout this book. Many of these rulings and procedures are included in their entirety as appendixes.

### Revenue Ruling 59-60

Revenue Ruling 59-60 is probably the greatest treatise ever issued on valuation. It is almost hard to believe that something this good came out of our government. It’s even better than the first four editions of this book! This ruling started out providing guidance on the minimum factors to consider for one to perform a competent valuation for estate and gift tax purposes. Its application was subsequently expanded to other tax matters. After reading this revenue ruling, reread it. After that, I suggest that the valuation analyst get into the habit of rereading it on a regular basis if he or she plans to perform business valuations. This ruling not only contains good stuff but also really emphasizes what the valuation process is all about. And the best part is that it is only seven pages long. Concise and great!

<sup>15</sup> David Laro and Shannon P. Pratt, *Business Valuation and Taxes: Procedure, Law and Perspective*, 2nd ed. (Hoboken, NJ: John Wiley & Sons, Inc., 2011): 21.

<sup>16</sup> Fishman et al., *Standards of Value: Theory and Applications*, 65.

<sup>17</sup> Shannon Pratt and Alina V. Niculita, *The Lawyer’s Business Valuation Handbook: Understanding Financial Statements, Appraisal Reports and Expert Testimony*, 2nd ed. (Chicago: American Bar Association, 2010): 280.

Revenue Ruling 59-60 has so many important factors that you will see references to it throughout this book. One of the most important points made in the ruling is that “valuation is a prophecy as to the future.” Even in 1959, the Treasury Department recognized that a willing buyer purchases the future, not the past. This may seem pretty logical, but there are an awful lot of individuals who regularly rely on history to perform valuations because they feel that forecasting the future is too speculative. If the valuation analyst believes that history is more important than the future in valuing a business or an investment, can I interest the analyst in buying some stock in Blockbuster?

Revenue Ruling 59-60 is also well known in the valuation field for its discussion of the eight factors to consider, as a minimum, in valuing closely held businesses. Throughout much of this book, I will be discussing the eight factors to consider. If nothing else, know and understand these eight factors. Consideration of these factors is required if the valuation analyst is going to perform a competent business valuation. Even though they will be seen again and again, let’s start the learning process by examining these factors for the first time. Acronyms will help a great deal with remembering some of this stuff. Let’s start with those.

When determining the fair market value of a business or business interest, the valuation analyst should consider NEBEDISM (box 4.2). The applicability of NEBEDISM will be discussed in many of the methods of valuation that will be addressed. I will point them out as we proceed. When you reread chapter 2, and you should do this, at a minimum, when you get to the end of this book, or sooner if you are studying for a test, you will find that the standards require us to consider these factors in the development stage of the process and report on them in a detailed report. Chapter 16 contains an annotation of this important document, which is also reproduced in appendix 4.

**BOX 4.2****NEBEDISM Factors for Determining Fair Market Value**

- (N) The nature of the business and history of the enterprise since its inception
- (E) The economic outlook in general and the condition and outlook of the specific industry in particular
- (B) The book value of the stock and the financial condition of the business
- (E) The earning capacity of the company
- (D) The dividend-paying capacity of the company
- (I) Whether the enterprise has goodwill or other intangible value
- (S) Sales of the stock and the size of the block of stock to be valued
- (M) The market price of stocks of corporations engaged in the same or a similar line of business and having their stocks actively traded in a free and open market, either on an exchange or over the counter\*

\* Revenue Ruling 59-60, 1959-1 C.B. 237, Sec. 4(01).

## Revenue Ruling 65-192

Revenue Ruling 65-192 modifies Revenue Ruling 59-60 by providing that the theory in Revenue Ruling 59-60 is applicable to income and other taxes, as well as to estate and gift taxes. This revenue ruling also indicates that the formula approach described in Appeals and Review Memorandums (ARMs) 34 and 68 has no valid place in valuing a business or business interest unless the intent is to value the intangibles. The ruling states that, even then, the formula approach should not be used if there is a better basis for valuing the intangibles. This revenue ruling was superseded by Revenue Ruling 68-609, which reiterates these points. See appendix 5.

## Revenue Ruling 65-193

Revenue Ruling 65-193 modifies Revenue Ruling 59-60 by deleting several statements about the separation of tangible and intangible assets. See appendix 6.

## Revenue Ruling 66-49

---

Revenue Procedure 66-49 is to be used as a guideline by all persons making appraisals of donated property for federal income tax purposes. It also provides additional insight into what is expected to be included in a formal appraisal report that is used to support the values determined by the valuation analyst.

This revenue procedure discusses factors to consider in arriving at the fair market value of the property. It states that “as to the measure of proof in determining the fair market value, all factors bearing on value are relevant including, where pertinent, the cost, or selling price of the item, sales of comparable properties, cost of reproduction, opinion evidence, and appraisals. Fair market value depends upon value in the market and not on intrinsic worth.” See appendix 7.

## Revenue Ruling 68-609

---

Revenue Ruling 68-609 covers what is known as the *formula approach* or *excess earnings method* of valuation. This is the successor to ARM 68. For most valuation analysts, this revenue ruling has become our nemesis. It is so frequently misapplied that even the IRS states that this method should not be used if there is a better method to value the intangible assets of the valuation subject. This is similar to the language found in Revenue Ruling 65-192.

First, how about a little history lesson? I’ll bet you did not expect history in a valuation book. Anyway, ARM 34, the predecessor to ARM 68, was promulgated in 1920. What happened in this year? Prohibition, that’s what. As a result of Prohibition, the Treasury Department needed to provide a methodology to help calculate the lost value attributable to the intangible assets of breweries and distilleries. Actually, because the government employees, like so many of us “normal” folks, could not drink, they came up with guidance on valuation. They probably would have been better off being drunk!

The ruling discusses the return on tangible assets and capitalization rates for intangibles. (Please note that the rates provided in Revenue Ruling 68-609 are examples only and are not intended to be the only rates used in the application of this methodology.) A detailed discussion of this revenue ruling appears in the discussion of the excess earnings method in chapter 12. Discount rates for intangible assets are discussed in chapter 13. See appendix 8.

## Revenue Ruling 77-12

---

Revenue Procedure 77-12 describes the acceptable methods for allocating a lump sum purchase price to inventories. This revenue procedure sets forth guidelines for taxpayers and IRS personnel to use “in making fair market value determinations in situations where a corporation purchases the assets of a business containing inventory items for a lump sum, or where a corporation acquires assets including inventory items by the liquidation of a subsidiary pursuant to the provisions of section 332 of the Internal Revenue Code (IRC) of 1954 and the basis of the inventory received in liquidation is determined under section 334(b)(2).” See appendix 9.

## Revenue Ruling 77-287

---

Revenue Ruling 77-287 was intended “to provide information and guidance to taxpayers, IRS personnel, and others concerned with the valuation, for Federal tax purposes, of securities that cannot be immediately resold because they are restricted from resale pursuant to Federal security laws.” This revenue ruling covers marketability discounts related to restricted stock. It recognizes the reduced value of closely held stocks as a result of not having an active trading market. Reference is made to “restricted securities” and other types of securities that are issued at a discount from their freely traded counterparts. This reduction in value is known as a *discount for lack of marketability* and is discussed further in chapter 15. See appendix 10.

## Revenue Ruling 83-120

Revenue Ruling 83-120 amplifies Revenue Ruling 59-60 by specifying additional factors that should be considered in valuing the common and preferred stock of a closely held corporation for gift tax and recapitalization purposes. This revenue ruling emphasizes that the value of preferred stock is determined by considering its yield, its dividend coverage, and the protection of its liquidation preference. See appendix 11.

## Revenue Ruling 85-75

Revenue Ruling 85-75 basically provides that the IRS will not be bound to accept values that it accepted for estate tax purposes as the basis for determining depreciation deductions or income taxes on capital gains from a subsequent asset sale. In this particular instance, a taxpayer relied on a valuation of depreciable property that was overstated for estate tax purposes. Because the IRS did not play “gotcha” on the estate tax return, they got their second chance on the beneficiary’s individual return. See appendix 12.

## Revenue Ruling 93-12

Revenue Ruling 93-12, which supersedes Revenue Ruling 81-253, allows appropriate lack of control discounts to be applied when minority interests of family members in a closely held corporation are valued. Formerly, the IRS looked to family attribution rules as a means to disallow these minority discounts. Revenue Ruling 81-253, which described the IRS’s position on the allowance of minority discounts in valuing a closely held family corporation’s stock that has been transferred to the donor’s children for federal gift tax purposes, was superseded by Revenue Ruling 93-12. Previously, the IRS’s long-standing position was that no minority discount should be allowed when a gift of minority shares was passed between family members. It was not a surprise that the IRS finally acquiesced on this point because they constantly lost this battle in court.

Fair market value assumes any hypothetical willing buyer, not the actual recipient of a gift. An actual buyer would be investment value. Therefore, even though a gift may be given to a taxpayer’s child, the block should be valued without regard to the family relationship. Unfortunately, the IRS did not see things this way until 1993, when they issued Revenue Ruling 93-12. Revenue Ruling 93-12 was a long time coming in light of the IRS’s inability to win cases involving Revenue Ruling 81-253. Do not get too comfortable, however, until you read Technical Advice Memorandum 94-36005. See appendix 13.

## Technical Advice Memorandum 94-36005

In 1994, the Treasury Department issued Technical Advice Memorandum 94-36005, which discusses the concept of applying a “swing premium” in a case in which a gift of a minority interest among family members creates a swing vote among the stockholders. This was the Treasury Department’s effort to circumvent Revenue Ruling 93-12 in which they finally acquiesced regarding minority discounts among family members. This technical advice memorandum does not have the same weight as a revenue ruling, but it shows that the Treasury Department is looking for ways to circumvent Revenue Ruling 93-12. Nobody really believed that they would give up on Revenue Ruling 81-253 that easily! This memorandum appears in appendix 14.

## Chapter 14 of the IRC

Readers are advised to become familiar with the Chapter 14 requirements of the IRC. Some of the more important provisions are covered in chapter 21 of this book in the discussion of estate and gift tax valuations.

## Conclusion

If I did my job, you now have more of an idea about the principles of valuation, standards of value, subsequent events, and the various IRS promulgations. By now, you must realize that the IRS has had a significant impact on the valuation process. Although the valuation analyst is bound to follow the mandates of the IRS only for valuation assignments that involve taxes, some of these revenue rulings make enough sense that it is actually good practice to follow them in many valuations.

# Chapter 5

## Data Gathering

### Learning Objectives

In this chapter, I will attempt to do the following:

- Explain which items have an impact on value
- Discuss internal information sources for gathering data
- Discuss external information sources for gathering data
- Inform you about some types of data sources

Let me caution you that the information contained in this chapter changes faster than I can write about it. As far as I know, this stuff was current when it was written. I will apologize in advance if you go to look for something and you can no longer find it, or it has significantly changed. That is beyond even my control. With that said, let's get started.

### Introduction

This chapter includes a discussion of internal and external sources of information that the valuation analyst will gather. Numerous references are provided about where you can locate information. This chapter lists all types of sites on the Internet for doing the required research.

### What Items Affect Value?

An important part of the valuation assignment is to determine the proper amount of information necessary to do the job competently. The information-gathering part of the assignment will generally require the valuation analyst to demonstrate knowledge about the subject company and the factors affecting its value. Both internal and external factors affect the value of a business or business interest. During the information-gathering step of the valuation process, a variety of information will be requested by the valuation analyst.

### Internal Information

Internal information obtained during the data-gathering process will consist of both nonfinancial and financial information. Each type of information will play an important role in the valuation process. In some instances, the valuation analyst should consider the nonfinancial information to be as important as, or more important than, the financial information. Too often, a telephone call comes in from the attorney who states, "I got you 5 years of tax returns and financial statements. Can you give me the value?" After you stop laughing, the attorney should be told, "Of course I can give you the value, but not until I get the other 47 things that are on my checklist." Although not every job will require 47 other items, there will always be more information needed.

### Nonfinancial Information

Nonfinancial information may be gathered through a document request, a management interview, or through independent research by the valuation analyst. Some of the more important information that the valuation analyst should gather includes the following:

- Legal documents
- Products and services
- Markets and marketing

- Physical facilities
- Equipment
- Personnel
- Other stuff

## Legal Documents

Some of the first pieces of information that an analyst needs in order to begin the valuation process include the various legal documents that determine how a business is organized and governed, what restrictions are placed on investors, and what the company can and cannot do. Some of the legal documents that are commonly requested include the following (this is not an all-encompassing list):

- Articles of incorporation and formation
- Shareholder, operating, and partnership agreements
- Bylaws
- Franchise agreements
- Management services agreements
- Employment agreements
- Non-competition agreements
- Buy-sell agreements

The form of ownership is an important component of the business valuation process because during the valuation process, the valuation analyst will have to consider the comparability of information obtained about other companies (known as *guideline companies* or, previously, *comparables*) or industry composite data. Good comparability must be maintained to ensure the quality of the data that will be used for comparison purposes during the valuation process.

Another reason to know the form of organization is that the legal rights applicable to the interest being valued must be considered by the valuation analyst for the determination of possible restrictions that apply to the subject company or the owners. For example, a minority (non-controlling) owner in a corporation normally does not have the ability to force the liquidation of a corporation. Therefore, that minority interest will most likely be valued using an approach that is not based on the value of the assets, which would have to be sold to realize their value. On the other hand, a minority interest in a general partnership is controlled by the Uniform Partnership Act, which states that any partner who withdraws from the partnership can cause a winding down and dissolution of the partnership, thus, providing him or her with the ability to obtain the proportionate share of the proceeds from the partnership's dissolution.

The ownership of the business is also important because the valuation analyst will need to assess considerations such as control, minority, or swing vote issues. This can be illustrated by considering the value of a 2 percent interest in a corporation. If there are 50 stockholders with a 2 percent interest in the company, each 2 percent interest would probably be worth very little. However, what if the 2 percent interest were to be valued when the other stockholders each own 49 percent? The 2 percent interest could have swing value, which could be very valuable to one of the other stockholders because it would give one of them control of the company. This could cause a premium to be associated with the 2 percent interest.

Let me give you another example of a real-life situation in which the rights of ownership can affect value. Years ago, I had the occasion to value a 1.6 percent beneficial interest in a trust for the IRS. Well, in that same job, the trust owned a 90 percent interest in a closely held investment holding company that owned, among other things, a 47.3 percent block of a thinly traded public company (*thinly traded* means that there are not too many shares trading on any given day). Because the stock was thinly traded, the valuation analyst who represented the taxpayer deducted a blockage discount. (This will be discussed in more detail in chapter 15, but, in the meantime, a blockage discount is a reduction in value because it will take a long time to sell.) When I first received the assignment, I asked the attorneys for the IRS for a copy of the bylaws of the public corporation so that I could see what rights, if any, were spelled out in this legal document. I was told that they would get the document for me, but until they did, because the company was incorporated in the state of Delaware, I should assume that a simple majority constitutes a controlling interest. By the way, the second largest block of stock (8 percent) was owned by the trustee of the trust that I was valuing an interest in. Got it so far? This is

the type of assignment that you either live for or die doing. Anyway, because the 47.3 percent interest in this public company had effective control (all they really had to do was show up to a stockholders meeting and they would carry the vote), and because the trustee owned the next largest block of stock, I took the position that the prudent thing for the board of directors to do was to find someone to purchase the company because it was undervalued according to my intrinsic analysis.

To make a long story short, I added a control premium to the publicly traded value instead of taking a blockage discount. To put things into perspective, the difference in value between my valuation and the other valuation analyst for the publicly traded stock alone was \$150 million. So where am I going with this story? A week before I was getting ready to testify in tax court, I received a phone call from the attorney for the IRS. He said, "I finally tracked down those bylaws that you asked me for (3 months ago!). Let me read something to you and see if it changes anything that you have done." I knew I was in trouble. The bylaws were from 1896 and had not been updated. They required an 80 percent supermajority to sell, liquidate, or merge the company. I said, "Settle the case." The rights of the shareholders made a difference of about \$150 million in this case. This will make more sense to you after reading chapters 14 and 15, but this was the logical place for this story, and it is my book, so I put it here.

Franchise agreements often dictate what the company must do as a part of its normal operations. Car dealerships are often required to update the appearance of their showrooms as the manufacturer changes its logos, branding, and image. This would necessitate occasional capital investments to update the facility, which would need to be accounted for in a forecast of net cash flow. McDonald's franchises had to update their facilities to put in a McCafé® when the franchisor decided to compete with its own coffee bar. In other franchise agreements, an analyst might come across a provision like the one shown in exhibit 5.1.

### EXHIBIT 5.1 Our Right to Purchase Business

- (1) **Exercise of Option.** Upon termination or expiration of this Agreement in accordance with its terms and conditions, we have the option, exercisable by giving written notice thereof to you (by the later of (a) sixty (60) days from the date of such termination or expiration or (b) seven (7) days after determination of the purchase price), to purchase the BUSINESS from you, including the leasehold rights to the Location, free and clear of all liens, restrictions or encumbrances. (The date on which we notify you whether or not we are exercising our option is referred to in this Agreement as the "Notification Date.") We have the unrestricted right to assign this option to purchase the BUSINESS. We will be entitled to all customary warranties and representations in connection with our asset purchase, including, without limitation, representations and warranties as to ownership and condition of and title to assets; liens and encumbrances on assets; validity of contracts and agreements; and liabilities effecting the assets, contingent or otherwise.
- (2) **Leasehold Rights.** You agree, at our election, to assign your leasehold interest in the Location to us or, to enter into a sub-lease for the remainder of the lease term on the same terms (including renewal options) as the prime lease.
- (3) **Purchase Price.** The purchase price for the BUSINESS will be its fair market value, determined in a manner consistent with reasonable depreciation of the BUSINESS's equipment, signs, inventory, materials and supplies, provided that the BUSINESS will be valued as an independent business and its value will not include any value for the Franchise or any rights granted by this Agreement, the Marks, or participation in the network of **DELICIOUS RESTAURANT** businesses.
- (4) **Fair Market Value.** The BUSINESS's fair market value will include the reasonable goodwill you developed since your commencement of operations that exists independent of the goodwill of the Marks and the System. The length of the remaining term of the lease for the Location will also be considered in determining the BUSINESS's fair market value.
- (5) **Exclusions.** We may exclude from the assets purchased hereunder cash or its equivalent and any equipment, signs, inventory, materials and supplies that are not reasonably necessary (in function or quality) to the BUSINESS's operation or that we have not approved as meeting standards for **DELICIOUS RESTAURANT** businesses, and the purchase price will reflect such exclusions.

(continued)

**EXHIBIT 5.1 Our Right to Purchase Business** *(continued)*

- (6) Valuation. If we and you are unable to agree on the BUSINESS's fair market value, its fair market value will be determined by a valuation analyst agreeable to both parties. If we and you are unable to agree on a valuation analyst, then the BUSINESS's fair market value will be determined by three (3) independent valuation analysts who collectively will conduct one (1) valuation. We will appoint one valuation analyst, you will appoint one valuation analyst and the two party appointed analysts will appoint the third valuation analyst. You and we agree to select our respective valuation analysts within fifteen (15) days after the date we determine that we are unable to agree on the BUSINESS's fair market value, and the two valuation analysts so chosen are obligated to appoint the third valuation analyst within fifteen (15) days after the date on which the last of the two party appointed valuation analysts was appointed. You and we will bear the cost of our own valuation analysts and share equally the reasonable fees and expenses of the third valuation analyst chosen by the two party appointed valuation analysts. You and we will take reasonable actions to cause the valuation analysts to complete their appraisal within thirty (30) days after the third valuation analyst's appointment.
- (7) Closing. The purchase price will be paid at the closing of the purchase, which will take place not later than ninety (90) days after determination of the purchase price. We have the right to set off against the purchase price, and thereby reduce the purchase price by, any and all amounts you or your Owners owe to us.
- (8) Instruments. At the closing, you agree to deliver instruments transferring:
- (a) good and merchantable title to the assets purchased, free and clear of all liens and encumbrances (other than liens and security interests acceptable to us, if any), with all sales and other transfer taxes paid by you; and
  - (b) all licenses and permits of the BUSINESS which may be assigned or transferred; and
  - (c) the leasehold interest in the Location and improvements thereon.
- (9) Escrow. If you cannot deliver clear title to all of the purchased assets, or if there are other unresolved issues, the closing of the sale will, at our election, be accomplished through an escrow arrangement with an independent escrow agent selected by us.
- (10) Releases. You and your owners agree to execute general releases, in form satisfactory to us, of any and all claims against us and our shareholders, officers, directors, employees, agents, successors and assigns.

So, what do the terms in exhibit 5.1 mean? This franchise agreement gave the franchisor the right to purchase the business at fair market value at the end of its 15-year term. This would provide the franchisee with a potential exit opportunity, which is a good thing, right? Well, not quite. This particular business was relatively capital-intensive, with about a \$1.5 million initial capital investment and a requirement to upgrade and renovate its facility every 5 years, which could cost anywhere between \$300,000 and \$500,000. All of the costs associated with advertising and building out the facility were the responsibility of the franchisee. Due to the nature of the business, revenues tended to peak in the third or fourth year and then gradually declined as competing businesses opened up in the area. At 10 years, many of these types of businesses were generating declining revenues and minimal (if any) profitability. This gave the franchisor the ability to purchase the business (equipment and all) at a depressed fair market value. In addition, the company would be valued as a standalone business without the use of any franchise trademarks. As an investor, would you be willing to make a \$2 million to \$3 million capital investment if, at the end of the franchise agreement term, you were obligated to sell the business and all of its assets for a depressed value? This would certainly affect the value of the business.

Some companies provide services to other companies under contracts that define the extent and cost of those services. In these cases, the agreement between the two companies can be very important to the valuation, especially if the company providing the service has only one or two clients. Selected portions of an agreement between a hospital and a health care management company are shown in exhibit 5.2. In this case, the management company made operational decisions for two hospitals, so the terms of the management agreements were extremely important to the valuation.

**EXHIBIT 5.2 Management Agreement****ARTICLE V  
COMPENSATION**

5.1 Management Fees. Subject to Section 5.2 below, as full and exclusive compensation for all of the services to be rendered by Manager during the Term, Company shall pay to Manager by the 15th day of each calendar month, beginning on January 1, 2012, at its principal office, or at such other place as Manager may from time to time designate in writing a monthly fee (the "Management Fee") equal to four percent (4%) of Revenues of the Facility derived for each calendar month of the Term. The Management Fee shall be calculated based upon the estimated Revenues of the Facility for such month. The Management Fee shall be reconciled on a quarterly basis based upon actual Revenues for the Facility. For the purposes of determining the Management Fee, "Revenues" means all revenues collected by Company in accordance with generally accepted accounting principles ("GAAP"), including, without limitation, all patient and/ or resident revenues received or receivable for the use of, or otherwise by reason of, all rooms, beds, units and other facilities provided, meals served, services performed, space or facilities subleased or goods sold on or from the Facility and all revenues for graduate medical education that are received or receivable by the Facility; provided, however, that Revenues shall not include non-operating revenues such as interest income or gain from the sale of assets not sold in the ordinary course of business; and provided, further, that there shall be excluded or deducted (as the case may be) from such revenues; (i) contractual allowances for billings not paid by or received from the governmental authorities or third party payors, (ii) allowances according to GAAP for uncollectible accounts, (iii) all proper patient or resident billing credits and adjustments according to GAAP related to health care accounting, (iv) deposits refundable to patients/ residents of the Facility, (v) provider discounts for hospital or other medical facility utilization contracts and (vi) any Grants and Subsidies (as defined herein). "Grants and Subsidies" includes all state and local charity care subsidies, hospital relief subsidies, mental health subsidies, stabilization grants, and any other similar grants or subsidies received by the Facility from whatever source derived, and any and all grants, subsidies or incentive payments received by the Facility, from a governmental source, in connection with the Facility's implementation of an electronic based medical records or electronic-based prescription system at the Facility.

**ARTICLE VI  
TERMINATION RIGHTS**

6.1 Termination by Company. (a) After the Initial Term of this Agreement, this Agreement may be terminated at Company's option, without cause and for any reason, upon one hundred twenty (120) days prior written notice to Manager.

(b) If at any time or from time to time during the Term Manager shall fail to keep, observe, or perform any material covenant, agreement, term or provision of this Agreement to be kept, observed, or performed by Manager, and such default shall continue for a period of thirty (30) days after written notice thereof by Company to Manager or, if such default is not subject to cure within thirty (30) days, such longer period as may be required to effect a cure, provided that Manager initiates certain action within such 30-day period and thereafter is diligently and in good faith pursuing such cure, then Company shall have the right to terminate this Agreement immediately and without any notice.

Although there were other terms in the agreement that had to be considered in the valuation, the terms associated with compensation and termination had the largest impact. The agreement tied the management company's revenue potential to the revenues of the hospital it was managing. This required us to analyze the hospital's future revenue potential. The termination clause allowed the hospital to exit the agreement with 120 days' notice for any reason, which was a primary source of risk for the management company. The two hospitals managed by the subject company in this case were related by common ownership. Therefore, if the owners of one hospital did not like the way the management company was running one facility, they could very well decide to cancel both contracts, which would have effectively reduced the management company's earning potential to zero.

Non-competition agreements, or covenants not to compete, can have a huge impact on the value of a business that depends on key managers or owners. Think about a medical practice with a single doctor, who has

developed professional relationships with his or her patients over 20 years. If another firm was to purchase the practice without the use of a non-compete agreement, the doctor could open up next door, and many of the patients at the purchased practice would leave to follow their long-time doctor. However, there are a number of factors to consider in valuing a non-compete agreement (which I will not go into in depth here) and, in some cases, those factors can only be considered through a review of the actual agreement. One such factor is whether or not the non-compete agreement is enforceable under state law. Depending on statutes (or case law, if no statutes exist), there is a chance that the terms of the governing agreement are too restrictive or not adequately defined, which may result in an agreement that is not considered to be enforceable (and, thus, would have zero value). Non-competition agreements will be discussed further in chapter 22.

All the preceding scenarios are meant to illustrate the importance of legal documents to any valuation. It is imperative that the valuation analyst consider all legal documents pertinent to the valuation subject and its value.

## Products and Services

It is generally a good idea to understand information about the products and services that the valuation subject sells to its customers. Besides the fact that you need to know this information to select guideline companies, it is also imperative that the valuation analyst understand information about factors that affect these products and services. For example, how do changes in the economy affect the demand for the products? A rise in interest rates would certainly have an impact on an automobile dealership. In fact, rising interest rates will cause new car sales to go down. However, rising interest rates will also cause people to keep their cars for a longer amount of time, thereby requiring more maintenance. That could cause the repair bays to become busier. It is also important to understand what alternative products are available in the marketplace to assess the future success of the products. If you were valuing a company that sold a standalone digital music device and did not have the ability to sell other more versatile mobile media devices, for example, Android phones and tablets, the likelihood that the company would continue to be successful in the future is slim because everyone and their mothers (even me) now own some type of mobile media device.

## Markets and Marketing

Part of the valuation process includes understanding the markets served by the valuation subject. Geographic diversification frequently does not exist for very small businesses. However, understanding the market for the products or services allows the valuation analyst to assess the degree of risk relevant to the lack of diversification. Understanding the market will also allow the valuation analyst to determine if there are alternative products in the marketplace that will have an effect on the subject company. Keep in mind that even smaller businesses are now able to diversify geographically, particularly with the Internet as a resource.

The marketing efforts of the subject company should also be considered because a large, visible company in the market will frequently attract more new customers than an obscure company that the public has never heard of.

## Physical Facilities

Factors to be considered in a business valuation assignment include information about the physical plant. This information would pertain to the plant's size and whether it is owned or rented, as well as the amount of room available for expansion. The valuation process requires the use of projections, which must consider whether the facilities are large enough to meet the expected production forecasts. If a plant is at full capacity and management provides the valuation analyst with forecasts that include significant growth, how can that growth be achieved without either expanding the current facilities or relocating to larger quarters? Either way, there will be an additional expense incurred by the company if it is to meet its expansion projections.

## Equipment

It is generally a good idea for a valuation analyst to learn about the equipment that is employed by the business to accomplish its business purposes. Even if an appraisal of the equipment is unnecessary, the valuation analyst should find out information about the type of equipment used, the age of the equipment, its capacity,

its maintenance schedules, the availability of parts, and its approximate replacement cost. The valuation analyst should also inquire about whether there is newer technology being used by the competition.

Older equipment usually means higher maintenance costs and a lower level of productive capacity. This could be an essential component of a cash flow forecast because asset replacement can be costly. Older equipment could mean difficulty in getting parts and service, which could force the replacement of equipment, creating a financial hardship for the company. However, there are many companies that can continue to use older equipment for a long time without a problem. These companies generally have a well-established maintenance schedule, and by examining the equipment, you can generally tell whether it is regularly maintained.

The valuation analyst should ask to review insurance policies to get an idea of the amount of coverage the company is carrying so that the valuation analyst can “ballpark” the replacement cost of these assets. The valuation analyst should also make certain that these policies have been kept up to date. Otherwise, the company may be exposed to an additional risk attributable to the replacement of the equipment in the event of a loss. This should be self-explanatory, but let me give you a true example. Over the course of a valuation I completed a while back, I discussed with management the fact that they received a \$3.2 million insurance settlement as a result of Hurricane Wilma. Since then, the company’s insurance premiums had risen so much that they had to lower the coverage to \$1.0 million. Think about the added exposure that the company has in the event of another hurricane. Although the valuation analyst does not necessarily forecast hurricanes, the business is in Florida (home of the hurricanes—and I do not mean the type you drink!).

## Personnel

The valuation analyst should seek information about the personnel requirements of the company. This includes gaining an understanding of the role of key persons in the company. In smaller companies, the owner is frequently the key person. The valuation analyst must determine what it would take to replace that individual with someone who is capable of getting the job done. Sometimes this may take two or more people. Other times, it may take people with different skills from those the owner has.

For example, in valuing an internal medicine practice, the valuation analyst may find that the doctor does not trust anyone in his or her office to do the bookkeeping. Therefore, the doctor performs this function in addition to all of the duties of being a doctor. What if the doctor is turning away new patients due to a lack of time because the bookkeeping is taking up 10 hours per week? The valuation analyst would consider replacing the doctor not only with another doctor but also with a part-time bookkeeper, which would allow the new doctor to spend the additional 10 hours seeing new patients. You are probably asking yourself, “What kind of doctor would do this?” If I had not seen this in reality, I could not have provided you with this example!

## Other Stuff

The valuation analyst should pay particularly close attention to other items that may exist for the valuation subject. These may include, but should not be limited to, operating data about the company’s products, competitors, suppliers, and customers so that you can demonstrate a clear understanding of the valuation subject. These items will help you make a determination regarding the risk involved in the subject company’s business. For example, few products, many competitors, high employee turnover, few sources of supply, and dependence on key customers add up to a lot of risk. This will affect value.

Other stuff can include information about patents, copyrights, proprietary processes, pending litigation, and environmental exposure. These items will either increase or decrease the value of a company, depending on the competitive advantage or disadvantage that may come with these items. Sometimes a valuation analyst will find that the competition holds an important patent in the field; therefore, breaking into the field may be impossible without different technology. All of these situations should be considered during the valuation process.

If the valuation is for an employee stock ownership plan (ESOP), make sure you get a copy of the plan documents so that you fully understand the terms. This will have an impact on marketability discounts, as well as

on other factors affecting your valuation. Because most small- and medium-sized businesses do not have ESOPs, I have not included a discussion about them in this book.<sup>1</sup>

As noted earlier, legal documentation (including copies of legal contracts and agreements affecting the company) should also be obtained. This will allow the valuation analyst to determine if there are any restrictions on the operations of the business, any restrictions on the owners, or any commitments that will require the company to perform in a certain manner that can affect operations in the future. You saw what a difference it made in my IRS job. Find out if there are any lawsuits against the company, either pending or threatened. A lawsuit may affect the financial success of the company and should be considered as a risk factor even if it cannot be quantified.

## Financial Information

The financial information requested will include annual financial statements for a relevant period of years. Most often, five years of data is obtained, but the valuation analyst should consider whether to ask for a longer or shorter period of time, if appropriate. This information should be from the most recent years preceding the valuation date. Ideally, the analyst would like to get as many years' financial statements as may be applicable to the subject's business cycle. This way, a more complete picture of the company can be obtained. Frequently, we ask for six years of financial statements so we can calculate a five-year compound annual growth rate. The procedures for performing this calculation will be discussed later.

Tax returns for the same period should be requested, so that any differences between tax and financial reporting that need investigation can be determined. Tax returns will also identify any subsidiaries that are part of a consolidated tax return or any other companies that are part of a controlled group of companies, as defined by the IRC. This may make the valuation analyst aware of other companies that may need to be considered during the valuation process. Even if the valuation assignment does not include the other companies, there can be transfer-pricing issues, dependence on the other companies, or a splitting of costs that would be discontinued if the valuation subject was sold.

Interim financial statements should be obtained for the period prior to the valuation date, and, if possible, for the same period in the prior year. This provides financial statements that may be closer to the effective date of the valuation, as opposed to the prior year-end, and also allows the valuation analyst to calculate the financial statements on a latest 12-month basis. I will demonstrate this shortly, so just be patient. Internal financial statements should be more carefully scrutinized because they may exclude many of the adjustments that the outside accountant makes at the reporting period. External financial statements must also be analyzed to ensure consistency in the reporting between the year-end and interim periods. For example, the interim financial statements may record inventory using the gross profit method (as a reasonable shortcut), whereas at year-end the company takes a physical inventory and values it properly.

Copies of forecasts or projections should be requested for several reasons. First, valuation is a prophecy of the future, and there may be no better indication than management's estimate of what it expects to happen. Second, reviewing prior budgets or forecasts and projections may provide the valuation analyst with a better understanding of how well management is able to direct the company's activities. I previously mentioned the forecast that management did in a litigation case that we finally got our hands on. They even valued a piece of the business for us.

The valuation analyst should request supporting information for the balance sheet items that may require fair market value adjustments. This is more important in valuing a controlling interest than a minority interest because the minority interest generally does not have the ability to liquidate the assets to realize the fair market value.

<sup>1</sup> For more information about employee stock ownership plans (ESOPs), see Willamette Management Associates, *Guide to ESOP Valuation* (self-published); Larry R. Cook, *Financial Valuation of Employee Stock Ownership Plan Shares* (Hoboken, NJ: John Wiley & Sons, 2005); or The National Center for Employee Ownership, *ESOP Valuation*, 3rd ed.

The valuation analyst should also request supporting information for income statement items that may require normalization adjustments. We will discuss the normalization process in chapter 6. For now, accept the fact that normalization is the process of removing those items from the financial statements that do not contribute to the economic earnings of the subject company on a prospective basis. This will make more sense in a little while.

## External Information

During the valuation process, the valuation analyst will also be required to perform research to obtain information about the environment in which the business operates. This information is known as *external information*. Some of the more important information that should be explored includes (1) economic data, (2) industry data, (3) publicly traded guideline company data, (4) transaction data, and (5) other miscellaneous data.

Revenue Ruling 59-60 specifically states that one of the factors to be considered in the valuation of a closely held business is “the economic outlook in general and the condition and outlook of the specific industry in particular.” Economic and industry information are key components of a business valuation assignment. Analysis of these items is discussed in the next chapter.

## Economic Data

Various economic data should be gathered by the valuation analyst. This data will allow an assessment of how the subject company will be affected by changes in the economy. For example, rising residential mortgage interest rates may adversely affect a construction company that is primarily engaged in building new houses. Changes in consumer confidence can affect a retail business.

An analysis should be performed to see how the subject company has performed in light of past economic cycles, and the past performance may be used to project how the company is expected to do based on economic forecasts. The analysis should consider all aspects of the economy that directly or indirectly affect the valuation subject. The valuation analyst should also think in terms of the factors that might affect the subject company’s customers or suppliers. Too often, these factors are overlooked.

A global approach to considering economic data is illustrated in figure 5.1. A broad spectrum of information should be considered with respect to the economy. Starting with the big picture, the valuation analyst should consider the international economic factors that may affect either the valuation subject or its customers or suppliers. The availability of supply, exchange rates, fluctuations in economic conditions abroad, and trade restrictions will all affect a global company.

**Figure 5.1**

After the global aspects of the economy are considered, the national economy should be next. After that, the geographic regions get smaller and smaller, but even the town in which the business operates could be extremely relevant to the valuation. What if a company depends on a military base for its business and the government announces a base closure? This can have a devastating effect on the company as well as on the community in which the company operates. The same holds true for communities after a layoff is announced by a major employer. However, this could be good news if the valuation subject has experienced a shortage of qualified labor and people now become available to them.

The local economy becomes an important component in the valuation of a small neighborhood business. Some of the factors and key economic indicators that should be considered and reviewed regarding the local economy can be found in box 5.1. For each of the items in box 5.1, the relevance to the valuation subject is important. Rarely will all of these factors be included in one valuation. The valuation analyst should not use a boilerplate discussion of the economy. I have seen a growing number of valuation analysts purchase an economic report from one of the data providers and merely slap it into an appendix at the back of their report. This is a very poor practice and is nothing more than a lazy way to try to comply with standards and the factors from Revenue Ruling 59-60. The economic data that should be included in a report should be relevant to the valuation subject and not merely boilerplate. Clearly, the economic factors that affect a construction company will be substantially different from the economic factors that affect a medical practice. When was the last time mortgage rates affected whether a person went to the doctor? Even with the high cost of health care, mortgage rates are not yet part of the discussion in the valuation of a medical practice.

There is a tremendous amount of economic data available on the Internet, but that does not mean you should abandon your local library. Often, the local public or business school library is the best place to find items that have not yet made their way on to the Internet or to gain access to otherwise prohibitively expensive databases. Also, I have found that a good librarian is invaluable. Whether he or she uses personal library resources, relies on the Internet, or uses a public library, box 5.2 includes sources that should be familiar to the valuation analyst.

The items included in box 5.2 should provide some idea of the abundance of information that is readily available. Although most of these resources started out as print publications, many are also available on the Internet.

## Statistical Abstract of the United States

This publication provides statistical data on various subjects, including population, education, the labor force, prices, vital

### BOX 5.1

#### Key Economic Indicators

- Foreign trade
- Foreign currency
- Gross domestic product
- Federal deficit and debt burden
- Inflation—consumer price index
- Unemployment
- Consumer confidence
- Business investment
- Interest rates
- Housing starts
- Building permits
- Demographics
- Health care
- Gross state product
- Labor supply
- Local unemployment
- Disposable income
- Wages
- Availability of materials
- Taxes
- Growth trends

### BOX 5.2

#### Sources of Economic Data

- Statistical Abstract of the United States
- Economic Report of the President
- Federal Reserve
- Congressional Budget Office
- Survey of Current Business
- Annual Metro, City, and County Data Book
- Business Conditions Digest
- Monthly Labor Review
- The Wall Street Journal
- Business magazines
- Trade magazines
- Professional magazines:
  - Medical Economics
  - Electrical World
- State agency reports:
  - Employment
  - Planning
  - Economic development
  - State websites
- Chambers of commerce
- Blue Chip Economic Indicators
- Blue Chip Financial Forecasts
- Value Line Investment Survey
- Stocks, Bonds, Bills, and Inflation Yearbook
- Valuation Handbook: U.S. Guide to Cost of Capital
- Valuation Handbook: U.S. Industry Cost of Capital
- Standard & Poor's Industry Surveys, Trends and Projections
- The Complete Economic and Demographic Data Source
- Consensus Forecasts—USA

statistics, the environment, income, gross domestic product (GDP), science, transportation, agriculture, construction and housing, trade, business enterprise, and energy. In addition to statistics, each subject contains a brief explanation of the contents of the data.

The statistical data is presented in various ways (graphs, tables, charts, and maps), depending on what is appropriate for the subject being analyzed. The data is also shown historically as percentage changes computed annually and monthly; in some cases, projections are given. The data is also divided into such classifications as age, race, marital status, sex, and religion. This book can be a useful resource tool because a huge collection of data regarding the nation is compiled into one reference source.

Until 2011, the *Statistical Abstract of the United States* was issued by the U.S. Department of Commerce, along with the Economics and Statistics Administration and the Bureau of the Census, and was made available for distribution by the U.S. Government Printing Office in Washington, D.C. In 2011, the Bureau of the Census determined that it would no longer prepare this publication due to budget cuts. The last version published by the U.S. Department of Commerce (fiscal 2011) and prior editions of the *Statistical Abstract of the United States* are available online at [www.census.gov/library/publications/time-series/statistical\\_abstracts.html](http://www.census.gov/library/publications/time-series/statistical_abstracts.html). This website also contains links to the sources that were previously used to compile the data contained within the abstract, which makes it a good (free!) starting point for economic research.

If you absolutely must have the *Statistical Abstract of the United States* in its published form, ProQuest has taken over the task of updating and releasing the publication. For more information, visit the ProQuest website online at [www.proquest.com/products-services/statabstract.html](http://www.proquest.com/products-services/statabstract.html). If you want this resource for free, steal it from your local library if they have it (only kidding!). Your local library may have a subscription.

## Economic Report of the President

This publication, which includes the *Annual Report of the Council of Economic Advisers*, contains the President's report on the economic condition of the United States to the Speaker of the House of Representatives and the President of the Senate. The *Annual Report of the Council of Economic Advisers* is an excellent source of various economic data relating to the nation. In this report, the council provides summarizations and corresponding charts on the various aspects of the U.S. economy for a specific time period, as well as the indicators that affect economic growth. Health care reform, income, inflation, monetary policy, trade policy, taxes, employment, economic trends, and the status of the United States in the global marketplace are discussed.

In addition, the book provides tables, charts, and boxes (highlighted captions that give further explanations and the views of the U.S. administration) pertaining to the economic condition at the time. The data in these tables and charts gives historical, current, and projected figures and is presented on an annual basis; for more current years, it is also presented on either a monthly or quarterly basis. The *Economic Report of the President* is a useful tool in the search for the economic condition of the nation, as well as for its future outlook and data relating to it.

The *Economic Report of the President*, including the *Annual Report of the Council of Economic Advisers*, is distributed by the U.S. Government Printing Office in Washington, D.C. It is available free online at [www.gpo.gov/erp/](http://www.gpo.gov/erp/). I like free!

## Federal Reserve

The Federal Reserve provides a wealth of economic data and commentary on various aspects of the U.S. economy via a number of publications. These publications provide detailed insight into monetary policy, economic outlook, and past economic performance and include the *Monetary Policy Report to the Congress*, *Summary of Commentary on Current Economic Conditions by Federal Reserve District* (commonly referred to as the Beige Book), minutes of Federal Open Market Committee meetings, and the *Federal Reserve Bulletin*.

The Federal Reserve also provides historical data on various business and financial subjects, such as money, stock and bank credit, GDP, the consumer price index, unemployment, interest rates, real estate, financial

markets, the stock market, securities, production, consumer credit, and income. This data is presented historically, annually, quarterly, monthly, or in combination and may be downloaded in spreadsheet format from the Federal Reserve's website at [www.federalreserve.gov](http://www.federalreserve.gov), and it is all available for free (there's that word again!).

## Congressional Budget Office

The Congressional Budget Office (CBO) provides information about the U.S. economy and federal budget. Anticipated levels of government expenditures, labor force and population growth, GDP growth and inflation, among other economic indicators, are provided through the various reports published by the CBO. Additionally, the CBO provides insight into government involvement in key industries, such as energy, health care, defense, and housing. Data provided by the CBO differs from other economic projections in that it often provides scenarios of economic consequences under different legislative actions. This information can all be found at [www.cbo.gov/topics](http://www.cbo.gov/topics).

It should go without saying that the figures provided within the Congressional budget should be used cautiously. Budgets frequently change, as has been quite evident with bipartisan turmoil in Congress regarding federal deficits and debt. Nonetheless, the CBO can provide a general indication about the direction in which spending is headed in the future and its effect on the economy or a certain industry. This can be particularly important for companies reliant on Medicare reimbursements, energy subsidies, or defense contractors.

## Survey of Current Business

This publication contains information from the National Income and Products Accounts (NIPA), which is used to add up GDP. A regular feature of this monthly publication is a description of the business situation, which is done in summary, tabular, and chart form. Economic growth as measured by the GDP, consumption expenditures, investments, interest rates, housing, imports and exports, the gross state product, involvement of the United States in foreign business, and other data that can be of use in analyzing the nation's economy can also be found in this publication.

*Survey of Current Business* is issued by the U.S. Department of Commerce, Economics and Statistics Administration and the Bureau of Economic Analysis (BEA) and is distributed by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. This monthly publication is also available at no cost on the BEA website at [www.bea.gov/scb/index.htm](http://www.bea.gov/scb/index.htm).

## Stocks, Bonds, Bills, and Inflation® Yearbook

This publication is an annual yearbook that contains historical data about returns in the capital markets since 1926 and through the current year. It supplies useful investment information and features sections reflecting highlights of the current year's market, major events, and highlights from the previous decade, along with corresponding charts and tables for further explanation.

A section of the book is devoted to returns on stocks and bonds of various types, along with statistical data and formulas, returns for different sizes of firms, and cost of capital and discount rate information. I discuss this publication in greater detail in chapter 13.

*Stocks, Bonds, Bills, and Inflation® Yearbook* (SBBI Yearbook) is published annually by John Wiley & Sons, Inc. More information on SBBI can be found on the Wiley website at [www.wiley.com/WileyCDA/WileyTitle/productCd-1119316405.html](http://www.wiley.com/WileyCDA/WileyTitle/productCd-1119316405.html). As will be discussed in chapter 13, Morningstar previously published a valuation edition of SBBI, which was discontinued in 2014.

## Valuation Handbook: U.S. Guide to Cost of Capital

After Morningstar discontinued the valuation edition of SBBI, Duff & Phelps picked up the reigns and began compiling the *Valuation Handbook: U.S. Guide to Cost of Capital*, which is published by Duff & Phelps. This publication contains much of the information that was previously contained within the valuation edition of SBBI. It will be discussed in much greater detail in chapter 13. For now, it is important to note this publication as an additional source of historical data related to rates of returns.

## Valuation Handbook: U.S. Industry Cost of Capital

This book is compiled annually by Duff & Phelps and is published by Duff & Phelps, with quarterly updates also available. The purpose of the book is to provide additional data that can be used to estimate the cost of capital. It does this by providing cost of capital information that is broken down by various industries. Within each of these industries, the data is also broken down by company size.

The information provided includes compound annual equity returns, five-year growth in net sales, and operating income and net income, as well as margins, capital structure ratios, equity valuation ratios, and betas.

*Valuation Handbook: U.S. Industry Cost of Capital* is a continuation of Morningstar's *Cost of Capital Quarterly*, which was discontinued along with the valuation edition of SBBI in 2014. I'll discuss the *U.S. Industry Cost of Capital* publication again in chapter 13.

## Newspapers and Magazines

*Business Week* publishes a number of articles that offer regular analysis on economic conditions, including "Economic Trends" and "Business Outlook." In addition, *Business Week* publishes a special edition in January covering a variety of industries. *The Wall Street Journal* publishes a column called "Tracking the Economy Statistics" on a weekly basis. Columns such as these can provide good additional perspective about how others are interpreting raw macroeconomic data.

## Internet Sources of Economic Information

The federal government collects vast amounts of economic and demographic data for the United States as a whole, as well as for states, counties, and many cities. Data is also collected on various industries. The information is available in print form and electronically on the government's many websites. Although the government-produced data may be available through other vendors' online services and print or electronic products, there is little reason to ever pay for this data, unless what you are looking for is very old. In that case, you might be better off in the public library.

Every department, bureau, and section of the federal government has a website. Every state in the United States has a website containing a variety of information about the state. Almost every U.S. county and many U.S. cities have websites as well. These may contain information of interest only to a tourist or other visitor, but some may also have economic or business information.

This section deals exclusively with electronic data sources located on the Internet. Let's begin with the U.S. federal government and then review private sources of data. Some of these websites are free and others are subscription services, which charge either a flat annual fee or a fee per use or article. Many of these websites are so rich that inclusion of the addresses of individual pages would become cumbersome. Therefore, I am only giving you the address of the home page and inviting you to visit the sites and explore them by clicking on the links. Do it in your spare time.

The discussion is subdivided into sections as follows:

- International information
- National information
- State and local information
- Market data (stocks and bonds)

## International Information

### *International Data*

Many of the websites I mentioned earlier include international information, as well as U.S. information. The Federal Reserve Board's website includes links to foreign central banks, which may have data on conditions in the countries in which they are located.

### **International Trade Administration** (<http://trade.gov>)

This site helps U.S. businesses participate fully in the growing global marketplace. The mission of the International Trade Administration of the Department of Commerce is to strengthen the competitiveness of U.S. industry, promote trade and investment, and ensure fair trade and compliance with trade laws and agreements. A related site, the U.S. Government Export Portal at <http://export.gov>, provides information for those businesses wanting to expand their export markets.

### **Organization for Economic Cooperation and Development** ([www.oecd.org](http://www.oecd.org))

This website has economic surveys for all member countries and some nonmember countries. Select data is available for free at [www.oecd.org/statistics/](http://www.oecd.org/statistics/). In most cases, you can download data in Microsoft Excel format, which makes for easier analysis.

### **CIA** (<https://www.cia.gov/library/publications/the-world-factbook/index.html>)([www.cia.gov/library/publications/the-world-factbook/index.html](http://www.cia.gov/library/publications/the-world-factbook/index.html))

*The World Factbook* is produced by the Central Intelligence Agency (CIA) and provides information on every country on the planet. Topics include geography, the people, government, economy, communications, transportation, military, and transnational issues. Some of the information might be a year or two old, but it will give a good overview of the country. *The World Factbook* is produced annually and can be downloaded from the CIA website starting with the 2000 edition at [www.cia.gov/library/publications/the-world-factbook/](http://www.cia.gov/library/publications/the-world-factbook/). Who knows, with this website, you may even learn how to become a spy!

### **Countries' Embassies**

Every country that has an embassy in the United States has a website, and these websites have a wealth of good information about the countries and, quite often, data on trade with the United States. You can find these using a search engine, such as Google.

## **National Information**

### **FedStats** (<http://fedstats.sites.usa.gov/>)

FedStats, perhaps the most comprehensive and easy-to-use government website, provides the full range of official statistical information available to the public from the federal government. Use the Internet's powerful linking and searching capabilities to track economic and population trends, health care costs, aviation safety, foreign trade, energy use, farm production, and more. Access official statistics collected and published by more than 100 federal agencies without having to know in advance which agency produces them. All of the statistical information available through FedStats is maintained and updated solely by federal agencies on their own web servers. And it's all free. The FedStats home page begins with easy-to-use links to statistics and statistical agencies, which are summarized in box 5.3.

Three principal statistical agencies gather data on economic activity, demographic trends, and industry developments in the United States, nationally, and on the state and local levels. These are as follows:

#### **Bureau of Economic Analysis (BEA)** ([www.bea.gov](http://www.bea.gov))

The BEA measures, presents, and interprets gross domestic product, personal income, corporate profits, and related items in the context of the NIPA. The BEA also maintains personal income and related measures for states and localities, the U.S. balance of payments accounts, and the foreign direct

#### **BOX 5.3**

#### **Related Resources Accessible Through FedStats**

- Topic links—A to Z (direct access to statistical data on topics of your choice—there are more than 400 of them)
- MapStats (statistical profiles of states, counties, Congressional districts, and federal judicial districts)
- Program/Subject areas are linked to summaries of the major statistical programs, such as agriculture, education, energy, and income, among many others
- Search by key words or phrases across all linked agency websites
- Agencies listed alphabetically (with descriptions of the statistics they provide and links to their websites, contact information, and key statistics)
- Press releases (the latest news and announcements from individual agencies)

investments accounts. Data is released monthly in the *Survey of Current Business* (available both in print and on the Internet) and can be downloaded in spreadsheet format using the website's interactive tables.

#### ***Bureau of Labor Statistics (BLS)*** ([www.bls.gov](http://www.bls.gov))

The BLS produces statistics on employment and unemployment, consumer expenditures, prices and living conditions, wages and employee benefits, productivity and technological changes in U.S. industries, projections of economic growth, the labor force, employment by industry and occupation, and occupational injuries and illnesses. This data can be downloaded in spreadsheet format using the website's interactive tables.

#### ***Bureau of the Census*** ([www.census.gov](http://www.census.gov))

The Census Bureau provides information on the number, geographic distribution, and social and economic characteristics of the nation's population. It conducts several periodic censuses every 5 years, covering the years ending in "2" and "7." The Economic Censuses include those of manufacturing, mineral industries, construction industries, retail and wholesale trade, service industries, and transportation and other businesses. The Census of Governments collects state and local data on public finance, public employment, and governmental organization, powers, and activities. Thousands of data series can be accessed by using the American FactFinder tool on the website.

The Census Bureau operates the Census Information Center (CIC) program, which is a cooperative effort between the U.S. Census Bureau and 52 national, regional, and local nonprofit organizations (including universities). These are listed at [www.census.gov/about/partners/cic.html](http://www.census.gov/about/partners/cic.html) and can be sources of additional, more specific data. The organizations range from the Arab American Institute to the William C. Velazquez Institute; contact information is available, including email addresses and websites.

A number of other statistical agencies collect data on more specific areas of the economy. For example, the Bureau of Transportation Statistics gathers data on the nation's transportation systems, and the Energy Information Administration collects information on energy reserves, production, consumption, and so on. Each of these agencies' websites can be accessed through FedStats. Most recent years' statistics and contact information are available.

#### ***USA.gov*** ([www.usa.gov](http://www.usa.gov))

This is an official U.S. government website that allows visitors to browse by topic and includes topics from Agriculture and Food (farms, food, and nutrition) to the United States in the World (defense, trade, and immigration). These topics provide links to the agency involved. There are links to the executive, legislative, and judicial branches of the federal government, as well as links to state and local governments. This site is free.

#### ***Federal Reserve*** ([www.federalreserve.gov](http://www.federalreserve.gov))

As I pointed out earlier in this section, the Federal Reserve provides numerous publications related to economic data, interest rates, monetary policy information, and international information. These publications, as well as all of the Federal Reserve's statistical releases (daily, monthly, quarterly, and so on) are available online. There are also links to each of the 12 regional Federal Reserve District Banks ([www.federalreserveeducation.org/about-the-fed/structure-and-functions/districts/](http://www.federalreserveeducation.org/about-the-fed/structure-and-functions/districts/)). Federal Reserve District Banks' websites contain district economic activity and other economic research. Many of the research pieces are very academic and technical, but some may be useful in a valuation analysis.

#### ***The Conference Board*** ([www.conference-board.org](http://www.conference-board.org))

This is a not-for-profit, worldwide research and business membership organization and a leading private source of economic and business intelligence. The Economics Program is a recognized source of business economics research and objective indicators, analyses, and forecasts. Several widely watched economic indicators are published by this program, including Consumer Confidence, Help-Wanted Advertising, U.S. Leading Economic Indicators, U.S. Regional Performance, and Business Executives' Expectations. U.S. Leading Economic Indicators were once produced by the Bureau of Economic Analysis. Business cycle indicators and general information about the economy are located at [www.conference-board.org/data/bci.cfm](http://www.conference-board.org/data/bci.cfm) as a public service. A subscription to Business Cycle Indicators is \$908 annually.

**Economagic** ([www.economagic.com](http://www.economagic.com))

This is a free service where you can browse over 400,000 data series within your Internet browser. You can browse by region or by source. Most of the data is from U.S. federal statistical agencies, but there are some links to foreign sources and a few trade associations and private companies. Although there is a lot of free data here, not all of it is currently updated.

According to the website, Economagic is meant to be a comprehensive site of easy-to-access economic time series data useful for economic research, particularly economic forecasting. The core data sets contain macroeconomic data at the national level; however, much of it is at the local level. Although data is visible within an Internet browser, a subscription is needed to download the data in spreadsheet format or to access economic forecasts. A one-year subscription to access all information offered on this site is \$200.

**Moody's Analytics** ([www.economy.com](http://www.economy.com))

This site has sections that are free and others that offer reports for a fee. Some specific areas of this website are as follows:

- *FreeLunch.com* ([www.freelunch.com](http://www.freelunch.com)). Free access to over one million economic time series in Excel file format—easy to use. Who says there is no such thing as a free lunch?
- *The Dismal Scientist* ([www.dismal.com](http://www.dismal.com)). Covers detailed information on the U.S. and global economies. This website is excellent because it includes analyses as well as raw data.

**Mercer Capital** ([www.mercercapital.com](http://www.mercercapital.com))

*The National Economic Review*, an overview of the national economy prepared specifically for the business valuation profession, is available on the Mercer Capital website. The reports take information from many business publications and government-produced data, are about 9 to 10 pages long, and include tables of statistics and references. They are offered on a subscription basis (quarterly issues), and quarterly reports can be obtained by request all the way back to 1992. A 1-year subscription costs \$250 (2 years for \$399), and individual quarterly reviews sell for \$150 each. The subscriptions may be worth it if you are not comfortable with interpreting the myriad statistics that are released each quarter on the nation's economy.

**BV Resources** ([www.bvresources.com](http://www.bvresources.com))

*Economic Outlook Update* is a quarterly update on the national economy that provides excellent support for the economic outlook section of a valuation report. This publication also has a monthly update. The quarterly report includes general economic indicators, consumer prices, inflation rates, interest rates, unemployment, consumer spending, the stock and bond markets, construction, manufacturing, future outlook, and more. A one-year subscription costs \$339.

## State and Local Information

**U.S. Census Bureau** ([www.census.gov](http://www.census.gov))

This site gathers and provides data at the state and local levels through the Economic Census link on its home page. This data includes industries in the area, number of establishments, number of employees, annual payroll, and sales. Data comes from the most recent economic census (year ending in 2 or 7). Data on population trends, employment, income, and other demographics is available at the county level as well.

The Census Bureau operates the State Data Center (SDC) program, a cooperative effort between the states and the Census Bureau that was created in 1978 to make data available locally to the public through a network of state agencies, universities, libraries, and regional and local governments. More information about this program and access to links to each SDC are available at [www.census.gov/about/partners/sdc.html](http://www.census.gov/about/partners/sdc.html). This web page has a map of the United States, and one mouse click will bring the visitor to the state of interest. Many states have more than one data center.

**Bureau of Economic Analysis** ([www.bea.gov](http://www.bea.gov))

Regional accounts data is available at [www.bea.gov/regional/index.htm](http://www.bea.gov/regional/index.htm). GDP by state and metropolitan area is available, as well as personal income information. The BEARFACTS reports consist of computer-generated narratives for states, counties, and metropolitan statistical areas. The narratives describe an area's personal income using current estimates, growth rates, and a breakdown of the sources of personal income.

**State and Local Government on the Net** ([www.statelocalgov.net](http://www.statelocalgov.net))

This is a guide to government-sponsored Internet sites maintained by Hello Metro. State and local links are to servers that are controlled and managed by state or local governmental agencies. They exclude personal sites, neighborhood pages, political advocacy and campaign pages, promotion and travel sites, and Chamber of Commerce sites. Although the State and Local Government on the Net pages are updated frequently, they are not as up to date as the information contained on individual state and local government servers.

**State Websites** ([www.state.xx.us](http://www.state.xx.us))

Here, "xx" is the two letter state abbreviation. A substantial amount of information can often be obtained from state websites about a local region. Hello Metro (see the preceding section) is a good resource for finding more local (county, city, and so on) government-sponsored websites.

**Market Data (Stocks and Bonds)**

There may be times when the value of a market index at some date a few years ago is needed, or one would like to include a discussion of stock market trends in his or her report. Rather than save old editions of *The Wall Street Journal*, this information can be obtained online.

**Yahoo! Finance** ([www.finance.yahoo.com](http://www.finance.yahoo.com))

A variety of market indexes can be retrieved from this site. On the left side of the screen, click the link "Market Data" to see market indexes (up-to-the-minute as well as historical). Individual company stock quotes, mutual fund data, news, interest rates, and much more can also be tracked on this site.

**NASDAQ Website** ([www.nasdaq.com](http://www.nasdaq.com))

This website has data on every stock that trades in the over-the-counter market and is listed in the NASDAQ system. Essentially, these are all of the publicly traded stocks that are not listed on the New York or the NYSE MKT. Available on the website are historical quotes for stocks and mutual funds and dividend information, as well as information about stock splits and the like. Daily, weekly, monthly, and quarterly results are available. There are links to news headlines, global markets, economic releases, and more. The information is all free.

**Other Sites**

Current and historical stock price information can be obtained from [www.bigcharts.com](http://www.bigcharts.com) or from [www.finance.yahoo.com](http://www.finance.yahoo.com). There are others as well, but this is a step in the right direction. These sites only provide stock price information for stocks that are currently trading. If data are needed for companies that are no longer trading, the valuation analyst will have to play hide and seek like the rest of us.

**Industry Data**

The valuation analyst should consider industry data that will generally include information about the competition, the general outlook for the industry (locally and nationally), and special industry situations, such as technological developments and the effect of regulatory activities. The purpose of obtaining industry data is to allow the valuation analyst to make an assessment of how the valuation subject compares with its peers. Determining the strengths and weaknesses of the valuation subject is an important element in the risk analysis and is necessary for the determination of appropriate pricing multiples for the market approach or discount and capitalization rates for the income approach.

One of the best places to start in the search for industry information is a trade organization. These organizations frequently publish trade journals, gather statistical data about members of the organization, and provide

other information that the valuation analyst can use. I have found that people working at trade organizations are generally very helpful.

Books such as Gale Research's *Encyclopedia of Associations*<sup>2</sup> can be found at the local library and provide information on trade associations (Gale's listings can be found online, but there is a fee for this service). The Center for Association Leadership website ([www.asaecenter.org](http://www.asaecenter.org)) is also a good resource that may be used to find trade organizations. Several Internet sources for trade association information are reviewed later. Some other helpful sources for the industry outlook can be found in box 5.4, and a description of many of these data sources follows. It should be a good way to get acquainted with them.

## Standard Industrial Classification (SIC) Manual

To find guideline company information, numerous sources are available to consult. Usually, the starting point for this analysis is to determine the subject company's SIC code. Once you know the SIC code for the subject company, various sources that categorize companies in this manner can be consulted. The *SIC Manual* can be consulted if it is unclear which SIC code is appropriate for the subject company. (Exhibit 5.3 contains a sample from this publication.) The *SIC Manual* classifies business establishments by industry, arranging them by the primary activity in which the company is engaged. The code system is used to assist in comparing similar companies within a specific industry. Each individual industry is classified by a major group number, then further classified by an industry group number, followed by an industry number. The industries are arranged in the book in numeric order and in the back of the book in alphabetical order by business classification. The major group, industry group, and industry numbers are explained, and a listing of industries included under each classification number is also given.

The *SIC Manual* is published by the Executive Office of the President, Office of Management and Budget, and is sold by National Technical Information Service, Springfield, Virginia. The publication is revised periodically to reflect the changes within the industrial organization in the economy. The last revision of the *SIC Manual* was in 1987.

If a copy of the manual is not readily available, search for a SIC code and its description online at [www.osha.gov/pls/imis/sicsearch.html](http://www.osha.gov/pls/imis/sicsearch.html) and use keywords to find what you need.

### BOX 5.4

#### Key Additional Data Sources for Industry Outlook and Financial Information

##### Industry Outlook

- Standard & Poor's (S&P) industry surveys
- The Value Line Investment Survey
- Brokerage house industry studies
- Regulatory agencies' reports
- Financial publications
- U.S. Industry & Trade Outlook (prior to 2000)

##### Financial Information

- Integra Information's Business Profiler
- Trade association surveys
- Corporation Source Book of Statistics of Income
- Partnership Source Book of Statistics of Income
- Sole Proprietorship Source Book of Statistics of Income
- Almanac of Business and Industrial Financial Ratios
- Financial Statement Studies of the Small Business
- RMA Annual Statement Studies
- S&P Analysts' Handbook
- D&B Industry Norms and Key Business Ratios

<sup>2</sup> Gale Research, Inc., *Encyclopedia of Associations* (835 Penobscot Building, Detroit, Mich. 48226-4095).

**EXHIBIT 5.3 Sample from SIC Manual****Major Group 72.—Personal Services  
The Major Group as a Whole**

This major group includes establishments primarily engaged in providing services generally to individuals, such as laundries, dry-cleaning plants, portrait photographic studios, and beauty and barber shops. Also included are establishments operating as industrial launderers and those primarily engaged in providing linen supply services to commercial and business establishments.

Industry  
Group No. Industry

**721 LAUNDRY, CLEANING, AND GARMENT SERVICES****7211 Power Laundries, Family and Commercial**

Establishments primarily engaged in operating mechanical laundries with steam or other power. Establishments primarily engaged in supplying laundered work clothing on a contract or fee basis are classified in Industry 7218.

Laundries, power: family and commercial	Power laundries, family and commercial
Laundry collecting and distributing outlets operated by power laundries	

**7212 Garment Pressing, and Agents for Laundries and Drycleaners**

Establishments primarily engaged in providing laundry and dry-cleaning services but which have the laundry and dry-cleaning work done by others. Establishments in this industry may do their own pressing or finishing work. Establishments operating their own laundry plants are classified in Industry 7211, and those operating their own dry-cleaning plants are classified in Industry 7216.

Agents, retail: for laundries and drycleaners	Press shops for garments
Bobtailers, laundry and dry-cleaning	Truck route laundry and dry-cleaning, not operated by laundries or cleaners
Cleaning and laundry pickup stations, not owned by laundries or cleaners	Valet apparel service

**7213 Linen Supply**

Establishments primarily engaged in supplying to commercial establishments or household users, on a rental basis, such laundered items as uniforms, gowns, and coats of the type used by doctors, nurses, barbers, beauticians, and waitresses; and table linens, bed linens, towels and toweling, and similar items. Establishments included in this industry may or may not operate their own laundry facilities. Establishments primarily engaged in providing diaper service are classified in Industry 7219.

Apron supply service	Shirt supply service
Coat supply service	Table cover supply service
Continuous towel supply service	Towel supply service, except wiping
Gown supply service, uniform	Uniform supply service, except industrial service
Linen supply service	

**7215 Coin-Operated Laundries and Dry-cleaning**

Establishments primarily engaged in the operation of coin-operated or similar self-service laundry and dry-cleaning equipment for use on the premises, or in apartments, dormitories, and similar locations.

Coin-operated laundries	Laundromats
Dry-cleaning, coin-operated laundrettes	Laundry machine routes, coin-operated
Self-service laundry and dry-cleaning	

*(continued)*

**EXHIBIT 5.3 Sample from SIC Manual** *(continued)***7216 Dry-cleaning Plants, Except Rug Cleaning**

Establishments primarily engaged in dry-cleaning or dyeing apparel and household fabrics other than rugs. Press shops and agents for drycleaners are classified in Industry 7212; establishments primarily engaged in cleaning rugs are classified in Industry 7217; and establishments primarily engaged in dyeing fabrics for the trade are classified in Manufacturing, Major Group 22.

Clearing and dyeing plants, except rug cleaning  
Collecting and distributing agencies operated  
by cleaning plants

Drapery dry-cleaning plants  
Dry-cleaning plants, except rug cleaning

**7217 Carpet and Upholstery Cleaning**

Establishments primarily engaged in cleaning carpets and upholstered furniture at a plant or on customers' premises. Establishments primarily engaged in rug repair are classified in Industry 7699, and those primarily engaged in reupholstering and repairing furniture are classified in Industry 7641.

Carpet cleaning and repairing plants  
Carpet cleaning on customers' premises  
Furniture cleaning on customers' premises

Rug cleaning, dyeing, and repairing plants  
Upholstery cleaning on customers premises

**7218 Industrial Launderers**

Establishments primarily engaged in supplying laundered or dry-cleaned industrial work uniforms and related work clothing, such as protective apparel (flame and heat resistant) and clean room apparel; laundered mats and rags; dust control items, such as treated mops, rugs, mats, dust tool covers, and cloths; laundered wiping towels; and other selected items to industrial, commercial, and government users. These items may belong to the industrial launderer and be supplied to users on a rental basis, or they may be the customers' own goods. Establishments included in this industry may or may not operate their own laundry or dry-cleaning facilities.

Clean room apparel supply service  
Flame and heat resistant clothing supply service  
Industrial launderers  
Industrial uniform supply service Laundered mat and  
rug supply service  
Radiation protective garments supply

Safety glove supply service  
Towel supply service, wiping  
Treated mats, rugs, mops, dust tool covers,  
and cloth supply  
Wiping towel supply service  
Work clothing supply service, industrial

**7219 Laundry and Garment Services, Not Elsewhere Classified**

Establishments primarily engaged in furnishing laundry and garment services, not elsewhere classified, such as the repair, alteration, and storage of clothes for individuals and for the operation of hand laundries. Custom tailors and dressmakers are classified in Retail Trade, Industry 5699; fur shops making fur apparel to custom order are classified in Retail Trade, Industry 5632; and press shops are classified in Industry 7212.

Diaper service  
Dressmaking services on material owned by  
individual customers  
Fur garments: cleaning, repairing, and storage  
Garment alteration and repair shops  
Hand laundries

Laundries, except power and coin-operated  
Pillow cleaning and renovating  
Repair of furs and other garments for individuals  
Reweaving textiles (mending service)  
Storage of furs and other garments for individuals  
Tailor shops, except custom or merchant tailors

## North American Industry Classification System (NAICS) Manual ([www.census.gov/eos/www/naics/](http://www.census.gov/eos/www/naics/))

Because having one classification system was not enough, our government decided to join forces with Canada and Mexico to come up with a new system. Those of us old enough to remember experienced this same disaster with the metric system. I think I still have a metric tool set that does not fit anything because our country never adopted the system. Well, this is another one of those questionable brainstorms.

The NAICS system is similar to the SIC system. It is more detailed and is designed to replace the SIC system. The official U.S. NAICS Manual, *North American Industry Classification System—United States*, includes

definitions for each industry, tables showing correspondence between current NAICS and 2002 NAICS for codes that changed, and a comprehensive index—features also available on the website. I would not order this manual in print as it is regularly changed. You can download it from the website.

## Trade Association Websites

As mentioned, broad industry data is available from the Census Bureau and the Bureau of Economic Analysis. Additional broad data may be available in the *Beige Book* of the Federal Reserve Board. More specific industry data are available through newspapers, magazines, trade publications, and the like. Almost every human endeavor seems to have a trade organization devoted to it. Many of these are listed in Gale's *Encyclopedia of Associations*. The listing gives addresses, phone numbers, contact information, number of staff, publications, and other information, including a website if there is one. Often, a website exists even if it is not listed in Gale's. Once a website is found, you can see what type of information is available through the organization. Sometimes, the information is free; often, there is a charge for a back issue of a publication or a survey.

## The Internet Public Library ([www.ipl.org/div/aon/](http://www.ipl.org/div/aon/))

The Internet Public Library produces a guide to websites of prominent organizations and associations. This website has an excellent collection of links to a number of business and economic sites.

## First Research Industry Profiles ([www.firstresearch.com](http://www.firstresearch.com))

First Research offers industry reports for more than 900 industry sectors. These reports are updated on a quarterly basis and provide a detailed description of the industry and its drivers, trends, and outlook. A subscription will allow access to all industry reports, or reports may be purchased as needed for \$139 each. First Research also offers U.S. state and Canadian province profiles for \$99 per report.

## Encyclopedia Britannica ([www.britannica.com](http://www.britannica.com))

This is the online version of the encyclopedia. There is information on a large variety of subjects, but much of it may require updating if the valuation date is fairly recent. The information is easily located and is available for a subscription price of \$69.95 annually.

## Wikipedia (<http://wikipedia.org/>)

Wikipedia is a multilingual, Internet-based encyclopedia project operated by the nonprofit Wikimedia Foundation. Wikipedia contains more than 19 million articles in 287 languages. Wikipedia's articles are written collaboratively by volunteers around the world, and the majority of them can be edited by anyone with access to the Internet. Steadily rising in popularity since its inception, it ranks among the top 10 most visited websites worldwide.

## LexisNexis ([www.lexisnexis.com](http://www.lexisnexis.com))

LexisNexis is one of the world's largest providers of online information services. Though not exclusive to business and economics, LexisNexis offers access to a wide range of information useful to the business valuation analyst, including comprehensive research by company, country, demographic focus, market, and industry. This resource provides access to thousands of publications from around the world. There is a cost to this service, and it varies with usage.

## ProQuest Dialog ([www.proquest.com/products-services/ProQuest-Dialog.html](http://www.proquest.com/products-services/ProQuest-Dialog.html))

This resource is a leading provider of Internet-based information. It was initially completed in 1966 and was the world's first online information retrieval center to be used globally. Dialog is currently owned by ProQuest. Dialog provides access to thousands of authoritative business, scientific, intellectual property, and technical publications. Among the wealth of information available is worldwide company and industry information, including trends, overviews, market research, and more. Full financial information is available at the company level. It can be accessed online with a subscription.

## Alacra ([www.alacra.com](http://www.alacra.com))

Alacra is a subscription-based service that provides access to more than 200 premium databases. Partnering with companies such as Dun & Bradstreet, Factiva, Fitch Ratings, LexisNexis, Moody's, and Thomson Reuters, this database provides a wealth of information about private and public companies.

## Financial Benchmarking Data Sources

### MicroBilt Corporation's Integra Financial Benchmarking Data

Chapter 6 of this book includes a complete discussion of how to use this database as part of the financial analysis process. This is one of my favorites.

### Sageworks

Sageworks aggregates private company financial statements from accounting firms, banks, and credit unions through a cooperative data model. This database is the largest real-time repository of private company financial data in the United States, including close to 2 million financial statements from more than 600,000 private firms. The data spans across 1,400 NAICS industry classifications and can be segmented by time period, geography, annual sales range, industry, and data source. It provides coverage for 70 financial items and ratios.

### Almanac of Business and Industrial Financial Ratios

This annually updated publication provides current corporate performance facts and figures for a specific accounting period, summarized from tax return data. This information can be used to make comparisons of specific companies to similar ones in the industry. Two types of tables are given for each industry. Both report the operating and financial information for corporations; however, one reports it including companies with and without net income, whereas the other reports it specifically for those corporations that were operating at a profit.

The book divides each industry into categories according to asset size. For each category, ratios are given for the operating factors (cost of operations, repairs, bad debts, and so on), financial ratios (current ratio, quick ratio, asset turnover, and so on), and financial factors (debt ratio, return on assets, return on equity, and return on net worth), which are also defined in the book for reference purposes. The information supplied in the *Almanac of Business and Industrial Financial Ratios*<sup>3</sup> is beneficial in determining how a company compares with its competition and in what areas improvements need to be made or costs need to be cut.

The industrial sectors that are covered in the *Almanac of Business and Industrial Financial Ratios* include construction, agriculture, manufacturing, mining, communications, transportation, banking, insurance, trade, real estate, holding and investment companies, and electric, gas, and sanitary services.

### Risk Management Association (RMA) Annual Statement Studies

This publication consists of composite financial data for a number of industries (including agriculture, wholesaling, contracting, services, manufacturing, and retailing), which are categorized by SIC codes. Common size financial statements and ratios are provided for each industry. Current data for each industry is sorted by sales and by assets, and comparative historical data is provided for both groups. Assets, liabilities, and income data are given with appropriate subdivisions (cash, inventory, payables, sales, and so on), and financial ratios are listed as well. These include liquidity ratios, coverage ratios, leverage ratios, operating ratios, and expense-to-sales ratios. In addition, formulas and explanations of the ratios are provided for a further understanding of their usefulness.

RMA, the publisher of the book, receives its data from sources that submit it on a voluntary basis, not on a randomly selected basis. These sources include banks that have obtained financial statements from companies that are looking to borrow money. Therefore, the data in this particular publication should not be used as

<sup>3</sup> The *Almanac of Business and Industrial Financial Ratios* is written by Leo Troy, Ph.D., in association with Prentice-Hall, Englewood Cliffs, New Jersey.

industry guidelines when comparisons are made to other businesses in the industry because there is a possibility that the data may not include all of the necessary information to make an absolute comparison.

RMA *Annual Statement Studies* is updated yearly, and the data it presents for the more recent years is in terms of fiscal years from April 1 to March 31 (for example, 2013–2014). An online version of the RMA *Annual Statement Studies* is available on the RMA website at [www.rmahq.org/tools-publications/tools/estatement-studies](http://www.rmahq.org/tools-publications/tools/estatement-studies).

### BizMiner's Industry Financial Profiles

BizMiner provides financial benchmarking data for more than 5,500 lines of business. Full income statement and balance sheet information by SIC code is available for 3, 5, or 9 years. Companies within each industry are categorized by size of revenues. BizMiner also provides various financial ratios to test solvency, profitability, debt-related risks, and turnover. In addition to its financial benchmarking product, BizMiner provides market research reports for thousands of industries. These reports are available for each industry at the national and local levels.

Financial benchmarking and industry reports can be purchased individually or accessed with a yearly subscription. Full access to BizMiner's products can be purchased for \$1229 per year, but there are other subscriptions available, as well. The cost for a single report can be as low as \$89. More information about this data source can be found at [www.bvresources.com](http://www.bvresources.com).

### IndustriusCFO Industry Metrics Reports

IndustriusCFO (formerly Fintel) provides industry financial data for more than 900,000 companies (mostly privately held) from more than 2,500 different industry groups. Reports can be searched based on SIC or NAICS codes and further narrowed based on location, size of revenues or assets, age of the firms, and number of employees. The reports provide the latest 4 years of income statement and balance sheet information on a dollar and common size basis. The Industry Metrics reports also provide 16 commonly used financial ratios for analyzing liquidity, asset efficiency, and profitability. Subscriptions are available from \$49 to \$129 per month. IndustriusCFO also offers a Business Analyzer product that is focused on the small business owner, rather than the small business analyst. More information can be obtained at [www.industriuscfo.com/](http://www.industriuscfo.com/).

### Key Business Ratios

This publication provides financial information on more than 800 lines of business and can be used for comparing companies in the same industry. The industries covered in the book are arranged numerically by SIC code. For each SIC code, the specific name of the industry that corresponds to the code is given, along with the number of companies in the industry that were surveyed for the determination of the statistical data. The financial information provided for each industry includes current assets, total assets, current liabilities, total liabilities and net worth, net sales, gross profit, net profit after taxes, and working capital, along with solvency, efficiency, and profitability ratios. The financial ratios are given for companies that fall into the upper quartile, lower quartile, and median.

The figures found in this publication can be used as a guideline in determining the financial condition of comparable companies, regardless of whether the company is operating above or below the norms in the industry. In addition to statistical data, the book gives an explanation of the use and meaning of the ratios, along with an explanation of their derivation.

*Key Business Ratios* is published by Dun & Bradstreet Information Services, a company of the Dun & Bradstreet Corporation. An online version of *Key Business Ratios* can be found at [www.mergentkbr.com/](http://www.mergentkbr.com/).

### Compensation Data Sources

Salary Assessor and the Executive Compensation Assessor, two products produced by the Economic Research Institute, contain salary information for more than 6,000 jobs compiled from salary surveys. The information is available online at [www.eri.com](http://www.eri.com). An alternative product is Compustat ExecuComp, which is

maintained and offered by CapitalIQ of Standard & Poor's. These are good sources for estimating a reasonable level of executive compensation for a particular industry. More information on Compustat ExecuComp can be found at [www.capitaliq.com/home/what-we-offer/information-you-need/qualitative-data/execucomp.aspx](http://www.capitaliq.com/home/what-we-offer/information-you-need/qualitative-data/execucomp.aspx).

Industry trade groups frequently conduct compensation surveys, either in conjunction with an industry survey or as a standalone study. Often, a hint of the study will be given on the trade association's website. Most of the studies are available to nonmembers for a fee, so it is worth it to check the website and perhaps call the association's headquarters to ask.

MicroBilt Corporation offers a terrific online product called *Integra Financial Benchmarking Data* (Integra), which provides detailed information on profiling small businesses and private companies. This resource covers more than 4.5 million privately held firms in more than 900 U.S. industries. It is capable of analyzing any size firm or 1 of 13 industry size ranges. See chapter 6 for more details about this product. It is one of my favorites.

Integra gets its information from 32 databases, which makes this product one of the most extensive of its kind. Included in the Integra data is a measure of officers' compensation for any group of companies within an industry and size grouping. Integra will sell you individual reports by SIC code on its website, [www.microbilt.com](http://www.microbilt.com). This is too good to be ignored! (And no, I do not own the company!)

BizMiner's BizBenchmarker product also provides an indication of the level of owners' compensation for each industry and size grouping.

## Publicly Traded Guideline Company Data

Another component of the data-gathering part of the assignment is to locate information about comparables. These comparables are also known as *guideline companies*. The business valuation committee of ASA captioned this terminology as a means of differentiating what the business valuation analyst does from what the real estate appraiser does in the application of the market approach. Because real estate appraisers can generally find comparables that are close enough to the valuation subject to use in the valuation process, this terminology seems appropriate. However, business valuation analysts do not enjoy the same luxury of finding other companies that are close enough to be considered good comparables. Instead, we use other companies to provide guidance; therefore, these companies are termed guideline companies.

## The Old Days (When the Dinosaurs Roamed the Earth)

When many of us gray-haired, old-timers started in this business, the only manner in which one could get public company data was to go to the library and go from book to book to book. Fortunately, those days are long gone. Therefore, instead of providing the old sources that were included in previous editions of this book, I am going to provide today's stuff.

## Finding Publicly Traded Company Information

As will be explained in chapter 9, the guideline company method of developing a conclusion of value involves finding publicly traded companies that are comparable to the one being valued. Perhaps the easiest way to do this is to find a database that is searchable by SIC code. This section provides some additional reference sources that might help in this search.

## S&P's Capital IQ NetAdvantage

S&P offers a number of products with which you can search for publicly traded companies. Many of these resources are included under S&P's flagship product called Capital IQ, which contains data on thousands of active and inactive publicly traded companies, including 20 years of historical data, if available. One such resource is NetAdvantage, which delivers a wealth of information to your computer—for a fee, of course.

S&P's NetAdvantage product is a comprehensive online database catering mostly to universities, public libraries, and corporate information centers. NetAdvantage is made up of several components, including the following:

- *Register of Corporations, Directors & Executives.* This directory allows users to search for businesses by industry, obtain background information on executives, and find information on various indexes.
- *Corporation records.* This component provides information on more than 10,000 publicly traded U.S., Canadian, and international companies, including financial statements, profiles, recent news, and shareholder reports.
- *Industry surveys.* S&P provides reports on more than 50 of the largest North American and global industries. Along with these reports, S&P also provides its *Trends & Projections* publication, which provides insight into various macroeconomic topics.
- *Stock reports.* S&P's *Stock Report* product provides qualitative and quantitative analysis on more than 4,000 publicly traded companies.

The NetAdvantage database is available on the Capital IQ website at [www.spcapitaliq.com/](http://www.spcapitaliq.com/). This may also be accessible for free at a library.

## Mergent

*Mergent Online* (formerly *Moody's Manuals*) consists of data on more than 25,000 public U.S. companies and their SEC filings, including current and historical annual reports. International company data and annual reports are also available. Access to Mergent Online is available at [www.mergentonline.com](http://www.mergentonline.com).

In addition to the online service, Mergent continues to offer a number of former Moody's publications in print format (see box 5.5). Information on Mergent's print products can be found at [www.mergent.com/mergent-solutions/academic-corporate-public-government-libraries](http://www.mergent.com/mergent-solutions/academic-corporate-public-government-libraries).

## Value Line Investment Survey

This survey is published weekly in three parts: "Summary & Index," "Selection & Opinion," and "Ratings & Reports." The "Summary & Index" section features a listing of companies alphabetized by company name and shows the price, beta, current price and earnings ratio, estimated dividends for the year, and other stock data for each company. There is also a listing of timely stocks in timely industries and various stock rankings and estimates. In addition, the index to part 3, "Ratings & Reports," lists the industries, the page references to them, and the rankings of each industry's probable performance.

Part 2 of the *Value Line Investment Survey* features articles, graphs, and tables on current economic conditions, the Federal Reserve's actions, stock market conditions, earnings estimates, Federal Reserve data, economic information on the GDP, consumer confidence, home sales and starts, and stock market averages.

Part 3 of the *Value Line Investment Survey* gives an in-depth analysis of each industry listed. Recent developments and actions that have affected the industry are discussed, and statistics and graphs showing both current and historical data are provided. News about the major companies involved in the particular industry is presented, along with stock information, the company's current financial position, quarterly earnings, earnings per share, and dividends. The information provided in the three parts of the *Value Line Investment Survey* can be used in analyzing the economy at specific time periods, analyzing industries, and making comparisons with those companies involved in a particular industry.

### BOX 5.5

### Mergent Print Publications

- Industrial Manual and News Reports
- OTC Industrial Manual and News Reports
- OTC Unlisted Manual and News Reports
- Transportation Manual and News Reports
- Public Utility Manual and News Reports
- Bank and Finance Manual and News Reports
- International Manual and News Reports
- Municipal and Government Manual and News Reports
- U.S. Company Archives Manual
- International Company Archives Manual
- Unit Investment Trusts Annual Payment Record and UIT Weekly Reports
- Dividend Record and Annual Dividend Record
- Bond Record and Annual Bond Record
- Industry Review
- Handbook of Common Stocks
- Handbook of NASDAQ Stocks
- Handbook of Dividend Achievers

The *Value Line Investment Survey* is published and copyrighted by Value Line Publishing Inc., New York. Information is available on the Value Line website at [www.valueline.com](http://www.valueline.com).

## Thomson Reuters

Thomson Reuters maintains a database called Thomson One, which is accessible through an Internet-based interface. The Thomson One database provides access to a number of resources, including Thomson Reuters Institutional Brokers Estimate System (I/B/E/S) and Worldscope, among many others. Subscribers can search for guideline companies, download search results and company details in spreadsheet format, and integrate financial data from the database into any valuation models. Although this database is geared more toward the investment banking side of finance, it is still a powerful resource available to the business valuation analyst. Access to this database requires an annual service subscription.

## NASDAQ

NASDAQ's website ([www.nasdaq.com](http://www.nasdaq.com)) makes information on publicly traded companies available for free. If a publicly traded company in the industry you are studying is known, it can be entered on the NASDAQ home page to obtain a quote. Below the quotes are links to additional information. One link is called "Competitors". Clicking on this link will reveal a list of other publicly traded companies in the same industry as the one originally entered. The search cannot be done by SIC code and must begin with a known company. This may not work well in all situations, but it is an overlooked source of a lot of free information about companies in a given industry. Yahoo! Finance and Google have similar links.

## Other Sources

Other financial and descriptive information about public companies can be obtained from Form 10-K, Form 10-Q, Form 8-K, and the annual reports of the guideline company, which are available either directly from the guideline company, the SEC, or through commercial vendors.

Sources of forecast financial data include the following:

- Brokerage houses
- I/B/E/S, available through Thomson Reuters
- *Reuters Estimates Consensus Report*
- Zack's Investment Research
- Bloomberg Financial Markets

## Transaction Data

In addition to locating specific guideline company information, the valuation analyst will also be looking for data about mergers and acquisitions in the same or similar industry as the valuation subject's. I will explain more about this in chapters 9 and 10, but first let's find out where you can get merger and acquisition information.

Merger and acquisition data can be obtained from the following sources:

- *The Annual Merger and Acquisition Sourcebook*
- *Mergerstat Review*
- *Mergerstat Control Premium Study*
- Computer databases:
  - The Institute of Business Appraisers Inc.
  - BizComps
  - Pratt's Stats
  - Public Stats
  - Done Deals
  - Thomson Financial
  - CapitalIQ
  - Mergerstat (this is sold by Alacra as well as by others)

## Mergerstat Review

This annual publication presents compiled statistics relating to mergers and acquisitions. For the current period, and historically, data on merger and acquisition announcements and purchase prices are presented annually and quarterly. Current transactions that are either completed or pending are also shown, as well as the prices offered and equity interest sought for companies that are in the \$100 million category.

The 100 largest announcements in history are featured, as are the largest by industry. The publication also has announcements on mergers and acquisitions for specific industries, including a ranking of the dollar value offered and the number of transactions in each industry. International transactions, divestitures, a transaction, cancellation roster by industry, and acquisitions of privately owned companies are other areas featured in the book. The information provided in *Mergerstat Review* can be used to identify industry guideline companies that were involved in actual transactions. The most widely used application of *Mergerstat Review* is the reporting of control premium data. This is discussed in greater detail in chapter 14.

*Mergerstat Review* is published by FactSet Mergerstat LLC. More information is available at [www.factset.com/data/company\\_data/mergersreview](http://www.factset.com/data/company_data/mergersreview).

## FactSet Mergerstat®/BVR Control Premium Study™ Database

FactSet Mergerstat®/BVR Control Premium Study™ is an online database available exclusively through Business Valuation Resources. This database delivers empirical support for quantifying control premiums, implied minority discounts, and public company valuation multiples. It allows you to quickly search nearly 10,000 transactions that detail up to 57 data points, including the control premium, the implied minority discount, and provides up to 5 valuation multiples for each transaction. In addition, you get free quarterly data summaries in printer-friendly versions as part of your subscription.

A list of the companies that were acquired, in addition to the companies that acquired those companies, is given, along with business descriptions and SIC and NAICS codes. Numerous tables relating to the acquisition are provided and contain such information as the acquisition announcement and closing dates, the value of the deal, the percentage of common stock held by the acquirer before and after the acquisition, the price of the stock per share for various time frames, selected ratios, the specific stock exchange on which the stock is traded, and the nature of the takeover. The *Mergerstat* unaffected price is featured (the common stock price per share that has not been affected by the announcement of the acquisition), as is the *Mergerstat* control premium (found by subtracting the *Mergerstat* unaffected price from the purchase price, then dividing the difference by the *Mergerstat* unaffected price). This database is available at [www.bvresources.com](http://www.bvresources.com).

## Other Sources of Data

### Access to Newspapers and Periodicals

Many local and regional newspapers publish articles on conditions in an area's economy. Every major city's daily newspaper and many small regional papers now have an Internet site. One such website is the "Mergers, Acquisitions and Divestitures" section of *The New York Times* ([http://topics.nytimes.com/top/reference/timestopics/subjects/m/mergers\\_acquisitions\\_and\\_divestitures/index.html](http://topics.nytimes.com/top/reference/timestopics/subjects/m/mergers_acquisitions_and_divestitures/index.html)). You can use the Keyword search function on this page to search for transactions or trends in the merger and acquisition market. Although you may not find a lot of quantitative data this way, you can usually find out what transactions have taken place.

Here are several other websites that have links to many other publications.

### American Journalism Review (AJR) NewsLink ([www.ajr.org](http://www.ajr.org))

The AJR site has links to thousands of U.S. and foreign newspapers. You will also find links to television and radio stations and newswire services. The publication websites that you find may or may not have an archive feature for older articles, and they may or may not charge a retrieval fee for articles. But you can retrieve current news articles from most of them.

### The Internet Public Library ([www.ipl.org/div/news/](http://www.ipl.org/div/news/))

This site has a comprehensive listing of newspapers that have websites located in Africa, Asia, Central America, the Caribbean, Europe, the Middle East, North and South America, the South Pacific, and the United States (by state).

You can also browse by title. The Internet Public Library is a public service organization and learning and teaching environment at the University of Michigan, School of Information. Their mission is to provide library services to Internet users.

A reference center is available at <http://www.ipl.org/div/subject/www.ipl.org/div/subject/browse/ref00.00.00> that includes links to sciences and technology, reference, education, arts and humanities, health and medical sciences, law, government and political science, computers and Internet, business and economics, social sciences, entertainment and leisure, and associations.

### Factiva ([www.factiva.com](http://www.factiva.com))

Factiva, formerly Dow Jones Interactive, provides access to a multitude of business news and information resources. Factiva provides access to thousands of media, trade, and consumer publications published in 28 languages from nearly 200 countries. Articles go back 35 years and include analyst reports. The top news sources include *The Wall Street Journal*, Dow Jones Newswires, and *The New York Times*.

### Additional Data Sources

Hoover's Company Database ([www.hoovers.com](http://www.hoovers.com)) contains a great deal of good information about publicly traded companies as well as industries. Most of it is available through a subscription, but a free search can be done for companies by industry type. The search will locate general information about the company for free; more detailed profiles are available to subscribers. The option to search by SIC code is also available to subscribers. These searches can locate both publicly traded and privately held companies.

The most economical method of creating a guideline company group is to use the databases available through NASDAQ or Hoover's. Another site with a lot of free information is [www.zacks.com](http://www.zacks.com), the home of Zacks Investment Research. A company search can be done by industry type, revealing analysts' reports on companies within the industry group. You will need a Zacks Premium subscription in order to access these reports. Earnings estimates are available for free in most cases. At the other end of the pricing spectrum is Standard & Poor's Capital IQ product, which will provide you with a wide range of financial data.

### EDGAR

The Electronic Data Gathering Analysis and Retrieval (EDGAR) database allows free access to SEC filings of publicly traded companies. EDGAR filings are available on the SEC website at <http://www.sec.gov/edgar/searchedgar/companysearch.html> [www.sec.gov/edgar.shtml](http://www.sec.gov/edgar.shtml).

In addition to the SEC site, third-party vendors offer EDGAR data with value-added features such as enhanced searching or more options for a fee. One of these vendors includes EdgarOnline ([www.edgar-online.com/](http://www.edgar-online.com/)).

Several of the databases mentioned here contain earnings estimates. I/B/E/S's earnings estimates are available electronically on its website, [www.thomsonreuters.com](http://www.thomsonreuters.com), for a fee.

Other sources include *Standard & Poor's Earnings Guide*, which contains consensus earnings estimates on thousands of stocks at [www.netadvantage.standardandpoors.com](http://www.netadvantage.standardandpoors.com). The *Value Line Investment Survey*, mentioned previously, includes at least two years of projected financial statement data for most companies. *Zacks Earnings Forecaster* and *Bloomberg Markets* are other sources. Analysts' reports are available from the major brokerage houses and contain earnings estimates, buy and sell recommendations, and sometimes forecast financial information. *Nelson's Directory of Investment Research* lists the names of analysts and the industries they follow. Some public companies make analysts' reports available to prospective investors.

## TagniFi

TagniFi, formerly FetchXL, helps business valuation professionals automate their guideline public company approach with high quality financial statement data, saving dozens of billable hours on every engagement. Their Excel add-in allows the ability to populate spreadsheets within seconds. Simply enter the valuation date and ticker symbols. TagniFi does the rest by populating spreadsheets with financial data that was available on the valuation date. The TagniFi search tool enables searching by keyword, industry, SIC code, or NAICS code. All TagniFi data go through hundreds of quality checks to ensure that the most accurate financial data is being used in the guideline public company approach. In addition, all of their data is fully auditable back to the source filing. TagniFi's monthly plans deliver a flexible and affordable solution for quality financial statement data. What is really cool about this product is the fact that TagniFi will create the link between the valuation analyst's spreadsheet model and its database, so the population of the data is seamless. My staff is so grateful that they do not have to enter data from public filings that I think even they have started to like me!

## PitchBook/BVR Guideline Public Company Comps Tool™

This is a product that is similar to TagniFi, brought to us by Business Valuation Resources, a company that every valuation analyst will get to know well. This searchable tool also drastically reduces the time it takes to develop and analyze a set of guideline public company comparables. PitchBook/BVR Guideline Public Company Comps Tool™ delivers all 10-Q and 10-K filings (from EDGAR) and valuation-date-specific public market prices for public comps that match the subject company. A really nice feature of this product is that the valuation analyst can even retrieve full data on delisted companies. Unfortunately, as with many of these types of products, it is not cheap. An annual subscription used to cost about \$3,600, but now, access to this database is available for \$1,039. A two-day access pass costs \$519. Unless the analyst is only going to do one job per year, why not sign up for the annual subscription at this price? Bill it to the client as an out-of-pocket cost. There will be much more about this product discussed in chapter 9.

## Stock Quotes

Because part of the pricing multiples that the valuation analyst may use includes the price of publicly traded guideline companies, I thought that it might also be a good idea to provide some sources for gathering pricing information. Historical and current stock prices for any publicly traded company are available on the websites of the New York Stock Exchange and the NASDAQ as well as on Yahoo! and Google. All of these sources are free, so there is no reason ever to pay for this information.

## SunGard's MarketMap

If the valuation analyst insists on paying for something that he or she can get for free, this database is available at <http://financialsystems.sungard.com/solutions/market-data/market-map>. MarketMap includes current and historical security pricing from more than 160 global exchanges and over-the-counter data sources. It also contains exchange rate, dividend, capitalization, and descriptive information about the companies. MarketMap is produced by SunGard Financial Systems.

## Finding Acquired or Merged Guideline Companies

There is no limit to the amount of information that can be retrieved if one knows where to find it. The scary part about what I do for a living is not knowing what is out there. I discuss the various databases that are used in chapter 10. Be patient, and you will eventually get there.

## Cost of Capital and Betas

Information about cost of capital and betas, topics to be discussed in chapter 13, is available from numerous sources. One can use Value Line projections to produce an estimate of expected returns on the market.<sup>4</sup>

Additional data sources include Standard & Poor's CompuStat, which is perhaps the best source for betas. *Standard & Poor's Stock Reports*, available in print and online, contains descriptive and summary financial

<sup>4</sup> David King, "The Equity Risk Premium for Cost of Capital Studies: Alternatives to Ibbotson," *Business Valuation Review* (September 1994): 123–129.

information on hundreds of publicly traded companies as well as on betas. For more information, go online to [www.standardandpoors.com/products-services/netadvantage/en/us](http://www.standardandpoors.com/products-services/netadvantage/en/us).

Betas for individual companies are available for free on the NASDAQ website. These betas use the S&P 500 as the underlying index to calculate performance of the market.

I think that I have provided the valuation analyst enough to get started. By now, he or she probably wishes that he or she was finished. The sources of information listed in this chapter are some of my favorites. Surely, once the valuation analyst logs on to the Internet and begin clicking around on things, he or she will find many of his or her own favorite sources. Be wary, though. A person can easily get lost in his or her Internet research. It has a way of drawing anyone in. Good luck and happy clicking!

Information about many of the databases and publications discussed in this section, as well as about others that the valuation analyst may want to become familiar with, is included in appendix 15 as a downloadable resource.

## The On-Site Interview

An important part of the data-gathering phase of the valuation engagement is the on-site interview. It is generally a good idea for the valuation analyst to see what he or she is valuing. Interviewing management at the company's facility has several advantages. First, seeing the physical layout of the facility can help the valuation analyst understand such items as the capacity of the plant and the working environment. (Is the place busy or can someone take a nap there?). Management will also feel more comfortable in its own environment. Being at the business location will also make it easier for the valuation analyst to obtain trade journals and other information that may not have been supplied yet.

The person or persons whom the valuation analyst chooses to interview will vary from job to job, but in general, the following interviewees should be considered:

- The client
- The company's officers and management
- The company's accountant
- The company's attorney
- The company's banker

The questions that should be raised at the interview(s) will cover such topics as operations, financial performance, depth of management, competition, history of the company, personnel, suppliers, customers, marketing, legal issues, and capital requirements. In addition, the valuation analyst should not forget to ask the client for any trade journal articles on how to value the client's business. If the valuation analyst does not find it himself, he may be confronted by the client afterward for not using a particular methodology. Exhibit 5.4 contains a monograph published by The Institute of Business Appraisers titled "Questions to Ask When Appraising a Business."

A valuation analyst will generally find that more information is gathered during the management interview than by reviewing the volumes of documents that are frequently gathered. Financial documents rarely tell the entire story. Management should be able to provide the valuation analyst with a good history of the company, an understanding of what made the company's financial results appear the way they do, and expectations about where the company is going. The history could even be written by the client. Sometimes, this information can be obtained by going to the company's website or by going through the company's brochures.

It's terrible to say, but frequently, valuation analysts must take what their own clients tell them with a grain of salt. For example, if the valuation analyst has a client who is going through a divorce, he or she is most likely to get a story of doom and gloom. However, if that same client is looking to sell the business, the future always looks great. The valuation analyst should not lose sight of the purpose and function of the valuation assignment when he or she conducts the interview.

Another practical consideration is whether the valuation assignment is impaired if the valuation analyst does not get to speak to management. It is not uncommon in litigation assignments for the valuation analyst to be prevented from speaking to the company's management. Even if the valuation analyst is allowed to speak to them, they may not be as cooperative as he or she may like. What does the valuation analyst do then? We are all tempted to teach them a lesson, but it is unprofessional and highly unethical to make a point by becoming adversarial. The valuation analyst may also not want to hit them if they are bigger!

### EXHIBIT 5.4 Questions To Ask When Appraising A Business

The answers to the following questions should give the appraiser a good base of information about the business he has been asked to appraise.

Not all of these questions will apply to all businesses, nor to all situations. However, many of them will apply in a given situation, and even those that do not apply directly may suggest other information that the appraiser may wish to obtain.

No list of questions about a business can be exhaustive. However, the following questions cover many of the most important aspects of a business that should be scrutinized when the business is to be appraised.

#### About the Form of Organization of the Business

Is the business a sole proprietorship, partnership, or corporation?

If a partnership:

- How many partners, and who are they?
- Are they all in favor of selling?
- If not, is this likely to be a serious problem?

If a corporation:

- How many stockholders are there?
- Who are the major stockholders, and what percentage of the total outstanding shares does each of them own?
- Are all of the stockholders in favor of selling?
- If not, what percentage of the total outstanding shares is represented by those stockholders who are in favor of selling?
- Are the stockholders who are not in favor of selling likely to be a serious problem?
- Is the stock traded on a market?
- What market?
- What are recent prices for shares traded?

#### About the Products/Services of the Business

- What are the principal products/services?
- For what length of time has each been sold?
- What has been the sales volume of each, for each of the past 5 years?
- What are the (a) costs and (b) gross profit for each of these products/services?
- What portion of the total cost is for materials?
- What portion is for labor?
- What portion is for overhead?
- Which of the products/services are proprietary?
- Which products are purchased from others, for resale?
- What is the nature of the agreement(s) with the supplier(s) of these products?
- What features of the business' products/services distinguish them from competition?
- What product/service warranties are given to customers?
- What is the forecast of future sales and profits for each major product/service?
- How do quality and price compare with similar products/services offered by competitors?
- To what extent does the business rely on the services of outside vendors or subcontractors?
- Who are the principal vendors/subcontractors?
- What other products/services could be produced/furnished with the existing facilities?

(continued)

**EXHIBIT 5.4 Questions To Ask When Appraising A Business** *(continued)***About Markets and Marketing**

- What are the principal applications for each major product/service?
- What are the principal markets for each major product/service?
- To what extent are these markets already established, and to what extent must they still be developed?
- What is the future outlook for growth, or lack of growth, of each of these markets?
- Who are the principal customers?
- What portion of the total sales volume does each of these customers represent?
- Which major potential customers have not yet been secured as actual customers?
- How do sales break down geographically?
- What is the present backlog for each major product/service?
- How has this backlog varied over the past 3 years?
- Who are the principal competitors?
- What are the relative strengths and weaknesses of each of these competitors?
- What is the estimated sales volume of each of these competitors?
- What is this business' relative position among its competitors with regard to sales volume?
- What is its relative position among its competitors with regard to reputation?
- Has the business' past sales growth generally followed the industry trend, or has it been ahead of or behind this trend?
- What is the forecast of future industry-wide sales for each of the business' products/services?
- What is the forecast of this business' future sales for each major product/service?
- Does the business regularly use the services of any advertising and/or public relations firms?
- Who are they?
- Is the marketing aggressive and skillful?
- Who is responsible for market research?
- Who is responsible for advertising and sales promotion?
- Who is responsible for product applications?
- Who is responsible for exploiting new markets?
- What is the nature of the direct selling organization (supervision, personnel, field offices, salary and other compensation)?
- What is the nature of the distributor and/or sales representative organization (list of distributors/sales representatives, exclusive or non-exclusive nature of agreements, expiration dates of individual appointments, past performance of each distributor/representative, commission and/or discount rates, contract terms)?
- What is the nature of the service organization (who is responsible for service, installation, maintenance, etc.)?
- Are there any foreign operations?
- Details?
- Does the business use the services of any outside consultants for market research or similar activities?
- Who are they?
- What is their past record of accomplishment?
- How are they compensated?
- Are any of them under contract?

**About the Financial Situation of the Business**

- What is the sales and earnings record of the business for each of the past 5 years?
- What salaries/dividends have been paid to owners/stockholders during each of the past 5 years?
- Are income/expense statements available for each of the past 5 years?
- Is a current balance sheet available?
- What are the details of the accounts receivable (from whom receivable, amounts, age, etc.)?
- What about inventory?
- What is normal inventory level?
- What is the actual inventory at present?
- How does this inventory break down among raw material, work in process, and finished goods?
- What is the condition (new, obsolete, damaged, etc.) of the existing inventory?
- Is any portion of the inventory on consignment?
- What portion?

## EXHIBIT 5.4 Questions To Ask When Appraising A Business

### About the Financial Situation of the Business (*continued*)

- Consigned to whom?
- For how long?
- On what terms?
- What are the details of the accounts payable (to whom payable, amounts, age, any special circumstances, etc.)?
- What loans are outstanding, to whom are they payable, and what are the terms of each loan (interest rate, payment schedule, collateral, etc.)?
- What is the amount of accrued expenses payable?
- What items does this include?
- Are all federal and state taxes (including employee withholding taxes) current?
- What is the present book value (net worth; invested capital plus retained earnings) of the business?
- What is the amount of available working capital?
- What is the business' depreciation policy for fixed assets?
- What overhead (burden) rates are used in determining costs?
- What are the various departmental budgets?
- What is the advertising and sales promotion budget?
- What is the total payroll?
- Does the business own equity in any other businesses?
- What liabilities, contingent or otherwise, exist in connection with product/service warranties?
- Are there any existing claims and/or known contingent liabilities of any nature whatsoever?
- Details?
- Are there any contract disputes or renegotiations pending?
- Are there any outstanding stock options, convertible notes, or the like?
- Is there an existing forecast of future sales, profits, and capital requirements?
- What does this forecast show?

### About the Physical Facilities

- Is a complete list of physical facilities and equipment available?
- Is the real estate owned or leased?
- If owned, what is the appraised value?
- When was this appraisal made?
- By whom?
- If leased, what are the terms of the lease (period, rental, security deposit, restrictions on use of premises, renewal options, etc.)?
- What are the zoning restrictions?
- Are any of the other physical facilities or equipment leased rather than owned?
- Details?
- Is there any excess or idle capacity?
- How much?

### About Personnel and Organization

- Is a complete organization chart available?
- Are position descriptions available?
- What are the functions of key executives and personnel?
- What is the total personnel complement?
- Are there established rates of pay or pay ranges for the various jobs?
- How do these rates compare with those of other employers in the general area?
- What is the wage and salary review policy?
- What employee benefits exist (life insurance, hospitalization insurance, vacation, sick leave, pension, profit sharing, etc.)?
- Is the cost of these benefits paid entirely by the business, or do the employees contribute part of the cost?

(*continued*)

**EXHIBIT 5.4 Questions To Ask When Appraising A Business** *(continued)*

- What part?
- Are the workers unionized?
- Which ones?
- What are the contract details?
- Have there ever been any unsuccessful attempts to organize the workers?
- Details?
- Have there ever been any strikes?
- Details?
- What has been the experience with respect to employee turnover?
- Are the employees given any formal training for theft jobs?
- Details?
- Is there a house organ, employee bulletin, or newsletter for employees?
- Details?
- Are written personnel policies and/or procedures available?
- What is the general situation in the area with regard to availability of labor?

**About Management**

- Is an organization chart available?
- What are the backgrounds of key members of management?
- What is the compensation of key members of management?
- Are any members of management (or any other employees) under contract to the business?
- Details?
- Will the sale of the business involve or require any substantial reorganization of management?
- How is it regarded by its bank(s), and by the financial community in general?
- How is it regarded by its employees?
- How is it regarded by the community in which it is located?
- Has the business or any of its principals ever been found guilty, or ever entered a plea of no contest or been a party to a consent decree, with regard to anti-trust laws, anticipation regulations, securities laws or regulations, or the like?
- Details?
- Has the business complied with applicable requirements of the Occupational Safety and Health Administration (OSHA) to the satisfaction of the cognizant OSHA office?
- What has been the past history of the business with regard to litigation?
- Is the business involved in any joint ventures or similar undertakings?
- Details?
- What are the business' major accomplishments?
- Where has the business failed to an appreciable degree?
- Which members of management can be expected to remain with the business following the sale?
- What are the management capabilities of the persons in charge of each of the key departments?
- How well is each of these departments staffed?
- How capable is the second echelon of management?
- Are there any strong differences of opinion among members of management?
- Details?
- Do separate departments cooperate willingly and effectively with each other, or are there cases where cooperation is grudging or non-existent?
- Is management progress-minded and willing to take reasonable risks?
- Who dominates the organization?
- If the business is a corporation, what control do major stockholders exercise over the company's policies and/or activities?
- Are there any proxy fights, or attempts by outsiders to take over control of the company?

## EXHIBIT 5.4 Questions To Ask When Appraising A Business

### About the Business in General

- When was the business established?
- For how long has it been owned by the present owner(s)?
- Does success of the business depend to an unusual degree on the capabilities, performance, and/or contacts of one or more key persons?
- Details?
- What potentially dangerous situations exist, or might arise, in connection with the business' management, products, services, markets, finances, facilities, legal obligations, etc.?
- How is this business regarded by its customers?
- How is it regarded by its competitors?
- How is it regarded by its suppliers?
- How is it regarded by cognizant government agencies?
- How is it regarded by its bank(s), and by the financial community in general?
- How is it regarded by its employees?
- How is it regarded by the community in which it is located?
- Has the business or any of its principals ever been found guilty, or ever entered a plea of no contest or been a party to a consent decree, with regard to anti-trust laws, anti-discrimination regulations, securities laws or regulations, or the like?
- Details?
- Has the business complied with applicable requirements of the Occupational Safety and Health Administration (OSHA) to the satisfaction of the cognizant OSHA office?
- What has been the past history of the business with regard to litigation?
- Is the business involved in any joint ventures or similar undertakings?
- Details?
- What are the business' major accomplishments?
- Where has the business failed to an appreciable degree?

(Miles, Raymond C. *Basic Business Appraisal*. Copyright © 1984 by John Wiley & Sons, Inc. Reprinted with permission.)

In a situation in which the valuation analyst is prevented from getting information from management, he or she must determine if the missing information will prevent him or her from being able to give an unqualified conclusion of value. One of the limiting conditions in the report will be something like this:

This valuation was conducted without the benefit of management's cooperation. We were not allowed to interview management. If we had been allowed to interview them, we might have discovered information that may have affected our conclusion of value.

This is called "protect thyself!" The last thing that the valuation analyst wants sprung on him or her are questions like "How come you didn't speak to management?" or "How come you did not know that the company was planning to file for bankruptcy?" or "Wouldn't your answer be different if you knew that 82 percent of the company's sales came from one customer?" An answer like "Of course it would" doesn't bode well before a judge or jury. Of course, they may laugh inside because they know that the valuation analyst is right.

In litigation engagements, the valuation analyst can and should request that a deposition of the management personnel be taken if they won't cooperate with the management interview. The valuation analyst can provide the client's attorney with all the questions that the he or she wants the attorney to ask. The questions should generally be as detailed as possible in order to get a full response. This is because the person being deposed, if prepared for the deposition, will give a lot of "Yes," "No," and "I don't remember" types of responses. The attorney asking the questions should be provided with an understanding of what the valuation analyst is trying to achieve. If permitted, the valuation analyst may even sit in the room while the deposition is taking place. Then, if there are additional questions that must be asked to clarify some of the answers given, the analyst can write them out and hand them to the attorney asking the questions.

## Conclusion

Now that you have finished this chapter, you should have a better idea about the data-gathering process. You should also be more familiar with many of the data sources that will be needed to do the valuation. At this point, you should also be familiar with the on-site interview. If not, reread this chapter before going any further.

# Chapter 6

## Data Analysis

### Learning Objectives

In this chapter, I will attempt to explain what to do with all the data that should have been collected in the previous chapter. This will include a discussion about how to use the data, as well as what it means. Therefore, in this chapter, I will discuss the following:

- Economic analysis
- Industry analysis
- Subject company analysis
- Financial analysis
- Financial statement adjustments

### Introduction

Data analysis is an important component of the valuation process. Because assessment of risk is a goal of the valuation analyst, the analysis of the information collected must be performed with a view toward the future of the business. In general, we feel more comfortable using historical information for a valuation, but we have to remember that a willing buyer is not interested in buying history. As valuation analysts, it is our role to assess how much the future will resemble the past. To the extent the past resembles the future, and to that extent the past is predictive of the future, only then can we value the business.

### Economic Analysis

Revenue Ruling 59-60 tells us to consider “the economic outlook in general and the condition and outlook of the specific industry in particular.” During the analysis of the economy, the valuation analyst attempts to determine the economic risks associated with the subject business. Questions regarding the demand for the company’s goods or services and the sources of supply are frequently asked. The outlook for the general economic trends that might affect supply and demand for the company’s goods and services should be thoroughly investigated. This analysis must be relevant to the valuation subject, not just taken from a boilerplate. For example, if the valuation subject is a construction company, economic factors such as interest rates, housing starts, and building permits may be important. How important are they if the valuation subject is a cardiovascular surgery practice?

Another component of the economy that should be considered by the valuation analyst is where in the economic cycle the valuation subject is at the date of the valuation. If the economy is in a recession, it will make a big difference whether the recession is just starting or is about to end. Depending upon where the company is in the economic cycle, the short-term and long-term projections may be radically different. Because valuation is a prophecy of the future, this would be extremely important to the willing buyer because he or she would have to ride out the balance of the cycle.

The economic analysis will be used in at least two sections of the valuation assignment: in forecasting the future performance of the subject company and to aid the valuation analyst in performing an analysis of the economic risk to which the company is exposed. This will be one of the many considerations in the determination of (1) the pricing multiples used in the market approach and (2) the discount or capitalization rates used in the income approach.

During the management interview, the valuation analyst will want to ask company representatives about how the economy affects the business. Some businesses are cyclical with the economy, and others may be counter-cyclical; these businesses react opposite to the economy. An example of one such business is a tractor trailer driving school. When the economy is strong, business is bad. When the economy is weak, business is good. Why? During a good economy, people are working, and they are not necessarily looking to be retrained in a new field. During a bad economy, economic layoffs require people to find new employment. The issues for the valuation analyst to consider about training schools are as follows: Is funding available for the students (if they are unemployed, they may not want to or be able to spend \$2,000+ for education), and after the students complete the course, will the economy turn around so that drivers will be needed? Exhibit 6.1 gives an illustration of a sample economic section from a real report.

Let me point out a few things to you about the exhibit. First, if you'll notice, we footnote our sources. Also, in this valuation, the local economy mattered as well, so we covered the parts of the state that we considered to be important to the valuation subject. This business was also affected by the demographics of the region, particularly because it provided certain types of health care.

### EXHIBIT 6.1 Economy Section

Generally, business performance varies in relationship to the economy. Just as a strong economy can improve overall business performance and value, a declining economy can have the opposite effect. Businesses can be affected by global, national, and local events. Changes in regulatory environments, political climate, and market and competitive forces can also have a significant impact on business. For these reasons, it is important to analyze and understand the prevailing economic environment when valuing a closely held business. Because the valuation process is a "prophecy of the future," it is imperative that the valuation analyst review the economic outlook because it would affect the valuation subject.

#### NATIONAL ECONOMY

After a weak first quarter affected by the winter, real gross domestic product (GDP) increased by 3.9 percent in the second quarter of 2015. Non-farm payroll employment rose only 142,000 in September 2015 and the unemployment rate has steadily declined from 6.1 percent in the third quarter of 2014 to 5.2 percent in the third quarter of 2015.<sup>1</sup> On October 12, 2015, a panel of prominent United States economic and financial forecasters were surveyed by Consensus Economics, Inc. for their predictions on a range of key economic variables. These forecasts are summarized in table 1.

<sup>1</sup> *Consensus Forecasts—USA*, October 12, 2015.

**EXHIBIT 6.1 Economy Section****TABLE 1 Quarterly Forecasts**

	2015		2016				2017

10 year Treasury Bond Yield, % <sup>1</sup>	2.0	2.3	2.4	2.6	2.7	2.8	3.0	3.2

\* % change from prior quarter, seasonally adjusted annual rate.

<sup>1</sup> End Quarter.

(Source: Consensus Forecasts—USA, October, 2015: 5, Consensus Economics Inc.)

Consensus Economics' forecasts indicate a steady economy over the next several quarters with GDP, disposable income, and personal consumption remaining relatively unchanged. Furthermore, inflation is forecast to remain soft while the unemployment rate is expected to continue to improve. These factors indicate that The Company will be operating in a stable economy in the near term.

#### REGIONAL ECONOMY

The Company is located in XYZ, Florida. XYZ is a town located in Central Florida in Sumter County. The Company's patient base is primarily in Sumter County, along with neighboring Lake County. It is important to understand the economic climate in this area in order to assess The Company's future prospects.

As of 2014, Sumter County and Lake County had populations of 111,125 and 309,736, respectively. Historic population estimates and future projections for these counties and the State of Florida are presented in table 2.

(continued)

## EXHIBIT 6.1 Economy Section (continued)

TABLE 2 Population Projections

County and State	Age Bracket	Estimates 2014	Projections								CAGR <sup>1</sup>	
			2015	2020	2025	2030	2035	2040

<sup>1</sup> Consensus Forecasts—USA, October 12, 2015.

(Source: Florida Population Studies, Bulletin 172, Bureau of Economic and Business Research.)

(continued)

**EXHIBIT 6.1 Economy Section** *(continued)*

Population in the area surrounding The Company is forecast to outpace the state as a whole. The fastest growing age bracket is 80 and over, which is forecast to increase by 3.3 percent and 6.6 percent per year in Lake and Sumter County, respectively. In Lake County, significant growth is also expected in the 65–79 age bracket which is forecast to increase by 2.7 percent per year. Sumter County is projected to experience faster growth in the younger age brackets, outpacing the State of Florida.

Medicare beneficiaries make up a significant portion of the population in Lake and Sumter Counties. This data is presented in Table 3.

**TABLE 3 Medicare Beneficiaries as a Percentage of Total Population**

	Medicare Beneficiaries	Population	Beneficiaries as a % of Population
Lake County	86,502	309,736	27.9%
Sumter County	52,142	111,125	46.9%
Florida	4,386,134	19,507,369	22.5%

*(Source: Center for Medicare and Medicaid Services.)*

Medicare beneficiaries make up 46.9 percent of Sumter County's population which is more than double the state's overall. A significant portion of Lake County's population also consists of Medicare beneficiaries.

The Company's patient base is primarily located towards The Villages, an unincorporated community of 107,056 residents. According to U.S. census data, The Villages, Florida's largest retirement community, is also the nation's fastest growing metropolitan area. Much of The Village's recent growth has been in Sumter County, where it has expanded into the city limits of Wildwood and built its newest town center. The Villages' pace of growth has not resulted in an overcrowding of the community as each residential development gets its own golf courses, pools, restaurants and other amenities<sup>2</sup>

Unemployment rates in Sumter and Lake County have decreased but still exceed national and statewide levels. Employment data for the local area, the State of Florida and the United States are summarized in Table 4.

In Sumter County, the labor market continued to increase in 2014 as total employment increased to 26,120. Although the unemployment rate decreased from 13.3 percent in 2010 to 7.7 percent in 2014, it remained well above national and state levels. In Lake County, the labor market has increased from 2010 to 2014 as total employment increased from 118,246 to 130,439 and the unemployment rate has steadily decreased from 11.8 to 6.4 percent.

**EXHIBIT 6.1 Economy Section** *(continued)*

Income levels in the local area have consistently lagged those of the rest of the state. Per capita personal income for Sumter County, Lake County and the State of Florida is presented in Table 5.

**TABLE 5 Income Data**

	2010	2011	2012	2013	2014
Sumter	\$29,191	\$32,930	\$35,300	\$36,481	\$37,558
Lake	32,253	33,239	33,946	34,637	35,786
Florida	38,718	40,538	41,249	41,309	42,737

(Source: Bureau of Economic Analysis.)

Conditions in the local economy should have a positive impact on The Company. The older demographic within the region presents many opportunities for home health services and growth within the older age demographics is expected to experience significant growth over the long term. Furthermore, the large Medicare population within the area should continue to support strong demand for The Company's services within the region.

## Industry Analysis

The purpose of the industry analysis is to allow a comparison of the valuation subject with the industry as a whole, as well as to allow the valuation analyst to use industry forecasts to help predict how the subject company will perform in the future. Box 6.1 includes questions frequently raised about the industry.

### Porter's Five Forces

Many of the questions posed in box 6.1 can be answered through a structured analytical process called Porter's Five Forces that was developed by Michael Porter of the Harvard Business School in 1979. Porter has since published a number of articles about the Five Forces; the first was in 1980 in his book *Competitive Strategy: Techniques for Analyzing Industries and Competitors*. The key point of Porter's theory is that increased competition reduces profitability for an industry as a whole. For the business valuation analyst, Porter's Five Forces should allow you to identify key industry drivers and give you a general idea of how an industry's future may affect growth and profitability for the subject company. The basic structure of Porter's Five Forces is shown in figure 6.1. Each part of this figure deserves a discussion.

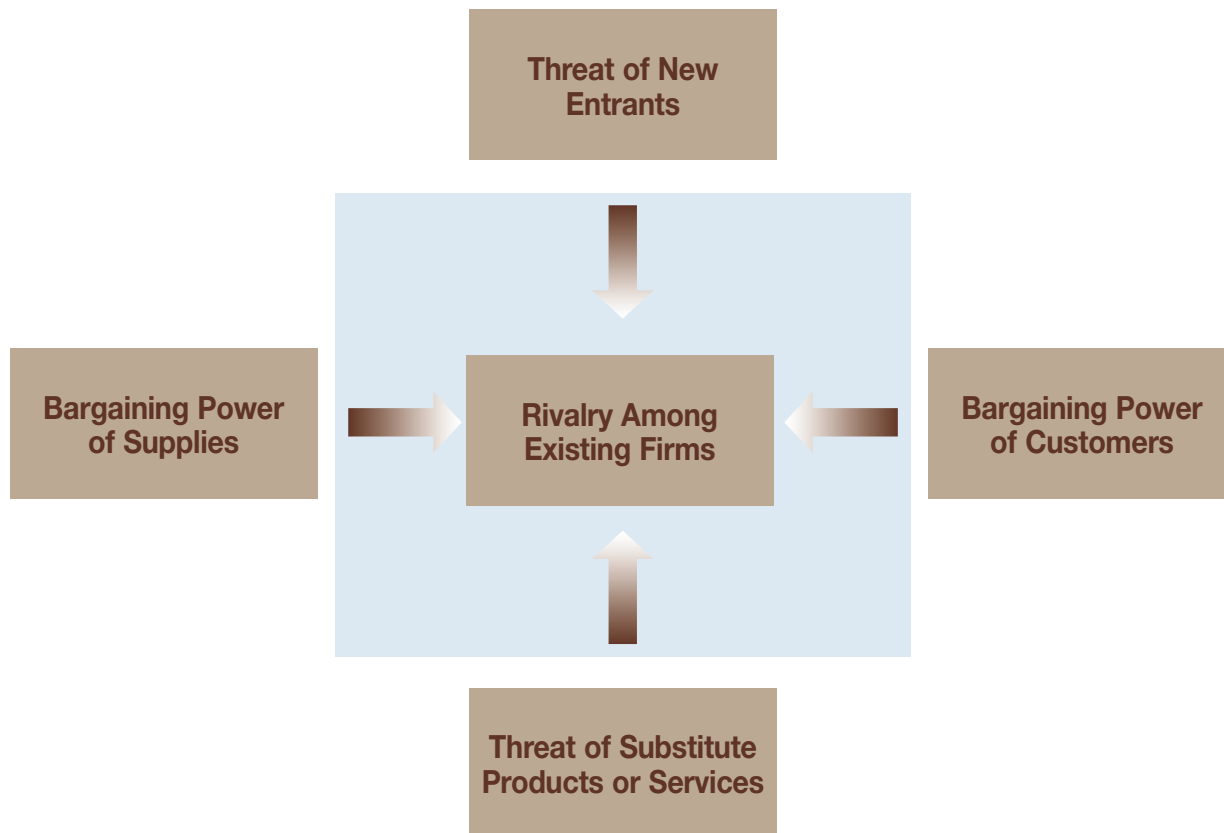

#### BOX 6.1

#### Frequently Asked Industry Questions

- Who makes up the industry? Are there many companies or are there very few companies that control everything?
- Is it a cyclical industry?
- Is it a new industry with many new companies entering it, or is it a mature industry that has reached its saturation point?
- What are the barriers to entry, if any, into the industry?
- Is this a self-contained industry, or is it dependent on another industry?
- Is the industry dependent on new technology? If so, is the valuation subject keeping up with the industry?
- Is the industry expected to change? If so, how will that affect the valuation subject?
- What is the forecast for growth within the industry?

Figure 6.1

## Threat of New Entrants

The threat of new entrants is, in part, determined by market conditions. Factors affecting new market entrants include economies of scale, product differentiation, capital requirements, switching costs for customers, access to distribution channels, cost advantages, and government policies. Barriers to entry are unique characteristics that define an industry. They reduce the rate of entry for new firms, thus, maintaining a level of profitability for those already in the industry. Clearly, the more numerous and difficult the barriers are within an industry, the lower the number of competitors and vice versa. In many cases (but not all), industries with higher barriers to entry will be more profitable. From a strategic perspective, barriers can be created or exploited to enhance a firm's competitive advantage. Barriers to entry arise from several sources:

- *Capital requirements.* Industries that are capital intensive may require a substantial amount of financial capital to enter the market. The most broad and obvious example of a capital intensive industry is manufacturing. Manufacturers require substantial fixed asset investment in order to operate. Industries that require investment in brand name or research and development (R&D) are capital intensive as well due to the funds required to advertise or develop a new product. These types of industries usually have few alternative products and are dominated by a few competitors.
- *Government.* Although the principal role of the government in a market is to preserve competition through antitrust actions, government also restricts competition through the granting of monopolies and regulation. Industries, such as utilities, are considered natural monopolies because it has been more efficient to have one electric company provide power to a locality than to permit many electric companies to compete in a local market. To restrain utilities from exploiting this advantage, government permits a monopoly but regulates the industry. Illustrative of this kind of barrier to entry is the local cable company. The franchise to a cable provider may be granted by competitive bidding, but once the franchise is awarded by a community, a monopoly is created. Local governments were not effective in monitoring price gouging by cable operators, so the federal government has enacted legislation to review and restrict prices.

- *Patents and proprietary knowledge.* These serve to restrict entry into an industry. Ideas and knowledge that provide competitive advantages are treated as private property when patented, preventing others from using the knowledge and, thus, creating a barrier to entry. This factor is sometimes referred to as the *experience curve*. Industries with companies that rely on proprietary process knowledge or equipment for operational efficiencies enjoy relatively high barriers to entry because a new entrant would suffer low or negative profitability in the process of developing its own efficient process. In industries in which such knowledge or equipment is commonly available, an experience curve plays little part in preventing new market entries.
- *Asset specificity.* Asset specificity is the extent to which the firm's assets can be utilized to produce a different product. When an industry requires highly specialized technology or plant and equipment, potential entrants are reluctant to commit to acquiring specialized assets that cannot be sold or converted into other uses if the venture fails. Asset specificity provides a barrier to entry for two reasons: First, when firms already hold specialized assets, they fiercely resist efforts by others to take their market share, and second, new entrants can anticipate aggressive rivalry.
- *Organizational economies of scale.* The most cost efficient level of production is the point at which unit costs for production are at a minimum. If the level of efficiency for firms in an industry is known, then one can determine the amount of market share necessary for low cost entry or cost parity with rivals. For example, in the long distance communications industry, roughly 10 percent of the market is necessary to reach the most cost efficient level of production. Thus, if sales for a long distance operator fail to reach 10 percent of the market, the firm is not competitive.
- *Retaliation from existing competitors.* Although somewhat rare, existing competitors sometimes take action to prevent other companies from entering a market. This is particularly effective in industries in which companies incur high fixed and low variable costs.

Exit barriers are also important to consider. In many ways, barriers to exit are functionally similar to barriers to entry. Exit barriers limit the ability of a firm to leave the market and can exacerbate rivalry; unable to leave the industry, a firm must continue to compete. In some cases, companies with low or negative profitability may continue to compete, increasing production capacity and supply, which typically results in lower profitability for the entire industry group. Some entry and exit barriers are summarized in figure 6.2.

### Threat of Substitute Products or Services

In Porter's model, the term *substitute products* often refers to products in other industries. To the economist, a threat of substitutes exists when a product's demand is affected by the price change of a substitute product. To be clear, a substitute product is not necessarily the product of a direct competitor. Substitute products can be provided by a separate industry designed to meet the demand of the same group of customers. For

example, the introduction of online streaming of movies and television shows has provided a substitute product to cable service and video rental stores.

A product's price elasticity is affected by substitute products. As more substitutes become available, the demand becomes more elastic because customers have more alternatives. A close substitute product constrains the ability of firms in an industry to raise prices. The effectiveness of a substitute product is determined by its price and quality, as well as the cost for customers to switch to it. Substitute products have a significant impact on other industries when they are produced by companies with high profitability or are becoming increasingly competitive in price. Ultimately, substitute products limit an industry's potential profitability.

## Bargaining Power of Suppliers

The bargaining power of suppliers within an industry can be measured by competitors' ability to change pricing, quality, and quantity of its products. Suppliers have stronger bargaining power when (1) they can integrate competing customers into their business, (2) there are few suppliers among which customers may choose, (3) there are few or no substitute products available, (4) the supplier's product is necessary to customers, or (5) customers would incur significant costs for switching to a different product. On the other hand, suppliers are weak when (1) there are many competitive suppliers and substitute products, (2) there is a threat of backwards integration by customers, or (3) there is high customer concentration.

A good example of a strong supplier can be found in the California pistachio industry, which is heavily influenced by Paramount Farms, the largest grower and processor of almonds and pistachios in the world. Through backwards integration and sheer volume of nuts processed and sold, Paramount Farms is able to dictate the market price of almonds and pistachios grown in California. Every year, Paramount Farms decides at what price U.S. grown almonds and pistachios will be sold. All other growers and processors must sell product at the same or similar cost or be pushed out by Paramount Farms. See? Being nuts can be a good thing! Another strong supplier would be a pharmaceutical company and its relationship with hospitals. Imagine a hospital that no longer wanted to carry Tylenol. I don't think so.

## Bargaining Power of Customers

Depending on the industry, customers may have significant bargaining power with their suppliers. Customers with strong bargaining power are able to influence change in the pricing and quality of products from suppliers. Customers tend to have strong bargaining power in industries with a low number of customers relative to suppliers, little product differentiation, and the availability of substitute products. Customers in industries that generate low profitability generally have higher bargaining power because they tend to search for alternative products at the lowest prices possible. In addition, customers with a high volume of product purchases or the ability to acquire competing suppliers can have a very powerful influence over suppliers. Finally, customers with full information about products and the prices available in the market generally are able to bargain better with suppliers.

It goes without saying that customers have little negotiating power with suppliers when the opposite is true. When suppliers can threaten forward integration, there are significant customer switching costs, there are many customers to available suppliers, or there are few or no substitute products.

A good example of a customer with strong bargaining power is the U.S. government. The large number of government contractors results in high competition in all industries that rely on business from the federal government. This heightened level of competition allows the government to negotiate the best prices, many times, through a competitive bidding process among contractors. In theory, the government should be able to negotiate well. The political process is vulnerable to lobbying and subject to constituent influence. For example, labor unions have convinced many governmental bodies that prevailing union wage rates should be charged for all government contracts. This requirement limits the ability of a governmental unit to obtain the lowest possible price. In other situations, graft, political corruption, and many other factors that I am not going to go into in this book frequently cause the government to be ineffective in negotiations.

## Competitive Rivalry Among Existing Firms

The four factors discussed in the preceding section all have a direct effect on the rivalry that exists between competitors. The number, relative size and diversity of competitors, industry growth, cost efficiencies, substitute products, cost to switch, and entry and exit barriers all have a direct impact on competitors within a given industry.

Firms within an industry may respond to rivalry by changing prices (raising or lowering prices to gain a temporary advantage), improving product differentiation (expanding features, implementing innovations in the manufacturing process and in the product itself), creatively using channels of distribution (vertical integration or using distribution channels novel to the industry), or exploiting relationships with suppliers with regard to quality, price, or volume. Rivalry is intensified when there are a large number of firms competing for the same customers and resources, market growth is slow, costs are relatively high among competitors, customer switching costs are low, and product differentiation is weak. All of these factors must be considered when analyzing any industry because they probably all have some effect on the company being valued.

Oftentimes, rivalry increases as one company attempts to take market share from its competitors. In some cases, attempts to gain market share can provoke competitors to follow suit. This type of industry-wide change (although good for customers) can hurt an industry. For example, a broad reduction in prices will decrease profitability for an industry as a whole. Although the largest competitors are able to absorb the negative effects of price increases through sales volume, smaller companies can be destroyed by it.

High exit barriers cause a firm to remain in an industry even when the venture is not profitable because there is a high cost to abandoning the product. A common exit barrier is asset specificity. When the plant and equipment required for manufacturing a product are highly specialized, these assets cannot easily be sold to other buyers in another industry.

Diversity of rivals with different cultures, histories, and philosophies makes an industry unstable. There is a greater possibility for mavericks and for misjudging rivals' moves. Rivalry is volatile and can be intense. The hospital industry, for example, is populated by facilities that (1) are community or charitable institutions, (2) are associated with religious organizations or universities, and (3) are for-profit enterprises. This mix of philosophies about mission has occasionally led to fierce local struggles by hospitals over which ones will get to deliver expensive diagnostic and therapeutic services. At other times, local hospitals are highly cooperative with one another on issues such as community disaster planning.

A growing market and the potential for high profits induce new firms to enter a market and incumbent firms to increase production. A point is reached at which the industry becomes crowded with competitors and demand cannot support new entrants and higher supply. The industry may become crowded if its growth rate slows and the market becomes saturated, creating a situation of excess capacity with too many goods and services chasing too few buyers. A shakeout ensues, with intense competition, price wars, and company failures. Additionally, market stability and changes in supply and demand affect rivalry. Cyclical demand tends to create cutthroat competition.

In bringing everything together, the best way to illustrate the use of Porter's Five Forces is to provide you with an example. In Porter's *On Competition*, an example of the application of the Five Forces theory is provided. Although the example isn't particularly deep in its analysis, it touches on all five industry forces to explain how Dr. Pepper was able to succeed in a market dominated by industry giants Coca-Cola and Pepsi Cola. You really should get this book so that you can read the example as well as the rest of it.

In assessing the outlook of a subject company, the analyst must consider what is happening in the company's industry. Porter's Five Forces provides a structured method to understanding the factors that drive a particular market. The analysis of the subject company and its industry will allow an analyst to assess its situation relative to its industry peers. This can be helpful when conducting a comparative financial analysis, selecting a discount rate for use with a discounted future benefits approach, and selecting market multiples based on publicly traded guideline companies. After completing a Porter's Five Forces analysis, you should have some idea about how an industry will react to a subject company's strategy. As an example, if the subject company is planning on entering an industry that has a history of dropping prices substantially upon the entry of a new

competitor, the risk of failure is higher and should be reflected in a higher discount rate or lower market multiple. However, always keep in mind that certain factors may be more important to your analysis than others depending on the nature of the business. For example, the bargaining power of The Home Depot or Lowes with their suppliers would not be comparable to the bargaining power of the local hardware store, which has no influence on an industry dominated by the two, billion dollar giants.

Porter's Five Forces has often been criticized for its simplistic nature. The methodology is difficult to apply in industries with high government regulation or industries with complex product interrelationships and strategic alliances among industry participants. Additionally, changes in business models due to drastic changes in technology are not considered by the Five Forces analysis. Nevertheless, Porter's Five Forces remains a good starting point for any industry analysis. It is also an excellent framework from which to present your analysis of the environment in which the subject company operates. Keep in mind that it is always important to consider the nuances of the particular industry with which you are dealing. In some cases, additional analysis will be necessary to account for all industry drivers.

## Other Considerations

If an industry is cyclical, as are automobile dealerships, consideration should be given to where in the economic cycle the industry is. If the economy is at the bottom of the cycle, the forecast for the next several years may look good. This will affect the forecast of future operations, as well as the risk component of the market multiples, discount rates, or capitalization rates that will be used. It is also important to understand which economic factors affect the industry, and sometimes, the industry(s) of its customers. For example, what is the impact of rising interest rates for an automobile dealership? Sales and leasing may go down, so this is a bad thing. However, people will keep their cars longer, and the repair bays may get busier because the older cars need more maintenance. This is a good thing. However, interest rates may not have a significant effect on a high-end dealership (think Porsche, Mercedes-Benz, and the like). As an example, many of the customers for a Porsche dealership in the New York City metropolitan area pay cash for new cars after receiving their annual Wall Street bonuses. Thus, interest rates would not have as big an impact on new vehicle sales as would stock market performance. Don't be quick to jump to conclusions.

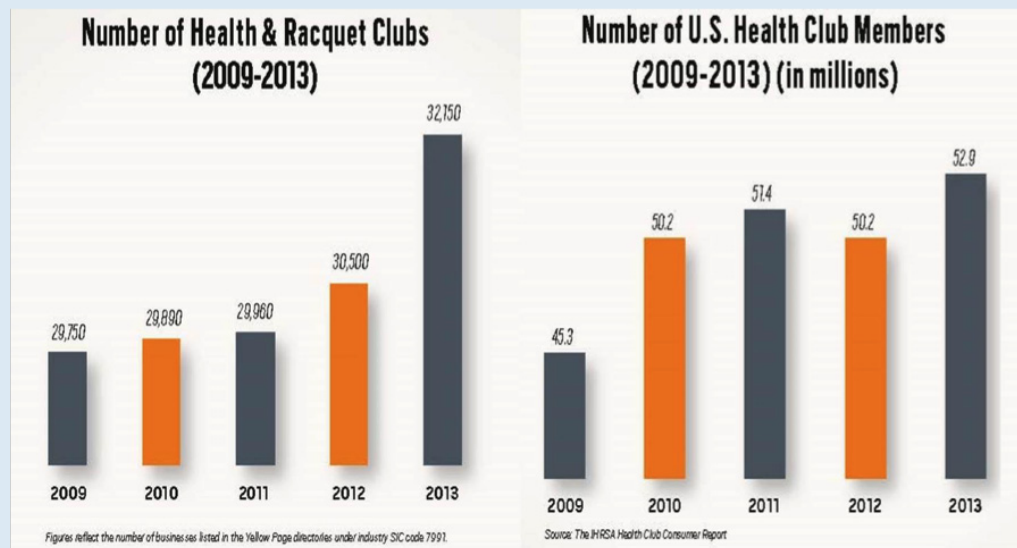

Sometimes, the industry analysis must extend beyond the valuation subject to its customers. Imagine a trucking firm that provides services for major retailers without a discussion about how the trucking firm's customers are expected to do. If the trucking firm is dependent on its customers, it would be negligent to ignore this important point. Another example might be a printing company that only services the pharmaceutical industry. The performance of the pharmaceutical industry would have a great impact on the printing company. Exhibit 6.2 illustrates an industry section taken from an actual report. Notice the many items that could affect a subject company in that same industry. Also, notice how our Porter Five Forces analysis is weaved throughout the discussion.

### EXHIBIT 6.2 Industry Section—Health Clubs

#### INDUSTRY

According to the IHRSA, there were 32,150 health and racquet clubs in the U.S. in 2013, which represents a 5 percent increase from 2012. Roughly 52.9 million Americans were health club members in 2013, which represents a 5.4 percent increase from 2012. Nearly half of all members indicated belonging to either a multipurpose or fitness-only club, while approximately 19 percent belonged to a fitness studio such as yoga/pilates/barre, indoor cycling/rowing, bootcamp/cross training, boxing/mixed martial arts and/or sports specific concept. At least 13 percent of all members belonged to more than one health club. Historic club count and membership data is presented in Figure 8.

*(continued)*

**EXHIBIT 6.2 Industry Section—Health Clubs** *(continued)*
**Figure 8**

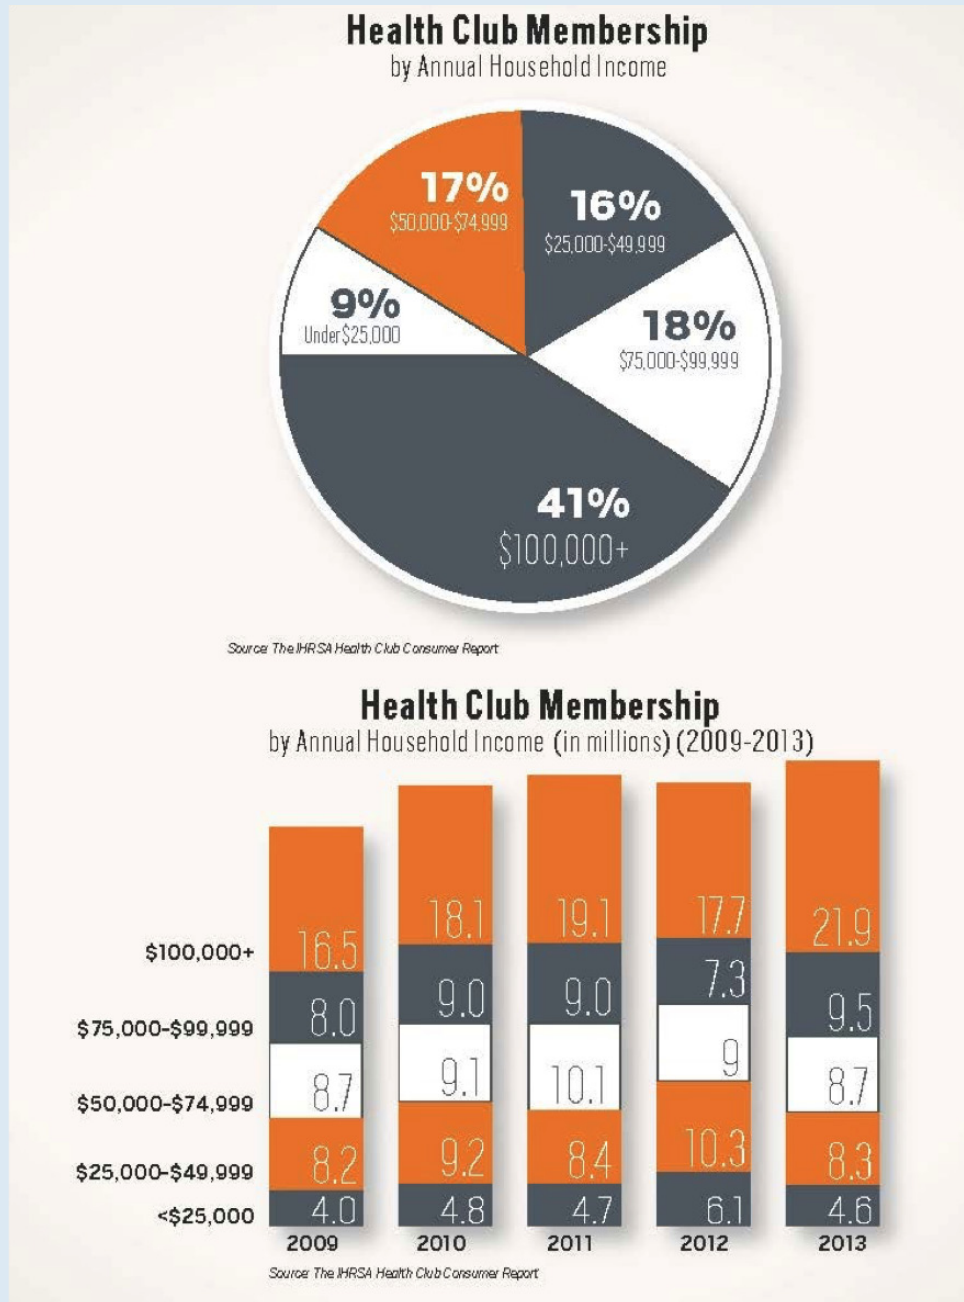

In 2013, the average member visited his or her club 102 times, four more days than in 2012. Roughly 44 percent of all members are “core” members; defined as those who use the club 100 days or more per year. This amounts to 23.2 million core members, which represents an increase of 4.5 percent from 2012, in which 22.2 million members were core members. Since 2009, there has been a 20 percent increase overall in the number of core members.

The average age of a health club member in 2013 was 40 years old. More than one out of four health club members (27 percent) were between the ages of 18 and 34 years old (14.2 million). The most represented age group was 35 to 54 year-olds at 35 percent of total membership (18.5 million). The oldest, 55+ age group represented 24 percent of all club members (12.4 million), while those under age 18 represented 15 percent of all members (7.7 million). The number of health club members under age 18 has grown from 4.6 million in 2009 to 7.7 million in 2013.

A major factor influencing health club membership is household income. In 2013, 41 percent of health clubs members had an annual household income of \$100,000 or more, while the second largest segment, 18 percent of members had an annual household income of \$75,000 to \$99,999. Health club membership broken down by income bracket is depicted in Figure 9.

**EXHIBIT 6.2 Industry Section—Health Clubs**

**Figure 9**

(continued)

## EXHIBIT 6.2 Industry Section—Health Clubs *(continued)*

As indicated in Figure 9, there is a direct correlation between the income bracket and the percentage of total membership. In 2013, the \$100,000 or more and \$75,000 to \$99,999 income brackets increased its share of total membership, while each of the other three brackets decreased.

Overall, the main reason that gym members say they return to their health clubs is for overall health and well-being. Staying healthy was the number one personal goal of health club members surveyed in the *IHRSA Trend Report*. When it comes to reasons why health club members left or quit their gyms or just did not join in general, the number one reason across the board was that health club memberships were too expensive. This says something about the perception of health club memberships and about price points in general. The annual industry data survey of the health and fitness industry has advised that club operators need to be aware of who is in their clubs - and who wants to be a part of their clubs—and offer tiered membership options.

In 2013, U.S. health club industry revenue totaled \$22.4 billion. Industry revenues have steadily increased since 2009. Historic industry revenue data is presented in Figure 10.

### Figure 10

From 2009 to 2013, industry revenues grew at a compound annual growth rate of 3.5 percent. According to IBISWorld, the industry as a whole is forecast to grow at an annual rate of 2.8 percent from 2014 to 2019, which is below the rate achieved historically.

Competition in the fitness industry is high and competitive pressures are expected to become more severe going forward. According to First Research, the industry is fragmented, with the 50 largest companies accounting for 30 percent of revenues. Large companies have economies of scale in advertising and in buying equipment, while small companies can compete effectively if they have favorable locations or meet customer demands for personalized service and a friendly atmosphere.

**EXHIBIT 6.2 Industry Section—Health Clubs**

Competition in the fitness industry comes from many facilities, including internal competition (other commercial fitness centers, nonprofits, government organizations, hospitals, businesses and salons), as well as external competition (condominium clubs, exercise studios, country clubs, weight loss centers, home fitness equipment businesses, bowling alleys and marinas). With the number of fitness centers increasing, particularly in certain urban markets, the market in these areas is becoming saturated. According to First Research, in many markets, consumers can choose from among a dozen fitness centers within a 15-minute driving distance. The competition for customers limits centers' ability to raise prices. Prices have also remained subdued due to the number of competitor clubs that are offering lower pricing and a lower level of service, which has continued to increase over the past several years.

Further increasing competitive pressures in the industry are low barriers to entry. According to IBISWorld, barriers to entry in the fitness industry were low in 2013 and were predicted to stay that way in the future. However, there is often a high cost associated with opening a gym and it takes time to build a brand, gain members and generate a profit. According to First Research, commercial grade fitness equipment typically costs from \$3,000 to \$10,000 per machine. Popular franchises require a cash infusion of around \$50,000 and a capital outlay of \$1 million to \$4 million. Furthermore, there is additional cost and effort related to training employees; keeping up to date with the latest fitness trends and offering popular classes.

Another challenge facing fitness centers is high member attrition rates. On average, about 40 percent of fitness club members do not renew memberships making revenue uncertain and requiring high marketing costs to get new members. Attrition for members who make installment payments is even higher for some clubs. To fight attrition, clubs promote programs to monitor diets, fitness levels, exercise regimens, and assess metabolic rates, oxygen use and body fat.

Growth in the fitness industry is expected to be driven by two primary factors. First, the younger generation is now being targeted as a strong opportunity for growth. Club operators will be looking for ways to get younger members to join and then come up with ways to retain that segment. The second major factor that is expected to drive growth is increasing concerns about health and the rising cost of health care. According to the Center for Disease Control and Prevention, during the period from 1990 through 2010, there was a dramatic increase in obesity in the U.S. and rates remain high. State prevalence of obesity continues to remain high across the country in 2012, with no single state having an obesity rate of less than 20 percent. In 2012, 41 states had a prevalence of 25 percent or more and 13 of these states had a prevalence of 30 percent or more. As healthcare costs continue to rise in the U.S., some of the focus on combating obesity and other diseases is being directed at prevention. Both government and medical research have shown that exercise and other physical activity plays a critical role in preventing obesity and other health conditions, thereby reducing healthcare costs for treating obesity-related sicknesses.

The subject company operates fitness centers in the five boroughs of New York, Westchester County and Rockland County. There are several industry trends specific to this region that will have an influence on The Company in the future; saturation, rising rents and low membership fees.

After several years of declining and flat growth, the number of fitness centers in The Company's territory began to trend upward in 2012. According to U.S. Census data, the number of establishments classified under Standard Industrial Classification ("SIC") code 7991 increased from 988 in 2011 to 1,002 in 2012. This same trend appears to be occurring statewide as the number of establishments increased from 2,134 in 2011 to 2,142 in 2012. While the U.S. Census Bureau will not release the 2013 figures until the summer of 2015, data from the IHRSA indicates that the number of gyms statewide has increased significantly since 2012; the number of gyms in the State of New York increased from 1,739 in 2012 to 1,864 in 2013. Historic establishment data from the U.S. Census Bureau and the IHRSA is summarized in Table 8.

(Source: IHRSA—Annual Industry Data Survey of the Health and Fitness Industry.)

The number of fitness centers in The Company's region is going to continue to grow. According to data from the New York City Board of Standards and Appeals ("NYCBOSA"), the number of permits issued for "Physical Culture Establishments," which is defined as "a health club or other business where customers go to exercise or to care for their bodies," increased significantly over the past three years. Historic permits granted by the NYCBOSA are summarized in Table 9.

## EXHIBIT 6.2 Industry Section—Health Clubs

(Source: New York City Board of Standards and Appeals Online Database, <<http://www.nyc.gov/html/bsa/html/decisions/decisions.shtml>>.)

In 2012, the number of permits issued increased from 23 to 29, representing the highest number over the seven-year period from 2006 to 2012. In 2013, the number of permits issued increased to 47 and through June 11, 2014, the number of permits already totaled 29, indicating that the city is on pace to have another record year in terms of permits issued.

According to an article in *The Wall Street Journal*, in the future, “gyms and boutique fitness businesses in Manhattan may be as convenient as the neighborhood coffee shop.” In 2013, the number of leases signed for gym and studio space in Manhattan more than doubled to 22, from the nine that closed in the previous year according to data tracked by Cushman & Wakefield. Savanna, a real estate private equity firm, signed a lease for Blink Fitness to take space on the ground and second floors of 31 Penn Plaza. The gym is part of Savanna’s overall efforts to transform the building since its acquisition in 2011. According to Kevin Hoo, vice president at Savanna, “Having an amenity in the building may form a part of a tenant’s choice to lease office or other space at the building, especially if health and well-being is an important part of its workforce culture. Also, this type of amenity, helps drive additional foot traffic for adjacent retailers who may also be looking to rent the property.”

The Company also faces competition from residential real estate developers. Gyms have evolved into an amenity that lends a competitive edge, much like balconies or rooftop decks. According to a spokeswoman from Related Cos., which bought the Equinox chain in 2006, a survey of tenants revealed that the “number one most valued amenity to them is a fitness amenity.” The same has happened at commercial buildings.

Fitness operators are able to take flexible approaches in neighborhoods where prices are high. Boutique studios specializing in a specific regimen rely on selling classes rather than memberships and often take smaller spaces of 3,000 to 9,000 square feet; much less than the 15,000 to 20,000 square feet required by a traditional gym. According to Jeffrey Roseman, an executive vice president at Newmark Goodman Knight Frank who has represented Blink in Manhattan, “Clearly you can’t compete in rent with a Starbucks or Coach.”

While the number of gyms in the New York City area are expected to increase in the near term, these gyms will face the challenge of rising retail rents throughout the region. Retail rental prices in New York City have risen in conjunction with strong retail demand. Asking retail rents by submarket in Manhattan are presented in Table 10.

(continued)

**EXHIBIT 6.2 Industry Section—Health Clubs** *(continued)***TABLE 10 Prime Q1 2014 Asking Retail Rents By Submarket**

Location	Asking Rent Per Square Foot/Year	% Growth (5 Years)	% Growth (1 Year)	Short-Term Vacancy Trend
Lower Fifth Ave. (42nd to 49th)	\$1,057	77.3%	-2.8%	Down
Upper Fifth Ave. (49th to 60th)	2,618	48.5%	-0.5%	Stable
Madison Avenue	1,466	54.8%	20.5%	Up
SoHo	456	89.2%	7.8%	Up
Third Avenue	276	N/A	5.7%	Up
Times Square	2,407	321.5%	8.3%	Up
Upper West Side	380	10.5%	8.9%	Up

Lower Manhattan	250	N/A	5.9%	Up

\*Newly created statistical submarket.

(Source: Cushman & Wakefield, Marketbeat Retail Snapshot, Manhattan, NY Q1 2014.)

Asking rents for retail space have grown significantly in certain submarkets of Manhattan over the past five years. In some submarkets, asking rents are in excess of \$1,000 per square foot. Positive real estate indicators also are occurring in the other boroughs. Out of the five boroughs, Manhattan actually witnessed the lowest gains in terms of new retail square footage from 2004 to 2014. During this time period, new retail square footage increased by just 0.4 percent while The Bronx, Queens and Staten Island posted 7.3, 13.5 and 12.5 percent increases, respectively. Brooklyn experienced the greatest increase in retail square footage, expanding 14 percent.

After the economic recession in 2008, a major growth market within the New York City region emerged. According to a November 2013 report from IBISWorld, after the 2008 financial crisis, “consumers became more budget conscious which stimulated demand for low cost gym memberships with few amenities.” This trend led to the emergence of the low cost fitness center sector which is populated by companies such as Planet Fitness, Retro Fitness, Blink Gym and Crunch.<sup>2</sup>

Over the past several years, Blink has also rapidly penetrated the local market. The brand, owned by Equinox which has historically focused on the luxury sector, is expanding rapidly throughout the five boroughs, Long Island, Westchester and New Jersey. Since 2011, Blink has opened 24 gyms and the company plans on doubling that number over the next 12 to 18 months. Its “opening season” list includes six more Blink locations during the first half of 2014 in Brooklyn, The Bronx, Queens, as well as Union and Jersey City in New Jersey. By comparison, Equinox, which has 21 locations in Manhattan and Brooklyn and five in Westchester and on Long Island, is scheduled to open just two new clubs this year. The Blink gyms, which lack amenities such as swimming pools and saunas are scalable and can be opened much more quickly than the full service Equinox gyms.

**EXHIBIT 6.2 Industry Section—Health Clubs**

According to industry consultant Rick Caro, president of Manhattan-based Management Vision, Blink is entering markets where typically a high-end club would not go. It is also raising the population of gym users beyond fitness buffs. Part of Blink's formula is to put its branches not just where people live, but also near transit stops and retail hubs. For instance, one of its newest locations in Astoria, Queens, is right next to the subway station and a major shopping district.

The low cost segment of the industry is known as high volume/low price, as the objective is to generate a large volume of members by offering affordable prices and controlling costs. In the case of Blink, instead of buying mid-level equipment like some of its competitors, Blink buys the newest and best equipment so it does not have to replace it as often. The company is able to do this because of Equinox's parent The Related Cos, which is one of the country's largest real estate and property management firms. The real estate parent also gives Blink an edge with site acquisitions.

The low cost segment of the fitness industry is hardly wide open. According to Eric Casaburi, CEO of Retro Fitness, Blink "is trying to play in a very crowded market with Planet Fitness and Crunch."

Retro Fitness is a franchise operation founded in 2004 which has gyms in 13 states, but is heavily concentrated in the New York area where it has about 80 locations. The company expects to add 20 to 25 clubs in the metropolitan area this year, including its first Manhattan site. According to Casaburi, "we can compete better because we know what we're doing. They're (Equinox) newbies at this part of the game. If they hired me as a consultant, I would tell them not to leave the sandbox they're familiar with because there are tons and tons of sand crabs."

Planet Fitness is focused on the low cost segment of the fitness industry. Planet Fitness is the fastest growing full-size health club in the United States, as the company opened 149 new clubs and signed more than 200 new franchise agreements in 2013. With more than 750 locations nationwide, Planet Fitness has more than tripled in size in the last five years alone, from 242 clubs in 2008 to 749 at the end of 2013. According to Brian Belmont, executive vice president of development and operations,

2013 was a record year for Planet Fitness' growth: Not only did we open the most locations in the company's history, more than 90% of new clubs were opened by existing franchisees which reinforces their confidence and commitment to growing the brand. We also opened our 700th club in the chain in Stockton, CA. We look forward to continuing our strategic and aggressive growth in 2014, opening clubs in both new and existing markets, and providing more and more people with access to an affordable, high-quality and non-intimidating fitness experience that only Planet Fitness can provide.

Planet Fitness' strategy is to target the non-fitness buffs who are looking to live a healthier lifestyle. According to co-founder and chief executive Chris Rondeau, most health clubs cater to the roughly 15 percent of Americans who consider themselves health nuts and love to work out. Planet Fitness's goal, on the other hand is to attract the much larger percentage of people who want to be healthier but may only use the gym a few times per month.

In order to accomplish this, Planet Fitness has mixed fitness with fun through its monthly pizza nights and bagel breakfasts on the second Tuesday of the month. Its facilities have mostly bright yellow and purple equipment, with an emphasis on cardio and weight-lifting machines. To keep costs down, the company omits amenities offered by more upscale gyms, such as juice bars and personal trainers.

Going forward, Planet Fitness does not have any plans to change its business model. According to Rondeau, the \$10 price tag and the uncompetitive atmosphere are the two big reasons Planet Fitness has been able to differentiate its product.

*(continued)*

**EXHIBIT 6.2 Industry Section—Health Clubs** *(continued)***SUMMARY AND OUTLOOK**

The Company will operate in a challenging environment in the near term. The health and fitness industry, particularly in The Company's territory, is highly competitive and competitive pressures are expected to strengthen in the near term. There has recently been significant increases in the number of permits issued for fitness centers and the number of leases signed for gym and studio space in New York City. Furthermore, The Company's competitors within the region have similar plans for expansion over the next several years, which would cause further crowding in an over-saturated market. In addition to direct competition, The Company faces a significant amount of indirect competition from boutique fitness studios and fitness centers located within apartment and office buildings. With retail rent rates increasing within the region, there has been an increased demand for smaller space, which has contributed to the emergence of boutique fitness studios such as Soul Cycle, Fly Wheel and Pure Barre.

Following the financial crisis of 2008, consumers became more budget cautious. This created a significant growth opportunity for the low cost segment of the fitness industry. Companies such as Planet Fitness, Blink and Retro Fitness were able to capitalize on this opportunity and have expanded operations throughout the region. Continued expansion at this rate could prove to be difficult going forward, not only due to competitive pressures, but also increasing rents for retail space throughout the region. Based on all of these factors, the growth outlook for The Company is modest and uncertain.

**Author's Note**

I have intentionally omitted footnotes from this section. I figured that you could live without them. In the real report, there were many.

The industry analysis will vary depending on the amount of information available, as well as the impact that it might have on the valuation subject. Obviously, the example in exhibit 6.2 contains a considerable amount of information. But think about this: While valuing a company in this industry, didn't this analysis cover everything that you can think of that may have been important? I hope so. Otherwise, we spent a considerable amount of time for no reason.

**Subject Company Analysis**

Item number one on the Revenue Ruling 59-60 hit parade tells us to consider the "nature of the business and the history of the enterprise from its inception." In other words, where has the company been and how did it get there? In this situation, the valuation analyst is looking to analyze not only the company's financial statements, but also the entire business operation. Of course, the financial statement analysis is an important component of the process, but at this stage in the valuation process, the valuation analyst is attempting to determine how effectively the company is being run. The analyst is also determining what risk factors are associated with the company and how they would affect the rate of return that an investor would require if a transaction were to be consummated. Box 6.2 captures some of the more common questions raised when performing a subject company analysis.

**SWOT Analysis**

A commonly used method of assessing the qualitative factors of a company is a SWOT analysis. SWOT stands for strengths, weaknesses, opportunities, and threats. This analysis provides the framework for identifying the internal and external factors

**BOX 6.2****Frequently Asked Subject Company Analysis Questions**

- How does the subject company compare with the entire industry? Is it a large player or a small player in the industry?
- Is it in its infancy, or is it mature?
- Has the company kept up with technology?
- What percentage of market share does the subject company have?
- Does the subject company distribute its products locally, regionally, nationally, or internationally?
- Are there alternative products available in the marketplace that may affect the future of the company's goods and services?
- What is the management structure of the company? Is the business highly dependent on one or a few key people?
- Is there a succession plan for management?

that affect a company's ability to do business. The SWOT analysis should be conducted within an organized framework such as what is shown in table 6.1.

<b>Strengths and Weaknesses</b>	<b>Opportunities and Threats</b>
Financial capital	Industry—Marketplace
Physical capital	Industry—Competitive forces
Human capital	Industry—Suppliers
Customer capital	Political
System capital	Economic
Organizational capital	Sociocultural
	Competitors

The manner in which the valuation analyst proceeds with a SWOT analysis will depend on the budget to perform the assignment. The first stage of a formal SWOT analysis is collecting input from the subject company's management team. The results are then tallied to determine the mean and standard deviation of management's opinions, which can subsequently be ranked according to the average scores. Personally, statistics make me nervous. Later in this book, I am going to explain some stuff about statistics. In the meantime, there are automated systems that allow the data from management to be processed, or the data can be computed in a spreadsheet program. Because the emphasis of this book is the small- to mid-sized company, I am assuming that the valuation analyst does not have the budget for this part of the analysis; therefore, I am not going to discuss this any further. Just be aware that there is software available if the valuation analyst needs it. We are going to concentrate on the qualitative analysis in this area.

In the next stage of the analysis, the analyst needs to build an understanding of management's input. For example, if management identifies the company's financial resources among its strongest qualities, the analyst needs to consider why that is the case. In this instance, the answer may be the company's cash reserves, ability to borrow, or access to equity financing, among other factors.

Finally, the analyst works with management to determine what implications the company's strengths, weaknesses, opportunities, and threats have on strategy, risks, future growth, and financial performance. This will help the valuation analyst to better understand the company's outlook.

The SWOT analysis has often been praised for its easy-to-understand approach to assessing a company's strength within an industry. However, it has also been criticized for its overly simplistic process. (I happen to like simple.) From a strategic planning standpoint, today's analytical processes are becoming increasingly complex and sophisticated, which can offer significant insight into a company's situation and outlook above and beyond what might be concluded through a SWOT analysis. Nevertheless, from a valuation standpoint, the SWOT analysis often can provide the framework needed to determine where a company sits within an industry and compared to its competitors.

Many variations on the SWOT analysis have been developed over the years. One variation appeared in Business Strategy Review, referring to the "Telescopic Observations" (TO) strategic framework.<sup>1</sup> TO addresses specific factors that affect a company's operating environment and operations from a high level view to one that is most relevant to the subject company. Exhibit 6.3 illustrates the TO framework.

<sup>1</sup> Panagiotou, George, *Business Strategy Review*, "Bringing SWOT into focus," 2003, Vol. 14, Issue 2, p. 8–10.

- S – Substitute Products and Services

You'll notice that some of the factors considered by the Telescopic Observation framework are also considered in Porter's Five Forces. In most cases, a thorough Strengths, Weaknesses, Opportunities, and Threats analysis paired with a Five Forces analysis will cover close to all of the industry and company-specific factors relevant to a valuation.

(Source: Panagiotou, George; van Wijnen, Riëtte [2005] 'The "telescopic observations" framework: an attainable strategic tool', *Marketing Intelligence and Planning*, Vol. 23, No. 2, pp. 155–171 [17].)

Ultimately, in looking at the strengths and weaknesses of a company, the valuation analyst should be able to explain what the company does well as opposed to what it does poorly. The competitive advantages and disadvantages of a company's current assets (tangible and intangible) are also important to consider. The analyst should know what aspects of the company's operations can be improved and whether the company needs new equipment, technology, or facilities to accomplish this. Does the company currently have, or can it gain, access to the financial resources to invest in its improvements? Does the company have the resources to withstand a downturn in business or survive an unforeseen negative event? These are all talking points during a management interview.

Another important aspect of a company's strengths and weaknesses is the existence of a corporate goal, strategic direction, and positive corporate culture. A company with stable employees working toward a common goal can typically utilize resources and capitalize on opportunities more effectively than one with no employee loyalties and no direction. A strong corporate culture also allows a company to attract and retain higher quality employees.

The market in which a company operates is very important to its success. To this point, the analyst attempts to identify the opportunities and threats relevant to the subject company. Changes in the company's current market can present opportunities if the company is positioned to take advantage of them. Potential expansions into new markets and geographic locations may also need to be considered. Changes in technology can reduce costs or increase efficiencies in the subject company as long as the subject company has the ability to invest in it. Many of the opportunities discussed in the preceding paragraphs can become threats to a company if the company is not able to take advantage of them. If an opportunity exists but the subject company is unable to capitalize on it, competitors may take advantage and gain market share. Similarly, advances in technology can allow competitors to operate more efficiently and offer lower prices, which means it can

take customers from the subject company if the subject company is unable to invest in the same technology. Changes in regulatory requirements and customer demand may also force a change in a company's products. If the company is unable to invest in its product to meet the change, it likely will have a significant impact on its ability to do business.

The answers to the many questions that the valuation analyst needs to have answered will serve dual purposes. The first purpose is to demonstrate that the valuation analyst understands the nature of the business, as well as what makes the business run. The second purpose, once again, is to perform a risk assessment of the subject company. What we are trying to do is determine whether the valuation subject is similar or dissimilar, or more risky or less risky, than other companies in the industry. Factors that the valuation analyst will analyze include the products and services offered by the company, customer base, suppliers, management, operations, and ownership structure. A good portion of this information will fit nicely into the history and nature of the company section of the valuation report. This will also assist the valuation analyst in developing market multiples, discount rates, and capitalization rates.

## Financial Analysis

The purpose of the financial analysis is to review the subject company's performance with respect to other companies, its industry peers, or itself. Comparing the subject company to its peers helps the valuation analyst assess whether the company is more or less risky in relation to its peer group. Comparing the company to itself allows the valuation analyst to determine how the company has performed in the past. This can help give the valuation analyst an idea of future trends that may occur.

During the financial analysis, the valuation analyst attempts to identify unusual items, nonrecurring items, and trends. An attempt should be made to explain what happened and why it happened. If there is a departure from the norms of the industry, this should also be investigated and explained.

The following analytical tools are used by the valuation analyst:

- Comparative company analysis
- Common size financial statements
- Financial ratio analysis
- Comparative industry analysis
- Trend analysis
- Operational analysis

## Comparative Company Analysis

Most business valuation analysts will request at least five years of financial information about the subject company. I like to request six. This way, a five-year cash flow for the subject company can be calculated. The amount of data will depend on the facts and circumstances of each assignment. However, a good rule of thumb is to ask for enough years of data to cover a complete business cycle. This will allow the valuation analyst to create a spreadsheet looking for trends that may have occurred, as well as inconsistencies in the reported data.

I cannot emphasize strongly enough how essential it is for the valuation analyst to seriously consider how much information to request. If the analyst was doing a valuation as of the end of 2011, for many businesses, 2011, 2010, 2009, 2008, and possibly 2007 (when the recession officially started) were pretty bad years. If the only information the analyst looked at were these five years, he or she most likely would be valuing the company at its low point in the economic cycle. Assuming that the company survived, the future may be much better than these years indicate. One way to determine this would be to request financial information for the years 2002–2006 also. Of course, sometimes it is difficult to get older financial information from the client. The valuation analyst can only hope that the client is a pack rat.

## Common Size Financial Statements

The use of common size financial statements is an excellent way to analyze the subject company with respect to other companies of different sizes. By presenting the data as percentages, the size differentials are eliminated between the subject company and its peer group. We are not ignoring size in selecting guideline companies; however, using percentages allows the valuation analyst to make a comparison in relative terms (for example, cost of goods sold as a percent of sales). A common size analysis also allows an analyst to identify relative trends (for example, expenses relative to sales and current assets to total assets). Exhibit 6.4 illustrates a common size analysis taken from an actual report. In this illustration, industry information was used as a comparison to the valuation subject.

### Author's Note

Some sources use average balance sheet figures, whereas others use year-end data in the calculations of ratios. Make certain that the valuation analyst is consistent in the calculations to ensure that he or she is using the same basis when comparing ratios with industry sources. Also, make sure that the ratios used from the comparative data are those that best match the time period of the valuation.

### EXHIBIT 6.4 Common Size Financial Analysis

Another financial analysis tool is to look at a company's common size financial statements. A common size balance sheet depicts each value as a percentage of total assets. Common size statements are used to look at trends in a company's financial position, as well as to compare the company with industry data.

In order to compare ABC Lumber to industry data, we determined the appropriate Standard Industrial Classification (SIC) code for ABC Lumber. A description of ABC Lumber and the services it provides was included in an earlier section of this report. Based on this description, we determined that ABC Lumber is best described by the following SIC code.

#### **5031 LUMBER, PLYWOOD, AND MILLWORK**

Establishments with or without yards, primarily engaged in the wholesale distribution of rough dressed and finished lumber (but not timber); plywood; reconstructed wood fiber products; doors and windows and their frames (all materials); wood fencing; and other wood or metal millwork.

We located composite industry data in the MicroBilt Corporation's Integra Financial Benchmarking Data (Integra). Integra compiles its database from 31 proprietary and publicly available sources. The database consists of information of more than 3.5 million companies in more than 950 industries.

The Integra database contained composite data for 8,809 companies classified in SIC code 5031. This was further stratified by sales range. Data for 1,066 companies with sales in the range of \$10 to \$24.99 million was included.

Table 3 presents the common size balance sheet for ABC Lumber, along with comparative data for companies classified within SIC code 5031.

Note: Figures may not add due to rounding.

An analysis of the common size balance sheet indicates that ABC Lumber's current assets as a percentage of total assets have increased consistently since 2011. Overall, ABC Lumber is significantly stronger than its industry counterparts in this category. However, ABC Lumber has a much lower percentage of fixed assets than its industry peers. This is because ABC Lumber's fixed assets are old and have been fully depreciated. However, the fixed assets are still in use by ABC Lumber.

On the liability side of the balance sheet, ABC Lumber appears to be weaker than the industry composite data. Although total liabilities have decreased from 64.08 percent of assets in 2011 to 58.79 percent in 2016, this is slightly higher than the industry, which has total liabilities of 56 percent of assets. However, this is due to the greater amount of debt ABC Lumber has.

The next step in the analysis was to look at ABC Lumber's historic income statements for 2011–2016. ABC Lumber's revenues have been fairly erratic over the period, decreasing from a high of \$12.3 million in 2011 to a low of \$10.3 million in 2014, and back up to \$11.4 million in 2016.

Despite the drop in revenues, ABC Lumber finished 2016 with net income of \$65,058. This was very close to the 2011 net income of \$66,518, which was the high for the period. Because revenues were lower in 2016 than in 2011, ABC Lumber has shown improvement in managing its expenses.

ABC Lumber's common size income statement was compared to industry composite data. This is presented in table 4.

**EXHIBIT 6.4 Common Size Financial Analysis****TABLE 4 Common Size Income Statement for the Years Ended December 31**

	2011	2012	2013	2014	2015	2016	INTEGRA
Total revenues	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%	100.00%
Total cost of sales	62.72%	64.97%	67.18%	67.12%	63.67%	62.86%	91.06%
Gross profit	37.28%	35.03%	32.82%	32.88%	36.33%	37.14%	8.94%
Total operating expenses	38.59%	35.61%	33.44%	33.40%	35.73%	36.30%	6.82%
Operating income (Loss)	-1.31%	-0.58%	-0.61%	-0.52%	0.60%	0.84%	2.12%
Interest expense	0.20%	0.46%	0.49%	0.47%	0.36%	0.35%	0.46%
Other income	2.25%	1.44%	1.62%	1.34%	0.00%	0.08%	0.33%
Income before taxes	0.74%	0.40%	0.52%	0.36%	0.25%	0.58%	1.99%
Income taxes	0.20%	0.09%	0.19%	0.11%	0.00%	0.01%	0.76%
<b>NET INCOME</b>	<b>0.54%</b>	<b>0.31%</b>	<b>0.34%</b>	<b>0.24%</b>	<b>0.24%</b>	<b>0.57%</b>	<b>1.24%</b>

Note: Figures may not add due to rounding.

The data in table 4 indicates that ABC Lumber's operating income as a percentage of revenue had been negative until 2015. Despite the turnaround, operating income is much lower than the industry counterparts. This is due to ABC Lumber's extremely high percentage of operating expenses. The industry average for operating expenses is 10.26 percent of revenues, whereas ABC Lumber's operating expenses were 36.30 percent in 2016. Over the six-year period, this percentage had not changed significantly. Some of the distinction is the classification of expenses; cost of sales for ABC Lumber is significantly lower than the industry, whereas operating expenses are higher. However, management has indicated that their expenses might be higher than the industry because of ABC Lumber's commitment to service. This causes a higher investment in payroll.

## Financial Ratios

The use of financial ratios allows the valuation analyst to analyze the subject company in terms of liquidity, performance, profitability, and leverage. These ratios are compared against industry data, guideline company data, or both, for the assessment of risk. Some ratios are more meaningful in different industries, but the analysis is essentially the same. For example, you would expect the inventory turnover ratio for a perishable food business to be greater than that for an automobile dealership. A description of some of the more common ratios follows.

### Current Ratio = Current Assets ÷ Current Liabilities

The current ratio measures the margin of safety that management maintains to allow for the inevitable unevenness in the flow of funds through the current asset and current liability accounts. A company needs a supply of current funds to be assured of being able to pay its bills when they come due. This ratio shows the company's ability to pay for its ongoing operations in the short term. A company's liquidity is essential to its good credit, its ability to grow with its own funds, and its ability to pay dividends to its owners.

### **Quick Ratio = (Cash + Marketable Securities + Accounts Receivable) ÷ Current Liabilities**

Quick assets include cash, marketable securities, and accounts receivable. Presumably, these items can be converted into cash quickly at approximately their stated amounts, unlike inventory, which is the principal current asset that is excluded from this calculation. The quick ratio is, therefore, a measure of the extent to which liquid resources are available to meet current obligations. This ratio tends to be a better measure of the company's short-term liquidity, particularly if cash needs to be generated quickly to pay bills.

### **Cash to Current Liabilities = Cash ÷ Current Liabilities**

Cash and cash equivalents are the most readily available assets with which to pay liabilities. This ratio indicates whether the subject company has a strong enough cash position to meet its short-term obligations. This ratio can also assist the valuation analyst in determining whether the subject company is carrying excess cash on its balance sheet. Excess cash may show a poor use of current assets by management. I wish that I had the problem of having excess cash. My kid made sure that never happened!

### **Accounts Payable to Inventory = Accounts Payable ÷ Inventory**

Businesses generally purchase inventory on credit. The ratio of accounts payable to inventory measures the extent to which a company's inventory is financed by the suppliers of that inventory. A low ratio may indicate that management is not taking advantage of the credit terms available from suppliers. When the ratio is used in conjunction with inventory turnover ratios, it might also indicate a high level of inventory being carried by the company.

### **Accounts Payable Payout Period = Accounts Payable ÷ (Cost of Goods Sold ÷ Number of Days)**

The accounts payable payout period measures the timeliness of paying suppliers. This figure is related directly to the normal credit terms of the company's purchases. This ratio allows the valuation analyst to consider the company's ability to obtain favorable terms from vendors because of good creditworthiness.

### **Debt to Equity = Total Liabilities ÷ Net Worth**

Debt is risky because if creditors are not paid promptly, they can take legal action to obtain payment, which, in extreme cases, can force the company into bankruptcy. The greater the extent to which a company obtains its financing from its owners, the less worry the company has in meeting its fixed obligations. The debt-to-equity ratio shows the balance that management has struck between debt and owners' equity. A proper capital structure should include a portion of debt because debt has a lower cost of capital. Different industries have different debt-to-equity relationships.

### **EBIT to Total Assets = Earnings Before Interest and Taxes ÷ Total Assets**

Earnings before interest and taxes (EBIT) to total assets is an important return-on-investment ratio that provides a profit analysis based on earnings before interest and income taxes. This ratio is best compared with a company's annual interest rate on borrowed funds. If the ratio of a firm's EBIT to total assets is higher than its weighted average cost of capital, the ratio is favorable.

### **Times Interest Earned = EBIT ÷ Interest**

The times-interest-earned ratio measures the number of times that the earnings before interest and taxes will cover the total interest payments on debt. The result indicates the level to which income can decline without impairing the company's ability to meet its interest payments on debt. If the ratio falls below 1.0, the firm is not generating enough earnings to cover the interest due on loans. This ratio indicates the financial risk of the company.

### Average Collection Period = Accounts Receivable ÷ (Credit Sales ÷ 365)

The average collection period can be evaluated against the credit terms offered by the company. As a rule, the collection period should not exceed one and one-third times the regular payment period; that is, if a company's typical terms call for payment in 30 days, the collection period should not exceed 40 days. Changes in the ratio indicate changes in the company's credit policy or changes in its ability to collect receivables.

### Inventory Turnover = Cost of Goods Sold ÷ Ending Inventory

Inventory turnover is an indication of the velocity with which merchandise dollars move through the business. An increase in the value of inventory may represent the additional stock required by an expanding business, or it may represent an accumulation of merchandise from a declining sales volume. In the latter case, the inventory turnover will decrease. A decrease in the inventory turnover ratio may be a significant danger signal.

### Inventory Holding Period = 365 ÷ Inventory Turnover

Some of the company's products come in and go out in a matter of days; other goods may stay in stock for six months or longer. The holding period differs for different products. Business managers and owners must be concerned with a holding period that is longer than necessary because of the high costs of tying up capital in excess inventory. On the other hand, reducing inventory levels too much could result in lost sales because certain products are not available when the customer wants them. The cost of carrying inventory has to be balanced against the profit opportunities lost by not having the product in stock, ready for sale. When inventory is financed or floor planned, interest rates influence the amount of inventory that may be carried. When rates are low, inventory balances tend to be high because there is not a great cost in carrying more inventory. When rates are high, the opposite is the case.

### Other Financial Ratios

There are many other financial ratios that can be considered by the valuation analyst. Profitability ratios are one group of ratios that are often considered by the valuation analyst. Some of the ratios that will be calculated may relate to the company's equity, whereas others relate to the company's invested capital. Invested capital is considered to be the company's long-term debt or nonworking capital debt plus the equity of the company. Because a proper capital structure will generally include an appropriate mix of debt and equity, some valuation analysts prefer to value the company in this manner. What this really does is allow the valuation analyst to value the company on an invested capital basis, eliminating differences in leverage between the subject company and the guideline companies. This becomes more important in the valuation of larger companies because the companies being used for comparison purposes may be publicly traded and have very different capital structures. We will discuss this further in chapter 9.

The return-on-equity ratio (also known as the *Dupont* analysis<sup>2</sup>) is considered to be one of the most important financial ratios because it measures profitability, turnover, and leverage all in one ratio. The Dupont formula allows the analyst to determine whether margin, leverage, or asset utilization (or some combination thereof) are driving returns to shareholders and, when compared to industry peer group data, how management manages these issues (better, worse, or differently) than the industry.

The mathematical breakdown of the return on equity ratio is as follows:

$$\frac{\text{Net Income}}{\text{Equity}} = \frac{\text{Net Income}}{\text{Sales}} \times \frac{\text{Sales}}{\text{Assets}} \times \frac{\text{Assets}}{\text{Equity}}$$

<sup>2</sup> For a really good article, see "Risk Assessment and the DuPont Formula," published in the October/November 2009 edition of *Financial Valuation and Litigation Expert*.

Another analytical tool used by valuation analysts is the compound growth rate. Compound growth rates are frequently used by the valuation analyst in the selection of guideline companies, pricing multiples, discount rates, and capitalization rates. Both revenues and net income (cash flow and assets can be used also) should be analyzed by the valuation analyst. The mathematical formula for calculating compound growth as a percentage is as follows:

$$\left( \sqrt[n-1]{\text{amount}_n \div \text{amount}_1} \right) - 1$$

The compound growth rate is calculated using historical data to give an indication of future growth. However, keep in mind that the formula considers only the first and last year being used in the analysis. Therefore, it does not calculate a change from year to year. Because of this, the valuation analyst must be careful in selecting the first and last years for the calculation. Ideally, the analyst wants to look at the business cycle (peak to peak or valley to valley) or look at a constant trend. When looking at growth, the valuation analyst should also examine the year-to-year changes. Over a longer period of time, this is very often more meaningful than the compound growth rate. Let's look at a simple example to illustrate this concept. Assume that Smith Company had sales as follows:

Year	Amount
2012	\$1,350,000
2013	1,675,000
2014	2,100,000
2015	2,200,750
2016	2,450,000

The 5-year compound growth rate for Smith Company is 16.1 percent (calculated as the fourth root of \$2,450,000 divided by \$1,350,000, or 1.1606, then subtract 1). If you do not know how to use a financial calculator, here are the keystrokes for an HP 12C calculator:

Enter	1,350,000	Press PV
Enter	2,450,000	Press CHS*, then FV
Enter	4	Press n
Press i		

\*CHS = change sign. One of the data points must be a negative.

You should get 0.160668, which you can round to 16.1 percent. If you do not have a financial calculator, you can do what I do: yell for a staff person to help (that only works if you are the boss and not a staff person or a student trying to do this stuff). A review of the increase in sales on an annual basis indicates that the company experienced growth in each year during this 5-year period. But what if the sales were as follows?

Year	Amount
2012	\$1,350,000
2013	6,450,000
2014	5,375,000
2015	3,900,000
2016	2,450,000

In this situation, the compound growth rate would be the same 16.1 percent, but look at the difference in the trend (figure 6.3).

**Figure 6.3 Compound Versus Year-to-Year Growth**

The solid line demonstrates the erratic year-to-year growth, whereas the dotted line illustrates the more consistent year-to-year growth over the same period. Pretty different, huh?

Clearly, although the beginning and ending points of this five-year period are the same in both series of numbers, the trends are dramatically different. The valuation analyst needs to pay attention to trends, not just a group of calculations. Remember that the goal is to be able to use this information to forecast the future and the risk of that future not occurring. What does the first illustration say about risk as contrasted with the second illustration?

In this instance, the valuation analyst would probably not use compound growth rates because they would have little relevance. The analyst must pay particular attention to the information and not just go through the motions of doing a series of calculations because he or she read a book or has a computer program that will calculate these ratios for her. *Analysis* means that the valuation analyst must *analyze* the information! Otherwise, financial analysis would be called “financial calculation.”

## Comparative Industry Analysis

The purpose of a comparative analysis is to compare the subject company’s operating performance with that of its peer group. This analysis is undertaken to determine the company’s position with respect to its peers. Is it more or less risky than its peer group? How well does the company perform compared with the peer group? Some of the more common sources for comparative data include the following:

- Trade association surveys
- MicroBilt Corporation’s Integra Financial Benchmarking Data
- Sageworks
- *Risk Management Association (RMA) Annual Statement Studies*
- *Almanac of Business and Industrial Ratios*
- *D&B Key Business Ratios*
- Bizminer
- Guideline companies

Comparative analysis is a useful tool for a valuation analyst to use only if the subject company can be meaningfully compared with either specific guideline companies or industry composite data. Common size financial statements and financial ratio analyses are much more meaningful if the results can be compared with guideline company results or industry data.

If a company is large enough, there may be publicly traded companies that can be used for this type of analysis. For smaller companies, and even sometimes for the larger companies, it is generally worthwhile to compare the subject to some form of industry data, whether it is obtained from a trade organization or one of the other sources previously mentioned.

I want to spend some time showing the type of information that can be obtained and used from a great resource. For many valuation analysts who value smaller companies, this is the ideal type of information to use as a basis for comparison. Let me demonstrate what I'm talking about. I am going to use the example of a restaurant.

Integra Financial Benchmarking Data is owned and maintained by MicroBilt Corporation and can be accessed at [www.microbilt.com/financial-benchmarking.aspx](http://www.microbilt.com/financial-benchmarking.aspx). After logging on, choose the type of report to be viewed (figure 6.4).

We use the Five Year Industry Report. After clicking on the link for the Five Year Industry Report, there will be an option to input a Standard Industrial Classification (SIC) code or North American Industry Classification System (NAICS) code. If the code is not known, push the button that allows the user search for the appropriate code. In addition to entering 5812 (the SIC code for Eating and Drinking Places), enter a sales range for the subject company to allow a better comparison to be made based on size. In this case, the screen looks like this (figure 6.5).

**Figure 6.5 MicroBilt Corporation's Integra Financial Benchmarking Data Sic Code and Sales Size Selection**

The screenshot displays the MicroBilt Integra Financial Benchmarking Data selection interface. The top navigation bar includes links for Contact us, Support, Advanced Search, a Keyword search input, and Log Out. Below this is the MicroBilt logo and navigation tabs for New Application, Application List, Preferences, and My Account. The main content area features a form with the following sections:

- Default**: Includes dropdowns for 'Default', 'Integra', and 'Five Year Industry Report'. Below are radio buttons for 'CLICK SINGLE' and 'SELECT PACKAGE', and a search input for 'Enter a Zip Code, Phone Number or Social Security Number'.
- Integra Industry Selection**: Contains a table for selecting NAICS or SIC CODE (with '5812' and 'Find' button), DESCRIPTION ('Eating and Drinking Places'), SALES(FIRMS INC) ('All Sales Ranges(57035)'), REPORT IS BEING PREPARED FOR ('XYZ Client'), and YEAR ('2015'). It also has radio buttons for PDF, HTML, and EXCEL.
- Business Information**: Includes fields for BUSINESS NAME, PHONE, FILE NUMBER/DSN, NUMBER, DIRECTION, STREET NAME, TYPE, STE, CITY, STATE, ZIP, DBA(DOING BUSINESS AS), TAX ID NUMBER, and E-MAIL ADDRESS.
- Notes**: A text area for entering notes.

At the bottom of the form are buttons for Submit, Save, and Clear.

(Source: Integra Information, a Division of MicroBilt Corporation.)

You may notice that there are 57,035 firms represented in this category. That is one of the reasons why I like this product. This amount of information makes it difficult to argue that the valuation analyst does not have a statistically valid sample size. Of course, not every SIC code has this many firms, but it is great when it does.

This screen allows us to choose the sales size that is pertinent to the valuation subject. In this instance, our subject has sales between \$500,000 and \$999,999. There are still 9,105 companies in this data set. If we click "Submit," we get a 9-page report that starts with this (figure 6.6).

(Source: Integra Information, a Division of MicroBilt Corporation.)

We get a five-year common size, comparative income statement. Notice that it breaks out items such as "Officer Compensation" and "Depreciation & Amortization." This may be very helpful when we have to adjust the financial statements for these items. We will talk about the adjustments in a little while, so be patient. After allowing us to compare the subject to the industry data, we then get the next page that provides us with the average dollars within the range of the companies based on the sales range selected previously. This allows us to see where the subject company falls with respect to size (figure 6.9 on the following page).

Two pages of financial ratios, 64 in total, provide the valuation analyst a more detailed financial analysis than he or she could ever have dreamed about. If the analyst cannot analyze the subject company upward, downward, and sideways, then I'm at a loss.

This is probably the most comprehensive product that I have ever seen for this type of information. What I also like about this product is that the ratios are calculated in the manner in which I was taught to calculate them in school. Turnover ratios use the average of the years, rather than only the year-end from one year. *RMA Annual Statement Studies* only calculates the ratios based on the end-of-year figures. It is just not right! However, every so often, I come across a SIC code that Integra does not cover, and so I use RMA or another data provider. When I do, I calculate the ratios in the same manner as RMA or the other data provider so that the comparison is based on consistent data.

The financial ratios even reflect a Z score under the risk category. If you are like me, you are probably wondering what this is. The *Z score* is a financial distress (or solvency) prediction model. In assessing a company's level of financial distress or solvency, 4 ratios are used together, and each ratio is weighted. The following weighted averages are used: working capital to total assets + net worth to total debt + net worth to total assets + operating income to total assets. A score greater than 2.90 is preferred, and a score less than 1.23 indicates significant risk of bankruptcy. Because you are probably thinking that a valuation analyst probably does not use this stuff, I have included a small section from a recent report that discusses Z scores. See exhibit 6.5.

### EXHIBIT 6.5 Z Score Analysis

In order to further analyze The Company's financial condition, the analyst performed a calculation of The Company's "Altman Z-Score" on an adjusted basis. The *Altman Z-Score* is a credit-strength test that gauges a manufacturing company's likelihood of bankruptcy. This methodology was originally devised by Edward Altman, a professor at New York University in the 1960s, for publicly traded manufacturing companies. In 2002, Altman created a revised formula that could be used for private companies, which is shown below.

$$\text{Z-Score} = ([\text{Working Capital/Total Assets}] \times 0.717) + ([\text{Retained Earnings/Total Assets}] \times 0.847) + ([\text{Operating Earnings/Total Assets}] \times 3.107) + ([\text{Book Value of Equity/Total Liabilities}] \times 0.420) + ([\text{Sales/Total Assets}] \times 0.998)$$

In general, the lower the score, the higher the chance of bankruptcy. For example, a Z-Score greater than 3.0 indicates financial soundness, whereas a Z-Score below 1.23 suggests a high likelihood of bankruptcy.<sup>1</sup> Based on The Company's adjusted financial ratios, The Company's Z-Score was calculated as follows:

$$\text{Z-Score} = (-0.097 \times 0.717) + (0.62 \times 0.847) + (-0.14 \times 3.107) + (0.47 \times 0.420) + (0.98 \times 0.998) = 1.21$$

A Z-Score of 1.21 indicates that the likelihood of bankruptcy for The Company is high. The Z-Scores for the Integra peer groups were 3.1, 2.15, and 2.92 for NAICS codes 313210, 313230, and 314999, respectively. The Company's weak Z-Score is further indication that it is basically insolvent and has a high risk of bankruptcy.

**Author's Note: The subject company actually filed for bankruptcy a week before trial. It is definitely better to be lucky than good!**

<sup>1</sup> See [www.investinganswers.com/financial-dictionary/financial-statement-analysis/altman-z-score-5188](http://www.investinganswers.com/financial-dictionary/financial-statement-analysis/altman-z-score-5188) (accessed June 1, 2015).

*Integra Financial Benchmarking Data* can be downloaded to Excel from the Internet. We wrote a macro in Excel that imports the data directly into our valuation model. No more data entry! Another cool thing. As with all databases, there are small annoying inconsistencies that arise from time to time. The valuation analyst must make sure he or she understands these discrepancies before using the data, especially if the analyst is going to be cross-examined in a litigation assignment. If the data does not look right, call the vendor and speak to someone.

Before we move off the topic of financial ratios, one other item needs to be raised. Frequently, the subject company financial statements have to be normalized (discussed in the following paragraphs) for economic adjustments that are necessary to present the subject company from the point of view that the willing buyer would be purchasing. This raises an issue: Should the valuation analyst use the unadjusted or adjusted figures to perform the financial analysis and compare the results against the industry group? The answer depends on the facts and circumstances of the valuation, as well as the nature of the adjustments that are made. Sometimes, we compare both the unadjusted and adjusted to the industry group. How is that for being definitive? All kidding aside, when the adjustments being made are significant enough to change the outlook of the subject company, we are more likely to compare both sets of data and highlight the fact that the adjusted figures are more meaningful for that analysis.

## Trend Analysis

The purpose of a trend analysis is to compare the subject company's performance over the past several years. The exact number of years used in the analysis depends on the facts and circumstances of each individual case. Although five years is the number commonly used, it is not always the correct number. Ideally, the period of years should cover a normal business cycle for the subject company. Certain industries may require the analysis to include many more years. There also will be times when the company has changed its operations in the near past, and, as a result, a shorter period will be more meaningful. Always keep in mind that more data, if meaningful, will allow the analyst to perform a more meaningful analysis.

During the trend analysis, the valuation analyst attempts to identify positive and negative trends affecting the company. The valuation analyst should review this data with the goal of determining the future prospects of the company based on historical growth patterns and based on the company's normal operations. This is a good time to identify items that are nonrecurring or excess items that will be removed during the normalization process and not considered in the forecast of future net earnings or cash flows.

Computer spreadsheet programs are an easy and efficient way to set up a trend analysis. The data entry can be viewed year by year to determine what is going on. It is also a good way to make sure that the data entry from year to year is consistent. For example, if there is an expense for four out of five years, what happened in the year that is blank? Did that expense not exist for a particular year, or did the company have two different accountants who classified items differently? Or for that matter, did the person who did the data entry categorize four years as "contribution expense" and the fifth year as "donations?" Obviously, these items should be treated consistently for the analysis to be meaningful.

## Operational Analysis

The purpose of performing an operational analysis is to determine information regarding the quality and stability of the earnings or cash flow from the business. The valuation analyst should be mindful that an equity investor is concerned with the ability of the subject company to provide earnings, cash flow, or both, so that he or she will obtain a return on investment (for example, dividends).

Some important components of this process include an analysis of (1) gross profit, (2) discretionary costs, and (3) financial statement consistency.

## Gross Profit Analysis

An analysis of the cost of goods sold will provide the valuation analyst with information about the gross profit that the company has been able to achieve. Because the selling price of the goods is dictated by competition, the company's gross profit should be in line with the industry's. The subject company must produce an adequate volume of sales if it is to cover its operating expenses.

A gross profit analysis is also a useful tool for determining if the inventory is properly valued or if there is unreported income. Although there is a difference between a valuation analyst and a forensic accountant, there are times when one professional may perform both functions. Let me share with you an example of how this analysis can affect a valuation. We valued a pharmacy that also sold liquor. The store never took a physical

inventory, and we found out from one of the owners that there was cash payroll. Our gross profit analysis is shown in exhibit 6.6.

### EXHIBIT 6.6 Gross Profit Analysis

To account for the significant amounts of cash not recorded by the company, as well as the ending inventory being calculated based on a gross profit percentage rather than a physical valuation, the valuation analyst has recalculated gross profit based on industry gross profit percentages. Using these industry averages, we can estimate the amounts of gross revenue and net income that ABC Drug Stores, Inc. (ABC Drugs), should have had each year.

In order to reflect the gross profit percentage of ABC Drugs, we have relied on industry data from MicroBilt Corporation's Integra Financial Benchmarking Data. To accurately calculate a gross profit percentage, we utilized data from both the drug store industry (SIC code 5912), and liquor store industry (SIC code 5921). The Integra data consisted of 1,050 drug stores with revenues between \$2.5 million and \$5 million, and 3,621 liquor stores with revenues between \$250,000 and \$500,000. The gross profit information is as follows:

Integra Gross Margins	2012	2013	2014	2015	2016
Drug stores	28.00%	27.60%	27.30%	27.00%	26.70%
Liquor stores	25.00%	24.60%	24.20%	23.80%	23.40%

The preceding gross margin percentages are then applied to the percent of revenues ABC Drugs received from the sale of drugs or liquor in each year. The breakdown of ABC Drugs' revenues by type is as follows:

ABC Drug Revenue Breakdown	2012	2013	2014	2015	2016
Drug revenues	91.10%	88.09%	88.58%	87.20%	86.97%
Liquor revenues	8.90%	11.91%	11.42%	12.80%	13.03%

Multiplying the revenue percentages by the industry gross margin figures in each year results in a weighted margin for drugs and liquor. Totaling the two figures in each year results in a weighted gross margin for ABC Drugs based on industry gross margins, and ABC Drugs' revenue breakdown by product type. The margin calculations are as follows:

Gross Margin Percentage Calculation					
	2012	2013	2014	2015	2016
Drug margin subtotal	25.51%	24.31%	24.18%	23.54%	23.22%
Liquor margin subtotal	2.23%	2.93%	2.76%	3.05%	3.05%
Gross margin percent	27.74%	27.24%	26.94%	26.59%	26.27%
Gross margin less 10%	24.97%	24.51%	24.25%	23.93%	23.64%

## EXHIBIT 6.6 Gross Profit Analysis

After calculating the gross profit margins relative to ABC Drug Stores, the valuation analyst applied a 10 percent discount to those figures in order to account for economic and industry-specific risk related to ABC Drug Stores. Based on the company's operation in a low-income area, which includes a significant number of customers utilizing government prescription plans such as Medicaid and the overall competitiveness of the retail pharmacy industry, especially within the metropolitan region in which ABC Drugs operates, a 10 percent discount was determined to be appropriate.

To account for the significant amounts of cash not recorded by ABC Drugs, as well as the ending inventory being calculated based on a gross profit percentage rather than a physical valuation, the valuation analyst has recalculated gross profit based on industry gross profit percentages. Using these industry averages, we can estimate the amounts of gross revenue and net income that ABC Drugs should have had each year.

Using the calculated weighted gross profit margin percentages, the estimated amount of cost of goods sold, as a percent of revenues, can be calculated. These figures are as follows:

Cost of Goods Sold Percentage Calculation					
	2012	2013	2014	2015	2016
Revenue %	100.00%	100.00%	100.00%	100.00%	100.00%
Less: gross profit %	24.97%	24.51%	24.25%	23.93%	23.64%
COGS %	75.03%	75.44%	75.75%	76.06%	76.36%

The preceding cost of goods sold percentages are then used to calculate the gross profit adjustment necessary to reflect the approximate amount of revenue that ABC Drugs should have achieved in each year. The gross profit adjustment for each year is listed in the income normalization table. With the addition of the gross profit adjustment to annual historic revenues and the cash payroll adjustment, the valuation analyst has reasonably calculated the annual revenues ABC Drugs attained each year.

A word of caution if attempting an analysis similar to this one: A good SIC or NAICS code is required for the subject company. I have seen too many valuation analysts use SIC or NAICS codes that have so many unrelated types of businesses included in the data that the results become flawed.

## Discretionary Costs

Several items included in the company's income statement may be discretionary and should be investigated by the valuation analyst. Some of the common items to be reviewed are repairs and maintenance (have they been deferred, or are there items that should have been capitalized?), R&D (is the company's policy to continue spending an equal amount on R&D, or is there a measurable payback for past R&D?), and advertising (is the company spending too much for too little?).

An analysis of discretionary costs will almost always be performed by a willing buyer because that individual will be interested in knowing how much of the company's expense structure can be done away with to produce the maximum return to him or her. Because of the synergies that the buyer will bring to the transaction, merger and acquisition valuations will also look to the level of discretionary costs that can be eliminated.

## Financial Statement Consistency

Just as an auditor looks for consistency in financial reporting, the valuation analyst should analyze the financial statements for consistency from period to period. The valuation analyst must pay particular attention to the company's accounting policies or possible changes in accounting principles. If the company has an aggressive capital expenditure expensing policy, the company's balance sheet will be understated for those assets

that were expensed, rather than capitalized. Not only does this understate the value of the balance sheet, but it also destroys the usefulness of many of the financial ratios calculated, common size analyses, and cash flow projections.

Consistency should also be investigated during a trend analysis because a review of a spreadsheet of the past several accounting periods may highlight discrepancies that exist between the reporting periods. For example, the data in table 6.2 shows a valuation analyst's review of insurance expenses from 2012–2016.

	2012	2013	2014	2015	2016
Insurance expense	\$39,888	\$62,255	\$22,984	\$45,977	\$47,395

Reviewing the figures in table 6.2 for consistency reveals that something happened in 2013 and 2014 that warrants further explanation. An inquiry by the valuation analyst determined that in 2013, this “cash basis” company made a \$21,000 insurance payment that was for 2014. The owner decided to accelerate the expense into 2013 so that she could reduce her taxes for that year. Let's hear it for the matching principle! For non-accountants, the matching principle is a basic accounting convention that says that revenues and expenses should be matched to the appropriate time periods so that the financial results are in the correct period and are reported on a consistent basis.

## Financial Statement Adjustments

Before the valuation analyst can determine whether there will be the need to adjust the financial statements, he or she will have to assess the quality of the available financial information. While reviewing the historical financial statements, the valuation analyst must determine the answers to the following questions:

- Are the financial statements complete with all footnotes and supplemental schedules?
- Is there sufficient detail to make the information usable in the comparative analysis to the industry and market data?
- Are the financial statements prepared under generally accepted accounting principles (GAAP) (and, for that matter, does it make a difference)?

## Conversion of Cash or Income Tax Basis to GAAP

In assessing the quality of the company's financial statement information, there may be times when adjustments are necessary to convert the information presented to GAAP. More often than not, this will prove to be an accounting exercise that may not add any value to the valuation process. The decision about whether to make this conversion will depend on the information that the valuation analyst will be using for comparison purposes. For example, if the analyst is valuing a medical practice that reports on a cash basis and comparing the practice to other practices reported on a cash basis, why bother going through the exercise of converting the financial statements to an accrual basis? Most likely, the balance sheet will need to be adjusted for accounts receivable and accounts payable, but the impact on the income statement may be relatively immaterial. (I love talking accounting talk!) This will be discussed further in chapter 23, which covers valuing professional practices.

## Tax Return Adjustments

There will be many times when a valuation analyst will work from tax returns and not have the benefit of having financial statements (the client is probably too cheap to pay for this level of service). When this occurs, the valuation analyst needs to make the necessary adjustments to account for the different treatment of certain income or expense items between the tax returns and what would have been in the financial statements had they existed. For example, entertainment expenses are only 50 percent deductible on a tax return. But if it's a legitimate expense, 100 percent should be considered in determining net income for valuation purposes.

In order to address the differences between book and tax items, we modified our valuation model to automatically adjust the appropriate lines from the historical data entry that may have been input from the tax returns. We allow the data entry to take place from the tax return, and we set up a separate sheet with formulas to combine those items that require combination. This way we do not have to worry about incorrect formulas and staff messing around with our templates. By the way, we password protect all fields that contain formulas. Nobody messes with my formulas! Even something like a Schedule C (sole proprietorship) should be adjusted for differences in reporting. Make sure that all material items are accounted for.

By the time we get through the tax return data, we produce a financial statement that ties out to the “book income” rather than the “taxable income.” This may require certain items to be picked up from Schedule K on an S corporation or partnership tax return or Schedule M-1 adjustments. Once we get to a clean starting point, we are able to consider making any adjustments that may be deemed appropriate for the valuation. By reconciling these various figures, we are also creating a good audit trail for the initial figures. This way, we do not have to worry that a figure was entered incorrectly.

## Understanding Financial Statements for Valuation Purposes

Before we go too much further, let’s talk about financial statements for valuation purposes. Although this book is published by an accounting organization, many of the readers are not accountants. Although the accountants probably think that they do not need this section, please pay attention to it because it is essential to understanding business valuation. Understanding the financial structure of a business is essential to many of the decisions that a valuation analyst will have to make as he or she proceeds with the valuation process. The balance sheet of a typical business appears in figure 6.15.

**Figure 6.15**

	Assets	Liabilities & Equity		
	<b>Cash Assets</b> Cash Accounts Receivable Inventory Other Assets	<b>Current Liabilities</b> Accounts Payable Accrued Expenses Income Taxes Payable Other Current Liabilities		
<b>Net Working Capital</b> 	<b>Fixed Assets</b> Equipment Buildings Land	<b>Interest Bearing Debt</b> (includes current portion and short term notes payable)	 <b>Invested Capital</b>	
	<b>Other Assets</b> Investments Life Insurance	<b>Stockholders' Equity</b>  <b>Preferred Stock</b>  <b>Common Stock</b>		
	<b>Intangible Assets</b> Identifiable Non-identifiable			

The assets of a business typically consist of the tangible and intangible assets owned by the company, which include operating assets (those assets that are used in the company’s operations); excess assets (those assets that could be used in the operations but are owned in excess of the assets that the company actually needs to operate the business, for example, excess inventory because the business purchased a

large amount to take advantage of a closeout from its supplier); and non-operating assets (those assets that are not and will not be used in the ordinary course of conducting business, for example a personal airplane).

There may also be non-booked or unrecorded assets such as the intangible or other assets that are not recorded on the company's financial statements. Per GAAP, the internally generated assets of the company are expensed and not recorded on the company's balance sheet. There may also be discarded assets or fully depreciated assets that may still have value to the business, such as molds or old equipment.

Types of assets that are generally used in the business include the following:

- *Liquid assets.* These include cash, accounts receivable, securities, short-term notes, and the like.
- *Inventory.* These include raw materials, work in process, and finished goods.
- *Other current assets.* These include additional assets that are expected to be used in the normal operating year of the company (within the next 12 months).
- *Fixed assets.* These are generally considered to be the long-lived assets (machinery, furniture, computers, vehicles, and the like) used in the business. These assets are recorded at their original costs and are then depreciated over their estimated economic or tax lives. They remain at their originally recorded cost basis even if their value increases (such as real estate).
- *Other assets.* These assets generally include additional assets that are not expected to be used in the normal operating year of the company, tangible assets not used in the operations of the business, purchased intangible assets, intellectual property and goodwill, and long-term notes receivable.

The liabilities of the business typically consist of the following:

- *Current liabilities.* These are the short-term obligations generally payable within 12 months by the company. These obligations generally consist of accounts payable, accrued expenses payable, the current portion of long-term debt, payroll payable, and other short-term notes payable.
- *Long term liabilities.* These are the long term obligations generally not payable in the next 12 months. These obligations consist of bank debt, notes payable, mortgages payable, and loans from stockholders.

Liabilities of the company can be interest-bearing and noninterest-bearing obligations. Interest-bearing liabilities include bank debt, mortgages payable, and notes payable and may or may not include loans from stockholders. Noninterest-bearing liabilities include accounts payable, payroll payable, accrued expenses, and often, loans from stockholders. The general characteristics of bank loans, mortgage notes, and notes payable to third parties are that they are secured interests (specific assets are generally pledged as collateral) and they carry terms related to repayment schedules, interest rates, and covenants.

The ownership equity section of the company's balance sheet generally depends on the type of entity we are dealing with. In a sole proprietorship, the owner's investment is generally referred to as the owner's *net worth or equity*. The business does not have any retained earnings in the business because the business' profits are considered to belong to the owner. In a partnership, a partner's direct investment is referred to as *partner's equity*. Any profits retained in the business are combined with previous invested amounts into the one partner's equity account. In a limited liability company, the *members'* equity is similar to that of a partnership. Even if it is a single member limited liability company, there is a member's equity. In a corporation, the ownership investment is referred to as *stockholders' equity*. The stockholders' equity is not directly allocated to individual owners in the accounting records. Shareholders' equity consists of paid-in capital in the form of preferred or common stock. This represents the direct investments the stockholders have made in the company. It may also include preferred stocks that generally have preferences on dividends and distributions from the company, meaning that the common shareholders receive their dividends and distributions after the preferred shareholders. Preferred stocks most often have a specified return on investment. The final component of shareholders' equity is retained earnings, or the current year's net income (less any dividends paid) plus all prior years' retained earnings. The equity of the business is the owners' interest in the property after deductions are made for all liabilities.

Here is where the accountants need to stop napping. From a nonfinancial reporting perspective on the components of the balance sheet, assets are listed on the balance sheet from top to bottom in order of liquidity: cash, accounts receivable, inventory, fixed assets, and other assets. Working capital is the difference between the total amount of current assets and current liabilities. *Invested capital* (a non-accounting term) is the sum of the stockholders' equity or partners' or members' equity and the non-seasonal interest-bearing debt. Invested

capital represents the complete financing of the nonworking capital assets of the company. It includes both debt and equity. Interest-bearing debt is referred to as the *debt capital* of the business. The economic return to debt holders is *interest*, and the stockholders' (partners' or members') equity section of the balance sheet is referred to as the *equity capital* of the business. The economic return to equity holders is *profit*. Equity capital and debt capital enjoy different rights and risks and, therefore, generally have very different rates of expected returns.

Liabilities on the balance sheet are presented differently for financial reporting and invested capital analysis purposes. For financial reporting purposes, liabilities are separated into current liabilities (payable in the next 12 months) and long-term liabilities. The short-term portions of long-term debts are recorded in the current assets section along with noninterest-bearing debts like accounts payable and payroll payable. For analyzing a company's invested capital, the liabilities are separated into 2 categories: current liabilities and interest-bearing debt. Long-term debt without interest obligations normally should be adjusted to fair market value, which would, in effect, convert some of the debt repayment to interest expense.

I am going to discuss the concept of invested capital in much greater detail in subsequent chapters, but you need to be introduced to some of this stuff now so that it will begin to make sense later. In order to measure returns on invested capital, the analyst must consider the returns to both equity holders and debt holders. Income differences relate to the return on the difference between equity and debt or interest expense. Cash flow differences relate to the differences in income plus the differences in cash flow related to debt acquisition and repayment. Figure 6.16 shows the differences between equity and invested capital returns.

It is extremely important that you understand the difference between equity and invested capital because you will see that the valuation analyst is faced with the choice of valuing a company using one or the other. The valuation analyst needs to understand what this means in order to do the job properly. But have no fear, I am going to explain it soon.

**Figure 6.16**

<u>Equity Cash Flow</u>	<u>Invested Capital Cash Flow</u>
Revenue	Revenue
less Cost of sales	less Cost of sales
less <b>Operating expense</b>	less <b>Operating expense</b>
= Operating income (EBIT)	= Operating income (EBIT)
less <b>Interest expense</b>	
= Pretax income	
less <b>Income taxes</b>	less <b>Taxes on EBIT</b>
= Net income	= Net operating profit after tax (NOPAT)
plus <b>Depreciation &amp; amortization</b>	plus <b>Depreciation &amp; amortization</b>
= Gross cash flow	= Gross cash flow
less Increase in working capital	less Increase in working capital
less Capital expenditures	less <b>Capital expenditures</b>
+/- <b>Change in debt principal</b>	
= <b>Equity Net Cash Flow</b>	= <b>Invested Capital Net cash flow</b>

## Analysis of Historical Balance Sheets

Once the valuation analyst is pretty sure that all of the data is gathered and input into some form of spreadsheet program, he or she can use all of the analytical tools that I discussed before to try to understand more about the subject company's operations and its industry. Some of the more frequently encountered issues addressed in the historical balance sheet analysis are included in box 6.3.

Many of these questions can be answered by reading the notes to the financial statements (when they exist); many will also be answered during the management interview.

## Analysis Of Historical Income Statements

The income statement analysis is also intended to answer many questions. Some of the more frequent items addressed in the analysis can be found in box 6.4.

## Bardahl Analysis

One of the factors that a valuation analyst is often faced with is the determination of how much working capital is required for the

subject company's operations. Frequently, there may be excess working capital, which becomes a non-operating asset (explained shortly). However, there may also be a deficit of working capital, which may become a reduction in the value of the company. There are a

number of ways to analyze the working capital needs of the subject company. One such way would be to review industry data about companies or groups of companies, such as from MicroBilt Corporation's Integra Financial Benchmarking Data. This could give you an idea regarding the norm in the industry. Another way to test the working capital needs comes from a court case titled *Bardahl Manufacturing Corp.*,<sup>3</sup> which includes a formula that is easy to build into a spreadsheet program. Exhibit 6.7 presents a Bardahl analysis conducted for a manufacturer of steel products.

### BOX 6.4

#### Frequently Asked Historical Income Statement Questions

- What is the method of recognizing income and expenses?
- What are the company's sources of income?
- What is the breakdown of the revenues in terms of dollars and percentages? How have these changed during the period analyzed?
- Which of the company's products and services are proprietary? Does this affect income?
- Which products are purchased for resale?
- What are the company's main expenses? How have these changed during the last five years?
- How are expenses allocated to inventories?
- Which of the expenses are fixed, semi-fixed, or variable in relation to sales?
- What are the company's gross margins by product and service?
- Are there any deferred charges? If so, do they have any value?
- Is depreciation included in cost of goods sold?

### BOX 6.3

#### Frequently Asked Historical Balance Sheet Analysis Questions

- What is the minimum amount of cash or working capital required to operate the company? (See the discussion of Bardahl analysis in this chapter.)
- What is the status of accounts receivable (that is, condition, turnover, bad debt experience, reserve, and aging)?
- What are the amounts, terms, and collectability of officer and employee loans?
- How are inventories valued? How does the company determine inventory quantity and pricing at year-end?
- Does inventory cost include material, freight, labor, and overhead, where applicable?
- What are the company's operating and non-operating assets and liabilities?
- What is the policy for capitalization of property and equipment?
- What depreciation methods and lives are used?
- Have writedowns for obsolescence or costs in excess of net realizable value been made?
- What are the terms of all interest-bearing debt?
- What are the trends in payables and turnover ratios?
- What are the terms of all long-term liabilities?
- Are there any preferences for classes of stock, rights, warrants, or options, among others?

The income statement and balance sheet data (Lines 11–14 and 17–22) are historical financial statement figures.

**Row 25, Inventory Turnover**

This row is calculated based on the average inventory (current and prior years), divided by Cost of Goods Sold (current year).

**Row 26, Accounts Receivable Turnover**

This row is calculated based on the average accounts receivable (current and prior years), divided by Sales (current year).

**Row 27, Accounts Payable Turnover**

This row is calculated based on the average accounts payable (current and prior years), divided by cost of goods sold (current year).

**Row 28, Operating Cycle Percentage**

This row is calculated based on row 25 plus row 26 minus row 27.

**Row 30, COGS + Other Operating Expenses—  
Depreciation & Amortization**

This row is calculated as defined.

**Row 32, Necessary Working Capital**

This row is calculated as row 30 times row 28.

**Row 34, Actual Working Capital**

This row is calculated as row 21 minus row 22.

**Row 36, Excess Working Capital**

This row is calculated as row 32 minus row 34.

So, what does this calculation do? It calculates the amount of working capital required for a manufacturing company after considering working capital turnover ratios, the level of cash expenses, and the noncash charges. It estimates the amount of working capital that the company needs to sustain itself based on its normal operating results. In the preceding example, the subject company held no inventory balances because raw materials were purchased on an as-needed basis. Because this is a normal occurrence for this company going forward, the Bardahl analysis can still be used to measure the normal level of working capital. If the company was planning on purchasing and storing inventory in the future, a Bardahl analysis based on the historical balance sheet would not be relevant because the company's required levels of working capital would change. As I have said before, no single analysis can be blindly applied to every valuation assignment we work on.

The Bardahl analysis also highlights the high level of excess working capital held by the subject company (which, in fact, was almost completely tied to large amounts of affiliate receivables and payables). Any large excess needs to be explained and adjusted to arrive at a normalized level of operating working capital. This normalization process will be explained in the next section. Exhibit 6.7 uses the subject company's historical financial information. Needless to say, it is important to conduct a Bardahl analysis using the historical and adjusted financial statements. This will allow you to identify potential non-operating amounts of working capital and determine whether the subject company (on a normalized basis) has an adequate or excess amount of working capital. Just so you can see the effect normalization can have on working capital, I have provided you with our Bardahl analysis using the subject company's adjusted historical financial statements (as shown in exhibit 6.8).

38								
39								
40								

In this instance, we identified the affiliate receivables and payables as being non-operating in nature, and we removed them from the balance sheet. This had the impact of significantly reducing the excess working capital to a more realistic level.

Although the Bardahl formula is not the only manner in which to calculate excess working capital, it is a very useful tool, particularly for manufacturing companies. However, it needs to be modified for other types of companies.

## Normalization Adjustments

Once all of the historical financial information has been analyzed, any potential adjustments should be made. Financial statement adjustments, frequently called *normalization adjustments*, are intended to place the subject company's financial information on an economic basis. During this process, a "cleansing" of the financial statements takes place. This cleansing is intended to remove those items that the willing buyer would not necessarily take into consideration in assessing the income or cash flow of the company. Another reason for these adjustments is to make the subject company's financial statements more comparable to either other companies that will be used in the analysis or the industry peer group.

The adjustments made to the financial statements will depend on the valuation approach and on whether a controlling interest or a minority interest is being valued. Because a minority interest may not be able to affect a change in the company's financial position, it may be inappropriate to make such adjustments. For example, if the minority interest cannot set the rent paid by the company to a related entity, an adjustment should probably not be made to the income stream. There may be times, however, that an adjustment of this type might be made for the minority. For example, if the rent is so far from market that it does not reflect the economic substance of the transaction, certain shareholder valuations could warrant an adjustment. The facts and circumstances of whether to make the adjustment, as opposed to a valuation textbook, must dictate what the analyst does. Use common sense and good judgment.

These adjustments are designed to provide better comparability to similar types of businesses or business interests. The normalization process involves adjusting items in the financial statements that are not considered to be normal operating expenses of the subject business. The result should be economic financial statements, rather than those that are GAAP- or tax-oriented. Most often, the normalization adjustments that are made are categorized as (1) comparability adjustments, (2) non-operating or nonrecurring adjustments, or both, or (3) discretionary adjustments.

The term *normalization* has changed in the valuation literature over time. Z. Christopher Mercer, ASA, CFA, distinguishes between different types of normalization adjustments from the literature published previously. Mercer takes what used to be grouped as normalization adjustments and divides them into *normalizing adjustments* and *control adjustments*. In fact, he distinguishes between these two types of adjustments as follows:

- With normalizing adjustments, we attempt to adjust private company earnings to a reasonably well-run, public company equivalent basis. Normalizing adjustments can be further divided into two types to facilitate discussion and understanding. Normalization adjustments are not control adjustments.
- Control adjustments adjust private company earnings (1) for the economies or efficiencies of the typical financial buyer and (2) for synergies or strategies of particular buyers. Control adjustments can therefore also be divided into two types.<sup>4</sup>

Further, Mercer states that

Normalizing adjustments adjust the income statement of a private company to show the prospective purchaser the return from normal operations of the business and reveal a "public equivalent" income stream. If such adjustments were not made, something other than a freely traded value indication of value would be developed by capitalizing the derived earnings stream.<sup>5</sup>

<sup>4</sup> Mercer, Z. Christopher. *The Integrated Theory of Business Valuation* (Brockton, MA: Peabody Publishing, 2004), 146.

<sup>5</sup> *Ibid.*, 149. (Analyst's note for clarification: The reference to "capitalizing the derived earnings stream" would also apply to discounting a future benefit stream, whether cash flow or earnings, because the capitalization model is a shortcut that is derived from a discounting model.)

I like Mercer's description of normalization adjustments because it begins to differentiate between the types of adjustments that we encounter in our daily practice. Exhibit 6.9 provides part of an internal form that our firm uses to make certain that the analyst does not overlook the obvious.

### EXHIBIT 6.9 Partial Internal Checklist for Normalization

#### TRUGMAN VALUATION ASSOCIATES, INC. BUSINESS VALUATION INTERNAL CHECKLIST

Company Name: \_\_\_\_\_

Completed by: \_\_\_\_\_ Date Completed: \_\_\_\_\_

**INSTRUCTIONS:** This form is to be completed and should become part of the working papers. It is intended to ensure that important items are not overlooked. Only the information that is relevant to the valuation should be obtained. If the information is not relevant, write "N/A" in the space opposite the step. If information is missing or incomplete, the analyst should let an officer of the company know before attempting to prepare a valuation report. The "Comments" section on the last page can be used to document problems that were encountered or to highlight unusual matters for discussion with others.

#### BALANCE SHEET NORMALIZATION

	Yes	No	N/A
<b>Cash</b>			
1. Is there excess cash on the balance sheet?			
<b>Accounts Receivable</b>			
2. Has accounts receivable been included in the balance sheet? If not, why?			
3. Did you tax effect the accounts receivable?			
<b>Inventory</b>			
4. Is inventory included in the balance sheet?			
5. Is it reflected on a first in, first out basis?			
6. Is there any excess inventory?			
<b>Marketable Securities</b>			
7. Are these nonoperating assets that should be segregated?			
8. Have they been reflected at market value as of the valuation date?			
<b>Stockholder Receivables</b>			
9. Are these collectible?			
10. Are they legitimate borrowings or just accounting adjustments?			
11. Have they been written off?			
<b>Fixed Assets</b>			
12. Is there real estate included on the books of the subject company?			
13. Is it a nonoperating asset?			
14. Has it been appraised?			
15. Why hasn't it been appraised?			

**EXHIBIT 6.9 Partial Internal Checklist for Normalization**

	Yes	No	N/A
<b>Fixed Assets</b> <i>(continued)</i>			
16. Have all corresponding mortgages been treated consistently with the treatment of the real estate?			
17. Have all real estate related expenses been segregated on the income statement for possible normalization adjustments along with rent expense?			
18. Have machinery and equipment, furniture and fixtures, vehicles, and other items been appraised?			
19. If not, did we use our depreciation template to estimate fair market value?			
20. Do we need to make a depreciation adjustment on the income statement?			
21. If there is high appreciation in these assets, have we considered taxes in our analysis?			
<b>Other Assets</b>			
22. Did we write off intangible assets that will be revalued?			
23. Do we know what all of the assets represent in this category?			
<b>Accounts Payable</b>			
24. Did we include accounts payable on the balance sheet?			
25. Did we tax effect it?			
<b>Notes Payable</b>			
26. Are these notes at market rates of interest?			
27. Have noninterest bearing notes been reflected at FMV?			
28. Are any of the notes considered to be nonoperating?			
29. If notes are high, did we consider using a debt free approach?			
30. Does the debt-equity relationship compare to the industry data to allow a reasonable analysis to be performed?			
<b>Stockholder Payables</b>			
31. Are these legitimate?			
32. Should they be reclassified as equity?			

**INCOME STATEMENT NORMALIZATION**

	Yes	No	N/A
1. Was officer's compensation adjusted?			
2. If yes, did you consider if any adjustment was required due to retirement plan contributions?			
3. Are there officer's perquisites that need to be adjusted?			
4. Are there any nonworking family members on the books?			
5. Are there any other payroll adjustments necessary (for example, maid)?			
6. Have you considered the reasonableness of the following: <ul style="list-style-type: none"> <li>a. Automobile expenses</li> <li>b. Travel</li> <li>c. Entertainment</li> <li>d. Non-arm's length rent leases</li> <li>e. Depreciation</li> <li>f. Interest expense</li> </ul>			

*(continued)*

**EXHIBIT 6.9 Partial Internal Checklist for Normalization** *(continued)*

	Yes	No	N/A
7. Have you added back federal taxes before recalculating taxes on the adjusted income?			
8. Have you added back state and local taxes before recalculating taxes on the adjusted income?			
9. Have you adjusted all nonoperating income and expense items?			
10. Have you adjusted all non-recurring income and expense items?			
11. Have you made generally accepted accounting principles adjustments to make the statements more comparable to the guideline companies?			
Comments. (This section may be used to document problems that were encountered or to highlight unusual matters for discussion with others.)			

## Comparability Adjustments

Certain types of adjustments are designed to make the subject company more comparable to the guideline companies or industry group being used as a means of comparison. For example, if the subject company uses last in, first out inventory accounting, a switch to first in, first out (FIFO) may allow the valuation analyst to compare the balance sheet of the subject company with those of the guideline companies more appropriately if the guideline companies are using FIFO. Depreciation methods are another type of adjustment that fall into this category. In some instances, even officers' compensation can fall into this category. This is especially true when the officers of the closely held business are taking a level of compensation out of the business that is dramatically different from the market. I will address this in more detail in a little while.

## Non-Operating and Nonrecurring Adjustments

According to the *International Glossary of Business Valuation Terms*,<sup>6</sup> the definition of a *non-operating asset* is an asset that is "not necessary to ongoing operations of the business enterprise." This can also be the case for a non-operating liability. Many times, these assets or liabilities, or both, have income and expenses associated with them. An example of a non-operating asset is a condo in Myrtle Beach, South Carolina that is owned by ABC Shoes, Inc., a shoe store in Miami, Florida. ABC also has a mortgage against this property, which makes this a non-operating liability. Included in the income statement are the rental income and expenses associated with the condo. If our assignment was to value the common stock of ABC Shoes, Inc., we would first remove the asset and related liability from the balance sheet. Next, we would remove all income and expense items that relate to these non-operating assets and liabilities. We can now value the operations of the shoe store as a standalone business. However, because valuing the equity of the company is our assignment, we must then add back the fair market value of the non-operating asset and subtract the fair market value of the non-operating liability. After all, the buyer may purchase only the operations, but the equity includes all assets and liabilities.

<sup>6</sup> AICPA: *International Glossary of Business Valuation Terms*. AICPA, NY: 2008.

Another type of non-operating asset that is commonly encountered in a business valuation assignment is real estate that is owned by the business but that does not necessarily have to be part of the business. For example, a corporation that operates a restaurant and owns the real estate that the restaurant is housed in does not need to own the real estate. Therefore, in this type of situation, it is common to treat the real estate as a non-operating asset, build a fair rent into the normalization of the income statement, and value the operating entity as if it were renting its facility. There is no reason that a restaurant could not rent its premises, therefore, the real estate is a separate asset that should be valued apart from the operating entity. What the valuation analyst has to pay close attention to are those types of businesses in which the real estate is an integral part of the business. Some examples of this include funeral homes, ski lodges, and many manufacturing businesses.

Nonrecurring items are also adjusted during the normalization process because the willing buyer would not expect these income or expense items to be pertinent to him or her in the future. An example of a nonrecurring item would be a one-time \$1 million contract that resulted in a net profit of \$350,000. Because the willing buyer would not expect to realize the benefit of this contract, it should be adjusted.

## Discretionary Adjustments

The last group of adjustments that I will discuss is the most common type of adjustments made for small- and medium-sized businesses. Although some of these adjustments will be applicable to larger companies as well, they will more frequently be applicable to the smaller ones. *Discretionary adjustments* are those items that relate to expenses that are solely at the discretion of management, generally, the owners. Some of the more common items include the following:

- Officer's and owner's compensation
- Owner's perquisites
- Entertainment expenses
- Automobile expenses
- Compensation to family members
- Rent expenses (if not an arm's length lease)
- Interest expense
- Depreciation expense

There also may be other items included in this list, although you will probably find that the preceding items are the most common. Let's discuss each one so that you can gain a better understanding of why we make these adjustments. Remember that most of these adjustments will be appropriate only when controlling interests are being valued. However, there may be times when some of these adjustments may be appropriate for minority interests, as well. I will discuss this in more detail later.

## Officer's and Owner's Compensation

Smaller businesses frequently pay their officers or owners an amount equal to what the officers need to live, or what the businesses' accountants tell them to pay to reduce taxes. A common tax planning technique used among smaller businesses is to bonus out profit at the end of the year to eliminate taxable income. For certain types of businesses, for example, S corporations, the owner may choose to reduce his or her salary below market levels and merely distribute the profit because it will be taxed as ordinary income anyway. By not taking salary, the owner is saving payroll taxes. For partnerships, limited liability companies, and sole proprietorships, there may be no salary taken at all. In these entities, distributions or draw is often the manner in which the owners remove money to live on. Sometimes, businesses are doing so poorly that they cannot afford to pay their officers a reasonable wage. Keep in mind that the owner of a closely held business receives two forms of compensation. First, as an employee, that individual is entitled to a return on his or her labor (salary for the job being performed). Second, as an owner, that individual receives a return on investment (dividends or capital appreciation). Be very careful not to confuse the two.

The officer's compensation adjustment is intended to restate the economic income statement of the company to a basis that includes the amount of salary that would be necessary to attract others who are qualified to perform the duties required by the company. I usually put myself in the position of an investor who will have to hire a replacement for the present management. How much will I have to pay to replace management going

forward? Many factors should be considered in the determination of reasonable compensation. Among others, consider the types of duties, education, experience, the number of hours worked, and the geographical region of the country.

Further guidance for reasonable compensation can be obtained from tax court cases in which reasonable compensation was an issue. I stated this in the last three editions of this book, and I still believe it to be true that one of the best constructed judicial opinions in this area can be found in *Mad Auto Wrecking, Inc. v. Commissioner*.<sup>7</sup> This opinion is discussed in greater detail in chapter 27. In this opinion, Judge Laro addressed, one by one, many points that eventually led to the allowance of what would otherwise seem to be a substantial amount of compensation for the two officers in an auto salvage business that had gross revenues of about \$2 million. But as good as this case is, keep in mind that the requirements for compensation to be a deductible expense under Section 162 of the IRC (deductibility for income tax purposes) is different than the criteria to determine a reasonable level of compensation for the officers of the business on a prospective basis.

Where do you look for reasonable compensation? I've been wishing for the past few years that someone (other than me) would write a book on that subject! Well, guess what? Someone did. Kevin Yeanoplos and Ron Seigneur wrote a book for Business Valuation Resources called *Reasonable Compensation: Application and Analysis for Appraisal, Tax and Management Purposes*. If researched and analyzed properly, this can be a time-consuming exercise. Reasonable compensation can be obtained from numerous sources. Some are easier to find than others. I prefer salary surveys that break out the levels of compensation by individual, rather than as a percentage of revenues. As the valuation analyst performs industry research, it is generally a good idea to inquire whether the trade organization has a salary survey. That is always a good starting point. The best bet will be to compare the officers of the subject company with officers of other companies in the same industry. If the company is large enough, salary disclosure information from the proxy statements of public companies can be used.

If this information cannot be narrowed down from the trade associations, another good alternative is other types of salary surveys. However, I can't really say that we go to any book on a regular basis that is applicable to all of our valuations. In fact, there are very few books in our library that we go to for compensation information more than a handful of times throughout the year.

It seems that surveys for professional salaries are more readily available than corporate salaries. We finally broke down and subscribed to the Economic Research Institute's (ERI's) Salary Assessor database. Talk about pricy; it is \$2,389 per year for a single user license. However, ERI is a well-known database used by the IRS in reasonable compensation determinations. It has all types of neat stuff in it, but it hurts to write the check every year. I just don't sell enough copies of my book yet! However, even when we use this service, there are deficiencies that we encounter. Like anything in our field, its usefulness depends on the facts and circumstances of how we are using it, as well as what we are using it for.

Then, there are industry-specific resources. Some of the more common ones that we use include the following:

- *AICPA Small CPA Firm Compensation Survey*—accounting firms
- *BAI Bank Compensation Study*—banks
- *DataMasters Computer Industry Salary Survey*—IT professionals
- *LawJobs*—lawyers
- *In-House Counsel Average Salaries*—more lawyers
- *General Counsel Salary Survey*—more lawyers
- *Survey of Law Firm Economics* (Altman Weil & Pensa)—a lot more lawyers
- *Medical Devices*—medical device and diagnostic industry

<sup>7</sup> *Mad Auto Wrecking, Inc. v. Commissioner*, T.C. Memo 1995-153, RIA T.C. Memo P. 95153, 69 CCH TCM 2330.

- *PAS*—construction industry
- *Physicians Search*—free salary information based upon a bunch of salary surveys conducted by the Medical Group Management Association and the American Medical Association, among others, and did I say doctors?

Other sources of compensation include business journals, specialized salary surveys published by employment agencies, and employment agencies. Don't be afraid to make telephone calls to executive recruiting firms or headhunters to find out what compensation a specific position would command in the marketplace. If we use headhunters, we generally call two or three firms so that we can try to get a consensus of opinion. The valuation analyst should make sure to carefully document his or her sources.

As a last resort, I will use publications such as *RMA Annual Statement Studies* and similar publications, or I might even go to MicroBilt Corporation's Integra Financial Benchmarking Data. It is not that these options are bad, but they present officer's compensation as a percentage of revenues based on the financial information that they accumulate. It is not possible to answer questions about how many officers were surveyed or what part of the country the data is from. This information can be useful, however, as a means of spot-checking other sources for reasonableness. Exhibit 6.10 shows a section from an actual report that addressed reasonable compensation. There is another example included in exhibit 6.11 further along in this chapter.

## Owner's Perquisites

During the analysis of the company's financial statements, pay close attention to owner's perquisites. Many business owners will take as much income as they can out of their businesses, whether as salary or as fringe benefits (perks). These perks can range from retirement plans, life insurance, and disability insurance to health club memberships and sky boxes at sporting arenas. After all, why own a business if you can't enjoy the fruits of your labor? Well, besides the fact that many of these items are often buried so that our friends at the IRS (one hopes) will not find them, they are also considered to be another form of compensation to the owner of the business.

Part of the normalization process involves removing those items that are considered discretionary, which do not necessarily have to be paid to someone else who would be hired to replace the owner. If the company has a retirement plan, a health insurance plan, a life and disability insurance plan, or other fringe benefit plans that are offered to all other employees, these items may not be considered a normalization adjustment. However, if the owner is getting a greater benefit than everyone else, a partial adjustment may be required. Whether you add back these expenses may also depend on the salary survey that you use to determine reasonable compensation. Sometimes, the surveys include not only base salary information, but also total compensation, including perks. Be careful of double counting!

## Entertainment Expenses

Entertainment expenses are reasonable and necessary expenses for many businesses. However, we all know that many business owners deduct entertainment expenses that really do not have anything to do with the business. There may be times when the amount of entertainment expense differs significantly from industry data. In this situation, the valuation analyst must investigate the reason for the differences. Ask yourself: Would the willing buyer have to spend that much on entertainment? If you answer "No," you probably need to consider an adjustment. For some reason, I see this happen frequently when we value medical practices. Specialists seem to have an incredible amount of entertainment on the books. When was the last time your doctor took you to lunch? Although they have some legitimate meetings with colleagues, many of the entertainment expenses are really perks.

### EXHIBIT 6.10 Reasonable Compensation

An estimate of reasonable compensation was made for services rendered by the officers of the company. In order to estimate this amount, several sources were reviewed.

Public companies that were considered similar to ABC Company were analyzed to determine the level of compensation being paid to officers. We analyzed this data by dividing it among all of the publicly traded guideline companies from our search under the market approach (explained later in this report) and those companies with revenues under \$200 million. This was intended to get closer to the size of the company. Data was also gathered from the ERI Executive Compensation Assessor database, a database frequently used by the IRS.

The data compiled from these sources was as follows:

	2014	2015	2016
<b>Public Co. Proxies: Percentage of Revenues (All companies)</b>			
Average	0.45%	0.42%	0.38%
Median	0.32%	0.29%	0.32%
Options (% of companies with options)	59.00%	52.00%	65.00%
<b>Public Co. Proxies: Percentage of Revenues (Under \$200 million)</b>			
Average	0.69%	0.63%	0.62%
Median	0.58%	0.64%	0.73%
Options (% of companies with options)	50.00%	33.00%	50.00%
Median comp. per officer			
All companies	\$308,447	\$319,908	\$ 361,765
Under \$200 million	260,425	241,603	232,783
Compensation for 3 officers			
All companies	\$925,341	\$959,724	\$1,085,295
Under \$200 million	781,275	724,809	698,349
ERI (based on \$150 million)			
CEO			\$ 493,087
President			324,387
Vice President			229,324
			\$1,046,798
As a % of Revenues			0.70%

### EXHIBIT 6.10 Reasonable Compensation

The ERI data is relatively close to the level of compensation indicated that is based on all of the public companies that were analyzed. Although the level of compensation is greater than the compensation for the “Under \$200 million” group, the analyst believes that the greater profitability of ABC Company can support a higher level of compensation. Also, the public companies, on occasion, provide stock options as an additional feature of officers’ compensation.

As a result of this analysis, the analyst believes that compensation can reasonably be reflected at \$1.047 million for the most recent year. We have then deflated prior years by 3 percent.

## Automobile Expenses

Once again, be on the lookout for automobile expenses that are not business related. There are many businesses that require a vehicle for business use. However, the adjustments made during the normalization process are intended to remove the expenses related to nonbusiness vehicles (such as the husband’s, wife’s, son’s, daughter’s, boyfriend’s, aunt’s, uncle’s, or cousin’s). Don’t forget to look at other line items on the income statement besides automobile expenses for the total expenses attributable to the vehicle. Automobile insurance may be in insurance expense. Automobile repairs may be in repairs and maintenance. Gasoline may be in utilities. Make believe that you are playing hide and seek!

Sometimes, the automobile will be a necessary business expense, but the type of vehicle may cause the expense to be excessively high. In this situation, the valuation analyst should try to estimate the normal vehicle expenses for the business. Similar companies can be a good source for this data. My all-time favorite automobile adjustment came as a result of the valuation of a two-doctor neurosurgery practice. Each doctor had a Lamborghini on the books (at an average cost of \$155,000). When I questioned the doctors about the need for these expensive cars, they told me that in the event of an emergency, they needed to get to the hospital fast! Despite my laughing hysterically, I normalized the expense.

## Compensation for Family Members

There is nothing wrong with family members working for the business, as long as they really show up and their pay is reasonable for the services that they render. Frequently, the spouse is on the books so that a contribution can be made to an individual retirement account, although no services are rendered for the compensation. (Well, that may not be the spouse’s position on the services that are rendered! Certainly, no business services were rendered.) In other situations, children are on the books as a means to get spending money and college expenses to them in a lower tax bracket. When family members work for the business, the valuation analyst should check to see if the amount of compensation would be the same if it were paid to a nonfamily member. If my daughter performs secretarial services for my firm, she should not be compensated as the chief financial officer. Heck, I do not even get compensated that well!

## Rent Expense

Frequently, closely held businesses operate in a facility that is owned by the owners or a related entity and is leased to the business establishment. This is not a problem if the lease is at a market rate of rent. More often than not, the rent being charged is based on the mortgage payment that the owner is required to make. A market rental analysis should be obtained by the valuation analyst to support the fair rental value of the premises. This can be obtained from a real estate appraiser or a local realtor who is familiar with market rents in the area for that type of property. Another factor to consider, although not necessarily a normalization adjustment, is if a business is operating without a lease. Rent may be paid to an unrelated landlord at market rates, which would not require an adjustment to be made, but the risk associated with not having a lease should be built into market multiples, capitalization rates, or discount rates. Also, consider the difficulty of selling the business to a willing buyer if a lease cannot be obtained. This could cause the business to be less marketable.

## Interest Expense

An adjustment for interest expense may depend on whether the valuation analyst is valuing the equity of the company or the invested capital of the company. In an equity valuation, the interest expense adjustment may relate only to interest paid on non-operating liabilities. This could be interest on the mortgage on the condo in Myrtle Beach that we discussed previously. Because the asset was considered to be non-operating, all associated income and expenses, including interest, should be removed during the normalization process. The valuation analyst also must pay attention to loans from the owners of the business. If no interest is being paid to the owners, but the loans are legitimate loans in lieu of bank financing, the valuation analyst may need to impute interest expense as a normalization adjustment. On the other hand, if the interest being paid to the owners is excessive (12 percent when prime is 3.5 percent), an adjustment to reduce the level of expense may be warranted.

The valuation analyst should also pay attention to sizable amounts of interest related to debt used to finance excessive compensation and perks. A company may be borrowing for working capital and using the proceeds of the debt to pay the owners. A willing buyer would not be expected to incur this debt; therefore, it should be removed during the normalization process.

When the valuation analyst values the invested capital of the company, the interest is added back to determine the earnings available to the invested capital holders. This can be useful when the valuation analyst values companies that have different capital structures from those of the guideline companies. This is not truly a “discretionary” adjustment, but the discretion is on the part of the valuation analyst to value the equity or the invested capital. There is more about this in chapter 9.

## Minority Interest Valuations

The conventional wisdom in business valuation is that the valuation analyst should not make adjustments to the financial statements that could not otherwise be made by the interest being valued. For example, the minority interest owner cannot determine the level of compensation for the officers of the company. However, with that being said, let’s be practical when we consider the appropriateness of the adjustments for the assignment at hand.

Would it be reasonable to ignore an adjustment for officer’s compensation in the following circumstance? A parent owns and runs a business, takes \$1 million out of the company as salary (when the market rate of salary is \$200,000 for those services), and reduces the profits of the company to \$0. The purpose of the valuation is for a 10 percent gift to the child of the owner. First of all, the answer is NO. It does not matter under fair market value whether the gift is to the child or not. Under these circumstances, in most jurisdictions, a 10 percent owner, child or not, could probably bring an oppressed shareholder lawsuit against the controlling owner. Stripping the business of any dividend-paying capacity for the benefit of the controlling owner and denying the minority of dividends would constitute oppression, in my non-legal opinion. The legal remedy, at that point, might be for the minority owner to be bought out at *fair value*, providing a value based on the *control* value of the interest, rather than the *minority value*. This would require the valuation analyst to make the adjustment for compensation and value the entity based on its true profitability.

In other circumstances, it may be necessary to make certain adjustments to make the company appear more comparable to the guideline companies. If the controlling shareholder is taking too little salary out of the company and chooses to take S corporation distributions instead, a proper comparison to publicly traded C corporations may require a salary adjustment even for a minority valuation.

What I am saying is use your head. Do not just blindly ignore adjustments because the valuation literature indicates that the valuation analyst does not make adjustments for the minority. There may be facts and circumstances that require reasonable adjustments to be made. Remember that Mercer distinguishes between normalization adjustments and control adjustments. The financial statements may need to be normalized, and the adjustment should not be considered a control adjustment. In chapter 11, I indicate that the asset-based approach is generally not applicable for minority interests that cannot cause the liquidation of the assets to get

at the value of those assets. However, we use an asset-based approach frequently when valuing family limited partnerships, many of which are being valued for gifting of minority interests. Like I said, there are very few, if any, absolutes.

Exhibit 6.11 contains a sample normalization section from an actual valuation report.

The example shown in exhibit 6.11 is a good illustration of the normalization process because it shows many of the abuses that a closely held business owner tries to get away with. Many closely held business owners are not too terribly different from the client in this assignment. This is one of the factors that makes this business so much fun. And by the way, the owner of the business was our client.

Once the financial statements have been normalized, the valuation analyst uses the adjusted information as a basis for the valuation. This information can then be used to forecast the future operating results of the business and analyze the economic return to the owner. The valuation analyst should not use an average of the historical figures unless the outcome reflects the anticipated financial results of the valuation subject. Remember, valuation is a prophecy of the future!

As a general rule, I like to use the adjusted figures in addition to the unadjusted figures when performing my ratio analysis. This gives me not only the unadjusted ratios that can be compared with similar data, but also the adjusted figures that can be used to assess the economic future of the company. This becomes an easy task if you use computer templates that you write yourself.

### EXHIBIT 6.11 Sample Normalization Section from a Report

The next step in the valuation process is to normalize the income statement. The normalization is shown in table 4.

**TABLE 4 Normalization of Income for the Years Ended December 31**

	2013	2014	2015	2016
Historic Net Income (Schedule 2)	\$ 98,550	\$ 82,213	\$ 89,662	\$ (26,315)
Adjustments				
Revenues <sup>1</sup>		16,308	7,119	27,648
Inventory Adjustment <sup>2</sup>	—	—	292,272	(292,272)
Smith Manufacturing <sup>3</sup>	46,741	42,715	70,555	34,723
Interest Expense <sup>4</sup>	—	—	10,600	10,686
Officers' Compensation—Addback <sup>5</sup>	148,400	215,700	86,400	158,400
Officers' Compensation—Reasonable <sup>6</sup>	(205,351)	(211,703)	(218,250)	(225,000)
Professional Fees <sup>7</sup>	81,115	—	—	21,399
Moving <sup>8</sup>	14,671	1,500	—	—

(continued)

**EXHIBIT 6.11 Sample Normalization Section from a Report** *(continued)***TABLE 4 Normalization of Income for the Years Ended December 31**

	2013	2014	2015	2016
Auto Expenses—Addback <sup>9</sup>	23,433	28,045	18,611	35,042
Insurance—Automobiles <sup>10</sup>	3,515	4,703	4,824	4,658

Payments to Susan & Greg Johnson <sup>13</sup>	44,194	25,474	15,941	21,339
Health & Company Life Insurance <sup>14</sup>	6,754	7,907	9,478	10,351
Telephone <sup>15</sup>	4,441	4,942	2,593	2,636
Miscellaneous <sup>16</sup>	7,100	11,895	8,455	8,501
Loss on Sale of Assets <sup>17</sup>	—	24,264	—	—
Historic Income Taxes <sup>18</sup>	58,286	43,263	41,615	(25,140)
<b>ADJUSTED PRETAX NET INCOME</b>	<b>\$398,236</b>	<b>\$381,871</b>	<b>\$512,721</b>	<b>\$(166,926)</b>
Income Taxes <sup>18</sup>	149,856	143,698	192,937	(53,952)
<b>ADJUSTED HISTORIC NET INCOME</b>	<b>\$248,380</b>	<b>\$238,173</b>	<b>\$319,784</b>	<b>\$(112,975)</b>

1. John Johnson deposited monies received from a vendor in his personal account instead of in the business. This adjustment is intended to show these monies as company revenues.
2. In 2015, an outside inventory service was hired to take a physical inventory. However, they missed some inventory that was written off in 2015. The amount of the error was \$292,272 and was corrected in early 2016. As a result of this error, 2015 net income was understated, and 2016 net income was overstated.
3. Smith Manufacturing was set up to do embroidery work for the company until May 2016 when it was merged into the company. During conversations with Mr. Johnson, he indicated that while the market rate was about \$0.10 per piece for embroidery, the company was paying between \$0.15 and \$0.25 per piece. A hypothetical willing buyer would not incur this additional expense over the market rate. Therefore, this overage must be added back to bring this expense back to a fair market rate.

We were provided with a report showing all payments to Smith Manufacturing for the period 2013 through 2016. We applied a market rate percentage to the amounts based on the difference between what the company was paying compared to what the market was paying. This was calculated as follows:

Market piece price	\$ 0.10
What the company paid (average of \$0.15 and \$0.25)	\$ 0.20
Market rate percentage	$0.10/0.20 = 50\%$

### EXHIBIT 6.11 Sample Normalization Section from a Report

This market rate percentage was then applied as follows:

	2013	2014	2015	2016
Net payments to Smith Manufacturing	\$93,482	\$85,429	\$91,111	\$69,446
Market rate percentage	50%	50%	50%	50%
Adjustment	\$46,741	\$41,715	\$45,555	\$34,723

In 2015, there was an unidentified payment of \$25,000 made by the company to Smith Manufacturing. With no support for this payment, it has been added back in its entirety. This brings the net adjustment in 2015 to \$70,555.

- This is the interest associated with the non-operating shareholder loan. It is added back because a hypothetical buyer would not incur this expense.
- Officer's compensation has been added back in its entirety because a reasonable level of compensation has been determined in number 6 below.
- In order to estimate the amount of reasonable compensation, several sources were reviewed. *Executive Compensation Assessor*, a database available from Economic Research Institute, was the first source. We searched this survey for companies classified under SIC code 5023 in Miami, Florida, with sales between \$5,000,000 and \$20,000,000. We did not find any usable data in this database.

We then looked at the National Compensation Survey—December 2016 published by the U.S. Department of Labor. We reviewed data for private industry workers: mean hourly earnings for full-time and part-time workers by experience levels in Miami-Fort Lauderdale, Florida. Within this group is a subset called Management Occupations, with the highest work level in this subject being level 12. The hourly rate given was converted to an annual figure using 2,080 hours and is shown as follows.

\$ 96.92	per hour
× 2,080	hours
\$201,594	

We also reviewed salary information located at salary.com. This database provided total compensation (salary, bonuses, and benefits) for a top operations executive. The complete package amounted to \$349,701, consisting of salary of \$217,416, bonuses of \$65,065, with the balance representing other fringe benefits.

Finally, we reviewed MicroBilt Corporation's Integra Financial Benchmarking Data, which provides officer's compensation by SIC code as a percentage of sales. Officer's compensation for businesses operating in SIC code 5023 with sales between \$10 and \$25 million included an average compensation from 295 businesses at 2.2 percent in 2016. Using the company's 2016 revenues results in the following:

2016 Revenues	\$ 11,122,116
Officer's compensation as % of revenues	× 2.2%
Officer's compensation	\$ 244,687

(continued)

**EXHIBIT 6.11 Sample Normalization Section from a Report** *(continued)*

Recognizing that this SIC code is extremely broad, we believe that compensation can be considered from this data because it includes 295 businesses within the sales range of the company. It is also within the range of the other sources we reviewed.

As a result of our analysis, we believe that reasonable compensation should be estimated at \$225,000 with prior years being deflated by 3 percent.

7. Professional fees were materially higher in 2013 and 2016 as compared to the other years. An adjustment was made to reflect a more normal level of expense based on an average of the other years. These calculations are as follows:

2011	\$ 26,913
2012	27,228
2014	30,173
2015	20,320
Total	104,634
	÷ 4
Average expense	<u>\$ 26,159</u>

This average expense was then subtracted from the actual expense in 2013 and 2016 to arrive at the adjustment amount. This is shown in the following table:

	2013	2016
Actual expense	\$107,274	\$47,558
Average expense	26,159	26,159
Adjustment amount	<u>\$ 81,115</u>	<u>\$21,399</u>

8. Moving expenses are considered nonrecurring in nature and, therefore, are added back.
9. Auto expenses include car payments and other auto-related expenses for the Johnson family, as well as other employees. Legitimate business expenses were considered to be all expenses paid for Robert Jones (unrelated sales manager), and one car for John Johnson. Our addback is calculated as follows:

**EXHIBIT 6.11 Sample Normalization Section from a Report**

	2013	2014	2015	2016
Total auto expense	\$46,122	\$45,861	\$35,959	\$53,111
Less: auto leases				
Robert Jones	5,868	5,868	6,265	6,464
John Johnson	7,365	8,635	10,412	10,123
Less: auto expenses				
Robert Jones	106	—	—	—
Net auto expense	\$32,784	\$31,358	\$19,282	\$36,524
Other lease payments <sup>A</sup>	14,083	24,732	17,941	33,559
Net operating auto expenses	\$18,701	\$ 6,626	\$ 1,341	\$ 2,965
Allowable portion (50%)	9,350	3,313	671	1,483
Disallowed portion <sup>B</sup>	\$ 9,350	\$ 3,313	\$ 671	\$ 1,483
Addback <sup>A+B</sup>	\$23,433	\$28,045	\$18,611	\$35,042

A Total lease payments from the general ledger less the leases listed above.

B Since most of the remaining expenses pertain to John and Elizabeth Johnson, we have considered only one-half to be a necessary business expense.

10. Included in insurance expense are premiums related to the vehicles that were adjusted for as shown previously.

11. Various other insurance policies were paid by the company on behalf of the Johnsons. These expenses are summarized as follows:

	2013	2014	2015	2016
Homeowners, flood and disability	\$ 3,983	\$ 4,040	\$ 1,137	\$ 1,909
Officer's life	6,397	7,010	9,213	13,472
Auto, Greg Johnson (son)	—	840	—	—
Totals	\$10,380	\$11,890	\$10,350	\$15,381

(continued)

**EXHIBIT 6.11 Sample Normalization Section from a Report** *(continued)*

12. Credit card statements were reviewed and nonbusiness-related expenses were added back because these monies would be available to a willing buyer. The summary of our analysis is as follows:

	2013	2014	2015	2016
Specifically identified <sup>A</sup>	\$44,574	\$43,598	\$41,545	\$35,599
Estimated items <sup>B</sup>	398	455	—	—
Unidentified payments <sup>C</sup>	—	15,133	—	—
Costco <sup>D</sup>	7,645	9,446	14,546	12,165
Sam's Club <sup>D</sup>	3,206	4,074	6,405	3,251
Lands' End <sup>E</sup>	183	48	—	22
<b>Total adjustment</b>	<b>\$56,007</b>	<b>\$72,755</b>	<b>\$62,496</b>	<b>\$51,036</b>

- A. These items were specifically identified as being personal in nature. We reviewed every available credit card statement with management for the years 2013–2016. Some of the items that were considered as nonbusiness-related were as follows:
- Restaurants around the family residence
  - CVS Pharmacy
  - Nail salon
  - Animal hospital
  - Various clothing stores
  - Grocery stores near the family residence
  - Trips to Jamaica
- B. Over 230 credit card payments and the accompanying statements were analyzed to separate personal from business expenses. Only 2 statements are missing in the amounts of \$478 and \$628. We estimated the personal amount by the relationship between business and personal charges in those particular years.
- C. The unidentified amount consists of three payments made to credit cards that were not identified as business cards.
- D. In our discussion with management, it was indicated that a majority of charges at Costco and Sam's Club were personal in nature. After further discussion with management, 80 percent of charges were considered to be personal.
- E. Some items purchased at Lands' End (towels) were business-related. In order to account for this, 50 percent was added back. Overall, this amount was immaterial.
13. Wages paid to family members would likely not be incurred by a hypothetical buyer of the company. As a result, wages paid to Susan and Greg Johnson have been added back, along with the associated payroll taxes.

We were provided with W-2 forms for Susan, representing gross wages. Payroll taxes were estimated to be 8 percent of gross wages. This is calculated as follows:

**EXHIBIT 6.11 Sample Normalization Section from a Report**

	2013	2014	2015	2016
Susan Payroll				
Gross from W-2's	\$12,000	\$12,000	\$ 3,840	\$ 9,555
Taxes (8%)	960	960	307	764
Total payroll	\$12,960	\$12,960	\$ 4,147	\$10,319

In addition, in 2014 there were checks payable to Susan in the amount of \$720 that were also added back. We were also provided with W-2 forms for Greg, and again, estimated payroll taxes at 8 percent of gross wages. This is calculated as follows:

	2013	2014	2015	2016
Greg Payroll				
Gross from W-2's	\$28,920	\$10,920	\$10,920	\$10,203
Taxes (8%)	2,314	874	874	816
Total payroll	\$31,234	\$11,794	\$11,794	\$11,019

It was discussed earlier that Greg received paychecks in order to receive health insurance. In addition to this, Greg received payments as a vendor for his actual services rendered. These amounts were not added back because the company would have had to pay someone else to do what Greg did.

The total adjustment is calculated as follows:

	2013	2014	2015	2016
Total Susan	\$12,960	\$13,680	\$4,147	\$10,319
Total Greg	31,234	11,794	11,794	11,019
Grand Total	\$44,194	\$25,474	\$15,941	\$21,339

14. Health insurance and company-sponsored life insurance for Mrs. Johnson, Susan, and Greg were added back. The 2014 and 2016 health insurance invoices were analyzed; the 2015 paid invoices could not be found. The actual premiums for Mrs. Johnson, Greg, and Susan for 2014 and 2016, along with the observed pattern of increases were used to estimate the 2015 amount. This is shown in the following:

(continued)

**EXHIBIT 6.11 Sample Normalization Section from a Report** *(continued)*

<b>2016 Totals</b>	<b>\$7,510.00</b>	<b>\$2,619.00</b>	<b>\$10,129.00</b>

An estimate was made for 2013 using the average change in premiums from 2014–2016, which was 15 percent. The company-sponsored life insurance plan only showed premiums for Mrs. Johnson and Greg of \$9.25 per month for the years 2014 and 2015. The annual amount is \$222 and is assumed to be the same in 2013 and 2016. This amount is added to the health insurance expense to arrive at a total adjustment as follows:

	2013	2014	2015	2016
Health insurance	\$6,532	\$7,685	\$9,256	\$10,129
Life insurance	222	222	222	222
<b>Total adjustment</b>	<b>\$6,754</b>	<b>\$7,907</b>	<b>\$9,478</b>	<b>\$10,351</b>

*(continued)*

**EXHIBIT 6.11 Sample Normalization Section From a Report** *(continued)*

15. This adjustment shows payments made by the company on behalf of the Johnsons. These are non-operating expenses and, therefore, are added back. The amounts are as follows:

	2013	2014	2015	2016
BellSouth	\$1,993	\$2,558	\$2,198	\$2,479
T-Mobile	1,106	2,076	395	158
Voicestream	1,342	—	—	—
Direct TV	—	308	—	—
<b>Total</b>	<b>\$4,441</b>	<b>\$4,942</b>	<b>\$2,593</b>	<b>\$2,636</b>

16. The miscellaneous adjustments are as follows:

	2013	2014	2015	2016
Camp Havefun <sup>A</sup>	\$ —	\$ —	\$1,705	\$ —
Checks to Elizabeth Johnson <sup>B</sup>	—	3,744	—	—
Checks to John Johnson & Cash for Travel Expenses (50%) <sup>C</sup>	7,100	8,151	3,750	8,501
Checks to Cash in 2015 <sup>D</sup>	—	—	3,000	—
<b>Totals</b>	<b>\$7,100</b>	<b>\$11,895</b>	<b>\$8,455</b>	<b>\$8,501</b>

- A. This is a non-operating expense and, therefore, added back.
- B. Checks written to Elizabeth Johnson were considered personal in nature and have been added back.
- C. The checks written to John Johnson are largely travel-related. However, the company's records are relatively poor; therefore, we have added back 50 percent as being nonbusiness-related.
- D. In 2015, there was a \$3,000 check made out to cash that was signed by Elizabeth Johnson and charged to warehouse expense. Because no support for this check has been provided, the entire amount has been considered discretionary and has been added back.

17. Losses sustained from selling assets are considered to be nonrecurring and have been added back to better reflect the operating income of the company.

18. Historic income taxes have been added back, and corporate taxes have been recalculated based on the adjusted net income.

## Conclusion

You should now have a better idea about what the valuation analyst does with the data that he or she collects. By now, you should be getting the message that the valuation analyst performs a risk assessment with the data collected. This information can then be used in the determination of market multiples, discount rates, and capitalization rates.

The data collected and analyzed is critical to the valuation process. If the valuation analyst is not comfortable with analyzing the gobs and gobs of data that he or she will be collecting, he or she may want to reread some financial statement analysis textbooks. I hope, for his or her sake, he or she is okay with this stuff. Those types of textbooks are like watching paint dry—real excitement!

## Chapter 7

# Statistics for Valuation and Economic Damages

### Learning Objectives

As I said in the last edition of this book, I am going to do something that I never thought that I would do in my lifetime: discuss statistics in a textbook. I am not sure which is scarier, the thought that this is the fifth edition of my textbook or the fact that I am going to include a chapter on statistics. Before you decide to skip this chapter, I promise to keep it simple. I have to keep it simple because I cannot make it complex. As much as I hate to do this, statistics has become an important part of a valuation analyst's toolbox when performing business valuations and economic damage analyses. Therefore, in this chapter, I will discuss the following:

- Population and samples
- Discrete and continuous variables
- Frequency distributions
- Measures of central tendency
- Measures of variation
- Probability
- Correlation
- Number crunching
- Drinking the statistics Kool-Aid

### Introduction

Okay, so here it comes—statistics for the statistically challenged. An understanding of statistical theory and its application aids valuation analysts in analyzing company, industry, and market data. Statistics are often used to evaluate company performance over time and against some set of peer data or evaluate the predictability of market multiples and other valuation variables. It is also used in forecasting. Let's define some of the basic statistics stuff. I am not going to get too complicated here, probably because I can't.

So, what is *statistics*? Statistics is concerned with scientific methods for collecting, organizing, summarizing, presenting, and analyzing data. It is also used to draw valid conclusions and make reasonable decisions on the basis of such analysis. Notice the word *reasonable*.

### Population and Sample: Descriptive and Inferential Statistics

It is impossible to evaluate all the data that a valuation analyst comes up with when performing an assignment. For example, in collecting data concerning the characteristics of a group of objects, such as the numbers of defective and non-defective screws produced in a factory on a given day, it is more often than not impossible or impractical to observe the entire group, especially if it is large. For those of us who are accountants, we learned about the need to test inventory when conducting an audit. Instead of examining the entire group, called the *population* or *universe*, we examine a small part of the group called a *sample*.

A population can be *finite* or *infinite*. For example, the population, consisting of all screws produced in a factory on a given day, is finite, whereas the population consisting of all possible outcomes in successive coin tosses is infinite (either heads or tails, unless you can figure out how to get the coin to stand on its side).

If a sample is representative of a population, what is observed in a sample can be generalized to the population. Making these kinds of generalizations to an entire population by observing only a subset cannot be made with absolute certainty. There is always some risk of error. We see this in political surveys that report that some percentage of eligible voters will vote for a particular candidate. These surveys also include a margin of error. Because there is always some degree of error when making inferences from a sample to the population, we try to quantify this error. In economics and finance, the conventional standard is a 95 percent confidence level, which means there might be up to 5 percent probability of an error. The part of statistics dealing with conditions under which such inference is valid is called *inferential statistics* or *statistical inference*.

The area of statistics that seeks only to describe and analyze a particular sample without drawing any inferences about a larger group is called *descriptive statistics*. So far, so good?

Before we go too much further, let's talk about some important mathematical concepts.

## Discrete and Continuous Variables

A *variable* is a symbol, such as X, Y, or Z that can assume any of a prescribed set of values called the *domain* of the variable. If the variable can assume only one value, it is called a *constant*. A variable that can theoretically assume any value between two given values is called a *continuous variable*, otherwise it is called a *discrete variable*.

Let's put this in English. The number of children in a family can assume any of the following values: 0, 1, 2, 3, or 4, but it can never be 1.5 or 2.675. This is an example of a discrete variable. However, the height of one of those children can be 59 inches, 61.6 inches, or 72.243 inches, depending on the accuracy of measurement, which is a continuous variable.

## Frequency Distributions and Measures of Variation

We frequently gather raw data that has not been organized in any fashion. A simple example of this would be the set of profits of 100 benchmark companies obtained from an alphabetical listing of industry players. An *array* is an arrangement of the raw numerical data in ascending or descending order of magnitude. The difference between the largest and smallest numbers is called the *range* of the data. In other words, a measure of variation is the *range*, which is defined as follows:

**Range.** The range is the simplest measure of variation to find. It is simply the highest value minus the lowest value. Because the range only uses the largest and smallest values, it is greatly affected by extreme values, that is, it is not resistant to change.

When summarizing large amounts of raw data, it is often useful to distribute the data into classes or categories and to determine the number of individuals who belong to each class. This is known as the *class frequency*. A tabular arrangement of data by classes, together with the corresponding class frequencies, is known as a *frequency distribution*. And you thought that you bought a book on business valuation?

## Central Tendency (Mean, Median, Mode, and So Forth)

Measurements of central tendency include the following:

**Mean.** Also known as the arithmetic mean; this is also referred to as the *average*. The mean is probably the most common measure of central tendency. I hope you know this, but in case you don't, the mean is calculated by adding up all of the values and dividing it by the number of values. I am going to demonstrate all of these calculations in a little bit. Be patient!

**Weighted arithmetic mean.** A weighted arithmetic mean is just what it sounds like. It is the average of the data with weight being assigned to an array of the data. Very often, valuation analysts want to put the greatest amount of weight on the most current year and will weight each previous year with a lesser amount of weight.

**Median.** The median is another measure of central tendency that is frequently used. It is the 50th percentile of a distribution, the number in the middle of an array of numbers that are lined up in order. To find the median of a number of values, first order them, and then find the observation in the middle: the median of 4, 8, 10, 14, and 18. (Note that if there is an even number of values, one takes the average of the middle two: the median of 8, 12, 16, and 20 is 14.) The median is often more appropriate than the mean in situations in which the figures are skewed due to very high or very low values. These outliers can cause a mean to be really *funky*. By the way, funky is a technical term.

**Mode.** The mode is the most common value in a distribution and is the least often used measure of central tendency. The only useful bit of information that a mode provides is that it lets you know which figure shows up most often. The question you have to ask is how useful is that piece of information?

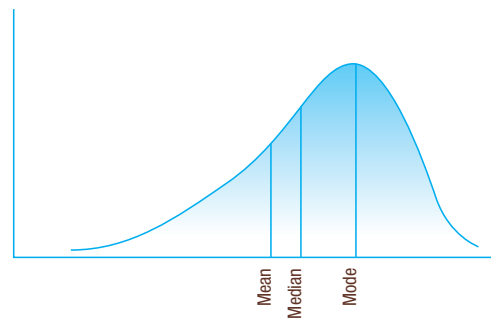

### Relation Between Mean, Median, and Mode

I illustrate the relative positions of the mean, median, and mode for frequency curves that are skewed to the right and left, respectively, in figures 7.1 and 7.2. For symmetrical curves, the mean, median, and mode will all coincide by often taking on the shape of a bell curve. A bell curve is just what the name implies, a curve that takes on the shape of a bell.

**Figure 7.1**

**Figure 7.2**

**Geometric mean.** The geometric mean of a set of numbers is the Nth root of the product of the numbers. The formula looks like this:

$$G = \sqrt[N]{X_1 \cdot X_2 \cdot X_3 \cdots X_N}$$

The geometric mean of 2, 4, and 8 would be calculated as  $G = \sqrt[3]{(2)(4)(8)} = \sqrt[3]{64} = 4$ . The geometric mean is a compound rate (for example, compound growth rate).

**Harmonic mean.** The harmonic mean is the reciprocal of the arithmetic mean of the reciprocals of the numbers. Now, doesn't that really help? The formula looks like it is something out of a horror movie, so I am going to spare you from seeing it. However, I will provide you with a simple example shortly. The *harmonic mean* is a better *average* when the numbers are defined in relation to some unit. The common example is averaging speed.

For example, suppose that you have 4, 10 mile segments to your automobile trip. You drive your car

- 100 miles per hour for the first 10 miles,
- 110 miles per hour for the second 10 miles,
- 90 miles per hour for the third 10 miles, and
- 120 miles per hour for the fourth 10 miles.

What is your average speed? Here is a spreadsheet solution:

Distance (miles)	Speed (miles per hour)	Time (hour)
10	100	0.100
10	110	0.091
10	90	0.111
10	120	0.083
40		0.385
103.80 Average Speed		

The harmonic mean formula (I know I said I was not going to give it to you) is

$$HM = \frac{n}{\sum_{j=1}^n \frac{1}{X_j}} = \frac{4}{\frac{1}{100} + \frac{1}{110} + \frac{1}{90} + \frac{1}{120}} = 103.8$$

Excel calculates this with the formula `=HARMEAN(100,110,90,120)`. Unfortunately, the formula will not work if the segments are not uniform.

## Relation Between Arithmetic, Geometric, and Harmonic Means

Unless you are really into statistics, you probably do not care. However, the geometric mean of a set of positive numbers is less than or equal to their arithmetic mean, but greater than or equal to their harmonic mean. Obviously, they can only be equal if all of the numbers are the same.

## Quartiles, Deciles, and Percentiles

If a set of data is arranged in the order of magnitude, the middle value is the median. But you know that already. The median divides the data set into 2 equal parts. Quartiles divide the data set into 4 equal parts; deciles divide the data set into 10 equal parts; and percentiles divide the data set into as many parts as you set up. In chapter 13, we will discuss data that is presented in deciles and percentiles. Frequently, we review data that reflects the 25th and 75th percentiles. These data points are the same as the first and third quartiles respectively.

Central tendency is used in valuation in a number of different ways. For example, when we perform a trend analysis, we frequently use common size financial statements. We benchmark the subject company against average data for a group of publicly traded guideline companies or a database like Microbit's Integra. The data that we are benchmarking against is frequently presented using central tendencies, whether it be a mean or a median. The calculation of pricing multiples is often done by using averages of the subject company's performance measures. For example, price to two--year average net income is a multiple that we may use in

the market approach. We also calculate market multiples from the average or median of the guideline companies, peer group data, or both. We will discuss multiples in chapter 9.

## Variation

The degree to which numerical data tends to spread about the mean is called the *variation* or *dispersion* of the data. The most common types of measures of dispersion are the range, mean deviation, semi-interquartile range, 10–90 percentile range, standard deviation, and variance. I am not going to cover all of them in this book, but any basic statistics textbook can be used to find them if you really have a burning desire to know about all of them. However, some of this information is important, so I am going to discuss the highlights in brief form. Some definitions of these other measures of variation are as follows:

*Standard deviation.* The most commonly reported measure of variability or spread of the data is the standard deviation. This is particularly true if the data is normally distributed, that is, in a bell curve. If a set of data is distributed some other way, standard deviation is a meaningless measure and is actually nonsensical in those distributions. Standard deviation is a way to describe or measure the dispersion of data away from the mean, but only if the data has a bell-shaped curve. Here comes the math: First, the deviations from the mean are calculated. Then, the deviations are squared. Next, the mean of the deviations is calculated. And because these calculations are so much fun, the square root of the mean is taken to obtain the standard deviation. Got that? I didn't think so. Neither did I, and I wrote this stuff. Relax, and I will do some number-crunching for you soon.

So, what information does the standard deviation tell us? It tells us how far the data is located from the mean. So, why do we care? We care because when data that is said to be normally distributed is reviewed, approximately 68 percent of the data (actually, 68.27 percent) lie within 1 standard deviation of the mean; approximately 95 percent of the data (95.45 percent) lie within 2 standard deviations of the mean; and approximately 99.7 percent of the data (99.73 percent) lie within 3 standard deviations of the mean. This gives us a pretty good idea of how much confidence we can have in the data. It's not really confidence about the entire data set; it's about confidence in something that we are trying to interpret from the data. That depends on what we're trying to do. For instance, when it comes to IQ, 68 percent of the population will be within 1 standard deviation on either side of 100.

Ninety-five percent of the population will be within 2 standard deviations plus or minus.

Graphically, the concept of standard deviation is illustrated in figure 7.3.

**Figure 7.3**

*Coefficient of variance.* The coefficient of variance is the degree to which a set of data points varies. Coefficient of variance is a way to standardize multiple measurements of standard deviation on different variables so that you can compare them. If I have price-to-sales multiples for several guideline companies, I can calculate the standard deviation, but I cannot compare that standard deviation to the standard deviation of their price to earnings multiple.

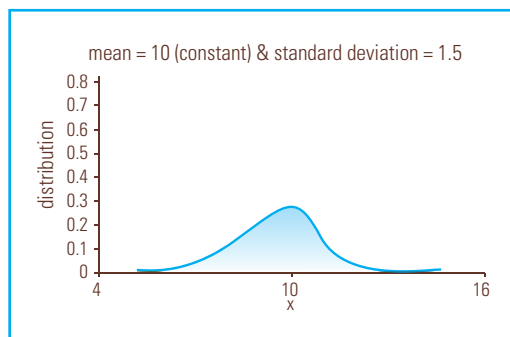

It is often called the relative standard deviation because it takes the mean (average) into account. The larger this number, the greater the variability in your data. The coefficient of variance is calculated by dividing the standard deviation by the mean and is typically displayed as a percentage. When assessing the quality of the results, the lower the coefficient of variance percentage, the more confidence you would have in using the standard deviation of a particular variable compared to the standard deviation of another variable. So what is this really telling us? Let's look at some pictures of central tendency and variation.

The following graphs represent symmetrical distributions.

All three graphs have the same mean, but the standard deviation (or  $\sigma$ ) for the first graph is larger than for the second, and the  $\sigma$  for the third is smaller than the second.

*Skewed distributions.* A distribution is skewed if one tail extends out further than the other. In other words, the data is not distributed symmetrically around the mean. A distribution has positive skew (skewed to the right) if the tail to the right is longer. A distribution has a negative skew (skewed to the left) if the tail to the left is longer.

Whenever measures of central tendency are applied, measuring how far the values differ from a certain point help develop an impression of how closely concentrated around the expected value the distribution is; it is a measure of the "spread" of a distribution about its average value. For example, if we calculate the mean and median price to book multiple, but find there is a *large variance*, then the "average" price to book multiple may be meaningless as a predictor of value. This can help you select the appropriate multiples to use. However, do not let statistics fool you.

## Probability

In a valuation or an economic damages engagement, the valuation analyst may be concerned with how likely a random event that occurred in the past will recur again in the future. For example, suppose an investment management firm generated a return of 30 percent during one year and the analyst wants to know the likelihood that such a return can be generated again. This question can be answered by performing a probability analysis.

A *probability* is a measure of the likeliness that a particular event will occur. A probability assumes a value between 0 and 1, where 0 indicates that an event is impossible, and 1 indicates that an event is certain to happen. For example, a probability of 30 percent means that there is a 30 percent chance that the event in question will happen. While I will not go into detail about probability theory and the various types of probability distributions, exhibit 7.1 illustrates an actual probability analysis that my firm performed for the valuation of a hedge fund.

**EXHIBIT 7.1 Probability Analysis**

In order to obtain a longer term view on the potential for the occurrence of an extreme market rally in the future, we performed a statistical probability analysis. The purpose of this analysis is to determine the likelihood of extreme positive market returns occurring in the future with a strong degree of statistical certainty.

We obtained historic stock market return data as far back as 1926 from Morningstar's 2011 *Stocks, Bonds, Bills and Inflation, Valuation Edition*. We performed the probability analysis based on this historic data. Annual large company stock returns from 1926–2011 are presented in table 1.

**TABLE 1 Large Company Stock Returns**

Year	Return	Year	Return	Year	Return	Year	Return	Year	Return
1926	11.62%	1946	-8.07%	1966	-10.06%	1986	18.67%	2006	15.79%
1927	37.49%	1947	5.71%	1967	23.98%	1987	5.25%	2007	5.49%
1928	43.61%	1948	5.50%	1968	11.06%	1988	16.61%	2008	-37.00%
1929	-8.42%	1949	18.79%	1969	-8.50%	1989	31.69%	2009	26.46%
1930	-24.90%	1950	31.71%	1970	3.86%	1990	-3.1%	2010	15.06%
1931	-43.34%	1951	24.02%	1971	14.30%	1991	30.47%	2011	2.11%
1932	-8.19%	1952	18.37%	1972	18.99%	1992	7.62%		
1933	53.99%	1953	-0.99%	1973	-14.69%	1993	10.08%		
1934	-1.44%	1954	52.62%	1974	-26.47%	1994	1.32%		
1935	47.67%	1955	31.56%	1975	37.23%	1995	37.58%		
1936	33.92%	1956	6.56%	1976	23.93%	1996	22.96%		
1937	-35.03%	1957	-10.78%	1977	-7.16%	1997	33.36%		
1938	31.12%	1958	43.36%	1978	6.57%	1998	28.58%		
1939	0.41%	1959	11.96%	1979	18.61%	1999	21.04%		
1940	-9.78%	1960	0.47%	1980	32.50%	2000	-9.10%		
1941	-11.59%	1961	26.89%	1981	-0.049%	2001	-11.89%		
1942	20.34%	1962	-8.73%	1982	21.55%	2002	-22.10%		
1943	25.90%	1963	22.80%	1983	22.56%	2003	28.68%		
1944	19.75%	1964	16.48%	1984	6.27%	2004	10.88%		
1945	36.44%	1965	12.45%	1985	31.73%	2005	4.91%		

*(continued)*

**EXHIBIT 7.1 Probability Analysis** *(continued)*

In order to analyze the historic stock return data, we calculated two statistics: the average and the standard deviation. The average is an indication of the central tendency of the data, whereas the standard deviation is a statistic that measures how much the data tends to deviate from its central tendency. The lower the standard deviation, the more the data tends to cluster around the average.

We calculated the average and standard deviation statistics over various time intervals. Various time periods were analyzed to observe the impact of extreme economic times that could potentially skew the data. Summary statistics over the various time periods appear in table 2.

**TABLE 2 Summary Statistics**

	Average	Standard Deviation	Sample Size
1926–2011	11.8%	20.3%	86
1936–2011	12.0%	18.2%	76
1946–2011	12.1%	17.4%	66
1956–2011	11.1%	17.2%	56
1966–2011	12.4%	17.5%	46
1976–2011	12.4%	16.8%	36
1986–2011	11.2%	18.0%	26

The average returns for large company stocks ranged from 11 percent to 12.9 percent over the various time intervals examined. The standard deviation of those returns ranged from 16.8 percent to 20.3 percent. The standard deviation was largest during the 1926–2011 time period. This is the result of the presence of extreme positive and negative returns that occurred from 1926–1936 as a result of The Great Depression. These extreme returns deviate significantly from the average return, resulting in a larger standard deviation statistic.

The summary statistics shown in table 2 can be used to perform a probability analysis. In other words, we can use this data to determine the likelihood that extreme positive returns will occur in any given year. We can quantify this likelihood by assuming that the historic return data takes the form of what is referred to in statistics as a *normal distribution*. According to H.T. Hayslett, Jr. in *Statistics Made Simple*:

There are a great number of continuous distributions. The normal distribution is undoubtedly the one that is most widely used in applications of statistics...A normal distribution is completely specified by two parameters: the theoretical mean and the theoretical variance<sup>1</sup> of the population.

Hayslett goes on to say:

One reason the normal distribution is so important is that a number of natural phenomena (that is, the *measurements* of these phenomena) are normally distributed or nearly so. Phenomena such as heights and weights of individuals, I.Q. scores, errors in measuring the length of a metal rod with high accuracy, and scores on mathematics tests, all have distributions that are normal. Practically speaking, this means that if we select a sample of one hundred people and measure their weights, then classify these observations and draw the histogram, the histogram will follow roughly the outlines of a normal curve.

<sup>1</sup> Represents the standard deviation squared.

### EXHIBIT 7.1 Probability Analysis

A normal curve can be described as a bell-shaped curve that takes the form shown in figure 1.

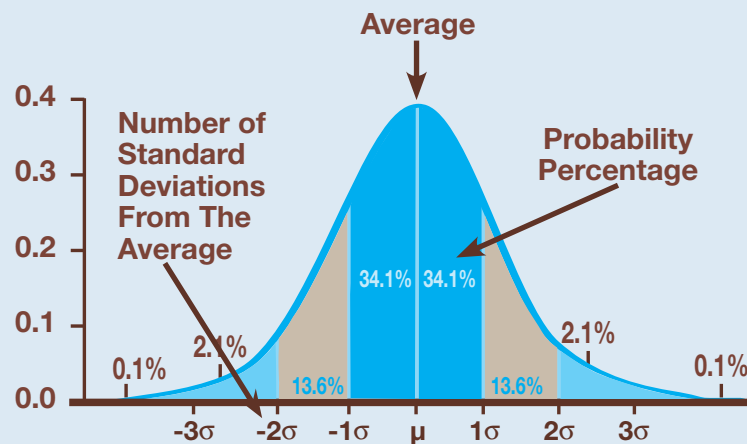

#### Figure 1 Normal Curve

The line down the middle of the normal curve represents the average of the data sample. The normal curve peaks at the average, which means that an assumed value at or around the average has the highest probability of occurrence. The width of the normal curve is dependent upon the standard deviation of the sample. Larger values of the standard deviation with respect to the average result in wider and flatter curves, which indicates more variability in the data. In other words, the smaller the standard deviation, the more the data will cluster around its average.

The area under the normal distribution curve represents the probability that a certain event will occur. This probability is based on the mean and the standard deviation of the sample. A sample normal distribution curve labeled with the corresponding probability percentages is shown in figure 2.

#### Figure 2 Normal Distribution Curve

The percentages in figure 2 represent probabilities that certain events will occur. For example, the probability of occurrence for an event taking place between the average and one standard deviation of the average is 34.1 percent. The probability of an event taking place within one standard deviation on either side of the average is 68.2 percent (34.1% + 34.1%). The probability of an event taking place more than two standard deviations above the average is 2.2 percent (2.1% + 0.1%). What can be seen from looking at the normal distribution curve is that the further away you move from the average, the lower the probability of occurrence.

We applied this same probability theory to determine the probability that The Fund can generate extreme positive returns in any given year. A summary of this analysis is presented in table 3.

2011	3.90%	34.76%	32.84%	31.85%	33.86%	34.63%	30.52%	34.20%	33.2%

**EXHIBIT 7.1 Probability Analysis**

We can draw several conclusions from the probability analysis. First, it is highly unlikely that The Fund can generate the level of returns achieved in 2003 and 2009 in any given year. The probability that The Fund can generate a return of 53.30 percent is 1 percent. This is because 53.30 percent falls more than two standard deviations away from the mean in most cases. The 1 percent figure represents the area under the normal curve to the right of 53.30 percent. Referring back to the normal distribution curve, the probability that an event will occur greater than two deviations above the mean is 2.2 percent. The fact that the return figure of 53.30 percent is more than two standard deviations above the mean in most cases results in a probability of only 1 percent.

The probability of a 53.30 percent return appears graphically in figure 3.

**Figure 3 Probability of a 53.30% Return**

Similarly, the probability that The Fund can achieve the returns generated in 2009 is extremely low, ranging between 5 percent and 6 percent, on average. In addition, although not to the degree of 2003 and 2009, the probability of achieving the returns generated in 2001 and 2010 are low as well.

In summary, the probability analysis reveals that the extreme returns generated in 2001, 2003, 2009, and 2010 are outliers that are unlikely to occur in any given year. Furthermore, analyst forecasts and index futures contracts indicate that an extreme market rally is unlikely to occur in the near future that would enable The Funds to generate extreme returns. Therefore, when forecasting future returns, we must remove the impact of these outliers because these returns are unlikely to occur and cannot be sustained.

**Correlation**

Another statistics term that you should be aware of is *correlation*. We often want to see what the cause and effect of something might be. For example, if we are going to forecast revenues for a trucking company, we might want to know how trucking revenues are correlated with gross domestic product. In order to do this, we might use some regression analysis. Exhibit 7.2 illustrates this analysis from a real assignment.

*Regression analysis.* Regression analysis is a statistical tool used for the investigation of relationships between variables. Usually, one seeks to ascertain the causal effect of one or more variables upon another—the effect of a price increase upon demand, for example. Regressions can test whether relationships exist, but they cannot examine causal effects. This gets to the distinction between correlation and causation. In general, causation comes from reason or theory, not statistics.

I am not going to go too crazy here because this can get way beyond business valuation or economic damages, and you did not buy this book to learn complex statistics. As a hint, Excel can do this for you if you know how! There will actually be an example in the next chapter on forecasting that will demonstrate how we use regression analysis to assist in that process. Be patient. We will get there.

## EXHIBIT 7.2

In order to forecast revenues, we are presenting four different models. These are being called:

1. Most Optimistic
2. Most Conservative
3. Most Likely
4. Based on their expert's report

### MOST OPTIMISTIC

The most optimistic forecast model uses sales that are forecast taking into consideration the statistical relationship of PDQ Trucking's revenues to Real Gross Domestic Product (RGDP). We used RGDP instead of Nominal GDP for two reasons: it had approximately the same statistical correlation and it resulted in more conservative growth rates.

We began our analysis by comparing RGDP to PDQ Trucking's revenues beginning in 1990, up to and including the latest 12 months ended June 30, 2009. These figures are shown in Table 22.

	Real GDP	Revenues
1990	8,033.9	\$114,041,000
1991	8,015.1	114,739,000
1992	8,287.1	103,438,000
1993	8,523.4	102,594,000
1994	8,870.7	103,298,000
1995	9,093.7	109,812,000
1996	9,433.9	123,381,000
1997	9,854.3	133,835,000
1998	10,283.5	139,272,000
1999	10,779.8	153,191,000
2000	11,226.0	166,173,000

*(table continued)*

**EXHIBIT 7.2**

**TABLE 22 Comparison of RGDP to Revenues** *(continued)*

	Real GDP	Revenues
2001	11,347.2	186,077,000
2002	11,553.0	193,422,000
2003	11,840.7	189,704,000
2004	12,263.8	213,733,000
2005	12,638.4	242,081,000
2006	12,976.2	254,772,000
2007	13,254.1	265,675,000
2008	13,312.2	246,350,000
<b>LTM June 30, 2009</b>	<b>12,901.5</b>	<b>224,713,000</b>

Using regression analysis, we determined that there is a high degree of correlation between the data in Table 22. In fact, the  $R^2$  indicates that there is a 92.6 percent correlation between RGDP and revenues. This means that about 93 percent of The Company's change in revenues can be explained by a change in RGDP. Perfect correlation would be 100 percent. Having 20 observations makes the statistical correlation very reliable.

Graphically, the regression analysis can be illustrated to show how the close proximity of predicted revenues would be to the actual revenues. This is presented in Chart 5.

**Figure 5 Regression Analysis Predicted Vs. Actual Revenues**

Note: All dates are as of December 31, except 2009, which is as of June 30.

(continued)

**EXHIBIT 7.2** (continued)

In order to use RGDP as a predictor of PDQ Trucking's revenues, we first had to forecast what RGDP would be after June 30, 2009. In order to accomplish this we turned to *Consensus Forecasts* and *Wachovia Economics*. These two sources provided us with the information necessary to review the quarterly and/or annual forecasted growth rates in RGDP. Using the annual growth rates published in these publications, we calculated RGDP as presented in Table 23.

**TABLE 23 Real GDP Forecast**

	Real GDP	Annual Growth Rate
Q2 2009 (Actual)	12,902	
Q3 2009	13,001	3.1%
Q4 2009	13,079	2.4%
Q1 2010	13,161	2.5%
Q2 2010	13,253	2.8%
Q3 2010	13,346	2.8%
Q4 2010	13,450	3.1%
Q1 2011	13,557	3.2%
Q2 2011	13,676	3.5%
Q3 2011	13,768	2.7%
Q4 2011	13,868	2.9%

Using the calculated RGDP forecast, we were then able to apply these figures as a predictor of revenues for The PDQ Trucking Entities on a latest 12 months basis. Applying the regression formula results in predicted revenues of \$249,094,543 and \$261,316,272 for the years ended December 31, 2010 and 2011, respectively. Therefore, this would be the predicted sales in the most optimistic forecast.

I have omitted the balance of this section because the computations are similar, and only the numbers changed. This should provide you with a good idea of how we use this stuff.

*Correlation coefficient.* A correlation coefficient is a number between -1.0 and +1.0 that measures the degree to which variations in two variables are linearly related. If there is perfect linear relationship with positive slope between the two variables, the correlation coefficient is 1; a positive correlation exists when one variable

displaying a high value (on the X axis) is shown to be related to a high value in the other variable (on the Y axis) and vice versa.

If there is a perfect linear relationship with negative slope between the two variables, the correlation coefficient is  $-1.0$ ; a negative relationship exists whenever one variable displaying a high value (on the X axis) is shown to be related to a low value on the Y axis and vice versa.

A correlation coefficient of 0 means that there is no relationship between the variables. This means that the relationship between the variables stinks. That may be the only part of this discussion that you are comfortable with.

In valuation, correlation is often used to preliminarily identify relationships between market data and a firm's financial data. For example, if there is a high correlation between the price-to-earnings multiple of guideline companies and the net income of those companies, then the price-to-earnings multiple may be a good predictor of value. Again, we will discuss this in chapter 9, so be patient.

## Let's Do Some Number-Crunching

By now, you have probably had enough of statistics (I certainly have), so let's do some number-crunching. If you are an accountant reading this book, by now, you are probably going through withdrawal. Assume that we have two sets of valuation multiples.

	Set 1	Set 2
Company 1	11.7	6.1
Company 2	14.2	11.6
Company 3	14.7	14.8
Company 4	15.1	17.2
Company 5	19.2	34.7

Let's calculate a number of common measures.

	Set 1	Set 2
25th Percentile	14.2	11.6
Median	14.7	14.8
Mean	15.0	16.9
Standard Deviation	2.7	10.8

Harmonic Mean	14.6	12.4
Coefficient of Variation	0.2	0.6

Note the differences between the two sets of data. Set 2 has a wider range of data and a much larger coefficient of variation. The medians are about the same, but the mean of set 2 is much higher, and the harmonic mean is much lower. Because I defined all of this stuff in the preceding section, you know exactly what I am talking about.

### Calculation of the Mean

The mean for set 1 is calculated as follows:

$$\frac{11.7 + 14.2 + 14.7 + 15.1 + 19.2}{5} = 15.0$$

### Calculation of the Harmonic Mean

The harmonic mean is calculated as follows:

$$\frac{1}{\left[ \frac{\frac{1}{11.7} + \frac{1}{14.2} + \frac{1}{14.7} + \frac{1}{15.1} + \frac{1}{19.2}}{5} \right]} = 14.6$$

### Calculation of the Standard Deviation

The standard deviation is calculated as follows:

$$\sqrt{\frac{(11.7 - 15.0)^2 + (14.2 - 15.0)^2 + (14.7 - 15.0)^2 + (15.1 - 15.0)^2 + (19.2 - 15.0)^2}{(5 - 1)}} = 2.7$$

### Calculation of the Coefficient of Variation

The coefficient of variation is simply:

$$2.7/15.0 = 0.2$$

### Calculation of Median and Percentile

The median and 25th percentile calculations are calculated using Microsoft Excel's "percentile" function. You didn't think I did this by myself? When using this function, the data values are first sorted lowest to highest. The lowest and highest values are assumed to be the minimum and maximum of the distribution of values.

The data values are then divided into the appropriate percentiles. In this case, the data can be thought of as being divided into four buckets: 11.7–14.2; 14.2–14.7; 14.7–15.1; and 15.1–19.2. The endpoint of the lowest of the four buckets corresponds to the 25th percentile; in this case, the value is 14.2. The middle value is the median and is 14.7.

## Be Careful Not to Drink the Statistics Kool-Aid: This Stuff Can Be Misleading

Benjamin Disraeli said “There are three kinds of lies: lies, damned lies, and statistics.” With that being said, the science of statistics has greatly improved since the former prime minister made this statement (sometime during his lifetime from 1804–1881). There are a number of folks out there who want to fool some of the people all the time with the improper use of statistics. However, do not get caught up in this because any reasonable statistician can have a valuation analyst for lunch. They can destroy arguments made through improper use of statistics, thereby raising doubt about the entire valuation.

There are a number of misuses that I have seen in practice. Some are worse than others. I will present some of them in no special order.

*Size matters: the inadequate or “no-data” analysis.* The data analyzed must be sufficient in terms of quantity to make the statistical analysis meaningful. The mean and median of a “two data point” sample is the same, and any analysis of variance is irrelevant. This gets back to sample size. The data set has to be large enough for the results to matter. Otherwise, use this stuff with caution, and be honest about its limitations.

Statistics are used to provide condensed information about the data set of samples; when the data set is small, the valuation analyst is well-advised to present the data directly and forthrightly. Simply because data sets are small does not mean they do not have value in the analysis. As valuation analysts, as long as we recognize that a small data set is typically a haphazard sample of a larger population, we can use it to our (limited) advantage. In short, some data points are better than none and far better than having a few and not presenting them. Just be careful about the conclusions that are reached, even from rather robust data sets that may not be derived from a representative probability sampling of the universe of interest. To the degree that the valuation analyst observes very low variance in the sample, he or she should allow himself or herself the luxury of some further inquiry about why that variance might be low: Is there a sample bias in the data? *Sampling bias* is when a sample is collected in such a way that some members of the intended population are less likely to be included than others.

*The assumption of representativeness.* A common mistake is to assume a higher level of representation in the data set than is actually there. For example, we might be tempted to assume that valuation multiples drawn from transactions involving restaurants in Arizona and Massachusetts are representative of the population of restaurants. However, this may not be true if the liquor laws are very favorable in these states, which, as a result, makes them excellent acquisition candidates, with higher multiples. This leads to an inherent (upward) bias in the sample about the pricing multiples for restaurants. If the valuation analyst is valuing a restaurant in South Carolina, the transaction data may well be misleading to the point of uselessness if there are a different set of liquor license laws in that state that drive down the multiples.

Unless the valuation analyst is able to exhibit equal-probability-of-selection sampling that underpins the representation of the data set that is being used, he or she has an inherent problem that the data may not be representative of the larger population the analyst wants to study. In financial data, it is virtually impossible to observe entire populations and obtain samples that are entirely random selections. Nevertheless, we must go on doing our work and recognize such limitations.

The argument that “I used all the data points available” simply isn’t good enough because in most cases, transactions occur based on nonrandom trigger events. In the simplest example, sales multiples for Internet companies were dramatically higher in the five years preceding 2000 than five years later. Most of us would not fall prey to the temptation to merge this data and assume it is representative of a hypothetical transac-

tion today, but the same problem exists in virtually every data set. The statistical problem is that there are two samples: Pre-2000 and post-2000, but we are mixing the two samples together. We can perform a statistical test to demonstrate that the data comes from two different samples. However, with this premise, the point that I am making is that somebody is trying to make an inference today from a sample that's pre-2000.

Exogenous forces, different situations and conditions, and an inherently non-representative sample of data points are the “facts of life” for a valuation analyst. When using data, the analyst must consider the facts and circumstances that underpin the data.

*The assumption of homogeneity.* Another common error is to assume that there is a high level of homogeneity embedded within samples of supposedly similar objects, such as companies. In some cases, this might be true, but in most cases, it simply is not. The classic valuation analyst paradigm is that firms of similar size, earnings, and growth in an industry are similar, and the variance is attributable to value drivers and management. This paradigm, while useful, tends to lead us towards an assumption of homogeneity that may, in fact, not exist. For example, not all Mexican restaurants in the local area are the same—some are upscale dining establishments, whereas others are simply casual dining restaurants. They may exhibit similar characteristics in measures of size and performance but may be driven by different underlying dynamics. The low-end establishments are driven by an influx of Mexican immigrants, and high-end establishments are driven by wealth effects in the non-Mexican population.

To that end, we watched an upscale Mexican restaurant of average performance double in profitability after switching owners. The new owners targeted the immigrant Mexican population with “home cooking.” The business rapidly morphed from an upscale dining establishment to essentially a catering organization providing daily food to the hard-working Mexican immigrant community.

One way to examine this assumption is to perform statistical tests, such as independent sample t-tests or ANOVA (analysis of variance) on the data set. With private firms, there's probably little chance of having enough data to use these tests. Although a description of these tests is beyond the scope of this book, the valuation analyst needs to be aware that there is more work to be done here to safeguard against making a mistake by blindly relying on a data set. In most cases, however, simple examination of the data will give the valuation analyst a very good idea about how homogeneous it actually is.

Examination of the variance in the data set is an exceptionally useful analysis and not difficult to do. One doesn't need to be a statistician to simply look at the data set in the spirit of inquiry, and ask “Why are these different?” Most often, a very cursory examination reveals some interesting points to consider when applying that dataset to extract parameters for use in valuation.

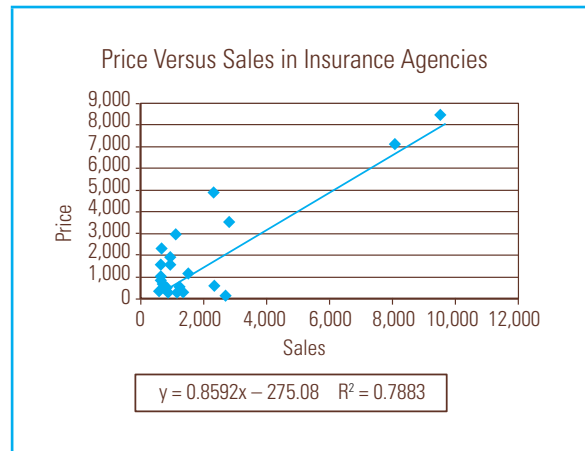

*Treatment of unfavorable data and outliers.* Financial data is often not normally distributed, and it is common for outliers to exist. For instance, if we are examining wages in the population, Warren Buffett, Bill Gates, and George Soros are outliers. In financial data, we often see a lot of giants and few dwarfs. This means the data is not normally distributed. It is one thing to remove outliers; it's quite another to remove data that biases your point of view. As valuation analysts, we are supposed to perform our work with integrity and objectivity. We are not supposed to be advocates for our client's position. Experts that eliminate data points do so based on a very good rationale: examination of the facts and circumstances, which is a core function of an analysis. What this means is that before the valuation analyst eliminates a data point, he or she would do well to develop a good understanding of why it should be eliminated. If the valuation analyst eliminates data points, it is good practice to at least footnote this in the report. Otherwise, it looks like the valuation analyst is trying to get away with something.

In most cases, there are points in a data set that look like they do not conform to the industry data; they are called *outliers*. Outliers are most instructive; they tell you a lot more about the nature of the value multiples that can exist in the industry than do a very tightly grouped set of multiples. You can think of outliers as a point of interest in what might otherwise be a very dull tour. Stopping to examine them can give the valuation analyst a great deal of insight that might be most helpful to the valuation. Perhaps more importantly, not examining

them may leave the valuation analyst open to severe criticism by someone who later makes even a casual analysis of the outlier.

Sometimes, it is absolutely essential to eliminate outliers to derive a reasonable analytic representation of the trends in the data set. The least squared formula for regression will invariably cause the regression line to run very close to an outlier, such that the outlier data point is disproportionately weighting the form of the regression. This requires considerable care but is most sensible if the outlier is very far away from the target firm in all aspects. Sometimes, we find it useful to eliminate observations in the extreme 1 percent or 5 percent in both tails. Not very scientific, but it frequently takes the skewing out of the data and allows a more meaningful analysis to take place.

Using a scatterplot before forming any conclusion regarding a relationship is always a good idea. The graph that follows illustrates that two outliers are driving the coefficient of determination of the regression. (A measure used in statistical model analysis to assess how well a model explains the dependent variable. It is indicative of the level of explained variability between the independent variables and a dependent variable. The coefficient of determination, also commonly known as  $R^2$ , is used as a guideline to measure the model's goodness of fit.) Although the regression statistic ( $R^2$ ) looks good (more than 0.50 is considered to be acceptable), it really is not very good at explaining the data. In this instance, only 50 percent of the variability is explained.

The whole point of this graph is to show that it is always useful to take a common sense look at the data and information the valuation analyst will be using. If the analyst were to eliminate the two top points, the graph would look very different. Removing the top two and bottom two points would have shown the valuation analyst not to rely on this regression statistic.

*The well-chosen representative statistic of central tendency.* Normally, we use some statistic of central tendency—mean, median, or mode—to describe the distribution of values. The one the valuation analyst chooses depends highly on the form of the distribution of values in the data set. In some cases, the mean of all samples is used. I find that the median is typically more useful because financial data is rarely normally distributed, and on a rare occasion, the mode might be. If the distribution of a population or its sample is bell-shaped (that is, normally distributed), then the valuation analyst need not be concerned about the source of the average because the mean, median, and mode will be approximately equal to one another. On the other hand, most business data, such as market multiples, often skews from a normal distribution. A common distribution of business statistics is the log-normal distribution. This appears as follows:

Reporting the median generally provides a more accurate assessment than means of the population or sample.

*The naked statistic and measures of variability.* An average value without a measure of the variability in a distribution or the degree of significance is a “naked” statistic. Getting naked woke you up! Assume the valuation analyst calculates the mean price-to-earnings multiple and price-to-revenue multiple for a group of guideline companies. Which one is the better indicator of value? Without additional analysis, the analyst cannot tell.

Measures of variability in the data set of statistics are critical; typically, the variance, standard deviation, or coefficient of variation is used. The problem is that if the distribution varies from a normal (that is, bell-shaped) curve, these measures are a bit less useful than they would be if the valuation analyst had a normal distribution. With that being said, for inferential statistics, this may not always be correct. The data does not need to be normally distributed. It’s the regression error term that has to be normally distributed. If we were performing a regression of age and wages, we would find that neither age nor wages in the population are normally distributed. Yet, we can perform a regression on those variables and be statistically valid, if the error term in the regression model is normally distributed. Second, for the script of statistics, this can be very much of an understatement. If the distribution is nowhere near normal, these measures are not very useful at all.

Because most business variables do not occur as normal distributions, the central limit theorem is helpful to describe the limits of the central tendency. The central limit theory is a statistical theory that states that given a sufficiently large sample size from a population with a finite level of variance, the mean of all samples from the same population will be approximately equal to the mean of the population. Furthermore, all of the samples will follow an approximate normal distribution pattern, with all variances being approximately equal to the variance of the population divided by each sample’s size.

*The “gee whiz” graph.* Be cautious of “gee whiz” graphs, tables, or pictures. We often show a picture, table, or graph to illustrate our statistical analysis. In order to create the perception of large, significant differences, just change the magnitude of the scale on the vertical axis and you would be amazed at the lies that can be told. Notice that the following graphs contain the same data. Is the growth rate illustrated equivalently?

An interesting text on generating graphs is Edward R. Tufte's *The Visual Display of Quantitative Information*, 2nd ed. (Cheshire, Conn.: Graphic Press, 2001) (ISBN: 0961392142). This book is well accepted, very useful, and interesting reading.

*Post-hoc rationalization.* Post-hoc rationalization is the fallacy of arguing from temporal sequence to a causal relation. Simply put, you can't simply assume that if B follows A, then A caused B. Correlation does not imply causality. For those readers who perform economic damage analyses, you are probably aware that a causal link frequently must be established between the event that caused the damage to occur and the economic damages. Be careful not to foolishly rely on correlation for this relationship.

We all are tempted to squeeze as much as we can from limited data. The problem with small data sets that we invariably use is that correlations occur that appear very strong, yet they are not borne out when tested against a larger sample. This is the nature of small data sets, yet we are all tempted to rely upon these correlations and make something out of them, which can be very embarrassing if the larger data set proves the valuation analyst wrong.

There exists a bootstrapping technique for testing these correlations statistically within a small data set. If you observe a particular correlation in a small data set that is absolutely central to the conclusion of value, I recommend that the valuation analyst use a bootstrapping technique to verify the correlation or test the correlation on a larger sample. This recommendation is purely the responsible use of statistics; if the valuation analyst is not comfortable doing this alone, a statistician can easily do it for him or her. Clearly, this discussion goes way beyond valuation.

*How to "statisticulate."* The act of misleading people through the use of statistics has been referred to as *statisticulation*. Some of the more common ways to statisticulate include the following:

1. The use of means when medians are more appropriate.
2. Misuse of significant figures (for example, "On average, I sleep 6.35 hours per night." [Who keeps track of sleep beyond the precision of about the nearest half hour?]).
3. Improper use of percentages (for example, "There's a 50 percent chance of rain on Saturday and the same on Sunday. So, don't make any plans for this weekend because there's a 100 percent chance of rain.").

*The general recommendation here* is, "Don't try to turn the use of statistics into a magic show." This field is very well understood, highly developed, and there are excellent experts available everywhere. The valuation analyst does not want to be on the receiving end of one.

*The semi-attached statistic.* The last, but certainly the most important, method of abusing or misusing statistics is the semi-attached statistic. Use of semi-attached statistics (or information) is perhaps the principal reason why bad statistics and snake oils have thrived. Subscribers to this philosophy believe that "if you can't prove what you want to prove, demonstrate something else and pretend they are the same thing." Somewhere buried in the semi-attached statistic is usually a trace of truth or fact, but the rest is a whole lot of fluff. Thus, it is very difficult to pin a "lie" on a semi-attached statistic.

In his book *Damned Lies and Statistics: Untangling Numbers from the Media, Politicians, and Activists*,<sup>1</sup> author Joel Best describes four personalities in regard to how people cope with statistics:

1. The *awestruck* understand very little about statistics, but that's of no real concern to them because statistics have magical powers, just like the products they use.
2. The *naïve* have a little more understanding of statistics but are basically accepting of what they are told.
3. The *cynical* are very suspicious of statistics in general, except when it comes to those that support their own beliefs. Overall, they don't trust in numbers and feel that "you can prove anything with statistics."
4. Finally, the *critical* take a more thoughtful approach to statistics that avoids the extremes of naïve ac-

<sup>1</sup> Joel Best, *Damned Lies and Statistics: Untangling Numbers from the Media, Politicians, and Activists* (Berkeley and Los Angeles, CA: University of California Press, 2001).

ceptance and cynical rejection. The critical ask important questions such as “Who is the source and how do they know? How were the statistics produced? Where is the measure of variability or degree of significance? Is the statistic being properly interpreted?” Most importantly, they ask, “Does it make sense?”

## Conclusion

If you did not have a statistics background coming into this field, by now you are probably scared out of your wits. You have two choices: (1) learn this stuff so that you can use it, or (2) hire some really good staff who can explain it to you. All kidding aside, statistics has become a more important part of our analysis, and you really need to understand the basics. You do not have to be a statistician to perform business valuation and economic damage analyses, but it is an essential tool for you to understand. We'll use some of this stuff in the next chapter and then we can get into a dose of valuation.

## Chapter 8

# Developing Forecasts for Business Valuations and Economic Damages

### Learning Objectives

In this chapter, I will attempt to explain the following:

- The difference between a forecast and a projection
- The factors to look for when evaluating a forecast provided by management
- The steps to take in preparing a forecast
- Sales forecasting techniques
- Forecasting various items on the income statement and balance sheet
- Applicable standards CPAs must follow when preparing a forecast for these types of engagements
- The acceptance of forecasts in various courts

### Introduction

In theory, a discounted future benefits method is one of the best methods of valuing a company. It may not be accepted by some courts, however, because of its reliance on forecasted future events. The values derived from these methods are only as accurate as the forecasts of future cash flows or earnings, and sometimes, these future events cannot be forecasted with sufficient reliability to make them usable. Understanding that no forecast is ever able to be determined with total accuracy, these methods may be problematic in either of the following situations:

- The valuation will be used by a client (or a judicial or regulatory body) that will not accept a value based on a discounted future returns method.
- Insufficient data exists to make a timely, reliable forecast of net cash flow or earnings for a reasonable period into the future.<sup>1</sup>

### Forecast Versus Projection

Before I go on to discuss the forecasting process, it is important to differentiate between a forecast and a projection. Although these terms are often used interchangeably, the AICPA uses two distinct definitions to differentiate these terms.

**Financial forecast.** Prospective financial statements that present, to the best of the responsible party's knowledge and belief, an entity's expected financial position, results of operations, and cash flows. A financial forecast is based on the responsible party's assumptions reflecting the conditions it expects to exist and the course of action it expects to take.

**Financial projection.** Prospective financial statements that present, to the best of the responsible party's knowledge and belief, given one or more hypothetical assumptions, an entity's expected financial position, results of operations, and cash flows. A financial projection is sometimes

<sup>1</sup> Jay E. Fishman, et al., *PPC's Guide to Business Valuation*, 26th ed., vol. 1 (Fort Worth, TX: Thomson Reuters, 2016): 5-5.

prepared to present one or more hypothetical courses of action for evaluation, as in response to a question such as, “What would happen if...?”<sup>2</sup>

As the definitions indicate, the primary difference is that forecasts are based on the conditions expected to exist and the course of action the business expects to take, whereas projections are based on one or more hypothetical courses of action. Based on these definitions, forecasts are generally used in performing the discounted future benefits method. The remainder of my discussion will focus on forecasts necessary for the completion of the discounted future benefits method.

## Management’s Forecast

A forecast needs to be obtained from management or prepared by the valuation analyst if the discounted future benefits method will be utilized. The forecast should represent what is expected to occur in the future based on existing operations and what is known or knowable at the date of valuation. Let’s start off with the assumption that management has provided us with a forecast. Upon receipt of the forecast, a reasonableness check should always be performed. Whatever the valuation analyst does, he or she should not blindly accept the client’s forecast.

I have seen the following scenario too often. The subject business has normalized earnings for the last five years as follows:

Year	Amount
2012	\$178,000
2013	170,000
2014	180,000
2015	175,000
2016	200,000

Now, the client provides me with the forecast. Going through a divorce, the client forecasts that business is terrible, the industry is falling apart, and the business will never be the same. Therefore, the next five years will look like this:

Year	Amount
2017	\$180,000
2018	170,000
2019	150,000
2020	135,000
2021	125,000

.....  
2 AT section 301, *Financial Forecasts and Projections* (AICPA, *Professional Standards*).

That poor, poor client! Now let's look at the information that the same client might give me if he or she was trying to sell the business. In this case, the forecast might be the following:

Year	Amount
2017	\$225,000
2018	250,000
2019	275,000
2020	300,000
2021	350,000

Don't you just love this business? Where else can the same client give the valuation analyst such nonsense? Part of the role of being a good valuation analyst is to maintain an objective attitude, which includes recognizing that the valuation analyst's client may try to help the analyst get to his or her desired end result by giving the analyst bad numbers. Sometimes, the valuation analyst will not be able to use this information, and the analyst will be required to consider other valuation methods. However, the valuation analyst shouldn't roll over and play dead just because the job is difficult.

What does the valuation analyst do if he cannot agree on a forecast with management? Occasionally, there are instances in which the valuation analyst cannot accept management's forecasts, or vice versa. When this occurs, every effort should be made to reconcile the differences, assumption by assumption. If all efforts fail, at least five solutions are possible.

1. Use management's forecast and label them as "Management's Pro Forma Forecasts." The fact that they are management's pro forma forecasts should be explained prominently in the text.
2. Insist on using the consultant's forecast, perhaps with footnotes about management's disagreements with the forecasts.
3. Use two or more scenarios for the forecasts, resulting in a range of estimated values.
4. Use management's forecasts and adjust the discount rate. This is usually accomplished through the specific company risk adjustment.
5. In extreme situations, the consultant should consider resigning from the engagement.<sup>3</sup>

I am not inclined to rely on management's forecast, particularly in a litigation assignment, if I do not agree with it. Labeling it as "Management's Pro Forma Forecast" will most likely not make a difference when the judge or jury rejects my conclusion of value that is based on a forecast that I believe is incorrect. Even if I do not state my disagreement, chances are that the other valuation analyst will find similar problems with the forecast that I found and will be extremely vocal about it. Relying on something that the valuation analyst believes is wrong can only bring him or her to a bad place.

Although most valuation analysts do not wish to turn away an assignment, there are times when the forecast is so critical to the valuation process that it becomes impossible to proceed with the job. An example would be when the valuation is being performed for the purpose of obtaining financing.

## Factors to Consider When Evaluating Management's Forecast

There are various factors the valuation analyst should consider when evaluating a forecast provided by management. These factors include the following:

- Company-specific factors
- Economic conditions
- Industry trends

<sup>3</sup> Fishman, et al., *PPC's Guide to Business Valuation*, 502.18.

## Company-Specific Factors

When evaluating a forecast provided by management, the valuation analyst should first ensure that the forecast is consistent with the company's future growth prospects and expectations. In addition, management's forecast should be compared to the company's actual historical financial results, when such information is available.

The information needed to gain a thorough understanding of a company's growth prospects can be obtained during the information-gathering and management interview process. The valuation analyst should obtain as much information as possible related to factors such as the company's customer base and capacity constraints.

An understanding of a company's customer base is essential for determining the reasonableness of management's forecasts. In some instances, the future outlook for a company's customer base can be used as the basis for the revenue forecast. For example, if management forecasts a "doom and gloom" scenario for the company, whereas the company's largest customers are forecasting growth in the near term, it may be improper to rely on management's forecasts.

The valuation analyst must also have an idea of the company's capacity constraints. For example, consider a manufacturing company with the following historical sales revenues:

2014	\$ 8,000,000
2015	\$12,000,000
2016	\$15,000,000

In looking at the company's historical revenues, it appears that the company has been achieving steady growth in recent years. In addition, economic forecasts reflect moderate economic growth well into the near term. Based on these factors, is it safe to assume that the company will experience moderate near-term growth in line with the overall economy? This could possibly be the case if the company didn't have capacity constraints. If management states that with its current facility, equipment, and labor force the company can only generate a maximum of \$18 million in sales, a forecast reflecting continued growth over the next 10 years is unreasonable unless a certain level of additional costs needed to increase capacity are incorporated into the forecast.

In instances in which the company has an operating history, management's forecast should be compared with the company's historical results. In addition, it would also be beneficial to obtain a historical budget versus actual report from the company in order to see how accurate the company's forecasts have been in years past and if they have historically been overly aggressive or conservative. For example, if a company has continuously missed its forecasts by 30 percent or more, it may not be beneficial to place a lot of weight on management's forecasts for a valuation engagement.

A company's historical financial performance is often a good benchmark to use and should be analyzed to see if the company's forecasted growth, profitability, and financial ratios are in line with historical levels. If management's forecasts are not in line with history, the valuation analyst must find out from management why the company is expecting either improvements or declines in its operating performance.

There are some cases in which the valuation or economic damages assignment involves an early stage company with limited or no operating history. In instances such as these, the valuation analyst must look to benchmarking data from either trade associations or the public market to determine if management's growth and profitability assumptions are reasonable. In addition, a sensitivity analysis may be appropriate to analyze the impact of changing the various assumptions in the forecast.

As a real-life example, we were once engaged to value an early stage company that had yet to generate revenues. This was a publicly traded company that was developing a new technology. Unfortunately, I cannot provide more information than this because I cannot take the chance that its identity might be discovered. As part of the valuation engagement, we received a forecast model from management that contained various assumptions that would affect the amount of revenues that would be generated by the company. In this instance, we determined that management had a better understanding of its own industry and operations than we did, so instead of refuting management's assumptions, we performed sensitivity and scenario analyses to determine how changing these various assumptions would affect management's revenue forecast. A listing of some of the assumptions used in the revenue forecast for this company was as follows:

- In some instances, the company would infuse carbon dioxide into its products, in other instances, it wouldn't.
- The company had different deal sizes, ranging from small to large.
- The company had different types of deals it offered to its customers.
- Each deal the company obtained had an assumption regarding the start date and the payment schedule.
- Management's forecast included an assumption regarding the number of deals it would obtain in each year.
- The company would increase its fees by approximately 20 percent once the product was accepted and tested in the marketplace.
- The company would earn royalties ranging from 6 percent to 7 percent of revenues once its products had been accepted in the marketplace.

After performing our sensitivity analysis, we determined that the infusion of carbon dioxide and the type of deal offered had a minimal impact on management's revenue forecast. Therefore, we did not change these assumptions. In addition, we classified all deals as large because we believed that smaller deals would be unlikely due to the significant start-up and installation costs associated with the company's products (the purchaser of this technology would have to make an initial investment of about \$650 million—that is large in my book!).

As of the valuation date for this engagement, the company already had a contract with one customer. One of the issues that we had to address is that we did not know exactly when the contract would become effective. Even the company was not sure when they would start seeing cash. Taking this into consideration, we changed several of management's forecast assumptions to reflect the terms of the company's existing contract. In particular, we adjusted the payment schedule to reflect payments over a longer period of time.

With respect to the fees that this start-up company would be able to charge, we determined that a 20 percent increase would be unreasonable due to potential competition that would enter the market. Therefore, we assumed no price increases. In addition, our research revealed that royalty rates of 6 percent to 7 percent of revenues were higher than those charged for similar types of products. Therefore, we reduced the royalty rate to 4 percent, which was more in line with the market.

After going through each of these assumptions, we had a base forecast scenario. The only unanswered question at this point was when the company would generate its first revenues. Due to the extreme level of uncertainty related to this assumption, we performed five scenarios: the base scenario in which we used management's assumption, three scenarios in which we delayed the timing of when the company would generate its first revenues, and a final scenario in which we reduced the number of deals the company would obtain in each year.

Now that we had the revenue part of the forecast taken care of, we continued down the income statement to review management's cost of goods sold assumption. The company's forecast model had a detailed breakdown of all of the costs associated with producing its products. These costs were related to salaries, overhead, and other costs. We determined that management's cost of goods sold assumptions were reasonable except for the fact that there was no inflation factor built into the model to account for cost increases in future years. Therefore, we built a 2.5 percent inflationary factor into the forecast.

The next part of this assignment was determining the level of operating expenses the company would need to incur in order to achieve its projected revenues. We had a start-up company with a short operating history, no truly similar companies, and no industry benchmarking data. Therefore, we searched SEC filings for public companies that were involved in a similar industry, even though they may have been different from the subject company. For example, instead of using companies that develop alternative sources to the actual product, we may have looked for energy companies that were in the solar development business. The goal was to find companies that we could use to benchmark the growth in expenses against. All of these start-up companies might have similar growth cycles. After our search and elimination process was completed, four companies met our criteria. We analyzed the S-1 registration statements and 10-K filings for each of these companies to analyze how their expense structures and research and development budgets changed from inception to maturity. After analyzing the data for the public companies, we determined that management's expense forecast was relatively in line with these other companies. Therefore, we made very few changes to management's expense forecast.

A challenging part of this assignment was forecasting the balance sheet. The company's historical financial ratios were determined to be meaningless because the company was still in its very early stages of operation. In addition, management's forecast model included only short-cut calculations to arrive at estimated net cash flow. Nevertheless, we proceeded to forecast the company's balance sheet based on the following assumptions:

- *Cash*. Calculated as 3 months of operating expenses and cost of goods sold. At this stage of the business' operations, cash was being burned. Our forecast had to consider when the burn would stop, as well as the normal level of cash that was expected to be maintained going forward.
- *Accounts receivable*. Assumed a 45-day receivable collection period based on management's estimate. This seemed reasonable after we reviewed financial data for other companies that were considered to be good benchmark companies.
- *Prepaid expenses*. Increased by an inflationary rate of 2.5 percent annually. Management did not account for inflation in its expense forecast, which we adjusted for. As a result, we believed that the prepaid expenses would be based on a higher level of expenditures.
- *Capital expenditures*. Used the company's capital expenditure projections for the first 2 years. Thereafter, capital expenditures were increased at a 2.5 percent inflationary rate over depreciation.
- *Other assets*. Remained constant throughout the forecast period. These were relatively minor.
- *Accounts payable*. Assumed a payment period of 30 days based on management's estimate. Management expected to pay its bills faster than it collected accounts receivable. This can create cash flow problems that must be considered as the valuation analyst reviews the results of the forecast.
- *Accrued expenses*. Increased at 2.5 percent annually to account for inflation.
- *Other liabilities*. Remained constant throughout the forecast period. Again, these were relatively minor.

At this stage in our analysis, we had all of the information necessary to forecast cash flow for the company. Based on our cash flow projections, we determined that the company would need to obtain additional funding in the short term in order to survive. The level of funding needed would depend on when the company's product would be accepted into the marketplace, allowing it to begin to generate revenues and, eventually, profits.

The preceding example details the level of analysis that is often required to properly evaluate a forecast provided by management. Performing this valuation required us to have a strong understanding of the company's operation, its potential customer base, its products and services, and its growth potential. The valuation analyst must have a clear understanding of all of the assumptions that go into management's forecast and how changes to these assumptions affect value. In the preceding case, simply accepting what management provided to us would have resulted in us overvaluing the company by a large margin. By the way, this public company had a market capitalization of over \$1.5 billion, but there was insider trading and a very thin float of the stock. A court appointed liquidator of a hedge fund that owned a controlling interest in this company wanted to know what it was really worth.

The level of scrutiny that the valuation analyst uses depends on many factors. Although this example was of a much larger company than many valuation analyst's value, even a smaller company can have similar issues. The only real difference is the amount of digits in the numbers. Obviously, with larger companies, the margin of error can be much greater.

## Economic Conditions

The valuation analyst should also consider how different economic factors, such as gross domestic product (GDP), inflation, interest rates, consumer confidence, and so on affect the demand for the subject company's products and services. If it is determined that the company is heavily dependent on the economic climate, the valuation analyst should ensure that management's forecast is consistent with the outlook for the economy.

Many of the valuations that we performed during the 2008–2010 time frame involved companies that were severely affected by the global economic recession. In many cases, clients used this economic downturn as a means to justify bleak forecasts, resulting in lower values. When evaluating management's forecast, the valuation analyst needs to have an understanding of what part of the economic cycle the country or world is in as of the valuation date. If the economy appears to be bottoming out, a forecast of continued poor performance may not be reasonable because the company could potentially benefit from a moderate recovery.

As a real-life example, I was involved in a shareholder litigation involving a trucking company in late 2009. Management of the trucking company believed that the deterioration in the economy would continue to weigh heavily on the company's performance in the near term. However, after a careful analysis of the company's customer base and economic and industry forecasts, we determined that management's expectations were inconsistent with our analysis of this external data. The analysis that ultimately resulted in us placing little weight on management's expectations and preparing various forecast scenarios that were more in line with near-term economic and industry expectations is shown in exhibit 8.1.

### EXHIBIT 8.1 Industry Analysis—Report Excerpt

Before we can properly forecast the company's revenues, we must look at the environment in which The Company operates. The economy was in turmoil during 2008 and a good part of 2009.

The U.S. economy entered a recession in December 2007. For the four quarters ended June 30, 2009, real gross domestic product (GDP) has contracted as follows:

**TABLE 16 Change in Real Gross Domestic Product From Preceding Period, Annualized**

	2008		2009	
	3rd Qtr.	4th Qtr.	1st Qtr.	2nd Qtr.
Change in Real GDP	-2.7%	-5.4%	-6.4	-0.7%

(Source: Bureau of Economic Analysis, Press release dated September 30, 2009.)

Although the economy had clearly suffered during the year ended June 30, 2009, more recent indications "suggest that the recession has bottomed out and a recovery may already be underway." According to a survey of prominent U.S. economic and financial forecasters conducted by Consensus Economics Inc. on September 14, 2009, the consensus forecast for real GDP is as follows:

(continued)

**EXHIBIT 8.1 Industry Analysis—Report Excerpt** *(continued)***TABLE 17 Forecast Change in Real Gross Domestic Product from Preceding Period, Annualized**

	2009		2010				2011	
	3rd Qtr.	4th Qtr.	1st Qtr.	2nd Qtr.	3rd Qtr.	4th Qtr.	1st Qtr.	2nd Qtr.
Real GDP	3.1%	2.4%	2.5%	2.8%	2.9%	3.2%	3.2%	3.5%

(Source: Consensus Forecast, U.S.A. [September 14, 2009].)

The *Value Line Investment Survey* included similar economic projections, calling for growth in the 2 percent to 3 percent range for the remainder of 2009 and continuing in that range in 2010. Once home prices and employment levels show improvement, Value Line predicts growth may surpass 3 percent on a sustained basis.

With resumed economic growth, corporate profits are expected to climb in 2010, and the consensus forecast expects nominal pre-tax corporate profits to grow by 9.7 percent in 2010 versus the prior year. Inflation is also expected to be a modest 1.9 percent in 2010.

The U.S. stock market appeared to be rallying on the improved outlook for the U.S. economy and had rallied considerably since bottoming out on March 3, 2009, as shown in table 18.

**TABLE 18 Stock Market Indices**

	March 3, 2009 Market Low (Closing Price)	October 2, 2009 (Closing Price)	% Change
S&P 500	672.88	1,025.21	52.36%
Dow Jones Industrial Average	6,547.05	9,487.67	44.91%
NASDAQ	1,268.64	2,048.11	61.44%

(Source: Yahoo! Finance.)

The recessionary environment hurt the trucking industry as shipping volumes declined with economic activity. This resulted in falling freight demand and increased competition. These factors, combined with falling fuel price surcharges due to declining diesel prices, resulted in revenue and profit declines for trucking companies. Fuel surcharges “move in tandem with the price of diesel fuel, which limits the effect that energy cost fluctuations have on earnings.”

Looking forward, an expanding economy should translate into improved results for the trucking industry. “Freight demand should pick up when economic conditions improve, since more goods will need to be shipped.” This should improve the profitability of the industry. With the prospects of increased diesel prices and improved demand, Value Line believes revenues will rise at a “fairly rapid clip.” Value Line’s forecast for the trucking industry is presented in table 19.

**TABLE 19 Value Line’s Forecast for the Trucking Industry**

	2009	2010	% Change	2012–2014	% Change
Revenues (% Mil)	\$23,135	24,650	6.5%	\$32,140	30.4%
Operating Margin	9.50%	11.60%		14.50%	

(Source: Value Line Investment Survey, September 4, 2009.)

**EXHIBIT 8.1 Industry Analysis—Report Excerpt**

Value Line's forecast suggests that the trucking industry is expected to bottom out in 2009, with improved revenues and operating margins expected in 2010 and beyond.

In addition to the economic and trucking industry forecasts, we examined the outlook for The Company's customers. Retailing companies are The Company's major customers. Although retailing had been hit hard by the economy, the industry is expected to bounce back in 2010. According to Value Line's retail store industry composite, industry revenues are projected to grow 6.7 percent in 2010 before advancing 17.9 percent from 2010–2014. Value Line's retail (special lines) industry composite is expected to experience 1.2 percent revenue growth in 2010, followed by 15.7 percent growth from 2010–2014.

In order to get more insight into The Company's prospects, we also looked at The Company's major customers. According to John Smith, The Company's top four customers, in no particular order are Best Buy, Target, TJX, and Macy's. We also looked at other large customers.

As a result of Circuit City's bankruptcy, Best Buy was growing, adding 2.7 percent market share in the three months ended July 31, 2009. Best Buy's comparable store sales were down 6.2 percent and 3.1 percent in the first two quarters of the year ended February 28, 2009. However, these sales are expected to improve going forward because Best Buy is projecting comparable store sales for the year ended February 28, 2010, to be flat to down 2 percent. For the year ended February 28, 2010, Best Buy anticipates adding 40–50 new U.S. stores to its existing 1,023 U.S. stores, an increase of 4 percent to 5 percent. Looking farther out, in its October 3, 2009 report, Standard & Poor expects approximately 50 new store openings in North America over the next six years, projecting mid-single digit annual growth in Best Buy's square footage over the next 5 years.

Pep Boys, a relatively new customer obtained by The Company according to John Smith's deposition, now ranks in The Company's top 10, saw revenues decline in 2008 and the first half of 2009 as the company continued a restructuring effort begun in 2007. After closing 33 stores in 2007, Pep Boys' store count remained unchanged in 2008 at 562 stores. However, Pep Boys' restructuring efforts were expected to bear fruit in the second half of 2009, as revenues are expected to grow for the remainder of the year. 2010 revenues are expected to grow by 2.5 percent, and the company hopes to add an additional 20–40 stores. Revenues are expected to grow 17.5 percent by 2014.

Target has weathered the recession quite well. Revenues increased 2.5 percent in 2008 thanks to the net addition of 91 stores, leaving the total store count at 1,682 at January 31, 2009. Although comparable store sales had declined in 2007 and the first half of 2008, this trend is expected to reverse and Standard & Poor expects a 1 percent same store increase in 2010. Value Line expects a significant improvement in comparable store sales in the third quarter of 2009. As a result of the economy, Target had slowed its store expansion in 2009. After averaging 94 new stores per year from 2005–2008, the company is expecting to add only 60 in 2009. Value Line expects 30 new stores in 2010 (1.7 percent growth) before expansion plans gradually ramp up. From 2010–2014, Value Line expects Target to add 160 stores, a 9 percent increase.

TJX Companies, Inc. has seen strong results despite the recession. Revenues increased 4 percent in 2008, with a 1 percent increase in same store sales. This strong growth has continued in 2009, as TJX's same store sales have continued to grow during the last half of the year by at least 3 percent for all of TJX's U.S. segments. Looking forward, TJX's management has forecast 2 percent to 4 percent same store sales growth in the second half of 2009. In 2010, Standard & Poor's expects same store sales to be flat to up modestly. Value Line projects an overall revenue increase of 3.3 percent in 2010. For 2009, TJX planned to be more conservative in its store openings as a result of economic conditions and planned to add 34 new U.S. stores, increasing its U.S. store total to 2,167, a 1.5 percent increase. Looking further out though, TJX plans to ultimately build 3,050 to 3,100 U.S. stores, an increase of 40.7 percent to 43 percent over projected store counts at the end of 2009. However, there is no time horizon provided for this ultimate expansion.

Macy's has been struggling since at least 2007, when sales first declined by 2.4 percent, followed by a 5.4 percent decline in 2008. Macy's store count has been declining modestly since the end of 2005: 5 in 2007 and 6 in 2008, leaving a count of 247 stores as of January 31, 2009. Looking at 2010, Macy's is expecting half of the slide that began in 2007. Value Line projects Macy's store count to be unchanged, whereas sales are expected to increase less than 1 percent. Although Macy's is expected to stabilize in 2010, sales growth is expected to continue to remain slow over the next several years.

*(continued)*

**EXHIBIT 8.1 Industry Analysis—Report Excerpt** *(continued)*

Sears Holdings Corp. is similar to Macy's in that its decline started before the recession began. Sears Holdings' domestic comparable store sales have declined every year since the predecessor's company's formation in 2003. In general, the performance of Sears stores has been the worst over the time period, as seen in the data in table 20.

**TABLE 20 Change in Comparable Store Sales**

Fiscal Year	Sears	K-Mart
2005	-8.4%	-1.2%
2006	-6.1%	-0.6%
2007	-4.0%	-4.7%
2008	-9.5%	-6.1%

Although Sears Holding Corp.'s sales have been declining, the store count has been relatively unchanged, as seen in table 21.

**TABLE 21 Sears Holding Corp. Store Count**

	Sears				Total Domestic
	K-Mart	Mall	Essential	Specialty	
2005	1,416	866	58	1,128	3,468
2006	1,388	861	74	1,095	3,418
2007	1,382	860	75	1,150	3,467
2008	1,368	856	73	1,233	3,530
% Change in Sears Holding Corp. Store Count					
2006	-2.0%	-0.6%	27.6%	-2.9%	-1.4%
2007	-0.4%	-0.1%	1.4%	5.0%	1.45%
2008	-1.0%	-0.5%	-2.7%	7.2%	1.8%

*(Source: Sears Holding Corp. 10-K Forms filed March 17, 2009, March 26, 2008, March 28, 2007 and March 15, 2006.)*

Looking forward, little is expected to change for Sears Holdings. In 2010, Standard & Poor forecasts a 6 percent decline in same store sales, with K-Mart continuing to outperform Sears. This continues the same trend that has generally been occurring since at least 2003. Store closures are expected to continue as well.

Clearly, 2008 and the first part of 2009 were tough periods for the economy, the trucking industry, and for The Company's customers. However, although the outlook for some of The Company's customers appears to be marginal at best, other customers are projecting a solid recovery as the economy improves. This bodes well for The Company in the future.

As can be seen in the analysis presented in exhibit 8.1, management's expectations of "doom and gloom" in the near term were inconsistent with short-term economic expectations. Economic forecasts indicated growth in the near term and, as a result, the company's largest customers were anticipating moderate near-term growth.

## Industry Trends

Industry trends should also be considered when evaluating a forecast provided by management. Industry factors can include the size of the market, demand drivers, the competitive environment, barriers to entry, and the maturity of the industry. This would be a good time for the valuation analyst to consider all the factors discussed by Porter.

An understanding of the industry is of significant importance when valuing or performing lost profits calculations for companies with limited or no operating history. Oftentimes, I will receive a forecast from management or an opposing expert in an economic damages litigation in which the forecast has the subject company easily penetrating an industry that is already saturated with companies that generate millions and, in some cases, billions of dollars in revenues. In addition, these companies have much larger advertising budgets, capital resources, and brand recognition than the subject. How realistic is it for a subject company with no brand recognition and an inexperienced management team to immediately enter a mature market with large companies that have already established a market presence and capture a 30 percent market share? This further stresses the importance of understanding the industry and its major players in order to better evaluate the growth potential for the subject company.

The following is a list from the American Society of Appraisers (ASA) of industry factors that the valuation analyst may need to consider in preparing a forecast:

1. Growth prospects for the subject company's industry at the national and local level
2. Demand factors
3. Maturity of the industry
4. Structure of the industry and level of competition
5. Technological or economic obsolescence factors
6. Barriers to competitor entry<sup>4</sup>

## Preparing the Forecast

Now let's assume that no forecast is provided by management or the forecast provided is not reasonable. What does the valuation analyst do? The lack of a forecast does not relieve the valuation analyst of the responsibility of preparing a forecast on his or her own. In fact, the ASA corroborates this practice and included the following statement in its course materials:

Practitioner—If the subject company does not prepare forecasts, the appraiser may consider either working with management to prepare forecasts or independently preparing a forecast.<sup>5</sup>

The starting point of the forecast process is the analysis and adjustment of historical financial statements to reflect the economic income of the business being valued. Some of the more common adjustments are as follows:

- The inventory accounting method may be adjusted to conform to industry practice or expected future treatment. This could include a change in inventory accounting from last in, first out to first in, first out.
- Depreciation may be adjusted to reflect current economic write-offs more accurately, based on the value determined by the machinery and equipment appraisers or real estate appraisers.
- Nonrecurring items should be removed.
- Non-operating income or expense items may be eliminated, if appropriate.
- Related party transactions may need to be adjusted if the results are different from those that would be negotiated at arm's length.

<sup>4</sup> BV202N, *The Income Approach*. (American Society of Appraisers Basic Business Valuation Course): 25 (2012 version).

<sup>5</sup> *Ibid.*

Some of the normalization adjustments will be made regardless of whether the valuation subject is a controlling interest or a minority interest. These types of adjustments would be those that affect the future benefit stream, particularly when the historical operations are expected to be different from the future operations. For example, a company may have incurred a hurricane loss in the past year that would not be expected to occur again in the foreseeable future. Certainly, as a valuation analyst, I do not want to start trying to forecast hurricanes. However, in certain parts of the world, this may be more predictable than in others.

Historical operating results should also be analyzed to gain an understanding of the quality of the earnings reported. The valuation analyst should also look for trends that may help predict the future with respect to the direction in which the company is headed. These trends may indicate growing, declining, flat, or volatile income streams. If a company has been growing at an exceptionally high rate, the likelihood is slim that this will continue into the future. Because this rate cannot be maintained, the valuation analyst must compensate for it in the forecast by reducing the growth going forward.

If the company is declining, the terminal value (the period that is after the discrete forecast period—discussed in more detail in chapter 12) may be calculated on the basis of liquidation, as opposed to that of a going concern. If a decline is forecast indefinitely into the future, the valuation analyst should consider whether the highest and best use of the business is in liquidation. If so, the business should be valued in this manner.

If the company's future appears to be flat, there is no reason to use a multiperiod valuation model; in this situation, a single period capitalization model will suffice (this will also be discussed further in chapter 12). When a company's results are erratic, forecasts become extremely difficult and may have little value in the valuation process. An averaging of history may prove to be beneficial, but this should be done only as a last resort.

The valuation analyst shouldn't forget to use other information that was gathered from the company or through his or her own research. Customer contracts can help the valuation analyst forecast expected changes as a result of a customer's growth. For example, if the valuation analyst was valuing a trucking firm that had major contracts with large retail customers, the economic and industry analysis would become important in helping to forecast the trucking firm's growth.

The next question that the valuation analyst should ask is how far into the future the forecast should go. The forecast should go out far enough that it represents sustainable future levels of income for the company. If the company has been showing losses, the forecast should go out far enough to allow the company to return to a level of normal sustainable profitability. The same is true if the company has been making large profits. Go out far enough to reflect the normal conditions for the company. The idea is to go out beyond periods that contain the peaks and valleys that may be short term. The willing buyer is going to be looking for the income stream that he or she can count on beyond the near term.

Another consideration related to the forecast period is that the forecast should go out far enough so that the business can get through a period of significant plant construction or expansion. If new products are being introduced, the forecast should extend to the point that the results of the new product's introduction can be understood. If a merger or acquisition is expected to take place or is in the process of taking place, the forecast should extend to the period after the combination is completed.

The anticipated rate of growth is the primary factor to be considered in how far the forecast should be continued. Stabilization is the goal to be achieved in the forecast period. This is frequently much more difficult than it seems. The valuation analyst will have to conduct a thorough analysis of the subject company, the economy, and the industry, if he or she hopes to get reasonably close. Keep in mind that during the earlier years of the forecast, year-to-year growth can exceed the discount rate selected, but that cannot continue beyond the terminal year because the discount rate minus growth (capitalization rate) cannot logically be less than zero. Imagine: a willing seller paying the willing buyer to take the business off his or her hands? A negative discount rate would create this result. Be patient and this will make more sense after reading chapters 12 and 13.

A common error made among inexperienced valuation analysts who rely on computer software to assist with (or do) the forecast is to allow these programs to determine the period to be used in the forecast. Most software programs allow either a 5- or 10-year period to be used for a forecast. This may not be the correct period for a particular valuation assignment. The facts and circumstances of each situation will be different and require a different forecast period. Do not depend on a software program to make decisions that require judgment!

In practice, the most common forecast period is five years. Some valuation analysts consider this period to be a normal business cycle, whereas others focus on Revenue Ruling 59-60, which suggests five years. There is no magic about five years. The period used can be two years, three years, seven years, or even longer. It is almost always difficult to forecast the future, especially if the future is many years forward.

Preparing forecasts is so dependent on individual characteristics that the standard business valuation literature provides little support on the actual mechanics involved. To accurately prepare a forecast will take adequate analysis, research, and documentation. Unfortunately, there is no quick or simple method. As long as the valuation analyst takes his time and applies common sense, a reasonable forecast can be prepared.

The process of creating a forecast can be broken down into a series of logical steps. First, the income statement must be forecast. The balance sheet is so reliant on the income statement that it becomes impossible to forecast the balance sheet first. After both the income statement and balance sheet are forecast, it then becomes possible to calculate net cash flow.

## The Sales Forecast

The forecast of the income statement must begin with the forecast of sales. Logically, how could the valuation analyst possibly determine cost of sales, variable costs, or taxes if she doesn't know what sales are? Sales are often the most important component of the forecast because nearly every number will rely on it. Obviously, the most time should be spent here.

Determining future sales will involve both qualitative and quantitative analysis. A series of questions must be answered. What has the company done historically? What are the growth trends? Are sales increasing or decreasing? Have there been any major changes (customers, products, facilities, and so on)? Is the company's growth similar to the industry? What is the outlook for the industry? How is the current economic climate affecting the company and the industry? These are only a few of the factors that must be addressed when forecasting sales.

When forecasting sales, the valuation analyst must first identify where the company is in its life cycle and how its product is positioned in the marketplace. Certain factors to consider when preparing a revenue forecast include the following:

- *Inflation.* Inflation should be considered in estimating future gross revenues. When current rates are extreme, relative to historical ranges, the expert should usually reflect gradual increases or decreases toward more normal rates during the forecast period.
- *Product demand.* Products typically go through a life cycle that includes four distinct phases: introduction, growth, maturity, and decline. In estimating future revenues, the valuation analyst should consider the life cycle stage of the company's primary products.
- *Competition.* Within each industry, many companies often compete for a share of the market, and such competitive pressures must be considered in estimating future revenues. Some factors to consider in estimating the effect of competition are as follows:
  - The company's current market share.
  - The company's trend in market share. (Is it increasing or decreasing?)
  - The company's business plan. This should specifically address how the company proposes to keep or increase market share through such means as reduced prices, increased promotional expenditures, and product improvements supported by increased research and development expenditures.

## Revenue Factors for Certain Industries

When estimating future revenues, it is always helpful to understand the key drivers for the particular industry in which the valuation analyst is working. This will allow the valuation analyst to formulate numbers that make sense and test the reasonableness of the result. Some of the factors to consider for certain industries are included in box 8.1.

### BOX 8.1 Industry Revenue Factors for Consideration

Consider the following industry revenue factors when preparing a forecast:

- Professional service businesses, such as engineering, accounting, and law firms' chargeable hours and average billing rates
- Nursing home and hospital beds available, occupancy rates, and average charge per patient
- Homebuilders' number of home sales closed and average closing prices
- Apartment lessors' units available, expected occupancy rates, and average rent per unit
- Restaurants' tables turned per day and average charge per table
- Commercial real estate lessors' net rentable area and average annual rent per square foot
- Manufacturers' units shipped and average selling prices
- Retail stores' floor space and sales per square foot
- Agricultural producers' acres planted, yield per acre, and selling price
- Associations' number of members and annual dues

## Sales Forecasting Techniques

There are various methods that can be used to forecast future revenues. These methods range from being as simple as using an average historical growth rate to as complex as running a Monte Carlo simulation. Whatever method is used to forecast revenues, the ultimate goal is to produce a forecast that is reasonable, supportable, and reflective of the company's future growth prospects and expectations. It is important to note that FASB has issued a new pronouncement on revenues, which will be effective for publicly traded companies in 2018 and for closely held companies in 2019. This new pronouncement will mandate a new five-part test to see if any particular invoice qualifies as revenue. Valuation analysts should be mindful of this new pronouncement and the impact it may have on the subject company's revenue numbers as they forecast future sales.

Many of the methods that will be discussed use the company's historical growth trends as a basis for predicting the future. Although revenue forecasts should be indicative of the future, historical performance is often a good indicator of what the future will look like. A discussion of some of the methods that can be used to forecast revenues follows.

### Average Historical Growth Rate

One way to forecast future revenues is to calculate a company's historical average revenue growth rate over a certain period of time and use this growth rate to increase revenues into the future. This method of forecasting revenues works well for mature, noncyclical companies that have achieved stable and predictable revenue growth historically.

There are various ways to calculate an average historic growth rate. The most commonly used methods are the arithmetic mean and the geometric mean. When forecasting the future, the arithmetic mean is the more appropriate measure to use because it incorporates the year-to-year variability of a company's revenue growth, whereas the geometric mean does not.

When forecasting revenues using an arithmetic average historical growth rate, the valuation analyst must ensure that the historic rate of growth achieved by the company is a good indication of the future. For example, if the valuation date is December 31, 2010 (and I picked this date because it was shortly after the really bad recession), calculating an average growth rate over the most recent five years will likely not be a good indication of the future for a company whose performance is tied to the economy.

Another factor that needs to be considered when forecasting under this method is the length of the forecast. An arithmetic average growth rate over the most recent 3 years may not be a good indication of a company's revenue growth over the next 10 years. The valuation analyst should carefully analyze trends in the company's revenues as far back as possible to determine the appropriate period of time that best reflects future expectations.

A portion of a real valuation of a company that owns and operates health clubs is shown in exhibit 8.2. This exhibit demonstrates what to do with management's forecasts (or budget, in this instance) and how to analyze the historical data to determine the reasonableness of the budgets.

### EXHIBIT 8.2 Sales Forecast

An important component of a business valuation involves the development of a financial forecast that can be used in the application of the income approach to valuation. This can be accomplished in a number of different ways. The courts have greatly favored the use of contemporaneous forecasts that are prepared by a company, as opposed to those that are prepared for a litigation. However, many companies do not forecast far enough into the future for the analyst to have the ability to solely rely on management's forecasts.

In this business valuation, the analyst was provided with annual budgets for the years ending December 31, 2014 and 2015, both prepared on a contemporaneous basis before this analyst was engaged to prepare this valuation. The 2014 budget would have been prepared before the litigation commenced, and the 2015 budget had started being prepared in February and March of 2014 and, therefore, was *known or knowable* at the valuation date.

The budgets provided by management for 2014 were extremely detailed and broken down on a month-by-month basis for the income statements. Management also provided a budgeted balance sheet and cash flow statement for the year ended December 31, 2015. These budgets were partially used in the application of the future in this analysis. This will be explained as the discussion of the underlying assumptions in the forecast proceeds.

Table 19 summarizes the annual 2014 and 2015 budgets prepared by management.

**TABLE 19 Management's Budgets**

	2014	2015
Total Revenue	\$73,165,223	\$86,120,938
Cost of Goods Sold	1,470,164	1,408,043
Gross Profit	\$71,695,059	\$84,712,894
Operating Expenses	62,816,507	75,689,268
Earnings Before Interest, Taxes Depreciation and Amortization	\$ 8,878,551	\$ 9,023,626
Other Income/Expenses		
Depreciation and Amortization	\$11,358,922	\$12,675,339
Interest Expense	2,425,928	1,801,389
State Income Tax Expense	300,000	300,000
Other Income/Expense	65,000	—
Total Other Expenses	\$14,149,851	\$14,776,728
<b>NET LOSS</b>	<b>\$(5,271,299)</b>	<b>\$(5,753,102)</b>

Note: Figures may not add due to rounding.

(continued)

**EXHIBIT 8.2 Sales Forecast** *(continued)*

After generating revenues of \$63,755,675 for the year ended December 31, 2013 and \$65,707,639 for the latest 12 months ended May 31, 2014, management was forecasting that The Company would generate \$73,165,223 of revenues in the year ending December 31, 2014. In addition, management expected The Company to grow further with revenues exceeding \$86,000,000 in 2015. This growth is expected to be driven primarily by opening new clubs in these years. On an unadjusted basis, profitability in 2013 was reported to be \$721,564, and for the latest 12 months ended May 31, 2014, The Company reported a loss of \$50,517. For 2014 and 2015, respectively, the losses are expected to exceed \$5,000,000 in each year. Management anticipates these losses to occur due to higher rental rates in the market and depreciation increases as a result of expected capital expenditures.

In order to test the reasonableness of management's budgets for the purpose of being able to utilize them in the application of the income approach, the analyst constructed a forecast based on historic operations, taking into consideration the Franchise Agreement and the economy and industry analysis that was discussed previously in this report. The analyst assembled financial statements for each of the health clubs owned and operated by The Company. Schedules 3–47 at the back of this report includes select financial data for each of the clubs operated by The Company since the year ending December 31, 2006. At the valuation date, some of these clubs are no longer owned and operated by The Company. This was discussed previously in this report.

The financial statement data for the corporate headquarters is provided in Schedule 48 for the same time frame. In order to proceed with the estimation of future club operations that are required to be opened up pursuant to the Franchise Agreement, the analyst analyzed the historic financial statements.

The analyst developed a profile to predict how a new club would perform in the future, and as a result, the historical financial statements for each of these clubs was restated based on the opening date of the club, to show the first five full years of existence. Each year was measured based on when the lease was signed for that club. This took into consideration the time and expenses incurred by The Company in performing build-outs and bringing clubs to an operational state. This is typical, because it takes many months, and sometimes greater than a year, to open a club from the date the lease is signed.

Schedules 49–85, in the back of the report, include the comparative income statements for those clubs remaining in the profile during the initial five year periods (that is, first year, second year, and so on, as opposed to calendar year 2006, 2007, and so on). This was accomplished by considering the number of days from when a lease was signed to 365 days. For example, if a lease was signed for a new club on December 9, 2009, the analyst combined 22 days of income statement data for 2009 and 343 days of data for 2010 to create a 365-day period from December 9, 2009 to December 8, 2010. This period would represent Year 1 for that club. Years 2–5 were calculated in a similar manner. The intention was to capture full years of revenues or expenses, or both, that also included average time periods between the signing of the lease and the opening of the club. This way, all pre-opening expenses would be properly captured in the profile.

The analyst used this data to create a profile of the “typical” club's income statements during the first five years of operations for the purpose of forecasting the results for the many new clubs required to be opened in the future. In order to accomplish this, the data was analyzed in several different ways, as follows:

- Simple average of all clubs
- Simple average of clubs with five or more years of history
- Weighted average of all clubs, weighted by the month that the lease was signed (clubs established more recently received greater weight)
- Weighted average of all clubs, weighted by the quarter that the lease was signed (clubs established more recently received greater weight)
- Weighted average of all clubs, weighted by the year that the lease was signed (clubs established more recently received greater weight)

Each scenario was summarized to include the first five years of operations. Reviewing this data on a year-by-year basis provides the analyst with a better picture about what took place under each scenario tested. The results of this analysis were further summarized comparing each scenario by year. There was a considerable difference in the averages for Years 1–4. The simple average for clubs with five or more years of operations included 10 clubs that signed leases during 2006–2008. These clubs appear to have generated more revenues and better profitability in the first four years of operations than the average and weighted averages for all clubs considered in the profile.

**EXHIBIT 8.2 Sales Forecast**

In Years 1–3, the weighted averages were consistent with one another and, notably, had lower revenues and profitability than both of the simple averages. This indicates that revenue growth and profitability have declined for new clubs in recent years. The industry analysis indicated that new clubs do not have the same ability to grow as quickly as the older clubs did because of significant competition in the marketplace. There are more industry players trying to attract a limited number of potential users of the facilities. The market has become saturated with the entrance of a number of competitors operating low-cost fitness centers. The result is slower revenue growth for newer clubs.

**Author's Note: I have omitted the expense discussion to save room**

Because the weighted average income statements were relatively consistent with one another, the analyst averaged the three scenarios to create the profile, which is summarized in table 20.

**TABLE 20 Club Profile—Average Of Weighted Average Profiles**

	Year 1	Year 2	Year 3	Year 4	Year 5
Revenues	\$ 538,861	\$1,732,928	\$2,309,748	\$2,582,288	\$2,682,457
Cost of Goods Sold	14,731	41,728	48,067	43,516	45,328
Gross Profit	\$ 524,130	\$1,691,199	\$2,261,681	\$2,538,772	\$2,637,129
Operating Expenses	798,885	1,296,796	1,481,649	1,451,180	1,374,585
Other Income	3,550	1,453	1,421	323	13,819
EBITDA	\$(271,206)	\$ 395,856	\$ 781,453	\$1,087,915	\$1,276,363
Depreciation and Amortization	153,030	272,603	304,798	227,136	199,576
EBIT	\$(424,236)	\$ 123,254	\$ 476,655	\$ 860,780	\$1,076,787
Interest Expense	36,969	68,193	54,202	40,920	29,256
EBT	\$(461,204)	\$ 55,061	\$ 422,452	\$ 819,859	\$1,047,532
Taxes	35	262	207	(174)	(821)
<b>NET INCOME (LOSS)</b>	<b>\$(461,239)</b>	<b>\$ 54,798</b>	<b>\$ 422,246</b>	<b>\$ 820,033</b>	<b>\$1,048,352</b>

Note: Figures may not add due to rounding.

Based on the profile, the typical new club generates revenues of \$538,861 in Year 1 and reaches maturity in Year 4 with about \$2.6 million in revenues. Net income increases from a loss of \$461,239 in Year 1 to positive income of \$1,048,352 in Year 5.

The analyst also analyzed the profile on a common size basis and by its growth rates, which are summarized in tables 21 and 22. Common size financial statements allow an analysis to be performed in which each line item is reflected as a percentage of revenues. This allows trends to be examined regardless of the magnitude of the dollars.

(continued)

**EXHIBIT 8.2 Sales Forecast** *(continued)***TABLE 21 Club Profile—Common Size**

	Year 1	Year 2	Year 3	Year 4	Year 5

**EXHIBIT 8.2 Sales Forecast**

The analyst noted a gradual decline in operating expenses as a percentage of revenues in Years 4 and 5. This makes sense because revenues continue to grow in these years. However, what is surprising is that the dollar amount of operating expenses also declines in these years. This causes a further decline in the percentage. This takes place because the number of clubs used in each year of the profile declines as the newer clubs lack financial history for the full 5-year period. Therefore, the profile relies more heavily on the older clubs in Years 4 and 5 as compared to Years 1–3. Considering this factor, the decline in operating expenses further highlights the fact that operating expenses have been lower for the older clubs than the more recently established clubs and suggests that Years 4 and 5 operating expenses could be higher than the profile indicates. Because the profile is based on The Company’s actual historical data that was *known or knowable* as of the valuation date, the analyst used the profile for the purposes of forecasting new club financial data. The analyst will consider the fact that the profile may understate operating expenses (and overstate profitability) later in the valuation analysis.

The Company’s forecasted income statement is presented in table 23.

**TABLE 23 Income Statement Forecast for the Years Ended May 31,**

**EXHIBIT 8.2 Sales Forecast** *(continued)*

As previously discussed, The Company carries a considerable amount of debt as part of its capital structure. As such, the analyst decided to use an invested capital basis (previously referred to as *debt-free*) to take the impact of the debt service out of the analysis because a hypothetical willing buyer could introduce a different capital structure into The Company. This eliminates the need to forecast potential rising interest rates, and it allows the analyst to consider The Company's profitability without interest expense. This is the manner in which most acquirers would view The Company.

On an invested capital basis, net income represents income to both the equity and debt holders. Cash flow is forecasted in a similar manner. The analyst will account for the actual amount of debt at the end of the valuation process.

The following assumptions went into the income statement forecast.

1. Revenues: In order to forecast revenues, the analyst analyzed the financial statements of the existing clubs based on the number of years each club was in operation. Clubs were grouped based on the number of years in operation so it was more evident about what trends were taking place within the profile of the existing clubs. Because the valuation date in this matter is June 11, 2014, the financial statements for the existing clubs were restated to include the financial results for the 12 months ended May 31 of each year. This is the information that was *known or knowable* as of the valuation date. The use of data subsequent to the valuation date would be improper and violate good valuation practice.

The analyst used the club financial statements that are presented in the back of this report as Schedules 3–37 and converted each club to a latest 12-month period ending May 31. These financial statements are included as Schedules 86–121 in the back of the report. The use of the fiscal year-end financial statements allows the analyst to forecast full year periods without having to use a stub period for 2014, which includes seven months. The results are the same, but the analysis performed provides a better comparison on a year-by-year basis between the historical and future financial performance of The Company.

The data in table 24 includes revenues by club for the years ended May 31, 2010 through 2014, the most relevant period used to forecast the future.

**TABLE 24 Revenues for the Years Ended May 31,**

(continued)

**EXHIBIT 8.2 Sales Forecast** *(continued)*

The last column in the previous table indicates the number of periods that the club has been in existence. For example, an item with “6+” indicates that this club has been operational for six or more years. Those items that are noted with an “NP” represent those clubs that were excluded from the profile for the new clubs. The reason that they are included in this table is to make certain that the figures are all accounted for from the financial statements. The total revenues by club were summarized from the internal financial statements, which were slightly different from the audited financial statements (under \$180,000 or 0.27 percent), but this difference is immaterial to the analysis. Therefore, the analyst feels confident that the correct level of revenues was captured for the analysis.

Using the information from table 24 allowed the analyst to summarize the information as presented in table 25.

Note: NM = Not meaningful.

The actual revenues and the related growth rates for the years ended May 31, 2010 through 2014 are presented in table 25. This table also includes those clubs that were not included in the profile, which ties the figures out to the total revenues generated by all the clubs. The historic revenue growth rates were analyzed, and it was noted that the clubs exhibited similar patterns of growth depending on which year of operation they were in. Clubs experienced substantial growth through their second or third year of operation, before growth moderated in the fourth year. Club revenues in the fifth year of operation experienced an 8.40 percent decline, whereas clubs in existence for six or more years experienced declines of 6.63 and 10.43 percent over the last two fiscal years, respectively. This decline is consistent with the saturation of the industry having an adverse impact on membership growth and, therefore, revenues. The analyst investigated this trend further by analyzing the changes in the average number of members for each of The Company's clubs.

The analyst was provided with the monthly number of members for each club in operation from 2010–2013. The 2010 data included the number of members per club from April–December of that year. The 2012 data only included membership figures from January–May of that year. This data represented all the membership information that The Company could provide. In order to analyze the trends in the membership, the analyst calculated the average monthly number of members in each period. Overall, the number of members declined in 2013 for clubs in operation for five or more years, while membership for newer clubs grew rapidly. A summary of these trends for clubs with two or more years of membership data is presented in table 26.

*(continued)*

**EXHIBIT 8.2 Sales Forecast** *(continued)*

The analyst also considered the change in the total number of members for clubs in their fifth and sixth years of operations. These groupings were consistent with the manner in which clubs were classified in table 26. Clubs in their sixth year of operation experienced declines in the number of members of nearly 30 percent in 2013. Clubs in their fourth year of operation exhibited similar declines in membership of 27.36 percent in 2013. These trends are presented graphically in figure 12.

**Figure 12 Percentage Change in Average Membership for Clubs in Years Five and Six<sup>1</sup>**

<sup>1</sup> In 2013, The Company adjusted its membership records to write off nonpaying members. This adjustment caused the 2013 decline to appear larger than it was. However, there was still a decline in paying members in 2013.

After considering the historical trend of revenues, the analyst forecasted revenues for existing clubs. For 2015, the analyst forecasted that the declines in revenues for existing clubs in their fifth or more year of operation would start to slow down but would still, nevertheless, take place based on continued market saturation in the City area. Thereafter, the analyst reduced each year's decline by 1 percent on the basis that these clubs cannot continue to decline by 10 percent per year or they would go out of business. Although the decline for clubs that had five years of operations was slightly lower, the analyst included the same 10 percent decline for 2015, with a 1 percent reduction each year thereafter in anticipation that these clubs would follow suit with the older clubs.

Clubs with four years of operations were forecast to continue to have a positive upward revenue trend of 11.8 percent based on the historical profile data. Thereafter, these clubs were expected to follow the same trend as the earlier clubs. Revenues for clubs in their third year of operations were forecasted to increase 33.29 percent in 2015 and 11.8 percent in 2016 based on the growth rates shown in the club profile. The growth rates from the club profile for other years were used.

For those older clubs that were not included in the profile, the same growth percentages as described previously based on their current year of operations were used. Based on the Franchise Agreement, The Company is obligated to open at least six new clubs per year. For those new clubs, revenues were based on the amounts in the new club profile. A summary of the revenue forecast is presented in table 27.

Total Revenues for All Clubs in Year 2	13,648,667	18,191,742	20,338,289	18,304,460	16,657,059
Clubs Not Included in Profile					
Total Revenues for All Clubs in Year 6+	7,745,356	7,125,728	6,698,184	6,430,257	6,301,652
Total Revenues for Club in Year 2	6,399,471	8,529,590	9,536,044	8,582,440	7,810,020
Total Revenues for Clubs in Year 1	1,077,721	3,465,856	4,619,495	5,164,576	4,648,118
Corporate	—	—	—	—	—
Total Current Clubs	\$79,282,545	\$84,224,072	\$ 84,096,709	\$ 78,153,620	\$ 72,498,441
New Clubs 2015	3,233,164	10,397,567	13,858,486	15,493,727	16,094,744
New Clubs 2016	—	3,233,164	10,397,567	13,858,486	15,493,727
New Clubs 2017	—	—	3,233,164	10,397,567	13,858,486
New Clubs 2018	—	—	—	3,233,164	10,397,567
New Clubs 2019	—	—	—	—	3,233,164
Total Forecasted Revenues	\$82,515,708	\$97,854,802	\$111,585,926	\$121,136,564	\$131,576,129
Growth Rates	25.24%	18.59%	14.03%	8.56%	8.62%

Note: Figures may not add due to rounding.

Overall, revenue growth is forecasted to decline from 25.24 percent in 2015 to 8.56 percent in 2018 and then increase to 8.62 percent in 2019. The slight increase in growth in 2019 is attributable to higher growth rates for the newer clubs more than compensating for the decline of the older clubs, particularly because the analyst forecast a declining rate of growth in the later years.

## Linear Regression Models

In the last chapter, I provided some information about statistics. To help prepare a sales forecast, various statistical tools can be used, one of which is a linear regression model. There are many individuals who will say that a regression model is not predictive. Although I agree that this model does not demonstrate cause and effect, it is a very useful tool (and I emphasize the word *tool*) that the valuation analyst can use to assist in the forecasting process. Whenever possible, it should not be used alone.

A linear regression model allows the valuation analyst to use one variable to predict the behavior of another variable and to quantify the strength of the linear relationship between the two variables. If used correctly, linear regression can be an effective tool to use to prepare a sales forecast. When performing a regression analysis, the valuation analyst begins with the *dependent variable*, which is the variable that he or she is attempting to explain. The *independent variable* is the variable that is used to explain the behavior of the dependent variable. For example, an analyst may want to use a regression model to forecast the sales of an automobile part manufacturing company based on automobile assembly data. In this instance, the sales of the automobile parts manufacturing company are the dependent variable, and the number of automobile assemblies is the independent variable.

Linear regression assumes a linear relationship between the dependent and independent variables. A regression model calculates a best-fit straight line based on a sample of data. The data is linear if the pattern in its data points resembles a line. A linear trend line usually shows that something is increasing or decreasing at a steady rate. Using a formula, a regression model will calculate the value of the dependent variable given a specific change in the independent variable. An example of how a linear regression model works can be seen in figure 8.1.

**Figure 8.1 Regression Model**

In figure 8.1, the dots represent the data in the sample set. The line represents the predicted values using a linear regression model. A linear regression model calculates the “best-fit line” through the numerous data points. The distance between the data point and the regression line (or the actual value and the predicted value) is called the *residual* or the *error*.

Before discussing how to utilize a linear regression to prepare a sales forecast, it is important to understand the assumptions of the model. Violating any one of these assumptions can lead to drawing incorrect conclusions about the statistical significance of the relationships between the two variables. Although not all the assumptions will be covered in this textbook, if a valuation analyst ever intends on using regression analysis in practice, it is important that he or she understands all the assumptions and how they affect the validity of the regression results. In order to demonstrate the importance of understanding these various assumptions, I will briefly discuss two of the major assumptions and how they can lead to erroneous conclusions.

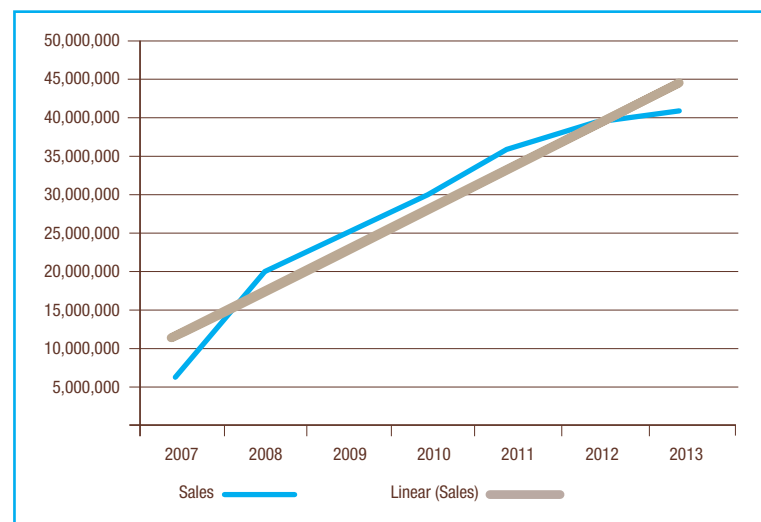

One assumption of a linear regression model is that the relationship between the independent and dependent variable is linear. Although this seems simple, this assumption is critical for a meaningful linear regression. For example, suppose a company’s historical and projected revenues are presented as follows:

Year	Revenues	Changes
2010	\$ 6,500,000	—
2011	20,000,000	207.7%
2012	25,000,000	25.0%
2013	30,000,000	20.0%
2014	35,850,000	9.5%
2015	39,350,000	9.8%
2016	41,500,000	4.6%

As indicated in the preceding table, the company’s revenues grew from approximately \$6.5 million in 2010 to \$20 million in 2011. Going forward, management projected that the company would continue to grow at double-digit rates over the next two years before its growth would decline to a more sustainable level.

Hypothetically speaking, let’s assume that the forecast needed to be extended for an additional five years. Also, let’s assume that the valuation analyst was considering using a linear trend line to forecast future revenues because the  $R^2$  statistic was 93.28 percent.

Graphically, the company’s historical and projected revenues appear as follows:

The preceding chart shows one of the problems associated with the use of a linear regression model. From approximately 2011–2015, the linear trend line consistently underestimated the company's sales. Beginning in 2016, the linear trend line appears to be overstating sales. This indicates that a linear trend line would be inappropriate in trying to forecast this particular company's sales. Therefore, before considering using a linear regression model, it is recommended that the valuation analyst graph the data to determine whether a linear regression model appears to make sense.

Another key assumption of a regression model is that the errors are uncorrelated across all observations. In English, the errors (the difference between the actual value of the dependent variable and the predicted value of the dependent variable), should be random and have no trends. For example, suppose a valuation analyst attempts to use regression analysis to forecast a seasonal data set. The  $R^2$  value is determined to be 93 percent, so the analyst is confident that the model is valid. However, after calculating and graphing the errors, the analyst sees the data in figure 8.2.

**Figure 8.2 Regression Error**

As can be seen in figure 8.2, there is a visible trend in the errors. When there is a visible trend in the errors, one of the linear regression assumptions has been violated, and the model is invalid. When using a linear regression model, the errors should look somewhat like the graph in figure 8.3.

Figure 8.3 A Better Looking Regression

In this instance, the errors appear to be random and have no visible trends. As a result, this model is not in violation of the linear regression assumption that the errors are uncorrelated across observations.

The preceding examples are intended to highlight how using regression analysis blindly can lead to unreliable conclusions. In actuality, there are numerous techniques and statistical tests that are beyond the scope of this book that need to be performed in order to ensure that a regression model does not violate any of the major assumptions. Furthermore, there are various statistics, such as the  $R^2$ , T-statistic, F-statistic, and so on, that must be analyzed in detail in order to determine whether a regression model is valid. Valuation analysts need to understand that performing a regression analysis is a much more vigorous exercise than merely plugging numbers into a statistical software program or even into Microsoft Excel without performing the additional analyses necessary to avoid leading to significant errors.

Now that I've scared the valuation analyst into not using regression analysis, I will discuss the various ways it can be used properly to prepare a sales forecast. A regression model can be calculated using two different types of data: cross-sectional or time-series. *Cross-sectional data* is a type of data that is collected by observing many data points at the same period of time. An example of cross-sectional data is a pricing multiple for a group of public companies in a particular industry. A valuation analyst may attempt to use regression analysis to determine if a significant relationship exists between the pricing multiples and some appropriate metrics for the group of companies for which the pricing multiples were calculated.

*Time-series data* is a type of data that is collected over time. For example, a company's sales over the past several years are an example of time-series data because it consists of consecutive measurements over equal time intervals.

Constructing a forecast using a linear regression model can be performed in many different ways. One way is through use of a time-series regression. A time-series regression would use time as the independent variable and sales as the dependent variable. This type of trend assumes that the company's revenues change at a constant rate with time.

For demonstration purposes, consider a company with the following historic revenues:

2011	38,663,000
2012	41,777,900
2013	44,750,100
2014	46,569,500
2015	56,532,800
2016	62,107,200

This same company's revenues appear graphically as follows:

As the preceding chart indicates, the company's sales have increased steadily over the past five years. The trend of the company's historical revenues resembles a line. In this instance, assuming that the company's future expectations are consistent with the past, a time-series linear trend may be a good way to forecast the company's revenues going forward. Forecasting this company's revenues using a time-series trend line results in the following revenue forecast:

Year	Revenues	% Change
2011	38,663,000	—
2012	41,777,900	8.06%
2013	44,750,100	7.11%
2014	46,569,500	4.07%
2015	56,532,800	21.39%
2016	62,107,200	9.86%
2017	64,730,593	4.22%
2018	69,396,453	7.21%
2019	74,062,313	6.72%
2020	78,728,173	6.30%
2021	83,394,033	5.93%

This data appears graphically as follows:

As the preceding chart indicates, the company’s forecasted revenues are calculated on a best-fit line that was calculated using the company’s historical revenues.

A disadvantage to using a time-series linear trend line is that it doesn’t incorporate economic or industry data into the sales forecast. Therefore, as was the case with the arithmetic average growth rate method for forecasting sales, the valuation analyst must ensure that the company’s historical results reflect its future prospects and expectations.

A solution to this problem could be to use economic and industry variables as the independent variables as opposed to time. For example, if the valuation analyst can establish a strong statistical relationship between a company’s historical revenues and a variable such as GDP, the company’s revenues can be forecasted into the future in relation to independent third-party economic forecasts of real GDP. In some instances, it may be appropriate to use more than one variable when forecasting revenues. Shown in exhibit 8.3 is a real-life example in which we forecasted revenues for a trucking company using real GDP as the independent variable.

The example presented in exhibit 8.3 brings up another point. When constructing a forecast using a linear regression model using a time-series, economic data, or industry data, the valuation analyst must still use his or her judgment and make sure that the forecast is reasonable. This is the same example as in the previous chapter. In this instance, we constructed three potential revenue scenarios to account for the various uncertainties associated with the company’s future financial results.

### EXHIBIT 8.3 Linear Revenue Forecast

In order to forecast revenues, we are presenting three different models. These are as follows:

1. Most Optimistic
2. Most Conservative
3. Most Likely

#### MOST OPTIMISTIC

The most optimistic forecast model uses sales that are forecast by taking into consideration the statistical relationship of The Company’s revenues to real gross domestic product (RGDP). We used RGDP instead of nominal GDP for two reasons: it had approximately the same statistical correlation, and it resulted in more conservative growth rates.

We began our analysis by comparing RGDP to The Company’s revenues beginning in 1990, up to and including the latest 12 months ended June 30, 2009. These figures are shown in table 22.

*(continued)*

**EXHIBIT 8.3 Linear Revenue Forecast** *(continued)***TABLE 22 Comparison of RGDP to Revenues**

	Real GDP	Revenues
1990	8,033.9	\$114,041,000
1991	8,015.1	114,739,000
1992	8,287.1	103,438,000
1993	8,523.4	102,594,000
1994	8,870.7	103,298,000
1995	9,093.7	109,812,000
1996	9,433.9	123,381,000
1997	9,854.3	133,835,000
1998	10,283.5	139,272,000
1999	10,779.8	153,191,000
2000	11,226.0	166,173,000
2001	11,347.2	186,077,000
2002	11,553.0	193,422,000
2003	11,840.7	189,704,000
2004	12,263.8	213,733,000
2005	12,638.4	242,081,000
2006	12,976.2	254,772,000
2007	13,254.1	265,675,000
2008	13,312.2	246,350,000
LTM June 30, 2009	12,901.5	224,713,000

Using regression analysis, we determined that there is a high degree of correlation between the data in table 22. In fact, the R2 indicates that there is a 92.6 percent correlation between RGDP and revenues. This means that about 93 percent of The Company's change in revenues can be explained by a change in RGDP. Perfect correlation would be 100 percent. Having 20 observations makes the statistical correlation very reliable.

**EXHIBIT 8.3 Linear Revenue Forecast**

In order to use RGDP as a predictor of The Company's trucking revenues, we first had to forecast what RGDP would be after June 30, 2009. In order to accomplish this, we turned to Consensus Forecasts and Wachovia Economics. These two sources provided us with the information necessary to review the quarterly or annual forecasted growth rates, or both, in RGDP. Using the annual growth rates published in these publications, we calculated RGDP as presented in table 23.

**TABLE 23 Real GDP Forecast**

	Real GDP	Annual Growth Rate
Q2 2009 (Actual)	12,902	
Q3 2009	13,001	3.1%
Q4 2009	13,079	2.4%
Q1 2010	13,161	2.5%
Q2 2010	13,253	2.8%
Q3 2010	13,346	2.8%
Q4 2010	13,450	3.1%
Q1 2011	13,557	3.2%
Q2 2011	13,676	3.5%
Q3 2011	13,768	2.7%
Q4 2011	13,868	2.9%

Using the calculated RGDP forecast, we were then able to use these figures as a predictor of revenues for The Company on a latest 12-month basis. Applying the regression formula results in predicted revenues of \$249,094,543 and \$261,316,272 for the years ended December 31, 2010 and 2011, respectively. This would be the predicted sales in the most optimistic forecast.

**MOST CONSERVATIVE**

In order to determine the most conservative forecast, we started with the actual sales volume for the 6 months ended June 30, 2009, rather than using the sales from the latest 12 months ended at that time. We divided that number in half in order to estimate the most recent quarter of sales. This amounted to \$51,550,000. We then applied the predicted growth rates using the RGDP relationship to revenues against the actual quarterly sales in order to grow The Company's revenues from the low base at which The Company is currently operating. This allowed us to forecast the remainder of 2009, plus the four quarters of 2010 and 2011, respectively. Our calculations are shown in table 24.

*(continued)*

**EXHIBIT 8.3 Linear Revenue Forecast** *(continued)***TABLE 24 Quarterly Revenues Using Predicted Growth Rates and Average Quarterly Revenues from Past 6 Months**

	Revenues	Predicted Growth Rate
Q2 2009 (Actual)	\$ 51,555,000	
Q3 2009	52,201,089	1.3%
Q4 2009	52,705,164	1.0%
Q1 2010	53,233,392	1.0%
Q2 2010	53,828,705	1.1%
Q3 2010	54,428,186	1.1%
Q4 2010	55,096,542	1.2%
Q1 2011	55,791,805	1.3%
Q2 2011	56,558,333	1.4%
Q3 2011	57,154,828	1.1%
Q4 2011	57,799,833	1.1%
Predicted 2nd Half 2009 Revenues	\$104,906,253	
Actual 1st Half 2009 Revenues	<u>103,110,000</u>	
Predicted 2009 Revenues	<u>\$208,016,253</u>	
Predicted 2010 Revenues	<u>\$216,586,825</u>	4.1%
Predicted 2011 Revenues	<u>\$227,304,799</u>	4.9%

In order to complete this portion of the forecast, we took the predicted revenues from the third and fourth quarter of 2009 and added them to the actual revenues for the first half of 2009. This provided us with an estimation of 2009 revenues in the amount of \$208,016,253. Using the predicted growth rates for 2010 and 2011 allowed us to grow the 2009 revenues to reflect estimated revenues for these subsequent periods. As indicated in the data in table 24, these amounts are \$216,586,825 and \$227,304,799, respectively.

In determining the reasonableness of the figures that we have calculated, we have considered the fact that in most instances, the first half of the year's revenues for The Company tends to be lower than the second half, due to the large shipping volume in the second half for the back-to-school and the holiday seasons. We performed a review of the revenues from the first half of the year to the second half of the year for 2006–2008. This information is presented in table 25.

**EXHIBIT 8.3 Linear Revenue Forecast**

**TABLE 25 Half-Year Revenues**

	1st Half Revenues	2nd Half Revenues	% Change
2006	\$119,921,000	\$134,851,000	12.45%
2007	124,464,000	141,211,000	13.46%
2008	124,747,000	121,603,000	-2.52%

What is noticeable about the 2006 and 2007 figures is the 12 percent to 13 percent change from the first half of the year to the second half of the year. Although 2008's figures were down approximately 2.5 percent, this was largely due to the failing economy, particularly in 2008. This also was significantly affected by the dramatic decline in diesel prices, which would have also affected the lag of the surcharges for the second half of the year. Diesel prices fell approximately 47 percent from June 2008 to December 2008. This would cause this unusual change from the first half to the second half of the year.

During the last half of 2008, GDP fell as well. This would explain the movement in the 2008 figures. Nevertheless, our calculation for 2009, where the second half of the year is predicted to perform better than the first half of the year, would create the expectation that second half revenues should be considerably greater than first half revenues. Places where we have predicted slightly higher revenues are certainly not in proportion to these other years. This is the reason why we believe this is an extremely conservative estimate for 2009 revenues. Because 2010 and 2011 are calculated based on the results of 2009, we believe this model represents the most conservative scenario of the three models that we present.

**MOST LIKELY**

Rather than presenting data solely based on one extreme to the other, we also presented what we believe is the most likely scenario for The Company. In this particular model, we once again use regression analysis to predict what the latest 12 months revenues would equate to for the third and fourth quarters of 2008, as well as the third and fourth quarters of 2009. Based on RGDP declining during 2009, relative to the same period in 2008, we calculated the average change that was being predicted for the second half of 2009 as compared to the second half of 2008. This amounted to a 2.3 percent decline in revenues. We applied this percentage to the second half of 2008 revenues in order to estimate the predicted revenues for the second half of 2009. Our calculations are presented in table 26.

**TABLE 26 Regression Equation Predictions**

	Predicted LTM	% Change from Same
Q3 2008	\$245,443,461	
Q4 2008	240,106,070	
Q3 2009	236,004,039	-3.8%
Q4 2009	238,282,989	-0.8%

*(Table continued)*

*(continued)*

**EXHIBIT 8.3 Linear Revenue Forecast** *(continued)***TABLE 26 Regression Equation Predictions** *(continued)*

Average Predicted % Change 2nd Half 2009 vs. 2nd Half 2008 -2.3%	
2nd half 2008 revenues	\$121,603,000
Predicted 2nd half 2009 revenues	\$118,803,002
Actual 1st half 2009 revenues	103,110,000
Predicted full year 2009 revenues	\$221,913,002
Predicted full year 2009 revenues	\$221,913,002
Predicted change 2010 vs. 2009	4.5%
Predicted 2010 revenues	\$231,981,805
Predicted full year 2010 revenues	\$231,981,805
Predicted change 2011 vs. 2010	4.9%
Predicted 2011 revenues	\$243,363,904

Based on the calculations in table 26, the predicted 2009 revenues amount to \$229,913,002. This is compared to a more conservative estimate of approximately \$208,000,000, and the most optimistic estimate of approximately \$249,000,000. For 2010 and 2011, we applied the predicted 2009 revenues against a predicted change for each of the subsequent years. These figures are shown in table 26.

When performing a linear regression for forecasting purposes, the valuation analyst should be familiar with the regression statistics, assumptions of a linear regression model, and other potential problems associated with linear regression models. Many of these issues are complex, and valuation analysts should familiarize themselves with these issues before blindly using a linear regression model. I have now made this statement twice.

### Monte Carlo Simulation

Another alternative to forecast sales is the use of a Monte Carlo simulation. In most projections, the outcomes depend on different inputs. Minor changes in one of these inputs can have more significant effects at the net income level. The Monte Carlo simulation deals with this by assigning probability distributions to each of the key factors. The power of Monte Carlo simulations to consider and account for potential variability of the inputs in a forecast makes it a useful tool for business valuations. The Monte Carlo simulation has become more popular in recent years. I am constantly surveying students in the classes that I teach to find out how many of them use this technique. It seems that only the large firms use it, probably due to the complexity of their assignments. A detailed discussion about this subject is beyond the scope of this book, but there are courses offered by various organizations on this topic, as well.

### Projecting Sales for a New Business

Most of the revenue-forecasting methods that have been discussed so far require sufficient historical data that will allow the valuation analyst to analyze a company's historical growth trends and use these trends to forecast the future. However, what happens when a company has little or no historical revenue data available? This is often the case in lost profits damages matters involving new businesses.

When forecasting revenues for a new business, the valuation analyst must perform a detailed analysis of the potential market in order to determine how the new business would fit in. It is important to gain an understanding of the competitive environment and the growth outlook for the target market, as well as to have an understanding of the various revenue streams anticipated by the new business. Historical financial information for companies with similar operations, products, and services serve as benchmarks for growth trends and expense structures for the new business.

A common mistake in forecasting revenues for start-up businesses is ignoring the effects of the competition in the marketplace. In one instance, we were engaged in a litigation involving the athletic apparel industry. This industry is heavily saturated with several billion dollar publicly traded companies. A forecast that we reviewed in this matter made the assumption that this new business would experience immediate product acceptance and capture 10 percent of the entire market in its first year of operations. These types of assumptions ignore the stages of the typical product life cycle, not to mention reality. When forecasting revenues for a new business, it is important to have a thorough understanding of the market that the new business is trying to penetrate, who the major players are in the industry, and how the company plans to position its products in the market.

A sales forecast that we prepared for a start-up operation is contained in exhibit 8.4. In this instance, the business was an international amusement park that was looking to expand its operations. In order to forecast revenues for this company, we had to perform a thorough analysis of the tourism market and the competitive environment in the country in which the expansion was taking place. We constructed the sales forecast for this company using comparative data from other facilities operated by management and benchmarking data that we were able to obtain from local competitors.

### EXHIBIT 8.4 Forecasting Sales For A New Business

According to management, visitors to The New Amusement Park most likely would have been nonresident tourists traveling into the country. Therefore, we believe that the tourist market provides a good indication of the potential market for The New Amusement Park.

We obtained historic tourist data for the years 2000–2010. This data is presented in table 13.

*Note:* Some tables were omitted to save space.

Year	Tourist
2000	600,000
2001	800,000
2002	900,000
2003	1,000,000
2004	1,300,000
2005	1,400,000
2006	1,500,000
2007	1,600,000
2008	1,700,000
2009	1,800,000
2010	2,000,000

*(continued)*

**EXHIBIT 8.4 Forecasting Sales For A New Business** *(continued)*

As the data in table 13 indicates, tourism has grown steadily from 2000–2010. The next step in the analysis involved constructing a forecast of future tourism. We located a forecast of overnight visitor arrivals for as far back as 2000 for the entire country in which The New Amusement Park was located from the World Travel & Tourism Council's (WTTC) online searchable database. Using this data, we performed a regression analysis by analyzing the historic tourism data for the entire country and the historic tourism data for the entire city from 2000–2010. From 2000–2010, the  $R^2$  statistic between overnight visitor arrivals in the entire country and tourists in the city was 98.5 percent. Statistically, this means that 98.5 percent of the changes in the number of city tourists can be explained by changes in overnight visitor arrivals for the country. With a strong correlation statistic, we performed a linear forecast of nonresident airport tourists by using the WTTC's forecast. The results of this forecast are presented in table 16.

**TABLE 16 Tourism Forecast**

	Overnight Visitor Arrivals—Country	Tourists—City	City as a % of Country
2000	5,000,000	600,000	12%
2001	5,100,000	800,000	16%
2002	5,200,000	900,000	17%
2003	5,300,000	1,000,000	19%
2004	5,400,000	1,300,000	24%
2005	5,500,000	1,400,000	25%
2006	5,600,000	1,500,000	27%
2007	5,700,000	1,600,000	28%
2008	5,800,000	1,700,000	29%
2009	5,900,000	1,800,000	31%
2010	6,000,000	2,000,000	33%
<b>2011</b>	<b>6,100,000</b>	<b>2,134,545</b>	<b>35%</b>
<b>2012</b>	<b>6,200,000</b>	<b>2,269,091</b>	<b>37%</b>
<b>2013</b>	<b>6,300,000</b>	<b>2,403,636</b>	<b>38%</b>
<b>2014</b>	<b>6,400,000</b>	<b>2,538,182</b>	<b>40%</b>
<b>2015</b>	<b>6,500,000</b>	<b>2,672,727</b>	<b>41%</b>
<b>2016</b>	<b>6,600,000</b>	<b>2,807,273</b>	<b>43%</b>
<b>2017</b>	<b>6,700,000</b>	<b>2,941,818</b>	<b>44%</b>
<b>2018</b>	<b>6,800,000</b>	<b>3,076,364</b>	<b>45%</b>

Bolded values represent forecasts.

**EXHIBIT 8.4 Forecasting Sales For A New Business**

Now that we have constructed a forecast of future tourism for the city, we have an estimate of the total potential market size for The New Amusement Park going forward. The next step in the analysis is to use this information to determine the number of people who would have attended The New Amusement Park for the years 2011 and beyond. Considering the fact that visitors to The New Amusement Park would have consisted of airport visitors, this would represent the pool of potential visitors to this park. Taking this into consideration, the number of estimated visitors to The New Amusement Park was forecast to increase based on the number of airport visitors expected to arrive in the city for 2011–2018. We had previously calculated the expected visitors to the park for 2009–2010. Although a regression analysis based on only two years would not be statistically valid, we tested a linear forecast to determine whether or not the percentage relationship would make sense compared to these other years. For 2009–2010, the tourist capture rate was approximately 4.4 percent, on average. We wanted to make sure that future results would approximate this capture rate. The results of these calculations are presented in table 17.

**TABLE 17 Visitor Forecast Amusement Park**

	Tourists The City	Visitors to The New Amusement Park	Tourist Capture Rate for The New Amusement Park
2000	600,000	—	—
2001	800,000	—	—
2002	900,000	—	—
2003	1,000,000	—	—
2004	1,300,000	—	—
2005	1,400,000	—	—
2006	1,500,000	—	—
2007	1,600,000	—	—
2008	1,700,000	—	—
2009	1,800,000	80,000	4.4%
2010	2,000,000	90,000	4.5%
<b>2011</b>	<b>2,134,545</b>	<b>96,727</b>	<b>4.5%</b>
<b>2012</b>	<b>2,269,091</b>	<b>103,455</b>	<b>4.5%</b>
<b>2013</b>	<b>2,403,636</b>	<b>110,182</b>	<b>4.6%</b>
<b>2014</b>	<b>2,538,182</b>	<b>116,909</b>	<b>4.6%</b>
<b>2015</b>	<b>2,672,727</b>	<b>123,636</b>	<b>4.6%</b>
<b>2016</b>	<b>2,807,273</b>	<b>130,364</b>	<b>4.6%</b>
<b>2017</b>	<b>2,941,818</b>	<b>137,091</b>	<b>4.7%</b>
<b>2018</b>	<b>3,076,364</b>	<b>143,818</b>	<b>4.7%</b>

Bolded values represent forecasts.

(continued)

**EXHIBIT 8.4 Forecasting Sales For A New Business** *(continued)*

The forecast presented in table 17 shows that The New Amusement Park would have captured between 4.4 and 4.7 percent of the total number of tourists that come into the city.

We compared the implied tourist capture rate from our forecast to tourist capture rates of other facilities with similar operations to those of The New Amusement Park. This comparison is presented in table 18.

**TABLE 18 Capture Rate Comparison**

Total Visitors as a % of Total Airport Tourists				
	Fun Land	Roller Coaster Adventure	Thrill Park Mania	The New Amusement Park
2006	16.40%	10.00%	9.49%	
2007	16.30%	9.50%	7.12%	
2008	16.20%	<b>9.00%</b>	5.20%	
2009	16.10%	<b>8.50%</b>	5.10%	<b>4.44%</b>
2010	16.00%	<b>8.00%</b>	5.00%	<b>4.50%</b>
2011				<b>4.53%</b>
2012				<b>4.56%</b>
2013				<b>4.58%</b>

Forecasted values in bold.

As the data in table 18 indicates, the implied tourist capture rate for The New Amusement Park lags those of Fun Land, Roller Coaster Adventure, and Thrill Park Mania. This makes sense because The New Amusement Park would be fighting for market share against competing facilities that have already established a market presence. Other factors that need to be considered include the fact that Fun Land's percentages are inflated because it is the only facility in the area, and it has a notable local market. Roller Coaster Adventure's figures are also likely overstated because the facility only had one competitor in 2006. Thrill Park Mania was the only facility in the market until 2007 when a competing facility completed its expansion and added roller coasters. As can be seen, the entrance of this competitor into the market, along with deteriorating economic conditions, significantly reduced Thrill Park Mania's tourist capture rate.

Now that we have forecasted the number of people expected to attend The New Amusement Park, we must determine two things:

1. What types of passes would these people have purchased?
2. What price would The New Amusement Park charge for these passes?

In order to answer these questions, we turned to data from Fun Land because the same activities at Fun Land would have been offered at The New Amusement Park.

We allocated the number of people forecasted to attend The New Amusement Park using percentages derived from Fun Land. The allocation percentages used for the forecast were calculated as presented in table 20.

**EXHIBIT 8.4 Forecasting Sales For A New Business**

**TABLE 20 Activities as a Percentage of Total Admissions for The New Amusement Park**

	2005	2006	2007	2008	2009	2010	Average
Regular Admission	29,445	32,085	32,430	32,854	17,055	8,943	25,469
% of Total Admissions	46.77%	51.48%	57.06%	66.37%	53.04%	41.78%	53.52%
Junior Admission	33,508	30,223	24,103	16,198	14,438	12,000	21,745
% of Total Admissions	53.23%	48.50%	42.41%	32.72%	44.90%	56.07%	45.69%
Senior Admission	5	200	300	400	60	193	
% of Total Admissions	0.01%	0.35%	0.61%	1.24%	0.28%	0.41%	
Two-Day Admission	8	100	150	265	400	185	
% of Total Admissions	0.01%	0.18%	0.30%	0.82%	1.87%	0.39%	
Total Admissions	62,953	62,321	56,833	49,502	32,158	21,403	47,591

As the data in table 20 indicates, the percentages for each type of pass varied from year to year but remained in a relatively tight range, particularly for regular and junior admissions. Therefore, we will calculate the revenue forecast using the simple averages of the percentages calculated in table 20 to account for the yearly variations in the data.

We must also determine the price for each activity. The quoted price from Fun Land's website for each activity is presented in table 21.

**TABLE 21 Fun Land Quoted Prices**

	Price
General Admission	\$50.00
Junior Admission	30.00
Senior Admission	30.00
Two-Day Admission	80.00

The next step is to determine how the prices charged at Fun Land differ due to the differences in the economic and competitive environments between the city in which Fun Land operates and the city in which The New Amusement Park operates. In order to determine if these prices should be adjusted, we first looked at hotel room rates in these two cities. Average daily rates for both cities are presented as follows:

Average Daily Hotel Rate—Fun Land's City	185.23
Average Daily Hotel Rate—The New Amusement Park's City	114.12
Adjustment Factor	1.623

(continued)

**EXHIBIT 8.4 Forecasting Sales For A New Business** *(continued)*

The preceding data shows that average daily rates for hotels in Fun Land's city are 62.3 percent higher on average than those in The New Amusement Park's city. This would indicate that prices at Fun Land should also be greater.

We also looked at prices charged by competing facilities in the area. This information is as follows:

- Roller Coaster Adventure—\$60 for general admission
- Thrill Park Mania—\$80 for general admission

The preceding pricing data indicates that competitors' prices range from \$60 to \$80 for passes into the park. Our estimated prices for The New Amusement Park range from \$30 to \$80 for the various types of passes. This falls in line with competitors' prices. Neither of the competitors offers junior, senior, or two-day admissions. Based on the analysis discussed previously, no adjustments were made to the prices for Fun Land because the prices fall in line with those charged by competitors of The New Amusement Park.

Prospectively, prices were increased by 4.56 percent per year. This represents the approximate annual growth rate of price increases at Thrill Park Mania from 2005–2010. Our assumption is that price increases for amusement parks in The New Amusement Park's city will be similar to those experienced on average historically.

Now that we have determined all of the necessary information related to visitors, activities, prices, and price increases, we can forecast activity revenue, which is shown in table 22 on the following page.

The next step in the revenue forecast for Phase 1 involves calculating revenues for the gift shop and the sale of food and beverages. We forecasted revenues for these categories by using the historical percentage of revenues for these items as a percentage of total activity revenues. This analysis is presented in table 29.

**TABLE 29 Other Revenues**

Historic Revenues—Fun Land							
	2005	2006	2007	2008	2009	2010	
Tickets and Transportation	\$8,614,202	\$8,499,853	\$8,211,912	\$8,342,581	\$5,725,053	\$3,881,298	
Gift Shop	2,166,372	2,161,553	2,117,417	2,044,346	1,434,983	979,433	
Food and Beverage	512,610	494,724	1,003,087	976,000	775,824	690,628	
Other Revenues—As a Percentage of Tickets and Transportation							
	2005	2006	2007	2008	2009	2010	Average
Gift Shop	25.15%	25.43%	25.78%	24.50%	25.06%	25.23%	25.19%
Food and Beverage	5.95%	5.82%	12.22%	11.70%	13.55%	17.79%	11.17%

As the calculations in table 29 indicate, other revenues for Fun Land have been 36.37 percent of tickets and transportation, on average, historically. This is consistent with management's estimate that other revenues consist of 33 percent of tickets and transportation revenues. This also happens to be the approximate median based on the data in table 29.

**EXHIBIT 8.4 Forecasting Sales For A New Business**

**TABLE 22 Activity Revenue Forecast**

	Tourists	Number of Participants	Regular Admission (55.62%)	Price	Total Regular Admission	Junior Admission (\$43.55%)	Price	Total Junior Admission	Senior Admission (0.42%)	Price	Total Senior Admission	Two-Day Admission (0.40%)	Price	Total Two-Day Admission	Total Activity Revenue

(continued)

### EXHIBIT 8.4 Forecasting Sales For A New Business *(continued)*

Accounting for all sources of revenue results in the following revenue forecast:

**TABLE 30 Total Revenue Forecast**

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Revenues: Activities	\$3,271,710	\$3,848,717	\$4,325,165	\$4,837,121	\$5,386,727	\$5,976,463	\$6,608,913	\$7,286,643	\$8,012,313	\$8,789,089
Gift Shop (25.9%)	847,373	996,818	1,120,218	1,252,814	1,395,162	1,547,904	1,711,708	1,887,241	2,075,189	2,276,374
Food & Beverage (11.17%)	382,790	450,300	506,044	565,943	630,247	699,246	773,243	852,537	937,441	1,028,323
<b>Total Revenue</b>	<b>\$4,501,873</b>	<b>\$5,295,834</b>	<b>\$5,951,428</b>	<b>\$6,655,879</b>	<b>\$7,412,137</b>	<b>\$8,223,612</b>	<b>\$9,093,864</b>	<b>\$10,026,421</b>	<b>\$11,024,943</b>	<b>\$12,093,786</b>

**EXHIBIT 8.4 Forecasting Sales For A New Business**

As a sanity check, we compared our revenue forecast to revenues of other facilities for which data existed. This comparison is presented in table 32.

**TABLE 32 Revenue Sanity Check**

	Fun Land	Roller Coaster Adventure	Thrill Park Mania	The New Amusement Park
2004	\$ 8,052,904	\$14,242,271	\$ —	\$ —
2005	\$11,293,184	\$16,576,124	\$ —	\$ —
2006	\$11,179,347	\$16,752,559	\$ 7,572,161	\$ —
2007	\$11,618,058	\$14,147,751	\$ 7,776,564	\$ —
2008	\$11,637,718	\$10,880,236	<b>\$ 9,219,113</b>	\$ —
2009	\$ 8,277,549	\$ 9,199,428	<b>\$ 9,704,432</b>	<b>\$ 4,501,873</b>
2010	\$ 7,993,510	\$11,224,286	<b>\$10,183,745</b>	<b>\$ 5,295,834</b>
2011	\$ —	\$ —	\$ —	<b>\$ 5,951,428</b>
2012	\$ —	\$ —	\$ —	<b>\$ 6,655,879</b>
2013	\$ —	\$ —	\$ —	<b>\$ 7,412,137</b>
2014	\$ —	\$ —	\$ —	<b>\$ 8,223,612</b>
2015	\$ —	\$ —	\$ —	<b>\$ 9,093,864</b>
2016	\$ —	\$ —	\$ —	<b>\$10,026,421</b>
2017	\$ —	\$ —	\$ —	<b>\$11,024,943</b>
2018	\$ —	\$ —	\$ —	<b>\$12,093,786</b>

Bolded values represent forecasts.

As the data in table 32 indicates, our revenue forecast is consistent and in line with the level of revenues achieved by facilities with similar operations to those of The New Amusement Park.

## Cost of Goods Sold

Once sales are forecast, it becomes possible to forecast expenses. Expenses can be broken down into two categories: fixed and variable. Obviously, sales will have a limited impact on fixed expenses. In the short run, these expenses will probably not change. However, over a long period of time, these fixed expenses will no longer remain fixed because even an expense such as rent will change as the business grows. If rent is \$10,000 a month, it is \$10,000 a month regardless of the sales volume; unless of course, the sales are so large that the business must expand into additional facilities. Variable expenses, on the other hand, are directly related to sales. These expenses are generally forecast as a percentage of sales. For example, if the product costs are \$20 for every \$100 in sales, it is easy to use 20 percent of sales to determine this expense. When

forecasting expenses, it is important to look at trends and management expectations to ensure that the valuation analyst's results are reasonable.

The expense forecast often begins with an analysis of the company's cost of goods sold. For companies that have sufficient historical financial data available, a good starting point to forecast cost of goods sold is to look at the company's historical gross profit margins. If the company's historical gross profit margins have been stable, this indicates that the company's cost of goods sold is primarily variable and can be forecasted as a percentage of sales. However, if the company's historical gross profit margins are volatile, the valuation analyst must determine the factors that are causing the company's gross profit margins to fluctuate from year to year. This could be the result of various factors including changes to the company's product lines, issues with the company's suppliers, or changes in raw material prices. When analyzing historical gross profit margins, the valuation analyst should be aware of any fixed or semifixed expenses, such as labor and depreciation, that may be included in the company's cost of goods sold.

Although the company's historical gross profit margins can be used as a starting point, a forecast should reflect future expectations and, as a result, the valuation analyst must understand the various factors that will affect the company's gross profit margins going forward. For example, if steel is the primary material used in the manufacturing of the company's products, the valuation analyst must understand how changes in steel prices affect the company's profitability. If the company is unable to pass through price increases of raw materials to its end users, it is likely that the company's gross profit margins will fluctuate with changes in these raw material prices. When this is the case, the valuation analyst should perform independent research to gain an understanding of the future outlook for these various raw material prices and determine how changes to these prices would affect profitability.

In some cases, a company will offer different product or service lines with different levels of profitability. In these instances, the valuation analyst should obtain from management historical revenues and gross profit margin information broken down by product line. This information could be useful in preparing a forecast of revenues and cost of goods by product line. We used this methodology to calculate cost of goods sold for the gift shop and the food and beverage revenues generated by The New Amusement Park in our example presented earlier. This example is presented in exhibit 8.5.

### EXHIBIT 8.5 Forecasting Cost of Goods Sold

Cost of goods sold was broken down into two categories: (a) food and beverage and (b) photo and gift.

We analyzed each of these items on a common size basis in relation to the sales amounts for each category. These calculations are summarized in table 35.

**EXHIBIT 8.5 Forecasting Cost of Goods Sold**

**TABLE 35 Cost of Sales**

	Historic					Common Size					4-Year Average		
	2005	2006	2007	2008	2009	2010	2005	2006	2007	2008		2009	2010
Food & Beverage Sales	\$ 512,610	\$ 494,724	\$ 1,003,087	\$ 976,000	\$ 775,824	\$ 690,628	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

**EXHIBIT 8.5 Forecasting Cost of Goods Sold** *(continued)***FOOD AND BEVERAGE**

For purposes of this analysis, food and beverage cost of goods sold consists of cost of goods sold for the snack bar, food and beverage supplies, and the category of expenses called “guest lunch costs,” which represents lunch costs for visitors into the park. As the data in table 35 indicates, cost of sales for food and beverages has declined over the past four years in comparison to 2005 and 2006. This is primarily the result of the significant increase in food and beverage sales that occurred in 2007. Therefore, we calculated an average based on the years 2007–2010 to calculate cost of sales within this category.

**GIFT SHOP**

Gift shop cost of sales as a percentage of sales has shown more stability in comparison to food and beverage. Therefore, we calculated the six-year average common size percentage to account for cost of sales in this category.

When analyzing a company’s gross profit margins, we often find it beneficial to compare the gross profit margins of the subject company to benchmarking data from composite data, industry surveys, or guideline public companies. In particular, Value Line’s industry and company reports contain forecasts for gross profit margins. This information can be useful in analyzing expected trends in profitability because Value Line’s forecasts typically account for factors such as expected changes in raw materials prices. Financial benchmarking data can be useful for forecasting gross profit margins for new companies or to serve as a reasonableness check for the gross profit margins forecasted for the valuation subject.

## Operating Expenses

Once cost of goods sold is forecasted, the next step is to forecast operating expenses. Before preparing a forecast of operating expenses, the company’s historical income statements should be normalized such that the historical expense data does not contain discretionary, non-operating, and nonrecurring items. Once the historical expense data has been adjusted for these items, a good starting point is to look at a company’s expenses, line item by line item, to determine which expenses are variable and which are fixed.

Variable expenses typically increase or decrease in accordance with some measure, usually revenues. In order to determine if a particular expense is variable, the valuation analyst can look at the company’s historical common size income statements. If the expense is dependent on revenues, the common size percentage for the expense items should be relatively stable. Some expenses may be variable in accordance with a measure other than revenues. For example, employee benefits and payroll taxes may vary with total salaries and wages as opposed to revenues.

Fixed expenses, on the other hand, are minimally affected by revenues in the short run. These expenses typically include rent, salaries, utilities, real estate taxes, and insurance. Because fixed expenses usually have a low correlation with revenues, the valuation analyst needs to review various documents, such as leases and insurance policies, to gain an understanding of how these expenses will change going forward. Oftentimes, forecasted inflation can be used to estimate future increases of some fixed expenses. The valuation analyst also needs to be aware that FASB has issued another new pronouncement on lease accounting. This pronouncement will have a significant impact by decreasing the number of operating leases and recording the discounted present value of all future lease payments in the liability side of the balance sheet and may change the classification of expenses formerly classified as rent. This pronouncement is effective for publicly held companies in the year 2019 and for closely held companies in the year 2020. Those folks at FASB have been busy, haven’t they?

## Depreciation and Capital Expenditures

Another expense that often needs to be forecasted is depreciation. The depreciation forecast should reflect the economic depreciation of the company's existing assets and capital expenditures to be made during the forecast period. If this is done, the impact on taxes must also be considered. Alternatively, if tax depreciation is used, the tax benefit should be reflected in the forecast. The type of depreciation used will depend on the purpose of the valuation assignment.

Before forecasting depreciation, the valuation analyst should ensure that the company is currently depreciating its fixed assets throughout their appropriate economic useful lives. If this is not the case, it may be necessary to normalize the company's historical depreciation before forecasting future depreciation.

In order to properly forecast depreciation, it is important to know the condition of the company's existing fixed assets to gain an understanding of what replacement expenditures the company will need to make in the near future. In addition, the valuation analyst should obtain anticipated capital expenditure data from management. The company's historical balance sheets can provide guidance on what a normal level of annual replacement expenditures have been historically. When forecasting depreciation, the valuation analyst should ensure that depreciation expense does not exceed capital expenditures in the terminal period because a company cannot depreciate more than it purchases into perpetuity (this will be discussed further in chapter 12). When a company reaches a stabilized level of performance, its depreciation expense and capital expenditures should approximate each other, with capital expenditures being greater than depreciation due to inflation. Oftentimes, it is necessary to extend the forecast out over a long enough period of time until depreciation expense and capital expenditure purchases stabilize.

## Interest Expense and Borrowing Needs

In some instances, it may be necessary to forecast interest expense. Interest expense should include interest on the company's existing debt and anticipated interest on future borrowings. If the company anticipates making significant capital expenditures in the near term, the valuation analyst should find out from management whether any of these expenditures will be financed by debt, and if so, how much. The interest rate will also need to be forecasted. In order to properly forecast interest expense, the valuation analyst should review copies of all of the company's loan documents and obtain information on the company's current and future borrowing needs. When forecasting future borrowings, the valuation analyst needs to ensure that the forecasted borrowings are not significantly increasing the company's forecasted cash flows, leading to higher valuations. In theory, a company should not be able to become more valuable by borrowing more money.

When forecasting additional borrowings, the valuation analyst needs to ensure that the forecast does not result in the company significantly deviating from its capital structure. FASB's pronouncement on lease accounting may have a significant impact on capital structure because more companies will have to increase their liabilities. The valuation analyst must pay attention to these changes in accounting because they will affect the analysis, comparisons, trends, and so on. The valuation analyst should discuss with management whether the company plans to continue to stay leveraged or eventually pay all of its debt down to zero. If the company plans to continue to finance a portion of its operations with debt, it should be assumed that the company will maintain a similar capital structure going forward. Both the company's own capital structure and the capital structure of similar companies need to be considered. Changing the capital structure may depend on whether a controlling or minority interest is being valued.

In control valuations, when the company's capital structure differs significantly from its industry peers, it may be appropriate to forecast the company's performance on an invested capital basis, which removes the impact of interest expense and changes in net borrowings from the cash flow forecast. An invested capital analysis may also be appropriate when the company's borrowing activity has been erratic in the past. In invested capital cash flow forecasts, it is assumed that negative projected cash flows would have to be financed by the company through the use of debt.

An example of an expense forecast for the valuation of a nursing school is illustrated in exhibit 8.6. As can be seen in this exhibit, when forecasting expenses, we analyzed each individual expense item and labelled it as a variable cost or a fixed cost. In addition, we had to incorporate a unique capital spending budget into the forecast.

### EXHIBIT 8.6 Expense Forecast

**Operating Expenses:** As part of its forecast, management provided details of its operating expenses for fiscal years 2015 and 2016. In a similar manner to revenues, we adjusted these operating expenses to reflect a 12-month period ending on November 30. We categorized The Nursing School's expenses into four categories: variable, labor, other, and rent for the main campus.

Variable expenses consist of student expenses and books, journals, and subscription expenses. These expenses were forecast to increase at the same rate as revenues because these expenses vary with the number of students and the level of tuition and fees.

Labor expenses consist of salaries and wages, independent contractors, and computer equipment and miscellaneous office repairs. According to management, most of the repair expenses consist of a contractor that The Nursing School uses for The Nursing School's IT needs. For salaries and benefits and independent contractors, we forecasted annual increases of 5 percent based on management's forecast. For computer equipment and miscellaneous office repairs, we forecasted annual increases of 10 percent based on management's forecast until The Nursing School reaches capacity during the 12-month period ended November 30, 2017. Upon reaching capacity, we reduced the annual rate of increase to 5 percent, which is more in line with The Nursing School's other forecasted labor costs.

Other expenses consist of non-variable expenses and non-labor-related expenses. These expenses were grown at an annual rate of 5 percent based on management's forecast until The Nursing School reaches capacity. Upon reaching capacity, growth of these expenses was reduced to an annual rate of 3 percent, which approximates historical inflation.

Rent expense for the main facility was adjusted in accordance with the deferred rent amortization schedule provided by management. The Nursing School recognizes its rent on a straight-line basis over the term of the lease agreement. By recognizing its rent expense in this manner, The Nursing School will show a stable rent expense over the term of the lease. In the early years, The Nursing School's cash rent expense is lower than its scheduled rent expense, which creates a liability that accrues over time. Eventually, the cash rent expense will exceed the scheduled rent expense, which will reverse and reduce the liability to zero.

In forecasting The Nursing School's expense, we used The Nursing School's interim financial statements and management's forecast to construct the latest 12-month rent expense ended November 30, 2015. The rent expense in each period includes the cash rent less the deferred benefit. The difference between these items reflects the actual rent expense that will be paid. Based on The Nursing School's deferred rent amortization schedule, cash rent is increased by an inflationary rate of 3 percent per year. Using this same inflation rate, we forecasted rent expense for the remaining term of the lease agreement, until the deferred liability was reduced to zero. These calculations are presented in table 14.

**EXHIBIT 8.6 Expense Forecast**

**TABLE 14 Deferred Rent Amortization For Remainder Of Lease Term**

LTM November 30,	Cash Rent	Deferred Benefit	Rent Expense Deferred Rent Liability	Deferred Rent Liability
2015	\$341,237	\$(33,427)	\$374,664	\$(296,679)
2016	351,474	(25,878)	377,353	(322,557)
2017	362,019	(18,103)	380,122	(340,660)
2018	372,879	(10,095)	382,974	(350,755)
2019	384,066	(1,847)	385,912	(352,602)
2020	395,588	6,649	388,938	(345,953)
2021	407,455	15,400	392,055	(330,552)
2022	419,679	24,414	395,265	(306,139)
2023	432,269	33,697	398,572	(272,441)
2024	445,237	43,260	401,978	(229,182)
2025	458,594	53,109	405,486	(176,073)
2026	472,352	63,253	409,099	(112,820)
2027	486,523	70,580	415,942	(42,239)
2028	501,118	42,239	458,879	—

**Depreciation and Capital Expenditures:** We forecasted depreciation based on the depreciation of The Nursing School's existing assets and the depreciation of the new assets that The Nursing School expects to acquire in the future. The Nursing School's fixed assets consist of leasehold improvements, furniture and fixtures, computer equipment, and medical equipment. We depreciated leasehold improvements over a 13.5-year useful life as The Nursing School is 1½ years into its lease agreement. In addition, we depreciated computer equipment and furniture and fixtures over their remaining economic useful lives, which were estimated as 3.5 and 10 years, respectively.

The next step in the forecast of depreciation expense is to forecast future capital expenditures. According to management, The Nursing School has the following short-term capital spending needs:

	Jan-15	Feb-15	Mar-15	Apr-15	May-15	Jun-15	Total
Simulator	\$ —	\$200,000	\$ —	\$ —	\$ —	\$ —	\$200,000
LHI Sim Lab	5,000	5,000	20,000	40,000	40,000	40,000	150,000
Sim Lab Furniture/ Fixtures	—	—	—	—	20,000	—	20,000
Sim Lab Computer/ Electronics	—	—	—	—	20,000	—	20,000
<b>Total</b>	<b>\$5,000</b>	<b>\$205,000</b>	<b>\$20,000</b>	<b>\$40,000</b>	<b>\$80,000</b>	<b>\$40,000</b>	<b>\$390,000</b>

(continued)

**EXHIBIT 8.6 Expense Forecast** *(continued)*

Based on The Nursing School's immediate needs, \$390,000 of capital expenditures were forecast to be completed during the 12-month period ended November 30, 2015. The simulator was depreciated over a 5-year useful life; the leasehold improvements were depreciated over a 15-year useful life; furniture and fixtures were depreciated over a 12-year useful life; and computers were depreciated over a 5-year useful life.

The next step in our forecast of capital expenditures is to forecast replacement expenditures of existing equipment and recently acquired equipment associated with the simulation laboratory. Replacement expenditures for each category of fixed assets are as follows:

*Simulator:* According to management, The Nursing School will need to acquire a new simulator approximately every five years. Therefore, built into our forecast was a large expenditure related to the purchase of a new simulator every five years. We adjusted the \$200,000 purchase price for annual inflationary increases of 3 percent throughout the forecast period. Future expenditures related to the purchase of a new simulator are as follows:

2015	\$200,000
2020	231,855
2025	268,783

*Computer Equipment:* Replacement expenditures for computer equipment were broken down into two categories: replacement of existing computer equipment and replacement of computer equipment associated with the simulation laboratory.

Replacement of existing computer equipment for the 12-month period ended November 30, 2016 was forecast to be \$15,000. This represents the approximate amount of The Nursing School's historic annual depreciation expense relating to computers, adjusted upwards for inflation, along with new equipment needed for additional employees to be hired. Going forward, capital expenditures relating to the replacement of existing computers are forecast to increase at an inflationary rate of 3 percent annually.

The replacement of computer equipment for the simulation laboratory was forecast to be \$4,200 for the 12-month period ended November 30, 2016. This represents an inflationary level over the annual depreciation expense associated with these assets.

*Furniture and Fixtures:* Replacement expenditures related to furniture and fixtures were also divided into the replacement of existing furniture and replacement of furniture associated with the simulation laboratory.

Replacements of existing furniture were forecast to be \$12,400 during the latest 12-month period ended November 30, 2016. This also represents the approximate amount of The Nursing School's historic annual depreciation expense related to furniture, adjusted upwards for inflation, along with new furniture needed for additional employees to be hired. Going forward, these expenditures were forecast to increase at an inflationary rate of 3 percent annually.

The replacement of furniture for the simulation laboratory was forecast to be \$1,800 for the 12-month period ended November 30, 2016. This represents an inflationary level above the annual depreciation expense for these assets.

*Leasehold Improvements:* Replacements of leasehold improvements were forecast to be \$5,000 for the 12-month period ended November 30, 2016. This \$5,000 reflects replacement expenditures for various leasehold improvements, including the security system, exterior signage, blinds, and various other recurring expenditures. The \$5,000 also reflects an upward adjustment to reflect additional leasehold improvements relating to the simulation laboratory. The capital expenditure forecast for the 12-month period ended November 30, 2016 through November 30, 2016 is presented in the following table.

**EXHIBIT 8.6 Expense Forecast** *(continued)*

LTM Ended November 30,					
	2016	2017	2018	2019	2020
Simulator	\$ —	\$ —	\$ —	\$ —	\$ 231,855
Computers	19,200	19,776	20,369	20,980	21,610
Furniture	14,200	14,626	15,065	15,517	15,982
Leasehold Improvements	5,000	5,150	5,305	5,464	5,628
<b>Total</b>	<b>\$38,400</b>	<b>\$39,552</b>	<b>\$40,739</b>	<b>\$41,961</b>	<b>\$275,074</b>

**Taxes:** Taxes have been calculated based on federal and state corporate income tax rates that were in effect as of the valuation date. Regardless of the type of entity that would operate The Nursing School, a willing buyer would either pay tax at the entity level or pass through enough cash flow to pay tax at an individual level. Therefore, these monies would not be available for reinvestment by The Nursing School.

## Balance Sheet Forecast

Once the income statement forecast is completed, it becomes possible to prepare a balance sheet forecast. Similar to the income statement forecast, the balance sheet forecast can be broken down into item-by-item steps. The easiest technique may be to simply go down the balance sheet, starting at cash and ending with equity.

Assets and liabilities can be forecast based on a variety of factors. These factors include historical common size analysis, ratio analysis (for example, days accounts receivable), management estimates, or as a percentage of an income statement item (for example, sales, cost of sales, operating expenses, and so on).

After completion of the forecast, it is necessary to review the forecast, item by item, to ensure that every number makes sense. Is the financial statement forecast of sales and net income reasonable? Does the balance sheet balance? Are the asset and liability levels reasonable? How do the forecasted common size financial statements and ratios compare to the historical items? Once the forecast is finalized, it becomes possible to complete the discounted future benefits method.

Once the forecast is reviewed and finalized, net cash flow can be calculated. Remember, the definition of *cash flow*, as used in a valuation context, differs from the traditional accounting definitions as described in FASB Statement No. 95, *Statement of Cash Flows* (codified in FASB *Accounting Standards Codification* 230, *Statement of Cash Flows*). There are two ways to calculate cash flow: one based on equity and one based on invested capital. Basic net cash flow (equity) is calculated as follows:

	Normalized net income
+	<u>Normalized noncash charges</u>
=	Gross cash flow
-	Anticipated capital expenditures
+ or -	Working capital necessary to support growth
+ or -	Debt borrowings or repayment
-	<u>Preferred stock dividends</u>
=	<u>Net cash flow to common equity</u>

The manner in which net cash flow is derived will depend on whether the valuation analyst is valuing the equity or the invested capital of the company. As a reminder, valuing the invested capital involves the valuation of the total capital structure (equity and long-term debt). This used to be called *valuing the company on a debt-free basis*. The net cash flow model illustrated previously is used by a valuation analyst when he or she is valuing the equity of the company. If the goal is to value the invested capital of the company, certain modifications must be made. Interest expense is added back, net of taxes, to restate the net income on an invested capital basis. Because interest expense gives rise to a tax benefit, the add-back must be reduced by the corresponding tax benefit. Another modification is that there will be no addition or subtraction for new borrowings or repayment of old borrowings. Logically, if I am attempting to derive an invested capital result, debt should be eliminated from the model. This results in the net cash flow model for invested capital.

	Normalized net income
+	Interest expense (net of taxes)
+	<u>Normalized noncash charges</u>
=	Gross cash flow
-	Anticipated capital expenditures
+ or -	<u>Working capital necessary to support growth</u>
=	<u>Net cash flow to invested capital</u>

Continuing with the nursing school example, the steps we took in order to derive a balance sheet and a net cash flow forecast are outlined in exhibit 8.7. As can be seen in this exhibit, we analyzed each balance sheet account, line item by line item, and used the college's historical financial ratios and common size percentages as guidance to determine what the future will look like. In addition, due to the erratic nature of the school's capital expenditures, we were forced to extend the forecast over a long period of time to allow the school to reach a stable level of performance.

### EXHIBIT 8.7 Balance Sheet and Cash Flow Forecast

The Nursing School's pre-tax income was negative during fiscal years 2013 and 2014 before earning a profit during the latest 12-month period ended November 30, 2014. As a result, The Nursing School would not have had the ability to pay distributions during fiscal years 2013 and 2014. Although The Nursing School was profitable during the latest 12-month period ended November 30, 2014, these profits would not be available for distribution due to large short-term capital spending requirements. However, a company's future net cash flow is an indication of its dividend-paying capacity. In order to determine future net cash flow, we first forecasted The Nursing School's balance sheet. The first five years of this forecast appears in table 15.

**EXHIBIT 8.7 Balance Sheet and Cash Flow Forecast**

**TABLE 15 Balance Sheet Forecast**

	2015	2016	2017	2018	2019
<b>Current Assets</b>					
Cash	\$1,859,501	\$2,128,453	\$2,251,459	\$2,355,026	\$2,463,358
Other Current Assets	22,599	25,868	27,363	28,622	29,938
<b>Total Current Assets</b>	<b>\$1,882,100</b>	<b>\$2,154,321</b>	<b>\$2,278,822</b>	<b>\$2,383,648</b>	<b>\$2,493,296</b>
<b>Fixed Assets</b>					
Gross Fixed Assets	\$1,652,896	\$2,042,896	\$2,081,296	\$2,120,848	\$2,161,586
Capital Expenditures	390,000	38,400	39,552	40,739	41,961
Accumulated Depreciation	(404,339)	(594,730)	(790,558)	(958,895)	(1,133,000)
<b>Net Fixed Assets</b>	<b>\$1,638,557</b>	<b>\$1,486,566</b>	<b>\$1,330,290</b>	<b>\$1,202,692</b>	<b>\$1,070,547</b>
Other Assets	\$58,557	\$67,026	\$70,900	\$74,161	\$77,573
<b>Total Assets</b>	<b>\$3,579,214</b>	<b>\$3,707,913</b>	<b>\$3,680,012</b>	<b>\$3,660,501</b>	<b>\$3,641,416</b>
<b>Total Current Liabilities</b>	<b>\$1,101,398</b>	<b>\$1,207,450</b>	<b>\$1,264,933</b>	<b>\$1,323,956</b>	<b>\$1,385,737</b>
<b>Total Long-Term Liabilities</b>	<b>296,679</b>	<b>322,557</b>	<b>340,660</b>	<b>350,755</b>	<b>352,602</b>
<b>Total Liabilities</b>	<b>\$1,398,077</b>	<b>\$1,530,007</b>	<b>\$1,605,593</b>	<b>\$1,674,712</b>	<b>\$1,738,339</b>
<b>Total Unrestricted Net Assets</b>	<b>2,181,137</b>	<b>2,177,906</b>	<b>2,074,419</b>	<b>1,985,789</b>	<b>1,903,078</b>
<b>Total Liabilities and Equity</b>	<b>\$3,579,214</b>	<b>\$3,707,913</b>	<b>\$3,680,012</b>	<b>\$3,660,501</b>	<b>\$3,641,416</b>

The assumptions for the balance sheet forecast are as follows:

*Cash:* Cash was forecasted by applying The Nursing School's cash turnover ratio of 2.85 as of November 30, 2014 to The Nursing School's revenues in each forecast period.

*Other Current Assets:* Other current assets consisting of prepaid expenses were forecasted to remain at less than 1 percent of sales over the forecast period. This was based on The Nursing School's most recent other current assets-to-sales ratio.

*Other Assets:* Other assets consist of deposits and are forecasted to remain at recent historic levels of approximately 1 percent of sales.

*Current Liabilities:* Current liabilities consist of accrued expenses, student deposits, and deferred tuition. Accrued expenses, consisting of accrued wages and vacation were forecasted as a percentage of salaries based on The Nursing School's accrued wages-to-salaries ratio for the latest 12-month period ended November 30, 2014.

(continued)

**EXHIBIT 8.7 Balance Sheet and Cash Flow Forecast** *(continued)*

Student deposits were forecasted as a percentage of tuition revenues based on the student deposits-to-tuition-revenues ratio for the same period. Deferred tuition balances were calculated to reflect two months of tuition revenues in each period going forward.

*Other Liabilities:* Other liabilities consist of deferred rent. Using The Nursing School's deferred rent amortization schedule provided by management, we calculated The Nursing School's deferred rent liability balance as of November 30 of each year. This liability reaches a balance of 0 by the 12-month period ended November 30, 2028.

Based on the forecasted financial statements, the first five years of forecasted debt-free cash flow are as follows:

**TABLE 16 Calculation of Net Cash Flow 12-Month Period Ended November 30,**

	2015	2016	2017	2018	2019
Debt-Free Net Income	\$ 116,079	\$ 269,853	\$319,535	\$362,995	\$386,656
+ Depreciation	159,879	190,391	195,828	168,337	174,105
– Capital Expenditures	(390,000)	(38,400)	(39,552)	(40,739)	(41,961)
– Increase in Working Capital	(146,907)	(166,169)	(67,018)	(45,803)	(47,868)
– Increase in Other Assets (Liabilities)	20,118	17,409	14,229	6,834	(1,565)
<b>Debt-Free Net Cash Flows</b>	<b>\$(240,830)</b>	<b>\$ 273,084</b>	<b>\$423,022</b>	<b>\$451,625</b>	<b>\$469,367</b>

As the preceding table indicates, The Nursing School incurs a large cash outflow during the first period. However, The Nursing School experiences solid growth in its net income as the result of the addition of new students and the commencement of the ABCD program.

In analyzing the first five years of the cash flow forecast, it becomes apparent that depreciation expense exceeds capital expenditures. This is primarily the result of the large annual depreciation expense related to the leasehold improvements completed in 2013. Depreciation expense in excess of capital expenditures cannot continue into perpetuity because The Nursing School cannot depreciate more assets than it acquires.

Another issue that arises is the treatment of The Nursing School's deferred rent liability. The Nursing School's cash flow cannot stabilize until this liability is completely removed from the balance sheet because this liability will not exist into perpetuity.

Based on these factors, we extended the forecast an additional 11 years until the leasehold improvements were fully depreciated and the deferred rent liability was completely reversed in order to allow for stabilization. The remaining cash flows are as follows:

**EXHIBIT 8.7 Balance Sheet and Cash Flow Forecast**

2020	\$256,253
2021	506,991
2022	525,260
2023	544,182
2024	563,762
2025	311,969
2026	603,078
2027	625,570
2028	629,493
2029	633,541
2030	638,481

As seen previously, net cash flow declines in 2020 and 2025 due to the purchase of a new simulator. By 2030, we anticipate that the gap between capital expenditures and depreciation will close because The Nursing School will incur lower depreciation expense as the leasehold improvements are fully depreciated. In addition, capital expenditures could potentially increase due to spending on additional leasehold improvements, the recurring need to purchase a new simulator, and the various recurring replacement expenditures. Based on these factors, we believe that The Nursing School's operating performance reaches a sustainable level by 2030.

## Applicable Standards for Forecasts in Business Valuation and Economic Damage Assignments

Because this book is published by an accounting organization, I feel obligated to discuss what the reporting requirements are for a CPA valuation analyst. CPAs have a number of standards to follow, including the following:

- Statement on Standards for Valuation Services (SSVS)
- Statements on Auditing Standards (SASs)
- Statements on Standards for Accounting and Review Services (SSARSs)
- Statements on Standards for Attestation Engagements (SSAEs)

Given the increasing number of members of the AICPA who are performing business valuation engagements or some aspect thereof, the AICPA Consulting Services Executive Committee issued SSVS No. 1, *Valuation of a Business, Business Ownership Interest, Security, or Intangible Asset* (AICPA, *Professional Standards*, VS sec. 100), in June 2007. The standard is effective for engagements entered into beginning January 1, 2008. I reviewed SSVS No. 1 for those statements applicable to forecasts or the discounted future benefits method. Paragraph .33 (reproduced, in part, as follows) outlines the factors to consider in performing the income approach:

*.33 Income Approach.* Two frequently used valuation methods under the income approach include the **capitalization of benefits method** (for example, earnings or cash flows) and the **discounted future benefits method** (for example, earnings or cash flows). When applying these methods, the valuation analyst should consider a variety of factors, including but not limited to, the following:

- a. *Capitalization of benefits (for example, earnings or cash flows) method.* The valuation analyst should consider the following:
  - i. **Normalization** adjustments
  - ii. Nonrecurring revenue and expense items
  - iii. Taxes
  - iv. Capital structure and financing costs
  - v. Appropriate capital investments
  - vi. Noncash items
  - vii. Qualitative judgments for risks used to compute discount and **capitalization rates**
  - viii. Expected changes (growth or decline) in future benefits (for example, earnings or cash flows)
- b. *Discounted future benefits method (for example, earnings or cash flows).* In addition to the items in item a, the valuation analyst should consider the following:
  - i. Forecast or projection assumptions
  - ii. Forecast or projected earnings or cash flows
  - iii. **Terminal value**

In addition to SSVS No. 1, what other standards are applicable to forecasts prepared for use in business valuations? To answer this question, I reviewed Interpretation No. 1, “Scope of Applicable Services,” of VS section 100 (AICPA, *Professional Standards*, VS sec. 9100 par. .01–.89). Illustration 22 (paragraphs .74–.75) indicates that the valuation analyst does not need to examine or compile prospective financial information in accordance with the SSAEs. Paragraphs .74–.75 are as follows:

*.74 Illustration 22.* In the course of performing a valuation under the Statement, if a valuation analyst prepares prospective financial information (for example, as part of a discounted cash flow or discounted earnings analysis within the income approach), does this require the valuation analyst to examine or compile such information in accordance with the Statements on Standards for Attestation Engagements (SSAEs) [AT sections 20–701]

*.75 Conclusion.* No, chapter 1, “Attest Engagements,” of SSAE No. 10, *Attestation Standards: Revision and Recodification* [AT section 101.01], states that the attestation standards apply when a practitioner is “engaged to issue or does issue an examination, a review, or an agreed-upon procedures report on subject matter, or an assertion about the subject matter..., that is the responsibility of another party.” If the valuation analyst has not been engaged to examine, compile, assemble, review, or apply agreed-upon procedures to prospective financial information, and does not issue an examination, compilation, assembly, or agreed-upon report on prospective financial information, the SSAEs [AT sections 20–701] do not apply (SSARS 14 [AR section 120]).

In performing forecasts for business valuation purposes, the valuation analyst needs to comply with SSVS No. 1 but is not required to examine or compile the forecasts in accordance with other accounting standards. Although this is the case, it is still a recommended practice to include a disclaimer such as the following:

In preparing these Financial Forecasts, we have relied upon historical financial information provided to us by management and derived from corporate tax returns. This information has not been audited, reviewed or compiled by us, and, accordingly we do not express an opinion or any form of assurance on any of this material. By their nature it is not possible to accurately predict future results of operations and financial positions of an entity. While these Financial Forecasts have been prepared in conjunction with management based on their views of the most probable assumptions as to future events and courses of actions, the actual results will differ from those projected and the variances may be material.

In other words, the traditional accounting standards do not apply to these types of engagements. However, common sense should guide the valuation analyst into doing the correct thing.

## Court Acceptance

In tax-related valuation assignments, Revenue Ruling 59-60 discusses the fact that, “valuation is a prophecy of the future.” This is an indication that the future is an important component of the valuation process. In *Central Trust v. United States*,<sup>6</sup> the court found that “past earnings are important only insofar as they reasonably forecast the future earnings.”

In the *Estate of Kirkpatrick*,<sup>7</sup> the court emphasized the fact that a potential investor would analyze the business enterprise from the viewpoint of its prospects as a money-making enterprise. In the Delaware Chancery Court, there have been numerous decisions relying on a discounted cash flow methodology. In some nontax-related appraisals (divorce appraisals), the courts are still uncertain about using forecasts. However, more and more courts are beginning to accept this methodology if a well-thought-out and properly presented forecast is used in a valuation. Some judges are uncomfortable with forecasts and discount their value.

It is up to the valuation analyst to be able to explain the importance of the future in the context of a valuation assignment. Who buys history? Many divorce-related valuations refer to Revenue Rulings 59-60 and 68-609, so the valuation analyst should remember that these rulings emphasize “probable future earnings.” The problem is that the judge gets an uncomfortable feeling because the forecasts are usually poorly done. This makes the forecasts seem highly speculative. Performing a forecast is not a guarantee that the company will actually achieve the forecast results, but not doing a forecast is like not really doing a valuation. Even if the valuation analyst uses historical data, he or she is effectively saying that the future is expected to resemble the past.

In *Valuing a Business*, the authors discuss the court acceptance of forecasts as follows:

In court, the parties to an action and the judge rely on evidence to support a particular position. Historical facts are often considered more credible evidence in the eyes of the court than future projections of what somebody thinks will happen. Therefore, when legal evidence is required, the focus tends to be on the historical record of financial performance; future benefits and their predictability as of the valuation date can be more difficult to establish, unless backed up with solid foundational research. The courts generally prefer provable historical results to unprovable expectations of future results, but some courts are becoming more amenable to accepting projections prepared in the ordinary course of business. The extent to which a court will accept projections as evidence in a valuation case is probably a function of the degree of confidence the court has in the validity of those projections based upon information available as of the valuation date, as well as the credibility of the evidence and the witness. While courts continue to apply judicial scrutiny to the reasonableness of specific projections, it is noteworthy that in recent years courts have become much more accepting of the application of the discounted cash flow method as a valuation methodology.<sup>8</sup>

The key to having the court accept a forecast is to properly document the assumptions. The valuation analyst should not just blindly ask the client for a forecast and accept it as if it is objective. Clients have desired end results, and despite what they say about not understanding the business valuation process, they almost always know if they need a good forecast or a “doom and gloom” forecast. The valuation analyst should not get caught up in being an advocate for his or her client, particularly in a litigation assignment, because it will come back to haunt the analyst.

An example of this took place in the Minnesota U.S. District Court in the case of *US Salt, Inc. v. Broken Arrow, Inc.*<sup>9</sup> The court had little trouble finding that the expert’s reports contained “very little analysis and were riddled with unsupported assumptions.” In fact, when asked in a prior deposition whether he had done anything to verify whether the information and projections relied upon were accurate, the expert answered quite frankly:

6 *Central Trust v. United States*, 305 F. 2d 393 (1962).

7 *Estate of Kirkpatrick*, T.C. Memo 1975-344.

8 Shannon P. Pratt and Alina V. Niculita, *Valuing a Business*, 5th ed. (New York: McGraw Hill, Inc., 2008): 57.

9 *US Salt, Inc. v. Broken Arrow, Inc.*, 563 F. 3d 687, Court of Appeals, 8th Circuit, 2009.

“not that comes to mind.” Without an independent, objective opinion on the part of the expert, the court found that the management’s estimates were “nothing more than optimistic projections.” Further, the court concluded that “[the expert’s] wholesale acceptance of [management’s] projections without any verification of these estimates or any independent market analysis is simply too speculative to submit to a jury.”

In another case, *Richard S. Gesoff v. IIC Industries, Inc., CP Holdings Limited, Kenyon Phillips Acquisition, LLC, Bernard Schreier, John Smith, Robert M. Levy, Robert Glatter, and Alfred L. Simon*,<sup>10</sup> the expert adjusted management’s forecasts, which created a result that differed considerably from the forecasts produced by management. According to the court

Defendant’s Expert personally prepared the forecasts used in his valuation for Zoko, purportedly based on management forecasts, but adjusted downward for various reasons having to do with Zoko’s business situation as of the valuation date. The Court is not persuaded that Defendant’s Expert’s revisions to the Zoko management projections are reliable, and their use would cut against this court’s belief that management projections are generally preferable to projections by third parties, especially projections by third parties created after the fact.

In these two cases, one expert relied on management’s forecast and the other adjusted management’s forecast; yet, each of these forecasts was deemed unreliable and was not used. What the experts failed to do was verify the acceptability of their forecasts and adequately document their assumptions. Once again, the valuation analyst should never blindly accept forecasts performed by management and if the analyst does adjust these forecasts, he or she needs to make sure to document the assumptions and make certain the final result makes sense.

## Conclusion

Forecasting is not an easy task if it is done properly. It requires a considerable amount of time to properly support all the assumptions used. It does not matter whether management has provided the forecast to the analyst or if the valuation analyst had to prepare it from scratch. At the end of the process, the forecast has to make sense. If the valuation analyst is not comfortable working with forecasts, business valuation may not be the right specialty for that person. There is no way to avoid having to deal with forecasts if business valuation is the field of choice. Let’s move on.

<sup>10</sup> *Richard S. Gesoff v. IIC Industries, Inc., CP Holdings Limited, Kenyon Phillips Acquisition, LLC, Bernard Schreier, John Smith, Robert M. Levy, Robert Glatter, and Alfred L. Simon*. 902 A. 2d 1130, Del: Court of Chancery, 2006.

## Chapter 9

# The Market Approach— Part I

### Learning Objectives

Now that all the gathering stuff has been explained, we can now start to discuss what to do with it. In this chapter, I will begin to explain the market approach. There is a lot of important information here! After an introduction to the market approach, I will cover the guideline public company method. This discussion will include the following:

- The guideline public company method
- Selecting potential guideline companies
- Analyzing guideline companies
- Using valuation multiples
- Advantages and disadvantages of the guideline public company method
- Illustrating the guideline company method

### Introduction

The market approach is probably the most fundamental approach in a fair market value assignment. Because fair market value is supposed to come from the market, it seems natural that this approach should be greatly emphasized. However, the application of this approach can, at times, be the most difficult approach to use in a business valuation. In real estate appraisal, the appraiser looks for properties similar to the piece of real estate being appraised in order to compare the similarities and dissimilarities between the properties. After the comparison is made, the real estate appraiser estimates the value of the subject property using a grid to analyze the various properties that were considered to be comparable to the subject property. The sales price of each comparable property is adjusted for each factor that the real estate appraisers believes is a difference (good or bad) between the property that was sold and the subject company. The adjusted comparable prices are then equated to the subject property to determine the fair market value of the property. A simplified grid analysis of the sales price of the comparable properties appears in table 9.1 on the following page.

This concept can be illustrated using the following example. Property A sold for \$200,000. It is a single-family house on a busy main road; it is on one acre of land and has three bedrooms, two baths, and a newly renovated family room. Property B sold for \$175,000. It is also a single-family residence in the same neighborhood, but it is further down the street, off the main road, on one acre of land, and it has two bedrooms, two baths, and a well-maintained interior. Property C sold for \$190,000 and is on the same block as property B; it is also on one acre, has two bedrooms and two and one-half baths, and is in relatively good shape on the inside. An appraisal of property D is requested. The comparative information about the properties is given in table 9.1 on the following page.

After a comparison of the features of properties A, B, and C with those of property D, it appears that property D most closely resembles property C, except the appraisal subject has an extra bedroom. Therefore, the real estate appraiser concludes that the appraised value of property D should be a little higher than property C because of the extra bedroom and is \$200,000.

This is a simplistic example and is not intended to make light of the role of the real estate appraiser. However, real estate sales are generally available in public records; therefore, the real estate appraiser has a definite advantage over the business valuation analyst. The point being made is that an estimate of fair market value is

**TABLE 9.1 Sample Real Estate Comparative Statistics**

	Property A	Property B	Property C	Property D
Sales price	\$200,000	\$175,000	\$190,000	Unknown
Acreage	1	1	1	1
Location	Main road	Quiet street	Quiet street	Quiet street
Bedrooms	3	2	2	3
Baths	2	2	2.5	2.5
Interior	New condition	Good condition	Good condition	Good condition
All else	Same	Same	Same	Same

an interpretation of market data indicating the worth of a property. The role of the valuation analyst is that of an interpreter, not a market maker. Our job is to use the information available in the market to estimate the value of the valuation subject. Despite the similarities to real estate appraisal, business valuation methods are a bit different.

The market approach emphasizes the principle of substitution, which was discussed previously. This means that given alternative investments, an individual would be expected to gravitate toward the property with the lowest price if all other attributes are the same. This gravitation may frequently involve the personal choices of the purchaser, but risk is a key ingredient in the selection process.

The market approach is the most direct approach for establishing the fair market value of a business. The methods that are used most often under this approach are (1) the guideline public company method, (2) the merger and acquisition method, (3) sales of the company's own stock method, and (4) the industry method (sometimes called *rules of thumb*). This chapter will be dedicated solely to the guideline public company method. Chapter 10 will discuss the other stuff.

Regardless of the method used, the valuation analyst must consider the sources of market data. Whereas in real estate appraisal the appraiser is able to obtain "good" information about the comparable properties, business valuation analysts do not always have the same luxury. The data that is available may differ significantly depending on the types and sizes of the companies. The data used for the guideline public company method will come from publicly traded companies, whereas the data used in the application of the merger and acquisition method may come from either the public market or businesses that are closely held. Both of these sources can present real problems to the business valuation analyst.

## Guideline Public Company Method

Proper application of the guideline public company method is labor intensive and will take time to perform. Following the basic steps laid out in this section will increase the valuation analyst's success in applying this method, but remember that valuation is an iterative process. Frequently, the valuation analyst will find that he or she is repeating these steps. Either practice makes perfect or it leads to being extremely frustrated.

The guideline public company method of valuation is based on the premise that pricing multiples of publicly traded companies can be used as an indicator of value to be applied in valuing the closely held valuation subject. Before we go too much further, let's just make sure that you understand what a pricing multiple is. A pricing multiple is a relationship between the price of a share of public company stock and some other factor, such as earnings, cash flow, revenues, and so on. For example, assume that a public company has a current market price per share of \$96. Also, assume that the last reported earnings reported for the company were \$8 per share. In this instance, the price-to-earnings multiple would be computed as follows:

$$\$96 \div \$8 = 12$$

The price-to-earnings multiple would be 12 in this example. Simply put, it means that the market participants are pricing the public company stock at 12 times earnings at that point in time. Not all multiples have to be calculated using earnings. We will soon discuss other multiples that can be used and when they might be appropriate.

Using multiples of public companies in this manner is suggested in Revenue Ruling 59-60 in the famous eight factors to consider (at a minimum). The ruling tells us to consider the *market price of stocks of corporations engaged in the same or similar line of business having their stocks actively traded in a free and open market either on an exchange or over the counter*.

The mechanics of the method require the valuation analyst to use the stock price of the public company in conjunction with some other factor (such as earnings, cash flow, or book value), to create a pricing multiple. With certain adjustments, the pricing multiple is applied to the valuation subject's similar factor to determine an estimate of value for the company. A price-to-earnings multiple would be applied to the company's earnings, a price-to-cash flow multiple would be applied to the company's cash flow, and so on.

To use this method properly, the publicly traded companies that are used as surrogates must be comparable to the closely held valuation subject. The comparable companies will not be identical to the valuation subject but should be similar enough to provide guidance to the valuation analyst during the valuation process. The similar companies, formerly known as *comparative companies* or *comparables*, a term taken from the real estate appraisal world, are known as *guideline companies* in our world. This terminology was suggested by the Business Valuation Committee of the American Society of Appraisers to highlight the fact that no two companies are truly comparable, but, rather, that similar companies can provide guidance about other companies in the marketplace.

In business valuation, the requirements for “similarity” are considered from an investment point of view. The factors that will be considered by the valuation analyst will vary from assignment to assignment. One concise list of factors to consider in determining the similarity of the guideline companies is impossible. However, some of the factors to consider have been included in the writings of Graham, Dodd, and Cottle;<sup>1</sup> Stockdale;<sup>2</sup> and Bolten, Brockardt, and Mard.<sup>3</sup> These writings have been around for some time now, but, quite frankly, the factors that determine similarity that these authors discuss have not changed that much. Some of the factors to consider, though not necessarily in any special order, are listed in box 9.1.

Various authors have created a substantial list of attributes to consider in determining whether the guideline companies are comparable enough to be used as good surrogates in a valuation. In order for a guideline company to be used properly, it must be *similar* and *relevant* to the valuation subject. Comparing the local hardware store with The Home Depot may involve similar businesses, but, let's face it, where's the relevance? Another error that I have been seeing much too often these days

**BOX 9.1****Common Assessment Factors for Determining Similarity in Selecting**

- Past growth of sales and earnings
- Rate of return on invested capital
- Stability of past earnings
- Dividend rate and record
- Quality of management
- Nature and prospects of the industry
- Competitive position and individual prospects of the company
- Basic nature of the activity
- General types of goods or services produced
- Relative amounts of labor and capital employed
- Extent of materials conversion
- Amount of investment in plant and equipment
- Amount of investment in inventory
- Level of technology employed
- Level of skill required to perform the operation
- Size
- Financial position
- Liquidity
- Years in business
- Financial market environment
- Quality of earnings
- Marketability of shares
- Operating efficiency
- Geographical diversification
- Similarity of business model

1 B. Graham, D. Dodd, and S. Cottle, *Security Principles and Technique*, 4th ed. (New York: McGraw-Hill, 1962).

2 John J. Stockdale, “Comparison of Publicly Held Companies With Closely Held Business Entities,” *Business Valuation Review* (December 1986), 3–9.

3 Steven E. Bolten, James W. Brockardt, and Michael J. Mard, “Summary (Built-up) Capitalization Rates for Retailers,” *Business Valuation Review* (March 1987), 6–13.

is the use of a large industry leader as a comparable company for a small start-up company. This is like saying if a small accounting firm was bigger, it would be PricewaterhouseCoopers. Although this may be true, there is so much that would have to happen to make a small accounting firm into the next PricewaterhouseCoopers that using it now as a comparable is like comparing night and day. In chapter 27, I discuss the tax court case of the estate of Joyce C. Hall. This case has some great stuff in it about choosing guideline companies. When you get to this chapter, read my summary, or if you really want to understand the market approach, read the actual case. This case is included on the portal included with this book from Business Valuation Resources. This will assist you further in understanding the concept of same or similar.

How do we identify guideline companies in practice? Earlier, I indicated the criteria for determining similarity. In the real world, the search for guideline companies can be accomplished the old fashioned way—by legwork at the library—or the modern way—by sitting at your desk in front of a computer. Those of us who started in this business a long time ago (it seems like when the dinosaurs roamed the earth) did not have a choice. Today, I opt for the latter alternative. It's much faster and a lot less work.

Before we walk through the process of finding guideline companies and figuring out what to do with them once we have found them, take a look at exhibits 9.1, 9.2, and 9.3. These are the document checklists that we use to help keep track of the basics. We have adapted them from Thomson PPC's *Guide to Business Valuations*. I already told you: If it ain't broke, don't fix it. These can be modified (as we have done) for the valuation analyst's own use.

### EXHIBIT 9.1 Guideline Company Checklist

Company Name: \_\_\_\_\_

Completed by: \_\_\_\_\_ Date: \_\_\_\_\_

**INSTRUCTIONS:** This form lists procedures commonly performed in applying these valuation methods. The exact procedures used are a matter of professional judgment based on the circumstances of each engagement, and this form should be tailored accordingly. The valuation analyst performing the procedures should initial the space labeled "Completed by" as each step is performed. If a procedure does not apply to a particular engagement, write N/A in the space opposite the step. If additional procedures are needed, document them on a separate page or memo. Use the "Comments" section on the last page to document problems encountered or unusual matters.

**Note:** This checklist is designed to determine an equity value. Modifications may be needed to determine an invested capital value.

PROCEDURE	Completed by or N/A	Working paper Ref
1. Obtain financial statements of the company being valued for a representative period of time. Adjust the financial statements for any GAAP errors or normalization adjustments. Recompute federal and state income taxes based on normalized pretax earnings.		
2. Identify guideline companies by performing the following procedures:		
<ul style="list-style-type: none"> <li>a. Assemble a list of potential guideline public companies. The list should normally be compiled in the following manner:</li> <li>b. Through discussions with management, identify the company's major competitors.</li> <li>c. Determine the company's Standard Industrial Classification (SIC) code(s) or North American Industrial Classification System (NAICS) code(s) and perform a search of published sources for companies with the same or similar code(s). The company's primary SIC or NAICS codes are as follows:</li> <li>d. Identify additional companies from other sources, such as trade magazines, or stockbrokers.</li> </ul>

**EXHIBIT 9.1 Guideline Company Checklist**

<b>PROCEDURE</b>	<b>Completed by or N/A</b>	<b>Working paper Ref</b>
3. Obtain financial and other information for each potential guideline company.		
4. Complete a “Guideline Company Comparison Worksheet” for each potential guideline company.		
5. If necessary, adjust the financial statements of the guideline companies to make them more comparable to the company being valued.		
6. Decide which multiples are appropriate for the engagement given the unique aspects of the company being valued and the definition of value.		
7. Determine what time period of operations (recent 12 months, recent fiscal year, and so on) should be used in measuring the company’s operations.		
8. Compute the selected multiples for each guideline company based on the adjusted financial information. You may use the “Value Multiple Computation Worksheet” to document each value multiple computation. Earnings or cash flow for each guideline company should be measured for the same time period as the company being valued.		
9. Select an appropriate value multiple based on the individual multiples of each guideline company. You may use the “Determination of a Single Value Multiple Worksheet” to document this selection.		
10. Increase or decrease the selected multiple based on differences between the guideline companies and the company being valued. Any adjustments should be documented in the “Determination of a Single Value Multiple Worksheet.”		
11. Multiply the selected multiple by the normalized benefit stream of the company (or ownership interest) being valued to arrive at the estimate of value.		
12. If more than one type of value multiple (price/earnings, price/revenue, and so on) was used on the engagement, determine the relative weighting to be given each type of multiple.		
13. Apply sanity checks on the values computed in step 11 to determine the reasonableness of those values.		
14. If there were any adjustments made in step 1 to the financial statements of the company being valued for any non-operating or excess assets, determine an appropriate value for those assets. Add the value of those assets to the values computed in step 11. If asset shortages were identified in step 1, determine if the value estimate should be reduced to reflect the value of such shortages. If the normalized income statement was adjusted to reflect the impact of identified asset shortages, it is not necessary to further reduce the value estimate.		
15. Determine whether the estimated values of the company that were determined in step 11 should be adjusted for marketability discounts, control premiums, minority interest discounts, or other premiums or discounts.

**EXHIBIT 9.2 Guideline Company Comparative Worksheet**

Company: \_\_\_\_\_ Valuation Date: \_\_\_\_\_

Prepared by: \_\_\_\_\_ Date: \_\_\_\_\_

**A. Potential Guideline Company Data**

**INSTRUCTIONS:** This form should be completed for each potential guideline company. The form is a guide to the key factors that should be considered in determining how similar each potential guideline company is to the company being valued. It is not necessarily a complete listing of all factors that might be considered. Specific engagement circumstances may require additional considerations.

Name of potential guideline company: \_\_\_\_\_

How was this company identified as a potential guideline company?

\_\_\_\_\_

\_\_\_\_\_

Briefly describe the operations of the potential guideline company, including its products, customers, geographic markets, and apparent strengths and weaknesses. Indicate the source of this information.

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

**B. Trading Activity**

Test for market activity in the guideline company's stock using data obtained from Yahoo! Finance or a similar source (adjusted for capital changes) (**Make certain that the trading volume has been adjusted for capital changes**) and the guideline company's current outstanding shares. This is done by downloading monthly stock pricing reports for the 12 months prior to the valuation date. Calculate the average trading volume for 6 and 12 months prior to the valuation date. Trading activity is equal to the calculated averages divided by current shares outstanding. This should be formatted as a percentage. See W/P reference \_\_\_\_\_ for a printout of this information. If the shares are too thinly traded, go to Part D of this form.

(Adapted from *PPC's Guide to Business Valuations*, Copyright © 2017, Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit [tax.thomsonreuters.com](http://tax.thomsonreuters.com).)

**EXHIBIT 9.2 Guideline Company Comparative Worksheet****C. Comparisons to the Company Being Valued**

Compare the potential guideline company to the company being valued in the following areas. Highlight significant difference and similarities.

## 1. Product similarity:

---

---

---

## 2. Similarity of customer services:

---

---

---

## 3. Competitive advantages and disadvantages:

---

---

---

## 4. Historical trends (including growth rates):

---

---

---

## 5. Financial risk (capital structure, credit status, liquidity, and so on):

---

---

---

## 6. Size, including geographic diversification:

---

---

---

## 7. Management depth:

---

---

---

(continued)

**EXHIBIT 9.2 Guideline Company Comparative Worksheet** *(continued)*

8. Other factors:

---

---

---

**D. Conclusion**

Check one of the following conclusions:

 The company is comparable to the company being valued in many material respects.

---

---

 The company is insufficiently comparable to the company being valued and, therefore, will not be used. (Explain.)

---

---

 The company's stock is too thinly traded to be useable as a guideline company.

**EXHIBIT 9.3 Valuation Multiple Worksheet**

Company: \_\_\_\_\_ Valuation Date: \_\_\_\_\_

Prepared by: \_\_\_\_\_ Date: \_\_\_\_\_

**INSTRUCTIONS:** The valuation analyst should complete one of these forms for each guideline company. The form is a guide to the key factors that affect the numerator and the denominator of the value multiple computation.

**A. General Information**

Name of guideline company: \_\_\_\_\_

Check the value multiple\*\* that will be computed for this engagement:

Measures of operations for the period ended: \_\_\_\_\_.\*

\_\_\_\_\_ Price/earnings \_\_\_\_\_ Price/gross cash flow

\_\_\_\_\_ Price/dividends \_\_\_\_\_ Price/revenues

Measures as of a single point in time

\_\_\_\_\_ Price/net asset value \_\_\_\_\_ Price/book value

**Note:** Adjustments for different time periods used are sometimes needed to make the guideline company more similar to the company being valued.

\*\* Multiples may be equity multiples or invested capital multiples. Modify this form to include the appropriate multiples used.

\* *Note:* The time period used for each guideline company should match exactly, or as closely as possible, the time period over which the same variable is measured for the company being valued.

(Adapted from PPC's *Guide to Business Valuations*, Copyright © 2017, Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit tax.thomsonreuters.com.)

**EXHIBIT 9.3 Valuation Multiple Worksheet**

If a measure of operations for a given period of time is selected in the preceding, indicate how the period will be determined:

\_\_\_\_\_ Most recent 12 months \_\_\_\_\_ Most recent fiscal year  
(or 4 quarters)

\_\_\_\_\_ Projected operations \_\_\_\_\_ Historical average

\_\_\_\_\_ Five-year \_\_\_\_\_ Three-year

\_\_\_\_\_ Simple \_\_\_\_\_ Weighted

\_\_\_\_\_ Other (Describe) \_\_\_\_\_

Indicate the type of value the value multiple will be used to determine.

**B. Numerator of the Value Multiple**

Indicate the stock price of the guideline company. \_\_\_\_\_

Note: This could also be the company price if it is based on a merger or acquisition transaction.

\_\_\_\_\_ What is the source of this stock price? \_\_\_\_\_

\_\_\_\_\_ Wall Street Journal dated \_\_\_\_\_

\_\_\_\_\_ Other (describe): \_\_\_\_\_

**C. Denominator of the Value Multiple**

Indicate the company's earnings (or other measure) \_\_\_\_\_

Note: This measure should be in total or per share, depending on how the stock price is measured.

Should the earnings (or other measure) be adjusted in any way? If so, describe the nature of each adjustment and how the amount of each adjustment was determined.

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

\_\_\_\_\_

Indicate the adjusted earnings (or other measure) of the comparative company. \_\_\_\_\_

**D. Computation of the Value Multiple**

Compute the value multiple by dividing the stock price of the guideline company from Section B by its adjusted earnings (or other measure) from Section C. \_\_\_\_\_

(Adapted from *PPC's Guide to Business Valuations*, Copyright © 2017 Thomson Reuters. All Rights Reserved. For subscription information, call (800) 431-9025 or visit [tax.thomsonreuters.com](http://tax.thomsonreuters.com).)

The procedures for employing the guideline public company method may go something like those listed in the following sections.

## Creating a List of Potential Guideline Companies

The first step in each guideline public company analysis is to generate a list of potential guideline companies. The first group of questions that should come to the valuation analyst's mind can be found in box 9.2.

It is important to consider as many potential guideline companies as possible, which means that the valuation analyst must perform a thorough and comprehensive search to locate as many as possible. I suggest that the valuation analyst consider, at a minimum, these four sources for learning about or finding potential guideline companies:

1. Management
2. Standard Industrial Classification (SIC) or North American Industry Classification System (NAICS) code search (I am going to refer to these as SIC, but NAICS can be substituted.)
3. Online databases
4. Industry research

### Management

A management interview is a useful part of every valuation assignment. While the valuation analyst is asking management about all the stuff that was on the questionnaire discussed in chapter 5, he or she should make sure to specifically ask about any publicly traded competitors. Good managers have a real handle on their competitive environment and will know who their public competitors are. This is a good starting point for each guideline company search. This will also be very helpful because many databases that classify companies by SIC code use different codes for the same company. If you perform a search of a database (which will soon be explained) and you do not come up with a company that management told you about, see what SIC code that company is categorized under and expand your search. You may find other companies there as well.

#### BOX 9.2

#### Questions to Ask About Comparability

1. What is the business of the subject company?
2. In what industry does the company participate?
  - a. Is the industry concentrated or fragmented?
  - b. Is the industry capital-intensive?
3. Is the company in one, two, or more than two lines of business?
  - a. If it has more than one line of business, how important are each of the business segments to the overall performance of the company? (Probably the most important measure of performance is profitability.)
  - b. How closely related are these businesses?
4. What is the nature of the market?
5. What are the nature, level, and basis of competition?
  - a. Is the company a market leader or follower?
  - b. Does the company have distinctive competencies?
6. Does the company have advantageous intellectual capital?
7. Does the company operate locally, regionally, nationally, or globally?
8. What has the financial performance of the company been like?

That recently happened to us and we explained this in our report as follows:

In an attempt to apply the market approach, the analyst performed computerized searches utilizing the Alacra Public Companies and PitchBook databases. In order to find guideline companies, the analyst used the following search criteria in the Alacra database:

- I. The company's NAICS code was 621493.
- II. The company operated in the United States.
- III. The company had a market capitalization of greater than \$100,000.

The initial search did not return any companies. Knowing that Adeptus is The Company's largest competitor, the analyst looked up Adeptus in the Alacra database in order to locate the NAICS code that Alacra used to classify Adeptus. That NAICS code was 622110: General Medical and Surgical Hospitals. Therefore, the analyst performed a second search using this NAICS code. This search returned 16 companies.

Imagine if we had not known about the one public company. We would have missed 16 other possible guideline companies.

## SIC/NAICS Code Search

An intuitive starting point when the valuation analyst is back at a computer is a SIC or NAICS code search. If the analyst does not know the SIC or NAICS code for the subject or is not sure if the subject is correctly defined, there are many sources for SIC or NAICS code information. The Occupational Safety and Health Administration (OSHA) website ([www.osha.gov](http://www.osha.gov)) will become the valuation analyst's best friend if he or she needs to look things up. Unfortunately, like all government websites, the analyst may need to click around to get to where he or she ultimately needs to go to. Let's make believe that we are valuing a chain of restaurants, and we are looking for the correct SIC or NAICS code. Figure 9.1 illustrates what the process is when using the OSHA website.

**Figure 9.1 OSHA Website**

Of course, this is only the top of the webpage. You want to click on the “A to Z Index” button at the top. You will then get what is illustrated in figure 9.2.

---

If the valuation analyst forgets the SIC code for restaurants, he or she can click here to find it. In a previous chapter, I discussed getting industry data from various sources that would have required the valuation analyst to have already done this. If you click on the first SIC item, you get what is shown in figure 9.4.

Figure 9.4 NAICS Search Screen

### North American Industry Classification System (NAICS)

On January 1, 2003 OSHA began using the North American Industry Classification System (NAICS) for industry identification in its various data sets.

NAICS uses a six digit hierarchical coding system to classify all economic activity into twenty industry sectors. Five sectors are mainly goods-producing sectors and fifteen are entirely services-producing sectors. This six digit hierarchical structure allows greater coding flexibility than the four digit structure of the Standard Industrial Classification (SIC) system. NAICS allows for the identification of 1,170 industries compared to the 1,004 found in the SIC. For detailed information on the NAICS coding structure please visit the U.S. Census Bureau.

The Standard Industrial Classification has been replaced by the North American Industry Classification System (NAICS), but several OSHA data sets are still available with SIC-based data. For information on the Standard Industrial Classification system, please visit Standard Industrial Classification (SIC) System Search.

If you notice, the website takes the valuation analyst to the NAICS referencing, rather than the SIC codes. The analyst can get back to the SIC codes if desired, but the NAICS coding system permits a more detailed search because of a greater breakdown of the codes within each category. The website provides a hyperlink that allows the user to go directly to the U.S. Census Bureau to further search for the NAICS codes. Figure 9.5 depicts that result.

### Introduction to NAICS

The North American Industry Classification System (NAICS) is the standard used by Federal statistical agencies in classifying business establishments for the purpose of collecting, analyzing, and publishing statistical data related to the U.S. business economy.

NAICS was developed under the auspices of the Office of Management and Budget (OMB), and adopted in 1997 to replace the [Standard Industrial Classification \(SIC\) system](#). It was developed jointly by the [U.S. Economic Classification Policy Committee \(ECPC\)](#), [Statistics Canada](#), and Mexico's [Instituto Nacional de Estadística y Geografía](#), to allow for a high level of comparability in business statistics among the North American countries.

This official U.S. Government Web site provides the latest information on plans for NAICS revisions, as well as access to various NAICS reference files and tools.

The official 2012 U.S. NAICS Manual includes definitions for each industry, background information, tables showing changes between 2007 and 2012, and a comprehensive index. The official 2012 U.S. NAICS Manual is available in print and on CD-ROM from the National Technical Information Service (NTIS) at (800) 553-6847 or (703) 605-6000, or through the [NTIS](#) Web site. Previous versions of the NAICS Manual are available.

Additional information on the background and development of NAICS is available in the [History](#) section of this Web site.

 2017 North American Industry Classification System (NAICS)

Notice that there are three different references to the NAICS system because they had been updated in 2002, 2007, and 2012. In this instance, I did a keyword search for “restaurant” because I knew that the SIC code was 5812, but I did not know what the NAICS code was. The search is shown in figure 9.6.

2012 NAICS Definition

T = Canadian, Mexican, and United States industries are comparable.

722511 Full-Service Restaurants

This U.S. industry comprises establishments primarily engaged in providing food services to patrons who order and are served while seated (i.e., waiter/waitress service) and pay after eating. These establishments may provide this type of food service to patrons in combination with selling alcoholic beverages, providing carryout services, or presenting live nontheatrical entertainment.

Cross-References: Establishments primarily engaged in--

- Providing food services where patrons generally order or select items and pay before eating--are classified in U.S. Industry [722513](#) (//cgs-bin/sssd/naics/naicsrch?code=722513&search=2012), Limited-Service Restaurants;
- Selling a specialty snack or nonalcoholic beverage for consumption on or near the premises--are classified in U.S. Industry [722515](#) (//cgs-bin/sssd/naics/naicsrch?code=722515&search=2012), Snack and Nonalcoholic Beverage Bars;
- Preparing and serving alcoholic beverages and known as bars, taverns, or nightclubs--are classified in Industry [722410](#) (//cgs-bin/sssd/naics/naicsrch?code=722410&search=2012), Drinking Places (Alcoholic Beverages); and
- Presenting live theatrical productions and providing food and beverages for consumption on the premises--are classified in Industry [711110](#) (//cgs-bin/sssd/naics/naicsrch?code=711110&search=2012), Theater Companies and Dinner Theaters.

1/2

The results of the search for an NAICS code provides us with a considerable amount of detail that the old SIC search did not. This is a really good way to isolate certain data from a larger population if you can benefit from the smaller grouping.

If the valuation analyst decides to use a SIC code instead, the OSHA website allows the analyst to review two-, three-, and four-digit SIC code descriptions, which is helpful in determining the subject's SIC code. There are still certain databases that do not use NAICS codes and require a SIC code to be entered.

Remember that the goal of this exercise is to locate companies that are in the same or similar industry as the subject company. Using the information available on these sites will help the valuation analyst research other NAICS and SIC codes to determine if he or she could possibly use multiple codes to search for guideline companies.

Now that the valuation analyst has an SIC or NAICS code or group of codes, he or she can use one of many search engines to find companies by industry code. The question becomes which one to use. There are not many free websites that allow the retrieval of information about guideline companies anymore. There are several fee-based websites that charge without mercy. Basically, it works out that the higher the fees, the more services the valuation analyst sometimes gets. I discussed some of these sites in chapter 5. For free public company information, the main option is the SEC ([www.sec.gov/edgar/searchedgar/webusers.htm](http://www.sec.gov/edgar/searchedgar/webusers.htm)).

There has been so much consolidation among data providers that many of the free or almost free sites have gone away. Although the valuation analyst can perform a search for a guideline company on the SEC site, it is cumbersome and not necessarily user-friendly. The analyst is probably better off going to a business school library and using one of the paid subscription services that they frequently offer without charge.

## Online Databases

There are a multitude of financial advice websites in existence that will provide some type of industry analysis. These tools should not be substituted for performing a thorough industry analysis, but they can serve as a useful resource for locating guideline companies. For instance, Hoover's Online ([www.hoovers.com](http://www.hoovers.com)) provides free industry lists on its website. However, these industry lists are nothing more than company names. I would not depend on these types of services as a sole source for locating guideline companies, but they do help to expand a potential guideline companies list.

Some of the more sophisticated databases allow the valuation analyst to put in greater search criteria than those which I just described. For example, using a database such as Standard & Poor's or Disclosure, the analyst can enter search criteria, which may include the NAICS or SIC code, country of location, and maximum sales volume. I will explain the maximum sales volume criteria in a little while. There are also databases such as TagniFi and Pitchbook that can help in this area as well. Each of these has significant advantages over the SEC's database, but there is a cost to subscribe. I am actually going to provide you with a bit of a demo of Pitchbook later in this chapter. It's a pretty neat database that is more affordable than many of the others.

## Industry Research

As previously discussed, an analyst should have a thorough understanding of the valuation subject and its industry. In performing the industry analysis, the valuation analyst will frequently become aware of publicly traded companies in the subject company's industry. Trade journals and published industry reports are excellent tools for locating potential guideline companies. Another great source of information is industry experts. Business brokers, financial analysts, accountants, and industry consultants can be excellent sources of information; the valuation analyst just needs to find them.

## Get the Business Description

After the possible guideline companies are identified by the initial set of criteria, we used to examine the corporate description included in databases such as Standard & Poor's. Now we look at the business descriptions that are included in the company's Form 10-K. Because access to the 10-K is free, we can view a more

in-depth description by looking at the databases. This allows us to look at the narrative about the possible guideline company to further determine if the company appears to be similar enough to use in our analysis.

From this description, the valuation analyst can find the business purpose, products, market segments, and many other significant pieces of information. The analyst can use this information to perform a qualitative analysis of the potential guideline company.

Search engines can also be a valuable tool when finding information about the guideline companies. A quick search on a company name can turn up valuable information that may not have been picked up by a major news service. In addition to getting the 10-K, we generally will visit the company's website.

## Size Criteria

If a valuation analyst who has valued small companies is reading this, by now, that person probably thinks I am nuts; there is no way someone will jump through all the hoops that I have been discussing. Number one, the analyst does not have the budget for it, and number two, he or she is never going to find a public company that is comparable to the small company that the analyst is valuing. I hear that nonsense all the time. If a student or a new valuation analyst is reading this, he or she may just think that I am nuts, but for other reasons. But, this is where I say "trust me."

Believe it or not, a valuation analyst can still use public company data when applying the market approach to smaller companies. First of all, the standards that were covered in chapter 2 do not differentiate between valuing large and small companies. The budget with the client certainly cannot influence the work the valuation analyst is required to do when performing a valuation engagement. Second, it is generally a good idea to place a size restriction as part of the criteria used to select guideline companies. The size restriction will depend. In a perfect world, I would like the guideline companies to be no more than 10 times the sales revenues of the valuation subject. However, this is not a perfect world. There will be times that I increase the size restriction to 20 or 25 times revenues. There are even times that I will go higher. For a company with \$100 million in revenues, a guideline company with \$4 billion may not upset me. In fact, the larger the subject company, the less restrictions I will place on the guideline companies for size. But, what about a \$25 million sales company? Would a \$2 billion sales company be a good guideline company? I doubt it. But with that said, I have used very large public companies as guideline companies in certain industries where the guideline companies would have been the logical acquirer of the smaller closely held company. It really does depend on the facts and circumstances of the assignment. In some instances, criteria other than revenues may be used to determine size. For example, a holding company's size may be better measured using asset size, rather than revenues.

Another interesting fact that you should be aware of is that at the time I was working on this book, there were 1,259 companies listed on a public stock exchange in the United States with revenues of \$10 million or less. There are a lot of small public companies. The problem with many of these companies is that they may be too thinly traded to be used as a good guideline company. I will discuss this further in a little while.

There are many valuation analysts who believe that no size restriction should be placed on the guideline company search criteria. Instead, they believe that the size differential should be adjusted in the multiple because of the risk factors relative to size. I have a difficult time comparing Microsoft with the local software company. Here also, common sense must be applied. If the guideline companies are too big, they lose relevance to the valuation subject. It is not so much that they are too big but, rather, that much larger companies tend to have a very different business model and are frequently much more diversified.

Individuals who disagree with the use of public company data for small, closely held companies generally state that the size differentials are often so great that the result is meaningless. I disagree. As I have already stated, there are many public companies that are small. In addition, when you look closely at these publicly traded companies, you will find that other than their financial ability to go public, they are not run much differently than many of our valuation subjects. Granted, there are differences, for example, fewer prerequisites for the owners, more reliable financial statements, and not much ability to raise additional capital.

## Active Trading and Penny Stocks

Once the valuation analyst has located possible guideline companies, it is generally a good idea to test these companies to see if their stocks are actively traded and make sure that these stocks are not penny stocks. According to Revenue Ruling 59-60, guideline companies should have their stock actively traded in the market. Active trading is essential if the market forces are to interact in the manner necessary to reach the equilibrium point in the market known as fair market value. Greater market activity increases the possibility that fair market value will be achieved because many of the personal motivations of particular buyers and sellers would have been eliminated by offsetting their unique situations in arriving at the equilibrium point.

The question is, what does active trading mean? None of the valuation textbooks that I have reviewed provides an explanation of active trading. I used to consider active trading to mean that at least 5 percent of the company's outstanding stock trades over the six-month period prior to the valuation date. However, like everything else in valuation, 5 percent is not a hard and fast rule. In fact, more often than not, we are not finding companies that have 5 percent trading volume. We have used companies with much less, but the valuation analyst really has to be careful when he or she does this. Keep in mind that more trading activity is better.

The problem with using stocks that are thinly traded is that the analyst must be able to investigate whether the trading that took place is among market participants or insiders. If insiders are involved, they may have knowledge that the hypothetical individual may not have, and, therefore, the true definition of fair market value may be violated. Many data sources provide information about insider trading, so this can be investigated.

With that being said, if the valuation analyst finds many companies that are thinly traded, it may still be better than having no guideline companies at all. It may come down to how much weight is placed on the conclusions derived using this method. Even if the analyst cannot use the guideline company method for this reason, it may serve as a good sanity check on the income approach.

## Stock Pricing Reports and Active Trading

Before selecting guideline companies from the pool of businesses that made our initial list, we check the stock price and trading activity of each. A monthly stock pricing report from Yahoo! Finance is depicted in figure 9.9 on the following page.

A pricing report such as this can tell you many important things about a company. From this report, you can see if a business has a very low stock price and would be classified as a penny stock. There is often speculation in the market for penny stocks, which may limit the quality of the pricing multiples. We generally prefer to use guideline companies when the stock is selling for at least \$2 or \$3 (used to be \$5, but we were eliminating too many possible guideline companies) per share. This gets rid of the speculators who violate the requirement that a willing seller be typically motivated. Speculation is not typical motivation. Here also, there is nothing absolute about a \$2 or \$3 price. We will use a lower price if it makes sense to do so. We certainly do not want to use stocks that are priced at \$1 or less. These are the true penny stocks.

Stock price volatility is another factor that can be seen on a stock pricing history. Highly volatile stocks, or stocks that have large swings in stock value, suggest that the valuation analyst should take a closer look at that company. Large price swings could indicate changes in the economy, industry, or company, and the valuation analyst will need to understand these factors to properly apply guideline company multiples.

Trading activity can also be calculated with the assistance of a stock pricing report. Calculating the average trading volume over a certain period will allow the analyst to see if the stock is trading regularly or if it is thinly traded. A trading activity analysis is shown in table 9.2. As seen in this analysis, we have divided the average monthly trading volume of the potential guideline companies by their respective shares outstanding to calculate a percentage of outstanding shares traded, which can be used as a criterion for thin trading. If some of the company's shares are owned by insiders, you might want to subtract those shares to get an average "float" for this calculation.

Figure 9.9 Yahoo! Finance

9/30/2016

T 40.80 0.07 0.17% : AT&T Inc. - Yahoo Finance

The screenshot shows the Yahoo! Finance website interface for AT&T Inc. (T). The current price is 40.80, up 0.07 (+0.17%) as of 2:30 PM EDT. The page includes navigation tabs for various sections and a 'Historical Data' tab that is active. Below the tabs, there are filters for 'Time Period' and 'Frequency' (set to Daily). A table of historical prices is displayed, showing columns for Date, Open, High, Low, Close, Adj Close, and Volume. The data spans from September 7, 2016, to September 30, 2016. To the right of the table, there is a placeholder for an Amazon.com advertisement and a 'Compare Stock Brokers' button. At the bottom of the page, there are links for 'Data Disclaimer', 'Help', 'Suggestions', 'Privacy', 'About Our Ads', and 'Terms', along with social media icons for Twitter, Facebook, and Tumblr.

Many of the small public companies are relatively thinly traded. Little activity makes it a bit more uncomfortable for the valuation analyst, but it does not mean that the company cannot be used. After all, what is the alternative? In general, thinly traded data can be used, albeit cautiously, if the valuation analyst can determine adequate information about the thin trading. In order to learn more about a company's trading activity, we will search the public documents filed with the SEC, look for press releases and other announcements, and even go as far as to call the investor relations people in the company to inquire whether there is anything special about the stock transactions that would disqualify the activity from being used in this analysis. Often, the thin trading takes place among insiders. This information can be used if it is determined that the logical market for the valuation subject is insiders.

Let's talk about insiders for a moment. There are many times when a valuation analyst must struggle to decide who the logical players are in the market. A fractional interest in a closely held business may be worth more in the hands of an insider than in those of an outside investor. As a matter of fact, there are many times when there may not be a market for a minority interest in a closely held business, other than for the other shareholders of the company. Swing votes and insider knowledge may create value for the insiders that an outsider would not be privy to. Remember, one of the components of fair market value is that the willing buyer and willing seller must have reasonable knowledge about the subject property.

### For Those That Pass Muster...

For those companies that pass muster, we now download financial information that is included as part of the Form 10-K filed with the SEC from one of the databases. In fact, we will generally download the entire Form 10-K so that we can gain a thorough understanding about the public company. This will allow us to take a much more detailed look at the company to determine its level of comparability to the valuation subject. The various sources of guideline public company data may make it easy for the analyst to plug financial information into a valuation model, but primary data sources should also be downloaded to make certain that the information from the various data providers is accurate. You would be amazed at how many errors we find.

So what are primary data sources? I would generally look at the following documents filed with the SEC:

- *Form 10-K*. The 10-K provides a narrative about the company's operations, competition, customer base, industry and employment force, as well as the balance sheet for two years and income statements and statements of cash flow for three years.
- *Form 10-Q*. The 10-Q is the quarterly financial statement filed with the SEC. This form may be necessary if a latest 12 months (LTM) analysis is to be performed.
- *Forms 10-KA and 10-QA*. These forms are issued when a correction needs to be made to an original filing. They can contain a correction to a financial statement or other nonfinancial information.
- *Form 8-K*. The 8-K is filed with the SEC to mark significant events in the company such as a change in key personnel, major acquisitions, divestitures, and so on.

There is a variety of other sources of financial statement information on public companies; virtually all provide data in electronic format. Besides the SEC website, these include Standard & Poor, Compustat, OneSource, EdgarScan, Hoovers, Value Line, Reuters, Bloomberg, Thomson, Dialog, Yahoo! Finance, 10K Wizard, Capital IQ, TagniFi, and Mergent.

The advantage of using electronic sources is that the data can be downloaded into a spreadsheet or some other computer program, eliminating the need for manual data entry. This can speed up the analysis and reduce the potential for data entry errors. In addition, many of these providers put the companies' data in a standard format; this facilitates cross comparisons.

The negative side of using any electronic source is in the existence of data errors; although they are infrequent, there are data entry errors in these sources. (The exception to this is with the SEC's website). Because the electronic documents filed with the SEC are now the official documents, they are, by definition, without error.)

With the standardization of data comes the loss of detail. This can be important for certain companies that have unique products or service mixes. Sales and profit information by product line is often shown as additional information in the 10-K. Much of this detail and precision is lost when the information is placed onto

electronic media. Further, when a company's written data is put into a standard format, the data entry clerk might misinterpret some of the information and categorize it incorrectly.

However, each of these electronic sources has certain advantages and disadvantages apart from the general issues discussed in the preceding paragraphs. Some of these data sets have a large amount of textual information (such as footnotes, names of auditors, and detailed business descriptions) but have a limited number of numeric concepts. This can be useful when the valuation analyst is trying to identify and obtain basic financial statement data on guideline companies. Other electronic data providers have very limited textual information but a large number of pre-calculated financial ratios as well as sophisticated analytical capabilities that allow users to create their own financial measures.

With the exception of the SEC, and the company itself, these types of data can be quite costly. Some of these data sets are available through large public or university libraries. Of course, the information is almost always subject to copyright restrictions.

Regardless of the source used, the valuation analyst still needs to perform a proper comparison between the subject company and the potential guideline companies. This can be accomplished by comparing financial ratios and other attributes of the guideline companies with those of the valuation subject. Before we can do this, certain adjustments may be necessary to the guideline company data.

## Analyzing Publicly Traded Information

Part of using public company information in the valuation process requires the valuation analyst to obtain and analyze the financial and operating data of the guideline companies. The valuation analyst will use this information to ensure that the valuation subject can be properly compared with these other companies. Sometimes, there will be differences in the manner in which the publicly traded company reports its financial results, or nonrecurring events may have taken place that require the valuation analyst to recalculate the multiples used after adjusting the public company data. These adjustments are made to compare the valuation subject more appropriately with the guideline companies.

The valuation analyst should always keep in mind that there are limits to what can be done with the information that is obtained. Exact comparability will most likely never be achieved. Don't let this upset you. The adjustments that will be made will generally be similar to the normalization adjustments discussed in chapter 6, particularly the comparability adjustments and the nonrecurring adjustments. Rarely will you have to make a discretionary adjustment. The stockholders of the public company would go bonkers! Besides, the CEO's nephew being on the books would be an insignificant adjustment that you could never find even if you were looking for it.

Some of the adjustments that are encountered as a result of the differences between public companies and closely held companies are for (1) inventory accounting such as LIFO-FIFO (last in, first out—first in, first out), (2) items that are nonrecurring, and (3) items that are extraordinary.

If the public company reports its results using the LIFO method of inventory valuation and the valuation subject uses FIFO, an adjustment is generally made to the public company data in order to compare these companies properly. It would be silly, and probably impossible, for the valuation analyst to convert the valuation subject to LIFO. Accountants reading this book will understand this better than anyone. The information necessary to perform a LIFO calculation is not available in any of the documents obtained by a valuation analyst. For the non-accounting types, LIFO inventory valuation is relatively complicated and requires more than a few words to explain it properly. Because this book is a valuation text and not a book on LIFO, my word on this will have to suffice. However, with that being said, an example of how the LIFO-FIFO conversion affects the financial statements is provided in exhibit 9.4. It is also a good refresher for the accounting types reading this book.

**EXHIBIT 9.4 Inventory Accounting**

Assume the following information:

	2012	2013	2014	2015	2016
<b>Summary</b>					
LIFO Reserve	\$ 80,200	\$ 85,200	\$ 90,800	\$ 94,400	\$ 98,800
Adjustment to Cost of Goods Sold		(5,000)	(5,600)	(3,600)	(4,400)
Adjustments to Earnings Before Tax		5,000	5,600	3,600	4,400
<b>Financial Details</b>					
Beginning LIFO Inventory		75,970			
Purchases		315,764	102,728	99,586	103,256
Ending LIFO Inventory	75,970	102,728	99,586	103,256	97,058
LIFO Cost of Goods Sold	341,300	289,006	268,898	250,752	226,378
LIFO Reserve	80,200	85,200	90,800	94,400	98,800
Beginning FIFO Inventory		156,170	187,928	190,386	197,656
Purchases		315,764	265,756	254,422	220,180
Ending FIFO Inventory	156,170	187,928	190,386	197,656	195,858
FIFO Cost of Goods Sold		284,006	263,298	247,152	221,978

Also, assume a 40% tax rate.

To adjust the balance sheet from LIFO to FIFO at year-end 2016, the accounting entry would be:

**Debit:**

Inventory                    98,800 (LIFO reserve)

**Credit:**

Deferred taxes                    39,520 (LIFO reserve × 40%)

Retained earnings                    59,280 (LIFO reserve at YE 2016 × (1 – 40%))

(The adjustment to Retained Earnings includes the impact on 2016 earnings.)

**EXHIBIT 9.4 Inventory Accounting**

Therefore, to adjust YE 2016 inventory from LIFO to FIFO, the calculation would be

Ending 2016 LIFO Inventory	\$ 97,058
Plus: YE 2016 LIFO reserve	98,800
Equals: Ending 2016 FIFO inventory	<u>\$195,858</u>

To calculate the adjustment to retained earnings (tax affected), the calculation would be: YE 2016 LIFO reserve

2016 LIFO reserve	\$ 98,800
Times: (1 – 40%)	60%
Equals: Tax-affected adjustment to retained earnings	<u>\$ 59,280</u>

To calculate the impact on 2016 net income of an adjustment from LIFO to FIFO, the calculation would be:

Change in LIFO reserve during 2016	\$ 4,400
Times: (1 – 40%)	60%
Equals: 2016 net income adjustment	<u>\$ 2,640</u>

The number of adjustments that a valuation analyst will make to the public company information is usually small. The adjustments are intended to achieve consistency. For right now, recognize the importance of being consistent in the analysis. The valuation analyst needs to compare apples with apples, oranges with oranges, and pears with pears. Otherwise, the valuation will take on the characteristics of a fruit salad: a little of this and a little of that.

Before we go to the next step, let's discuss one other item. When searching for publicly traded company financial information, the valuation analyst wants to get as close to the date of the valuation as possible. Many times, this will mean calculating the latest 12 months (LTM) financial results. You may also choose to do this for the subject company, depending on the valuation date. Whenever possible, we will use this information. For an example, see exhibit 9.5.

### EXHIBIT 9.5 Calculating LTM Results

If the intention is to calculate the latest 12 months values, the following simple formula can be used:

Last Full Year Results

+ Current Year Partial Results

– Last Year Partial Results

= LTM Through The Recent Date

In the following example, we are doing a valuation as of June 30, 2016, and we wanted to determine the profitability for the latest 12 months ended June 30, 2016. Our calculations are shown as follows.

	December 31, 2015	June 30, 2016	June 30, 2015	LTM June 30, 2016
Revenues	\$2,189,924	\$1,364,215	\$1,119,501	\$2,434,638
Total Cost of Sales	453,937	343,522	201,664	595,795
Gross Profit	\$1,735,987	\$1,020,693	\$ 917,837	\$1,838,843
Operating Expenses				
Advertising	\$ 65,786	\$ 18,904	\$ 34,551	\$ 50,139
Auto Expense	34,652	16,757	17,033	34,376
Bad Debts	53,648	—	53,648	—
Bank Charges	1,872	1,170	713	2,329
Charitable Contributions	2,270	1,250	1,250	2,270
Depreciation	46,123	1,263	1,434	45,952
Entertainment	7,009	1,008	1,145	6,872
Officers' Compensation	198,746	118,530	99,373	217,903
Insurance—General	28,803	45,631	29,038	45,395
Licenses & Fees	170	—	35	135
Miscellaneous	1,188	937	(24)	2,149
Office Expenses	5,196	5,669	1,905	8,961
Pension, Profit-Sharing Plans	6,463	7,537	2,194	11,806
Postage & Delivery	990	1,551	1,000	1,541

**EXHIBIT 9.5 Calculating LTM Results**

<i>(Table continued)</i>	December 31, 2015	June 30, 2016	June 30, 2015	LTM June 30, 2016
Professional Fees	95,451	24,295	5,705	114,041
Rents	92,415	46,223	41,211	97,428

<b>Income Before Taxes</b>	<b>\$ 243,938</b>	<b>\$246,048</b>	<b>\$250,937</b>	<b>\$ 239,049</b>

We typically present financial statements for the guideline companies for periods similar to those that we have for the subject. Doing so allows us to look at trends in operating performance of the guideline companies over as much time as possible. These trends, among other things, will indicate a level of comparability. For instance, if all the guideline companies experience a sales decline but the subject company's sales do not, it may indicate that the subject company is not sensitive to similar economic factors. Another tool that will help us in this analysis is a financial ratio analysis. Comparative financial ratio analysis allows us to look at what some businesses do better, or worse, than others and gives us a quantitative basis to use to compare the subject to the guidelines.

It is a good idea to set up a spreadsheet that will automatically calculate ratios based on the financial statements that have been input. This can be done on a historic basis as well as on an adjusted basis. Tools such as this are helpful in speeding up the analysis for a business, and by setting it up in advance (and checking the formulas), the valuation analyst may limit errors that result from creating the spreadsheet for each valuation. I respect the work that my staff does, but we have password-protected the majority of our spreadsheet template to avoid someone making a mistake by changing a formula. Better to be safe than sorry.

A sample ratio analysis of some guideline companies with the narrative that accompanied it in a report appears in exhibit 9.6.

## EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies

The next step in the analysis is to compare the Triad Entities' financial results with its public counterparts. Select financial ratios appear in table 1. These ratios have been analyzed in order to make quantitative and qualitative assessments regarding the similarities and dissimilarities between the companies. The last column of the balance sheet reflects the balance sheet of the latest quarter prior to the valuation date.

**TABLE 1 Adjusted Financial Ratios**

**EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies** *(continued)*

Looking at the ratios in totality reveals many differences between the Triad Entities and the guideline companies. In order to do a more comprehensive analysis, we analyzed specific figures and ratios by ranking the information contained in table 1 from highest to lowest to determine how the Triad Entities stack up against the 12 guideline companies.

The first area observed is the size of the company from both a revenue and an earnings standpoint.

Size of Revenues (\$000)		Size of Earnings (\$000)	
ABFS	1,437,279	WERN	\$36,380
JBHT	1,352,225	AIND	30,501
WERN	576,022	SWFT	23,040
AFWY	572,100	HTLD	20,586
SWFT	458,165	MSCA	13,152
MSCA	333,070	AFWY	13,083
AIND	330,136	JBHT	8,725
TRUKQ	289,527	TCAM	6,106
XPRSA	282,468	<b>TRIAD</b>	<b>4,179</b>
HTLD	191,507	XPRSA	2,837
TCAM	144,254	TRUKQ	982
<b>TRIAD</b>	<b>109,812</b>	OTR	(157)
OTR	49,211	ABFS	(31,495)

The Triad Entities are smaller than all the companies, except OTR; most of the companies fall within 5 times the company's revenues, although ABFS and JBHT are 13 and 12 times revenues, respectively. The company has less earnings than most of the guideline companies. This does not necessarily mean that the Triad Entities are less profitable, though. This will be discussed when we look at profitability ratios.

### EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies

In conjunction with the size of revenues and earnings are compound annual growth rates. Three-year rates are shown as follows.

3-Year CAGR—Revenues		3-Year CAGR—Earnings	
AFWY	31.98%	ABFS	NM
SWFT	28.61%	OTR	NM
OTR	26.72%	TCAM	61.40%
MSCA	21.74%	SWFT	37.01%
ABFS	19.30%	HTLD	29.86%
TCAM	17.49%	WERN	10.19%
WERN	17.35%	AIND	1.00%
XPRSA	16.75%	MSCA	-1.66%
JBHT	15.09%	<b>TRIAD</b>	<b>-2.43%</b>
AIND	10.03%	AFWY	-11.62%
TRUKQ	7.61%	XPRSA	-35.08%
<b>TRIAD</b>	<b>3.46%</b>	TRUKQ	-43.18%
HTLD	-9.92%	JBHT	-52.22%

Three-year compound annual growth in revenues indicates that the Triad Entities' revenues have been growing more slowly than all the guideline companies, except one. Looking at earnings growth reveals that the Triad Entities fall about midway between the faster earnings growth and the faster earnings losses. As previously discussed, the economy faltered somewhat in the recent past, resulting in a "down" year for the industry. Analysts who follow these companies have indicated that they expect better results in the near future.

(continued)

**EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies** *(continued)*

Current Ratio		Quick Ratio	
HTLD	1.97	HTLD	1.63
WERN	1.86	WERN	1.37
AFWY	1.47	AIND	1.14
XPRSA	1.47	AFWY	1.08
AIND	1.41	XPRSA	1.03
SWFT	1.11	SWFT	0.96
ABFS	1.06	<b>TRIAD</b>	<b>0.92</b>
<b>TRIAD</b>	<b>1.05</b>	JBHT	0.80
MSCA	1.01	ABFS	0.67
JBHT	1.01	MSCA	0.67
TRUKQ	0.84	TCAM	0.47
TCAM	0.78	TRUKQ	0.38
OTR	0.40	OTR	0.35

In looking at these ratios, the Triad Entities are closest to JBHT despite the difference in the companies' sizes. From a current ratio and quick ratio standpoint, the Triad Entities fall right in the middle.

Two other liquidity ratios, days accounts receivable, and days working capital appear to contradict one another somewhat.

**EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies**

Days Account Receivables		Days Working Capital	
XPRSA	44.48	HTLD	41.29
OTR	42.75	WERN	24.62
SWFT	42.20	AIND	22.70
ABFS	39.80	XPRSA	19.52
JBHT	37.96	MSCA	16.14
WERN	34.98	AFWY	11.03
HTLD	33.81	SWFT	8.26
MSCA	33.41	<b>TRIAD</b>	<b>3.14</b>
AIND	32.91	JBHT	0.78
TCAM	30.58	ABFS	(2.34)
<b>TRIAD</b>	<b>30.54</b>	TRUKQ	(2.84)
AFWY	29.97	TCAM	(5.20)
TRUKQ	29.61	OTR	(55.85)

Although the Triad Entities collect their accounts receivable faster than most of the guideline companies, they have approximately three days of working capital available. Despite this, a number of the guideline companies appear to be ever weaker in this area.

*(continued)*

**EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies** *(continued)*

Turnover ratios measure how effectively a company utilizes its assets.

Current Asset Turnover		Fixed Asset Turnover		Total Asset Turnover	
AFWY	8.70	ABFS	4.62	ABFS	2.40
OTR	7.62	<b>TRIAD</b>	<b>4.14</b>	<b>TRIAD</b>	<b>2.31</b>
JBHT	7.34	XPRSA	2.86	XPRSA	1.83
SWFT	6.92	HTLD	2.33	TCAM	1.64
TCAM	6.31	TCAM	2.30	SWFT	1.61
WERN	6.09	SWFT	2.11	AFWY	1.37
TRUKQ	5.74	AIND	1.79	JBHT	1.35
MSCA	5.71	JBHT	1.69	AIND	1.30
ABFS	5.66	AFWY	1.64	HTLD	1.30
<b>TRIAD</b>	<b>5.46</b>	TRUKQ	1.58	TRUKQ	1.22
XPRSA	5.27	MSCA	1.54	WERN	1.20
AIND	4.90	WERN	1.49	MSCA	1.20
HTLD	3.02	OTR	1.36	OTR	1.15

Overall, the Triad Entities are stronger in utilizing their assets than the guideline companies. Any weakness that exists is in their current asset turnover, which confirms their liquidity ratios. Although the Triad Entities utilize their asset base more efficiently, their liabilities are high, which adds weakness.

**EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies**

The debt ratios indicate that the Triad Entities are more than able to service their debt and they utilize more debt than most of the guideline companies. This is depicted in the following rankings:

Times Interest Earned		Total Liabilities to Total Assets		Total Liabilities to Equity	
AIND	NM	ABFS	0.98	TRUKQ	12.69
HTLD	385.46	TRUKQ	0.93	<b>TRIAD</b>	<b>4.57</b>
WERN	26.74	<b>TRIAD</b>	<b>0.82</b>	OTR	4.34
SWFT	6.96	OTR	0.81	XPRSA	2.48
TCAM	6.26	XPRSA	0.71	JBHT	1.85
MSCA	4.72	JBHT	0.65	TCAM	1.74
<b>TRIAD</b>	<b>3.70</b>	TCAM	0.63	AFWY	1.44
AFWY	3.09	AFWY	0.59	SWFT	1.40
XPRSA	1.92	SWFT	0.58	MSCA	0.84
JBHT	1.56	MSCA	0.46	WERN	0.64
TRUKQ	1.00	WERN	0.39	HTLD	0.60
OTR	0.89	HTLD	0.38	AIND	0.46
ABFS	(1.68)	AIND	0.32	ABFS	(31.13)

With respect to profitability, the Triad Entities fall in the middle of the grouping.

(continued)

**EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies** *(continued)*

EBITDA Return on Net Sales		After-Tax Return on Net Sales	
HTLD	25.41%	HTLD	10.75%
AIND	22.25%	AIND	9.24%
WERN	21.38%	WERN	6.32%
MSCA	19.58%	SWFT	5.03%
OTR	17.37%	TCAM	4.23%
SWFT	17.14%	MSCA	3.95%
TCAM	15.96%	<b>TRIAD</b>	<b>3.81%</b>
<b>TRIAD</b>	<b>14.59%</b>	AFWY	2.29%
TRUKQ	14.04%	XPRSA	1.00%
JBHT	12.49%	JBHT	0.65%
AFWY	12.07%	TRUKQ	0.34%
XPRSA	9.74%	OTR	-0.32%
ABFS	1.25%	ABFS	-2.19%

When looking at after-tax income, the company is closest to MSCA, which is slightly more profitable. Of the 12 guideline companies, 6 are more profitable and 6 are less profitable. This is influenced greatly by debt structure, age of the fixed assets, and tax rates. Therefore, another comparison utilized is EBITDA (earnings before interest, taxes, depreciation, and amortization) to sales. In utilizing this category, the Triad Entities fall in the middle of the group, with 7 companies showing more profitability.

### EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies

One final profitability measurement is the EBITDA return on invested capital, which reflects the amount of profits generated to a company's capital holders. Here, the Triad Entities are at the high end of the ranking. This could be the result of the company's reduced equity due to financial difficulties in the past.

EBITDA Return on Invested Capital	
HTLD	48.99%
AIND	37.25%
<b>TRIAD</b>	<b>36.64%</b>
SWFT	36.08%
WERN	35.28%
TCAM	31.35%
MSCA	30.11%
JBHT	23.26%
XPRSA	21.55%
OTR	19.44%
TRUKQ	18.52%
AFWY	17.57%
ABFS	4.34%

**American Freightways (AFWY):** AFWY is five times the size of the Triad Entities, with faster growing revenues, but weaker earnings growth. Whereas the Triad Entities have low liquidity ratios and working capital, AFWY is highly liquid. AFWY also operates with considerably less debt. Despite all of these factors, the Triad Entities were more profitable in the most recent year.

**Arkansas Best Corp. (ABFS):** ABFS is 13 times the size of the Triad Entities and has revenues that are growing considerably faster. Despite this, earnings have been growing at a negative rate over the past 3 years, and ABFS showed a substantial loss in the most recent period. Looking at liquidity and turnover indicates that each company has strengths and weaknesses, and these are neutral factors. After removing non-operating assets from ABFS's balance sheet, the company shows negative equity. Therefore, we looked at the company's historic debt-to-equity ratio, which is 2.39, and considerably lower than the Triad Entities. Finally, due to ABFS's most recent year loss, the profitability ratios indicate that the Triad Entities are stronger.

**Arnold Industries (AIND):** AIND is approximately three times the size of the Triad Entities and is experiencing faster revenue growth. Earnings growth has been flat, which is positive because many companies have experienced negative earnings. The Triad Entities appear to have weaker liquidity and profitability than AIND and utilize considerably more leverage. Overall, despite the similarity in size, the Triad Entities appear to be weaker than AIND.

(continued)

### EXHIBIT 9.6 Financial Ratio Analysis With Guideline Companies *(continued)*

**Builders Transport (TRUKQ):** TRUKQ is slightly less than three times the size of the Triad Entities in revenues. Revenues have grown a little faster over the past three years and were flat in the most recent year; earnings, on the other hand, decreased considerably over the last three years, particularly in the most recent period. TRUKQ utilizes considerably more debt than the Triad Entities and was less profitable. Finally, its liquidity was extremely weak. Overall, TRUKQ is a very weak company, and the Triad Entities are considerably stronger.

**Heartland Express (HTLD):** HTLD is only two times the revenue size of the Triad Entities. Overall, its growth, liquidity, and profitability are all stronger than the Triad Entities, and HTLD utilizes much less debt. The only weak portion of HTLD is that the company experienced negative revenue growth over the last three years. In spite of this, the company has experienced 30 percent earnings growth over the past three years. Overall, despite its smaller size, HTLD appears to be a strong, well-run company.

**J.B. Hunt Transport Services (JBHT):** JBHT is more than 12 times the size of the Triad Entities. Despite 15 percent growth in revenues over the last 3 years, JBHT's earnings have declined significantly. The company's utilization of debt is considerably lower than the Triad Entities, making it stronger in this area, yet JBHT is still less profitable and its liquidity ratios do not indicate strength. Overall, despite JBHT's size, the company appears weak financially.

**M.S. Carriers (MSCA):** MSCA is approximately three times the size of the Triad Entities but has experienced revenue growth of approximately 22 percent and relatively flat earnings. MSCA utilizes very little debt yet does not show stronger liquidity or profitability than the Triad Entities.

**OTR Express (OTR):** OTR is approximately two times the size of the Triad Entities and has experienced substantial revenue growth over the past three years. The company's earnings had been increasing over the four-year period leading up to the most recent year, but the company experienced a loss in that year. OTR utilizes less debt than the Triad Entities but has very weak liquidity; the company's working capital deficit has been growing and was in excess of \$10 million at the end of the most recent year. Due to OTR's loss in that year, its profitability ratios were also weaker than the Triad Entities.

**Swift Transportation (SWFT):** SWFT is approximately four times the size of the Triad Entities, with revenues and earnings growth of 28.6 and 37 percent, respectively. SWFT utilizes less debt, is more liquid and more profitable than the Triad Entities, and overall appears to be stronger.

**Transport Corp. of America (TCAM):** TCAM is approximately the same size as the Triad Entities; in the most recent year, its revenues were only about 30 percent higher. TCAM has been growing very quickly; earnings and revenues have experienced annual compound growth of 61.4 and 17.5 percent, respectively. This fast growth has created liquidity problems, and at the end of the current year, TCAM had a working capital deficit of \$6.2 million. However, the company has a very strong leverage structure and could possibly borrow money to meet its current obligations. Along with the growth in earnings, TCAM has also been fairly profitable. Overall, TCAM is stronger than the Triad Entities.

**US Xpress Enterprises (XPRSA):** XPRSA is approximately two times the size of the Triad Entities and, despite increasing revenues, is suffering from decreasing earnings. Despite this, XPRSA has built up \$19 million in working capital and has stronger liquidity ratios than the Triad Entities. XPRSA utilizes less debt than the Triad Entities but appears to be less profitable. XPRSA does not appear to be substantially stronger or weaker than the Triad Entities.

**Werner Enterprises (WERN):** WERN is more than five times the size of the Triad Entities. Despite flat earnings from last year to this year, WERN has experienced both earnings and revenue growth over the past three years. Overall, WERN is more liquid and more profitable than the Triad Entities and operates with less debt. It appears to be stronger overall than the Triad Entities.

As you can see from exhibit 9.6, there can be a tremendous amount of analysis required in the application of the guideline company method. Although this analysis is a bit unusual, particularly because we had 12 good guideline companies, it is a good teaching tool because the analysis is the same regardless of how many guideline companies you find. The more guideline companies that the valuation analyst ends up with, the more time will be spent. The valuation analyst needs to make sure that an adequate amount of time is built into the budget when fees are quoted! What you just saw is an analysis that was done to determine the true level of comparability between the subject company and each of the guideline companies.

This analysis will allow us to select the best guidelines for our subject and ultimately perform our SGLPTL analysis. What is SGLPTL (pronounced “single pittle”)? No, it is not what your puppy does on the carpet. If you read the checklist earlier in this chapter, you saw it there. How come you didn’t ask about it then? Well, it stands for *size, growth, leverage, profitability, turnover, and liquidity* (SGLPTL).

SGLPTL is a great analytical tool for comparing the subject and guideline companies. These are the six categories of factors that assist the valuation analyst in determining comparability as well as justifying the multiples that are selected. I will discuss this part of the analysis later.

## Using Valuation Multiples

Valuation multiples are considered to be usable if the valuation analyst has good information about companies that are similar enough to the valuation subject and if the engagement is to value the equity or invested capital of the valuation subject. The old conventional wisdom says that the value derived from the guideline public company method results in a minority marketable estimate of value because the pricing multiples are determined from the public market. In fact, there are still courts and many valuation analysts without recent valuation training that believe this is true. However, as we will discuss in a short while, this is not always the case. In fact, the old conventional wisdom is incorrect and has been replaced.

Once the multiples are derived from the marketplace, they must be adjusted for the differences between the valuation subject and the guideline companies. The multiple that will ultimately be used for the valuation subject will probably not be exactly the same as that which was derived from the guideline companies. Risk and other characteristics generally play an important part in the process of adjusting the multiples. For example, if the publicly traded guideline companies have price-to-earnings multiples of 15 (assume an incredible coincidence and that all companies were the same), and the closely held company that is being valued is considered to be more risky, the logical conclusion is that the closely held company would be worth less. Therefore, a lower multiple would be used.

### BOX 9.3

#### Commonly Used Multiples

##### Equity Multiples

- Price to net earnings
- Price to pretax earnings
- Price to cash flow
- Price to operating income
- Price to book value
- Price to dividend paying capacity or dividend yield

##### Invested Capital Multiples

- MVIC to revenues
- MVIC to EBIT
- MVIC to EBITDA
- MVIC to net operating profit after tax
- MVIC to tangible book value and debt

The price represented in equity multiples is the equity price of the common stock of the public company. In other words, it is the price of a share of common stock that you could look up in the newspaper. This is used when the valuation analyst chooses to value the equity directly. There will be times when the valuation analyst chooses to value the invested capital of the company. This is usually done when there are significant differences in the financial leverage (amount of debt on the balance sheet) between the subject and guideline companies. Some of the more commonly used equity and invested capital multiples are listed in box 9.3. Be patient, and I will demonstrate this point in a little while.

In these instances, MVIC represents the market value of invested capital, defined as the market value of equity and debt.

Those valuation analysts who value small- and medium-sized companies often lose sight of the reason why certain multiples are used, rather than others. Comparability is probably the single most important factor in choosing a particular multiple. Sometimes, the choice of multiples depends on the availability of good data. The valuation analyst should avoid choosing a favorite multiple and using it in every valuation. Chances are, if the valuation analyst sticks with the same multiple all of the time, he or she will be wrong a good portion of the time. On the bright side, the analyst will be consistent. Unfortunately, being consistently wrong is not necessarily a good thing.

## Price-to-Net Earnings

The appropriate situation for using a price-to-net earnings multiple is (1) when the valuation subject has relatively high income compared to its depreciation and amortization or when depreciation represents actual or economic physical wear and tear and (2) when the valuation subject has normal tax rates. If a company has higher net income compared to depreciation and amortization, a price-to-net earnings multiple is considered to be the appropriate multiple to use. However, this considers the fact that the depreciation and amortization must be a good representation of the actual wear and tear of the assets so that replacements are being accounted for properly. If book or tax depreciation is used, rather than economic depreciation, the company may need to replace these assets either more quickly or more slowly than the manner in which depreciation is being recorded. Capital expenditures can greatly affect the cash flow of the company and, therefore, have an effect on its value. In that case, a cash flow, rather than a net earnings multiple, would be more appropriate.

A company with normal tax rates allows comparison to publicly traded guideline company data that is reported on an after-tax basis. If the company has a unique tax structure (for example, S corporation, limited liability company, or interest charge domestic international sales corporation [IC DISC]), better comparability may be achieved by using pretax earnings. For nontax people, an IC DISC does not pay tax. The shareholders are taxed on the income when it is distributed. Of course, a valuation analyst could also tax-affect the subject company's earnings to make them consistent with those of the guideline companies. Tax-affecting pretax earnings means that a provision for income taxes is subtracted as if the company paid these taxes in the normal course of business.

## Price-to-Pretax Earnings

A price-to-pretax-earnings multiple should be used when the subject company (1) has a relatively high income compared to its depreciation and amortization or when depreciation represents actual physical wear and tear but (2) has abnormal tax rates. Once again, the same rules apply for the first two items. Pretax earnings should be used when taxes are different from those of the guideline companies. I generally prefer to use pretax earnings for smaller companies because they frequently pay no taxes. Most smaller companies (and professional practices) conduct business in a manner that minimizes taxes, as opposed to maximizing shareholder wealth. Comparing these companies with similar companies or industry composite data (not large public companies) will frequently be more meaningful if it is performed on a pretax basis (you know, apples with apples, oranges with oranges).

## Price-to-Cash Flow

A price-to-cash-flow multiple is generally used when the valuation subject has a relatively low level of income compared to its depreciation and amortization or when depreciation represents a low level of physical, functional, or economic obsolescence. Low levels of physical, functional, or economic depreciation generally mean that the assets will not have to be replaced in the near term. Many profitable businesses go out of business because of insufficient cash flow. On the other hand, many businesses that have high levels of depreciation and amortization are cash machines, generating very high levels of cash for the owners in comparison to low earnings. These are typical situations in which a cash flow multiple makes sense.

Many experienced business valuation analysts are of the belief that "cash is king." Let's face it: the more cash you have, the more you can buy. This is certainly the theory that my daughter operates under. Therefore, it seems logical that a great emphasis should be placed on cash flow. Thinking of my kid, I wonder if we can

### Author's Note

In chapter 18, I discuss the valuation of pass-through entities, such as S corporations, limited liability companies, and so on. Although this discussion usually takes place with a slant on the income approach, something that the valuation analyst should also think about, particularly in the application of the market approach, is whether the tax rates used to tax-affect the valuation subject are truly comparable to the guideline companies. There have been empirical studies performed that indicate that the average public company only pays about 17 percent in taxes. The question that needs to be addressed is that if different tax rates are applied to the valuation subject than the guideline public companies, are we possibly mismatching the financial information? Unfortunately, I do not have some definitive words of wisdom that I can give you here. I just want to call any potential issue to your attention.

use a multiple of price-to-credit-card? Anyway, in many small companies, there is little difference between cash flow and earnings, so either becomes a pretty good surrogate for the other.

### MVIC-to-Sales

An MVIC-to-sales multiple is generally appropriate in two situations. The first situation is when the valuation subject is “homogeneous” to the guideline companies in terms of operating expenses. The second situation when this multiple may be appropriate is when smaller businesses, particularly cash businesses, are valued. Service companies and companies that are light in tangible assets are considered to be candidates for the application of an MVIC—to-sales multiple.

Some analysts use a price-to-sales multiple based on an equity price, rather than invested capital, under the theory that there is no major difference between the two. For smaller businesses that do not have a lot of debt on their balance sheets, this is probably true. Just keep in mind that whichever is used, the answer needs to make sense.

### Price-to-Dividend or Dividend-Paying Capacity

A price-to-dividend multiple is probably best utilized when the valuation subject actually pays dividends. It can also be useful when the company has the ability to pay dividends, even if it does not actually pay them. Of course, dividend-paying capacity can be measured only after the valuation analyst considers the valuation subject’s ability to finance its operations and growth. Revenue Ruling 59-60 tells us to consider “the dividend paying capacity of the company.” But even the revenue ruling suggests that this is not as important as the other factors to consider.

In a valuation of a minority interest, actual dividends are more important than the dividend-paying capacity because the minority interest cannot force dividends to be paid. Sometimes, you may find that actual dividends paid are disguised as excess compensation. For example, assume the valuation analyst is valuing a 45 percent interest in GRT Corp. The company has two stockholders: One owns 55 percent of the stock, and the interest that the valuation analyst is valuing owns the balance. Compensation and bonuses are taken in proportion to the stockholdings. The salaries were \$55,000 and \$45,000, respectively, and the stockholder-officers received bonuses of \$110,000 and \$90,000. The minority stockholder received a total compensation of \$135,000.

Some valuation analysts argue that if the minority interest is truly a minority, the compensation should not be adjusted because that individual cannot change the policy of the company, nor can he or she force dividends to be paid. However, if the valuation analyst looks at the relationship between the two individuals in my example, he or she may find that they run the company together, they have been friends and business partners for quite a while, and all major decisions are made jointly. In this situation, he or she may also find that *reasonable compensation*—defined as what it would take to replace the individual with someone of sufficient talent, experience, and so forth to do the job that is currently being done—will be less than the sum of the salary and the bonus. If reasonable compensation is deemed to be \$75,000, a dividend was actually paid ( $\$135,000 - \$75,000 = \$60,000$ ). In this instance, a multiple of dividends may allow the valuation analyst to value the minority interest directly by using multiples from the public market and adjusting them for risk.

Another consideration in determining the dividend-paying capacity for minority shareholder valuations is whether the minority shareholder would be considered *oppressed* under state statutes. *Oppression* is a legal term, and the valuation analyst should not try to make a determination without input from legal counsel. If a company has the ability to pay dividends but the controlling shareholder refuses to do so, the minority shareholders may have recourse against the controlling shareholder under the oppressed shareholder statute in that jurisdiction. This could result in a mandatory buyout at fair value, or dividends may have to be paid. What all of this means is that a minority shareholder may have legal rights, at the expense of litigation, to force dividends. This could make this multiple feasible even when dividends are not actually being paid. There is a discussion about stockholder litigation in chapter 24.

## Price-to-Book Value

A price-to-book-value multiple may be appropriate when the valuation subject is in an industry that has a meaningful relationship between the book value and the price of the company's stock. This would require guideline companies to be used. In the determination of the book value, smaller companies would use the sales price of the entire company as the "price" and only those assets that were actually to be sold. The valuation analyst can use return on equity to assist in the adjustment of the price-to-book-value ratio to compensate for differences in quality between the company being valued and the guideline companies being used to assist in the development of the multiple.

Very often, in practice, we see a price to tangible book value multiple used to avoid the vast differences between companies that have recorded intangible assets through acquisitions and those that have grown organically and, as such, do not have many intangible assets on the balance sheet.

## Valuing Invested Capital Instead of Equity

As indicated previously, there may be circumstances in which it makes more sense to value the invested capital of the valuation subject instead of the equity. One of the questions often posed in a valuation assignment is when to use invested capital methods. If the valuation subject's capital structure is significantly different from those of the publicly traded guideline companies, consider using an invested capital method. For example, if the valuation subject is either highly leveraged or significantly under-leveraged but the industry has a very different debt-to-equity relationship, it could make sense to eliminate the effects of leveraging to make a more meaningful comparison. This does not eliminate the financial risk of the subject company. This assumes, however, that the interest being valued has the ability to change the capital structure of the business. A minority interest does not, and, accordingly, the capital structure will generally not be altered in the valuation.

Smaller, closely held companies frequently have debt on their balance sheets that may have been used for either non-operating purposes (a mortgage on a ski resort in Vail, Colorado, when the company is a manufacturer in New Jersey) or to finance the owner's perks (the owner would not have to borrow if an excessive salary was not being taken or if a Ford was the company car instead of a Ferrari). Using valuation multiples that include the non-operating debt, or even operating debt that is out of line with the industry, would result in an incorrect estimate of the value of the company. A willing buyer will rearrange the debt-to-equity relationship as necessary to optimize the value of the company if that is prudent. It may also be necessary to adjust the capital structure of the subject to make it more comparable to the guideline companies. Otherwise, a proper comparison cannot be made.

When an invested capital method is used, the valuation analyst will determine the value of the company's total invested capital (equity plus debt at market values), rather than just the equity. When a valuation analyst values a company based on the total invested capital, some modifications are generally made during the valuation process. Some of these modifications include the following steps:

- Add the market value of the publicly traded guideline company's equity (price per share times the number of shares outstanding) to the guideline company's market value of the interest paying debt. The sum of these two items takes the place of the "price" in the various multiples previously discussed.
- Interest expense reflected on the income statement is added back to the earnings (or cash flow) used in the denominator of the various multiples. If the valuation analyst is using an after-tax basis, interest expense is added back to earnings or cash flow, net of taxes, because there is a tax benefit that is derived from the deductibility of interest expense.
- Once an estimate of value has been reached on a total-invested-capital basis, the valuation analyst then deducts the fair market value of the valuation subject's debt to determine the value of the company's equity.

I will illustrate these computations with an example. But before I illustrate the invested capital computations, let's further explore the concept of using multiples and go over a little more theory, and then you will be ready for some number crunching.

## Adjusting Public Company Multiples for Risk

Once valuation multiples are determined for the guideline companies, it becomes necessary for the valuation analyst to adjust these multiples for the qualitative differences between the guideline companies and the valuation subject. Different risk factors that the valuation analyst should generally consider are included in box 9.4. However, this list does not contain all potential risk factors. These qualitative differences will most likely relate to factors such as expected growth and the risks attributable to the valuation subject that are different from those of the guideline companies.

There are many other risk factors to be considered as well, but these are some of the more important items that a valuation analyst must think about in the application of not only the market approach, but also (as you will see in chapter 12) the income approach. Each of these risk factors should be analyzed from the point of view of how the valuation subject differs from the guideline companies. Most of the information about risk will be obtained from sources other than the financial statements. (Imagine that! There is more to business valuation than number crunching!) Let's discuss the risk factors.

### BOX 9.4

### Valuation Risk Factors

- Economic risk
- Business risk
- Operating risk
- Financial risk
- Asset risk
- Product risk
- Market risk
- Technological risk
- Regulatory risk
- Legal risk

### Economic Risk

Economic risk is analyzed as part of the economic analysis performed by the valuation analyst. Revenue Ruling 59-60 suggests that consideration be given to “the economic outlook in general and the condition and outlook of the specific industry in particular.” The valuation analyst must determine how the subject company will be affected by changes in the economic environment in which it operates. Economic conditions at the valuation date and how they affect the company must also be considered. For example, if the valuation analyst was valuing an automobile dealership, consideration would have to be given to the effect that interest rates have on auto loans. If the economic forecast was that interest rates were expected to go up, one would think that car sales may be affected if people could not afford to borrow at the higher rates. However, the dealership may experience an increase in its service revenues because people may keep their cars for a longer period, thereby requiring more maintenance.

To the extent that the guideline companies selected are good comparables, economic risk will be incorporated in the pricing multiples. The adjustments to be made will more likely compensate for differences between the guideline company and the valuation subject that are due to factors such as regional or local economic risk. The valuation subject may operate in an area that is different from that of the guideline companies, for example, a single location in New Hampshire versus multiple locations in the southwest United States.

### Business Risk

Business risk involves the analysis of the valuation subject's business. Once again, we are interested in how the subject company differs from the guideline companies. The valuation analyst analyzes the company in terms of the risk associated with factors such as sales volatility and the volatility of the company's growth. If a company has revenues that fluctuate widely, a greater risk exists than if the company is somewhat stable. Volatile growth is obviously a greater risk as well when the valuation analyst considers the cash flow needs of a growing company. If growth is volatile, it may be difficult for the company to raise the necessary capital to foster that growth. The banks may be reluctant to lend money to a company that may not be able to repay its debt next year if a reversing trend takes place.

### Operating Risk

The operating risks associated with a business include such factors as the fixed versus variable cost structure of the valuation subject. The valuation analyst must analyze the cost structure of the valuation subject to determine how much risk the company is exposed to as a result of the commitments and costs associated with the business operations. If a company has a high level of fixed costs, this may not bode well in times when revenues decrease. Obviously, if two companies are the same, except that one company has higher fixed

costs than the other, the company with the higher level of fixed costs would be considered to be more risky and, therefore, worth less.

## Financial Risk

The financial risks associated with a company pertain to the amount of leverage the company uses and the company's ability to cover its debt payments. The valuation analyst must pay particular attention to the capital structure of similar companies to analyze the valuation subject. Companies that are heavily leveraged can find themselves in trouble when a recession hits. To determine the valuation subject's level of risk, different debt structures should be analyzed when one performs the valuation.

Proper capital structure plays an important part in the financial success of a business. Companies that are overcapitalized or undercapitalized are not necessarily comparable to companies that have a normal capital structure. A normal capital structure is one that is similar to that of other companies in the same industry. If the valuation subject is heavily leveraged, the valuation analyst may want to consider using an invested capital approach using earnings before tax and interest (EBIT) or earnings before interest, taxes, depreciation, and amortization (EBITDA) in the pricing multiples.

I keep discussing companies that are highly leveraged, but, sometimes, a company that is underleveraged may be just as risky. Although being underleveraged will not necessarily hurt the company when the economy becomes troubled, being underleveraged can also mean that management is not taking advantage of the growth opportunities in its industry because using debt service almost always costs less than using equity. I will discuss this concept further in chapter 13 when I discuss the cost of capital components. However, at least think about the fact that being underleveraged can be a sign of poor management. And yet, there are some managers who do not believe in debt. In some cases, these are some of the wealthiest people that I have ever met, so who am I to question their judgment? Although, if they are not growing their companies as fast as their competitors, how long will they exist?

In many instances, smaller companies that are heavily indebted are structured in that manner as a result of the owner of the business choosing to finance his or her excess salary and perks; therefore, the interest and liability should be treated as non-operating items because they do not affect the business operations of the company.

## Asset Risk

Asset risk relates to the age and condition of the company's assets. Older assets represent a higher degree of risk for a company in terms of higher maintenance costs, a lower level of productivity, and functional and technological differences in available production. Not only do these items increase the level of expenditures for the company, but the future cash flow needs may also be greater due to replacement needs, which further increase the risk of the enterprise.

## Product Risk

Product risk relates to a company that has little diversification in its product line or has a product line that may become extinct with the introduction of a newer product by a different company. An example of this is the effect that smart phones are having on the point-and-shoot digital cameras.

## Market Risk

Market risk relates to how geographically diversified the company is. If the company operates within a local marketplace, it can be greatly affected by changes in that local area. A more diversified market reduces the risk associated with a company. An illustration of market risk is a local restaurant that operates in a community that is dependent on a military base for business. If the government decides to close the military base, what do you think will happen to the restaurant's business?

## Technological Risk

New technology can adversely affect a company if it does not have the ability to keep up with other companies in the valuation subject's industry. For example, a company that is unable to automate its factory would be at a competitive disadvantage, which increases the risk of the company.

## Regulatory Risk

Regulatory agencies can also adversely affect a business. Environmental regulations are probably one of the best examples of the risks that a company faces. A chemical manufacturing company can be put out of business in a very short time by the Department of Environmental Protection. This increased risk will generally cause a willing buyer to pay less for a business because he or she must be able to generate a faster return on the investment to compensate for the possible effect of new regulations. Obviously, only those regulations that can be reasonably forecast can be considered in this analysis. Do not forget about possible clean-up costs if a problem is discovered. A valuation analyst may not be able to quantify these costs, but the increased risk will affect market multiples, discount rates, and capitalization rates.

## Legal Risk

The cost of litigation in today's society can mean the end of any successful business. Even if it is successful, litigation can create such a financial burden on a business that it can be greatly exposed to the risk of being put out of business. Product liability claims, employee discrimination claims, anti-trust litigation, and a host of other types of claims will, at times, significantly affect the value of a business enterprise by affecting future margins, capital expenditures, and so forth, but if these are industry-wide, market prices may have already taken these issues into account.

## Valuation Considerations

Because valuation is premised on investment theory, the valuation analyst must perform a comparative analysis of qualitative and quantitative similarities and differences between the guideline companies and the valuation subject to assess the investment attributes of the guideline companies relative to the valuation subject. Not all pricing multiples will be appropriate for each guideline company. Therefore, the valuation analyst should use only those multiples that are deemed to be appropriate based on the underlying financial data of each guideline company. Financial ratios for the guideline companies, as well as the comparative analysis of the qualitative and quantitative factors regarding the differences between the guideline companies and the valuation subject, should be used together to determine the appropriate valuation multiples to apply to the valuation subject.

Various valuation multiples may be selected for application to the valuation subject, and this results in several value estimates. In arriving at the valuation conclusion, the valuation analyst should consider the quality of the information that is available for the determination of each multiple.

Another consideration is the time period to be covered in the application of pricing multiples. The following are some of the more common time periods that are used:

- Pro forma period
- LTM
- Last fiscal year
- Year ahead
- Average (mean) over number of years
- Weighted average over number of years

Regardless of which time period a valuation analyst uses, Revenue Ruling 59-60 makes it clear that "valuation is a prophecy as to the future." Whether a three-year average, a five-year average, or pro forma earnings are used in the application of these multiples, the ultimate decision on which period will be used is a subjective one on the part of the valuation analyst. Which time period is most representative of what is expected to occur in the future?

The factors to consider in selecting the time period and the method of calculating the earnings base will depend on the valuation analyst's (or management's) ability to forecast the future. For example, if the company has cyclical earnings, the valuation analyst may want to consider an arithmetic average. This has the tendency to smooth out the effect of the periodic cycles of the business. If the past five years, on average, are expected to resemble the next five years, plus or minus some growth, using an arithmetic average as a base and adding or subtracting some growth may be perfectly acceptable.

Because we are addressing the market approach (and not the income approach), consideration must also be given to the timing of the earnings or cash flow of the guideline companies as compared to the subject. For example, let's assume that the subject company went through a large expansion in the most recent year, but the guideline companies went through their expansion last year. In order to capture the expansion of all of the companies, a two-year average of the historical results may be required.

If the valuation subject is experiencing modest growth, the valuation analyst should consider weighted average earnings, the earnings for the LTM, or pro forma earnings. In high growth companies, the valuation analyst should consider a discounted future benefits method (this will be discussed in chapter 12). Because the intention of the valuation process is to arrive at a "prophecy of the future," caution must be exercised when one uses a weighted average, particularly when the company is growing. The result of the weighted average will rarely, if ever, reflect "probable future earnings" (this is the future concept discussed in Revenue Ruling 68-609). The danger in using a weighted average is illustrated in exhibit 9.7.

### EXHIBIT 9.7 Danger of a Weighted Average

Assume that a company's earnings grew from \$1,000 to \$25,000 over a five-year period. If the earnings were as indicated in the table, the weighted average would be calculated as follows:

Year	Earnings		Factor		Extension
2016	\$25,000	×	5	=	\$125,000
2015	15,000	×	4	=	60,000
2014	10,000	×	3	=	30,000
2013	5,000	×	2	=	10,000
2012	1,000	×	1	=	1,000
			15		\$226,000
			$\$226,000 \div 15 =$		\$ 15,066

In the foregoing example, the weighted average earnings would be \$15,066. Clearly, the company's growth would not justify a forecast of earnings of \$15,066 in the subsequent period. The growth would warrant a forecast of earnings greater than \$25,000, all other factors remaining constant. Therefore, applying a pricing multiple to the weighted average earnings would result in a value that is not truly representative of what a willing buyer would use to assess an investment decision, unless the guideline companies have similar trends, which may cause their price-to-five-year weighted average earnings multiple to be pretty high. This same concept applies in the application of the income approach. Using a weighted average is appropriate only if the result reflects the "probable future earnings" of the valuation subject or if the earnings trends are the same for the guideline companies.

If the company's earnings are relatively stable, it does not matter what earnings base is used, as long as it reflects the facts of the engagement. If the historic stable earnings are a reasonable representation of the future, by all means, the valuation analyst should use them. It is not too often that a valuation analyst will get lucky enough to have this portion of the assignment made easy. Forecasting is like using a crystal ball. Good luck!

If the company's earnings are declining, the valuation analyst may want to consider weighted average earnings, the LTM earnings, or pro forma earnings, assuming that a turnaround is expected to take place. If it is not, declining earnings may also require the valuation analyst to consider a liquidation method if the decline appears to be long term or permanent. Applying the concept of "highest and best use" requires the valuation analyst to consider whether the shareholder's value would be maximized by liquidating at the date of the valuation. Continuing to operate could cause the company's equity to decline. Obviously, this is a consideration only if the interest being valued has the ability to liquidate the company.

If the valuation assignment involves a company whose earnings are volatile, the valuation analyst must use common sense and good judgment. Experts in the valuation field who are much smarter than yours truly could not give a valuation analyst better advice. A company with erratic earnings is one of the most difficult valuation subjects. Other than applying common sense to valuation methodologies and trying to support the assumptions with good reasoning, in this situation, the valuation assignment is almost impossible. After the valuation analyst writes the report in this type of case, it is more important than ever to have another valuation professional review the work to see if the valuation analyst's logic holds together. The valuation analyst should make believe his or her doctor just revealed that he or she needs a serious operation. Get a second opinion!

## What Price Do We Use in the Multiples?

Once the earnings base is determined, the next step is to determine the price to be used in the determination of the multiples. For public companies, the price of the stock on the valuation date will be used in most instances. The average of the high and low prices for the day may be preferred to the "close" price; this eliminates any last minute price run-ups that may have taken place on the valuation date. In fact, valuations performed for tax purposes must be performed this way. However, price run-ups may reflect the market; these various prices are generally pretty close to each other. If they are not, that may indicate that the public company may be thinly traded and lacks liquidity.

There may be times when the valuation analyst will choose to use an average of the high and low prices over some time period other than the valuation date in order to compensate for unusual peaks and valleys in the market. For example, a valuation analyst may wish to compensate for stock prices on any day when there was a significant change in the market. These types of unusual stock market corrections can cause the pricing multiples to be skewed.

The valuation analyst must be very careful if he or she uses some date other than the valuation date for the price because the analyst may be changing the standard of value from fair market value.

## Regression Analysis

One of the tools that valuation analysts frequently find useful is the statistical technique known as regression analysis. If you are a statistical nerd like me, you hate this stuff. However, like it or not, the valuation analyst better know how to use it. I gave you a taste of this stuff in chapters 7 and 8. Unfortunately, this statistics stuff is needed in several areas of what we do. I am not trying to turn the valuation analyst into a statistician, but the analyst needs to be familiar with these concepts, particularly if performing services in a litigation arena. I was involved in one case where the opposing expert was disqualified because of the incorrect use of statistics.

## Adjusting Multiples Based on SGLPTL

So, what's the deal with this SGLPTL stuff? This is a technique that I learned from several co-instructors when I was teaching for one of the valuation organizations. It is one of the most logical, well-organized concepts that I have seen. For valuation analysts, one of the most difficult parts of applying the guideline public company method is figuring out how to get from the public company multiples to an appropriate multiple for the subject company. The purpose of the SGLPTL worksheet is to help the analyst do just that.

For each pricing multiple that is chosen to be appropriate in the valuation assignment, we create a separate worksheet. The worksheet in table 9.3 is for a price-to-revenue analysis. The public company multiples are listed across the top of the worksheet. The analyst will then consider each of the six elements of SGLPTL and the similarities or dissimilarities between the public company and the subject company. The question asked is whether the subject company is stronger, weaker, or the same as the public company with regard to each attribute. If the subject is stronger, the analyst knows that the multiple should be higher than the public company multiple and puts a “+” on the appropriate line. A weakness gets “-”, and the same gets a “+/-”.

**TABLE 9.3 SGLPTL Analysis**

Price-to-Revenues Analysis						
	A TEC	MTMC	SVTG	SYCM	Mean	Median
Multiple	0.21	0.26	0.25	0.09	0.2	0.2
Size <sup>1</sup>	-	+	-	+		
Growth <sup>2</sup>	-	+/-	-	+		
Liquidity <sup>3</sup>	-	-				
Profitability <sup>4</sup>	+	-				
Turnover <sup>5</sup>	+	+	+			
Leverage <sup>6</sup>	+					
GPCM multiple*	0.2	0.25	0.2	0.15	0.2	0.2

“+” Indicates that the subject company ratios are higher than the guideline company.

“-” Indicates that the subject company ratios are lower than the guideline company.

+/-” Indicates that the subject company ratios are similar to the guideline company.

\* Guideline public company method.

<sup>1</sup>Size was based on revenues for the most recent period.

<sup>2</sup>Growth was based on three-year and five-year compound average growth of revenues, unless otherwise noted.

<sup>3</sup>Liquidity was based on the current and quick ratios.

<sup>4</sup>Profitability was based on return on sales.

<sup>5</sup>Turnover was based on the working capital turnover.

<sup>6</sup>Leverage was based on the long-term debt-to-equity ratio.

Then, the analyst has to decide which of the six factors are the most important in the view of investors. Typically, growth drives the public market. The really high multiples that we see are created because the investors are paying for anticipated growth. Usually, the higher the growth, the higher the multiples. Our analysts will perform a regression analysis using the guideline company data to see what the investor seems to be putting the most weight on. For example, is the multiple more highly correlated with a return on equity, return on invested capital, or profitability? The analyst must then use his or her subjective judgment to determine the appropriate multiple for the subject company compared to that one guideline company. The same process is then performed for each guideline company.

One quick word of advice is to be careful with any regression analysis that has a limited number of guideline companies. The statistics can become misleading if used as anything more than it is meant to be—a guide. The valuation analyst must also perform the proper amount of research and analysis to confirm that the correct multiples are being used for the right reasons.

The result of the analysis is that the analyst has considered the differences between each public company, individually, compared to the subject and has chosen what is believed to be an appropriate multiple.

Based on the analysis that was performed, the analyst concluded a range of possible multiples for the subject company from 0.15–0.25, fitting well within the range of the mean and median guideline company multiples. In this case, a multiple of 0.2 was chosen. If you notice, this multiple is better than some of the guideline companies and worse than others. The narrative that would appear in the working papers, and eventually the report, would be similar to the example that you saw in exhibit 9.5.

There is no doubt that the valuation process requires the valuation analyst to exercise subjective judgment. We cannot merely apply a mathematical formula to do this. If we could, none of our clients would pay us the kind of fees that we get for this stuff. Although the valuation analyst cannot *quantify* every aspect of the assignment, he or she can at least attempt to *qualify* the judgment calls. This will allow the analyst to explain the thought process that went into selecting multiples to the reader of the report. Hopefully, there is a thought process behind it! Is it perfect? Of course not. That is why we try to use several different pricing multiples in our analysis, as well as why we consider other approaches to valuation as well. Until we have a chance to reconcile all the approaches and methods and then perform additional sanity checks to test the reasonableness of the result, we cannot possibly know if we are in the ballpark. Before we get too far into additional ways to adjust multiples, I want to provide you with some number crunching so that you can catch up on how to do the stuff we have discussed.

A simple example illustrating the application of the market approach using guideline company information is presented in exhibit 9.8. One of the sample reports included in the downloadable materials that accompany this book contains a full-blown market approach from a real report. Be patient! As you review the example in exhibit 9.8, there are several points to keep in mind. First, the selection of the guideline companies would have come from a careful review of many of the items discussed previously that makes these companies similar to the valuation subject. Another consideration is that the median multiple, rather than the arithmetic average, is calculated. This is because the median is often a better statistical measurement because it eliminates highs and lows that may skew the average.

### EXHIBIT 9.8 Example of the Guideline Public Company Method

#### Guideline company information

Guideline Companies	Price/Earnings	MVIC/Sales	Price/ Book Value
ABC Toy Company, Inc.	8.70	55.30%	2.85
XYZ Funtime, Inc.	9.30	47.43%	4.65
Toys, Inc.	8.50	35.25%	3.65
Games Corp.	6.60	54.80%	3.90
Fun Corp.	7.80	48.20%	4.25
<b>Median multiple</b>	<b>8.50</b>	<b>48.20%</b>	<b>3.90</b>
<b>Selected multiple</b>	<b>6.20</b>	<b>44.00%</b>	<b>2.50</b>

(continued)

**EXHIBIT 9.8 Example of the Guideline Public Company Method** *(continued)*

The selected multiples are now applied against the figures of the valuation subject.

Guideline Companies	Price/Earnings	MVIC/Sales	Price/ Book Value
After-tax earnings	\$ 959,446		
Gross sales		\$13,983,541	
Book value (without Non-operating items)			\$2,415,822
Multiple	x 6.20	x 44.00%	x 2.50
Operating entity value	\$5,948,565	\$ 6,152,758	\$6,039,555
Net non-operating assets	+ 250,000	+ 250,000	+ 250,000
Total entity value	\$6,198,565	\$ 6,402,758	\$6,289,555
Rounded	\$6,200,000	\$ 6,400,000	\$6,300,000

This example intentionally omits any calculation of valuation discounts or premiums, which are discussed in chapters 14 and 15.

According to the old conventional wisdom, the results, as presented in exhibit 9.8, represent the value of the company on a marketable, minority basis because the pricing multiples are derived from the public stock market. This also assumes that discretionary normalization adjustments (also considered to be *control* adjustments) were not made for the valuation subject. The old thought process was that stock market activity consists primarily of minority shareholders who trade in a free and active market. Therefore, this was considered to derive a minority basis value. However, today's thinking has changed. The value indication only stays on a minority basis if the valuation analyst does not make *control* normalization adjustments. The stock market is considered to be neutral with regard to control versus minority thinking. This is the same discussion that we will have when you get to the chapter on cost of capital (chapter 13). According to Duff & Phelps, discount rates are neutral with respect to the issue of control or minority. Because discount rates are related to market multiples (which I will explain further shortly) and because they both come from the same market, how can market multiples be considered to be minority if discount rates are not? They can't. Today's thinking is being consistently taught by all the leading valuation organizations. The thinking is that control versus minority is determined based on the normalization adjustments made to the benefit stream used in the application of the multiples. Although there are many practitioners who continue to practice the old way, they are not keeping up with modern thinking. Now, with that said, there are, unfortunately, many courts that are still following the old conventional wisdom because they have not been educated about the new thought process. This leads to confusion and bad results in the case law.

Furthermore, public company shareholders have the ability to call their stockbrokers to sell these shares, and they will generally have their money within three business days. This makes these shares marketable. Regardless of which type of interest (control or minority) is being valued, a discount for lack of marketability would probably be required because a closely held stock is not as marketable as its publicly traded counterparts. This will be discussed in chapter 15.

The selection of the multiple is a subjective process based on the analysis that the valuation analyst performs throughout the valuation assignment. This process considers the risk elements as well as the differences between the guideline companies and the valuation subject with respect to growth expectations, size, financial

performance, and everything else that makes these companies different. Unfortunately, if you bought this book looking for the answer to the mysterious multiple questions, you're out of luck. Seriously, the differential in the multiples has to consider the differences between the companies under analysis, and the valuation analyst has to test his or her conclusion to see if it makes sense.

There are no magic tables that the valuation analyst can turn to for help. Remember, our job is to opine on value, not to develop multiples. If the value conclusion makes sense, the multiples are probably reasonable.

You will also notice that the multiplication of the base amount by the multiple results in the value of the operating entity. This amount includes all the company's operating assets and liabilities (assuming that the valuation analyst is valuing the equity). The non-operating assets and liabilities are added to or subtracted from the value of the operating entity to reach the final entity value. However, this assumes that the non-operating income and expenses were adjusted in the first place. There may be the need to adjust this figure further for items that are not necessarily non-operating, however, they would not be considered as part of the operations of the business. A sample section of a report that addresses this very point is provided in exhibit 9.9.

One item should be noted in the illustration in exhibit 9.9. This valuation was done for a shareholder litigation, and the standard of value was *fair value*. The only manner in which the minority shareholder could have received compensation for the assets of ABC II was to treat it in this fashion. It was his sacrifice of dividends during the construction period that helped build this facility.

### EXHIBIT 9.9 Sample Section of Report Addressing Non-Operating and Other Items

Therefore, in our opinion, the fair value of the Smith Entities as an operating concern is estimated to be \$195.0 million. In addition, the value of the segregated non-operating assets of the company must be added to derive the equity value of the Company. Using book value as a surrogate for market value of the intercompany and shareholder/partner loans, the value of the non-operating assets is approximately \$15.362 million.

As stated previously in this report, the assets and liabilities of ABC II, a related real estate entity, are being treated separate and apart from the operating entity. At the valuation date, the Smith Entities were in the process of constructing a state-of-the-art distribution facility within this entity. It was still under construction as of the valuation date, so all future benefits that would be realized by the Smith Entities (and their owners) would not occur until after the valuation. These future benefits have not been factored into the expected cash flows of the company.

Because ABC II has been considered to be an entity that is not part of the operating business at the valuation date, the value of this entity should be included at this point based on its appraised value. According to the real estate appraisal performed by We Are Real Estate Appraisers, Inc., the value of this property at November 29, 2016 was

\$23.93 million. In addition, according to correspondence from Barry Gold, Esq., ABC II had already spent \$1,852,590 in the year 2016 toward the installation of the new material handling unit.

The value of the assets and liabilities of ABC II are as follows:

Cash	\$ 22,488
Intercompany loans	(8,893,538)
Partner receivables and loans	3,976,197
Equipment	1,852,590
Real estate	23,930,000
Fair value	<u>\$20,887,737</u>

(continued)

### EXHIBIT 9.9 Sample Section of Report Addressing Non-Operating and Other Items *(continued)*

After reflecting the assets and liabilities of ABC II, the net addition to the operating value of the Smith Entities is \$20.887 million, rounded.

Therefore, the fair value of the Smith Entities is derived as follows:

Fair value of operations	\$195,000,000
Fair value of non-operating assets	15,362,000
Fair value of ABC II (net)	<u>20,887,000</u>
Fair value of entity	<u>\$231,250,000</u>

Now that we have the basic concept of the guideline company method for equity under control (ha ha!), let's go back to our discussion about valuing the invested capital of the valuation subject. As indicated previously, there are several different steps that the valuation analyst must take to accomplish this. Let's use one of the guideline companies from exhibit 9.8 for our example. ABC Toy Company, Inc. (ABC) had a price-to-earnings ratio of 8.70 on the valuation date. If the price of ABC's stock was \$47.50 on this date, this means that ABC's earnings would have to have been \$5.46 per share. The price-to-earnings ratio would be calculated as follows:

$$\begin{aligned} \text{Price/earnings} &= \text{Multiple} \\ 47.50/\$5.46 &= 8.70 \end{aligned}$$

To convert the price-to-earnings ratio from an equity multiple to an invested capital multiple, we need to adjust both the price and the earnings. First, the price. To determine the market value of the company's equity, we would multiply the price per share by the number of outstanding shares. The outstanding shares can be obtained from the annual report. Let's assume that there were one million shares outstanding. This would make the market value of ABC's equity equal to \$47.5 million (1,000,000 shares × \$47.50 per share).

ABC's balance sheet includes interest-bearing debt in the amount of \$5 million. Assume that this debt is at a market rate of interest (this way, the market value of the debt is equal to the face amount). Therefore, the market value of the company's invested capital is \$52.5 million, or \$52.50 per share. This becomes the new price in the price-to-earnings ratio. The price is now referred to as MVIC.

Now, we need to adjust the earnings. The earnings previously calculated for ABC were \$5.46 per share. This means that the net income, after taxes, was \$5.46 million (\$5.46 × 1,000,000 shares). Upon review of the company's income statement, you find that the interest expense was \$500,000 for the year. The adjustment to the earnings in the price-to-earnings ratio would be as follows:

Net income after taxes		\$5,460,000
Add: Interest expense (net of taxes)		
Interest expense	\$500,000	
Effective tax rate	× 40%	
Tax benefit	\$200,000	\$ 300,000
Net operating profit after tax		<u>\$5,760,000</u>

ABC's earnings have now been adjusted to an invested capital basis of \$5.76 million, or \$5.76 per share. The new MVIC to net operating profit after tax (NOPAT) ratio would be

$$\$52.50/\$5.76 = 9.11$$

This same calculation would be performed for each of the guideline companies. The valuation analyst then selects the appropriate multiple to apply to the valuation subject's NOPAT. In this situation, our valuation subject had an after-tax net income of \$959,446. Its interest expense, net of taxes, would be added back to get to the NOPAT. It would be this figure against which a multiple would be applied. Let's recalculate the price-to-earnings portion of exhibit 9.8 and do the new calculations. For simplicity, the data in exhibit 9.10 already has the new MVIC to NOPAT multiples for the guideline companies.

### EXHIBIT 9.10 Guideline Public Company Method Using Invested Capital

#### Guideline company information

Guideline Companies	MVIC/NOPAT
ABC Toy Company, Inc.	9.11
XYZ Funtime, Inc.	10.15
Toys, Inc.	9.45
Games Corp.	7.30
Fun Corp.	8.90
<b>Median multiple</b>	<b>9.45</b>
<b>Selected multiple</b>	<b>6.90</b>

The selected multiples are now applied against the figures of the valuation subject.

	MVIC/NOPAT
After-tax earnings	\$ 959,446
Add: Interest (net of taxes)*	90,000
NOPAT	\$1,049,446
Multiple	× 6.90
Value of operating invested capital	\$7,241,177
Net non-operating assets	+ 250,000
Total value of invested capital	\$7,491,177
Rounded	\$7,500,000

\* Interest expense for the year was \$150,000. Effective tax rate was 40 percent.

We have once again intentionally omitted valuation discounts or premiums from this example.

The use of the invested capital pricing multiple is illustrated in exhibit 9.10. If you look at the multiples for the guideline companies, you will see that they were higher on an invested capital basis. This makes sense because the result is the value of the companies' invested capital. The result is that the multiple used for the valuation subject was also higher (6.90 instead of 6.20). A similar type of analysis of the qualitative differences between the guideline companies and the valuation subject would have been performed to derive the selected multiple.

There should always be a correlation between the multiples that you select, regardless of what earnings base you apply them to. In the example in exhibit 9.10, the valuation analyst can test the validity of the selection process by subtracting the interest-bearing debt from the value of the invested capital of the valuation subject. If the valuation subject's balance sheet includes debt in the amount of \$1.3 million, the value of the equity would be calculated as follows:

Value of invested capital	\$7,500,000
Less: Interest-bearing debt	1,300,000
Value of equity	<u>\$6,200,000</u>

The value of the equity is similar to the values illustrated in exhibit 9.8. Rarely will they be exactly the same.

## Making Quantitative Adjustments to Multiples

Most of the adjustments made to the pricing multiples are qualitative in nature. However, many valuation analysts have been attempting to quantify the adjustments in order to remove some of the subjectivity from this process. This is probably as good a time as any to present some of the techniques to you.

There are several different models that can be used to help quantify market multiple adjustments. These models involve adjusting the multiples based upon an analysis of the correlation of changes in a financial performance metric and changes in the market multiples, as well as for differences in size or for differences in the outlook for growth. Observations from a correlation relationship can provide direct methods of quantifying market multiple adjustments. This type of adjustment is especially useful for adjusting book and revenue multiples.

On a more theoretical basis, the adjustments for size and growth can have a considerable impact on value. The idea behind this is to adjust each of the guideline company's pricing multiples for differences between size-related risks and growth rates implicit in the guideline company multiples and the size-related risk and growth rate of the subject company. Before we go any farther, let me provide you with a basic fact: A capitalization rate is the inverse of a pricing multiple. We will talk about capitalization rates in another chapter, but I need to introduce the concept here. The formula to derive a market multiple is as follows:

$$\text{Market Multiple} = \frac{\text{Market Price}}{\text{Operating Performance}} = \frac{1}{(k - g)}$$

Where

k is the risk and benefit adjusted required rate of return, and  
g is the present value weighted perpetual growth rate.

Basically, a capitalization rate is a discount rate minus growth ( $k - g$ ). In simple terms, if the market multiple is equal to 8, the capitalization rate would equal 1 divided by 8, or 12.5 percent. With that brief explanation, the following should make a little more sense to you. The size and growth adjustments are made only to

income-statement-based multiples because they are based on the following relationship between capitalization rates and pricing multiples:

$$\text{value} = \frac{\text{benefit}}{k_B - g_B} \text{ which implies } \frac{\text{value}}{\text{benefit}} = \frac{1}{k_B - g_B} \text{ or } \frac{\text{benefit}}{\text{value}} = k_B - g_B$$

Where

$k_B$  is the discount rate related to that particular benefit stream, and  
 $g_B$  is the expected perpetual growth rate related to the benefit stream.

It should be noted that value/benefit is simply the pricing multiple related to the benefit stream or operating metric being used to apply a multiple to. The size and growth adjustments represent ways to quantify the adjustments that valuation analysts have made qualitatively for years. Of course, these adjustments are only appropriate when the analyst believes that there are significant differences between the various guideline companies and the subject company.

Let's first discuss adjustments based on correlation between performance and the pricing multiple. One example of this would be the correlation between return on equity and the price-to-book value multiple. In this instance, the analyst may want to explore the possibility that a close correlation exists between the guideline companies' returns on equity and their price-to-book value of equity (where price equals market capitalization). Theoretically, there should be a positive correlation because a higher return on equity provides equity investors with higher current returns and higher reinvestment for future capital appreciation. Obviously, this relationship assumes that measures of return on equity are close to normalized expected future return on equity performance.

Correlation between profit margin and price to sales can also be explored to see if the possibility that a close correlation exists between the guideline companies' profit margins (that is, returns on sales) and their corresponding price-to-sales multiples. Theoretically, there should be a positive correlation because higher profit margins provide equity investors with higher current returns and higher reinvestment for future capital appreciation. Obviously, this relationship assumes that the profit margins are close to normalized expected future profitability performance.

Theoretically, the "price" in the price-to-sales ratio should be an invested capital price (total capitalization plus interest-bearing debt), and return on sales should be an invested capital return (EBIT or net operating profit after tax). In practice, many analysts also consider this correlation on an equity basis, with the *price* in the price-to-sales ratio defined as total capitalization and an equity return (pretax income or net income).

Other correlations between market multiples and other operating performance metrics may also be possible. If close correlations are observed, then the valuation analyst may want to use these relationships as a method of quantifying the corresponding market multiple.

## Adjusting the Market Multiple for Size

The small size of a company is frequently associated with a number of risk factors, including the following:

- Lack of management depth
- Lack of product diversification
- Lack of geographic or global diversification
- Reduced access to capital to fund growth
- Limited research and development and marketing resources

The principal study that examines the effect of size on equity returns is the *Duff & Phelps Risk Premium Report*, which is included in the *Valuation Handbook: U.S. Guide to Cost of Capital* (which I will discuss in chapter 13). The discount rate is the place for the adjustment to be made because we have data quantifying the size effect on returns. There have also been studies demonstrating that pricing multiples vary inversely with

firm size; however, the data on firm size and returns is readily available and well accepted. The basic equation is as follows:

$$\frac{\text{benefit}}{\text{value}} = k_{GPC} + [k_{\text{size}_{\text{subject}}} - k_{\text{size}_{GPC}}] - g_{GPC}$$

In this instance, the  $k_{\text{size}}$  is the appropriate rate of return premium due to size (also referred to as the *size premium*). Even though we have not discussed this yet, it is important to note that this size premium is based on those measures that are used for the build-up method and not the capital asset pricing model (to be covered in chapter 13—I figure by the time you are ready to use this adjustment, you will have already read the balance of the book so that this will make sense to you), that is, they should not be adjusted for beta (this process can be used with the premiums adjusted for beta, but it is much more complicated and will not be discussed here). Furthermore, in order to apply this adjustment, we do not need to know the discount or growth rates of the guideline companies; we just need to know the size premium differential between the two.

Because the base on which the size premium is calculated is the same irrespective of the size of the company, the size premium differential is equal to the total return differential (where total return is only a function of size). For example, the size differential between a company in the 4th and 10th deciles is equal to the difference in the arithmetic mean returns of 20.97 percent and 13.91 percent, or 7.06 percent. This might be an appropriate amount to substitute for  $[k_{\text{size}_{\text{subject}}} - k_{\text{size}_{GPC}}]$  in the preceding equation. This assumes that the subject company is about the same size as the 10th decile companies in the public market.

The size premiums, as presented by Duff & Phelps, correspond to cash flows to equity holders because they are measured by observing total returns in the stock market. Relating this to the preceding equation, the *benefit* would have to be the cash flow to equity holders (assuming that a very close proxy is net income), and the *value* is the market value of equity. Assume the original price-to-earnings multiple for a guideline company is 17.0, the guideline company is in the 4th decile, and the subject company would be in the 10th decile.<sup>4</sup> The steps in adjusting the guideline company multiple for the size of the subject would be as follows:

1. Compute the benefit/value ratio (which is just the reciprocal of the pricing multiple):  $1/17.0 = 5.88\%$ .
2. Add the size differential between the guideline company and the subject company (as computed in step 1):  $5.88\% + 7.06\% = 12.94\%$ . This is the adjusted benefit/value ratio.
3. Take the reciprocal to get the new pricing multiple adjusted for size:  $1/0.1294 = 7.7$ , which would now become the recalculated guideline multiple for size. This multiple might then be further adjusted for all the risk factors that I discussed before.

In the most general form, the discount rate and size premiums (as well as the growth rate) in the preceding equation are functions of both the benefit and the value. If benefit and value are other than net income and market value of equity, respectively, the process becomes a bit more complicated. The more generalized approach is discussed by Mattson, Shannon, and Drysdale in the September/October 2001 *Valuation Strategies* article, "Adjusting Guideline Multiples for Size." The generalized equation they use is as follows:

$$\text{Adjusted Multiple} = \frac{1}{\left(\frac{1}{\text{Multiple}}\right) + [\alpha \Sigma \theta]}$$

<sup>4</sup> Although I am discussing this in terms of deciles, the Duff & Phelps publication provides this information in two different formats: 10 deciles and 25 percentiles. Either can be used by the valuation analyst.

It can also be expressed as

$$\frac{\text{benefit}}{\text{value}} = r_{GPC} + \alpha \Sigma [k_{\text{sizeSubject}} - k_{\text{sizeGPC}}] - g_{GPC}$$

Where  $\theta$  is the size premium differential,  $\alpha$  is an adjustment made to  $\theta$  when using a multiple other than one based on net income or net operating profit after tax, and  $\Sigma$  is an adjustment made to  $\theta$  when there is debt in the capital structure and a pricing multiple based on MVIC is being used. Get the article to find out more about this exciting stuff.

## Adjusting the Market Multiple for Growth

We use the same basic equation to adjust for growth; however, this is not as easy as the size adjustment. There are issues with the calculation, the valuation analyst needs to understand what he or she is doing before blindly making this adjustment and saying “Trugman said so.” The  $g_{GPC}$  for each of the guideline companies must be replaced with the  $g_b$  for the subject company. This is done in the following manner:

$$\frac{\text{benefit}}{\text{value}} = k_{GPC} - g_{GPC} + [g_{GPC} - g_{\text{Subject}}]$$

Taking the reciprocal of the benefit/value ratio results in the new pricing multiple. To implement this adjustment, it is not necessary to know the discount rate of the guideline company or the subject; only the perpetual growth rate differential between the subject and guideline company needs to be known. This is problem number one. We rarely know the perpetual growth rate. I will discuss this again in subsequent sections.

Let's discuss another example. Assume the original pricing multiple is 19.0, the perpetual growth of the guideline company is 7.0 percent, and that of the subject company is 5.0 percent. The steps in the calculation are as follows:

1. Compute the benefit/value ratio (which is just the reciprocal of the pricing multiple):  $1/19.0 = 5.26\%$ .
2. Add the growth differential between the guideline company and the subject:  $5.26\% + (7.00\% - 5.00\%) = 7.26\%$ . This is the adjusted benefit/value ratio.
3. Take the reciprocal to get the new pricing multiple adjusted for growth:  $1/0.0726 = 13.8$ , which is the guideline company pricing multiple to be applied to the subject company after adjusting it again for all the other risk factors.

## How to Calculate the Present Value Weighted Perpetual Growth Rate

I really hate to do this, but I need to cover this stuff. If it hasn't been confusing enough already, it's probably about to get worse. If I did not think this was important, I would not have included it in this book.

One of the statistics generally available for public companies is growth. This is the expected growth, as opposed to the actual historical growth, in earnings per share (EPS) over the next five (or so) years. Frequently, it is available for less than five years. This information can be obtained from individual equity analysts or some of the consensus reporting services, such as Zacks Investment Research or Yahoo! Finance.

Three things should be noted about estimates obtained from most consensus reporting services. The first is that these growth figures usually represent annual growth in EPS for the next three to five years; these are not long-term growth estimates. (This is the second time I've mentioned this; it must be important.) In some cases, revenue growth rates may be provided. Second, the analysts from whom these estimates are obtained are from the sell side, meaning that they tend to be quite optimistic about the prospects for these companies

because they work for firms that want to sell the stock. Also, some of these estimates may be a “consensus” of only one analyst. Smaller companies tend to be followed by fewer analysts. Great statistical sample, huh?

The last item of note is that not all publicly traded companies will be covered by these services. In such cases, and in cases in which there is only one analyst following the stock, it might be better to use industry growth estimates if they are available or not use this adjustment. Of course, the implicit assumption here is that the guideline company’s growth is consistent with the industry’s growth. This may not be the case.

In using these growth estimates, the valuation analyst assumes that the average annual growth in net income, EBIT, EBITDA, and the like for the next three to five years is the same as that for EPS. This may not be an unreasonable assumption; however, there may be certain cases in which it is not appropriate. Because the typical analysts’ growth estimate applies only for the next three to five years, an estimate must also be made for the subsequent period (years four, five, six, and beyond), so that a blended average annual growth rate for the period from today into perpetuity can be obtained (again, the growth rate in the preceding equations— $g$ —is the rate into perpetuity, and three to five years is only a small part of that). The blended growth rate— $g$ —that is included in each of the guideline company’s pricing ratios must satisfy the following:

$$\text{Value} = \frac{CF_1}{k-g} = \frac{CF_1}{(1+k)^1} + \frac{CF_1(1+g_1)}{(1+k)^2} + \dots + \frac{CF_1(1+g_1)^4}{(1+k)^5} + \frac{CF_1(1+g_1)^4(1+g_2)}{(1+k)^5(k-g_2)}$$

Where  $g_1$  is the annual growth rate for the first five years and  $g_2$  is the average annual growth rate for each year thereafter, into perpetuity.

This equation assumes two growth rates: one for the next five years and another for everything beyond five years. That is, it is the single growth rate that gives the same value as multiple growth rates. Consequently, not only are the growth rates important, but so is the discount rate. For example, assume a discount rate of 20 percent, a short-term growth rate of 15 percent (four years) and a long-term growth rate (beyond five years) of 5 percent. The steps in the calculation are as follows:

1. Compute the present value of \$1 per year growing at 15 percent for the four years (we assume this first \$1 has already been grown by 15 percent) and 5 percent into perpetuity:

Year	Growth Rate	Cash Flows	Discount Factor @ 20%	Present Value
1	15%	1.00	0.8333	0.83
2	15%	1.15	0.6944	0.80
3	15%	1.32	0.5787	0.77
4	15%	1.52	0.4823	0.73
5	15%	1.75	0.4019	0.70
Perpetuity	5%	1.84	0.4019	4.92
<b>Total Present Value</b>				<b>8.75</b>

2. Now solve the following equation for  $g$ :

$$8.75 = \frac{1}{0.20 - g} \text{ which implies } g = 0.20 - \frac{1}{8.75} = 8.6\%$$

3. The following tables show blended growth rates given short-term growth and long-term growth at two different discount rates.

	Using a 20% Discount Rate Long-Term Growth Rate			
Analysts' Growth	3%	5%	7%	10%
0%	1.57%	2.77%	4.12%	6.51%
3%	3.00%	4.15%	5.43%	7.68%
5%	3.89%	5.00%	6.24%	8.40%
10%	5.90%	6.92%	8.05%	10.00%
15%	7.64%	8.58%	9.60%	11.35%
20%	9.15%	10.00%	10.93%	12.50%
25%	10.45%	11.23%	12.07%	13.47%
30%	11.58%	12.28%	13.04%	14.30%

	Using a 25% Discount Rate Long-Term Growth Rate			
Analysts' Growth	3%	5%	7%	10%
0%	1.32%	2.77%	4.12%	5.36%
3%	3.00%	3.97%	5.04%	6.90%
5%	4.05%	5.00%	6.05%	7.85%
10%	6.46%	7.35%	8.33%	10.00%
15%	8.59%	9.42%	10.33%	11.86%
20%	10.45%	11.23%	12.07%	13.47%
25%	12.09%	12.80%	13.58%	14.86%
30%	13.53%	14.19%	14.90%	16.07%

An alternative to this can be employed if two pieces of information are known about the guideline companies. The first is the pricing multiple and the second is the related discount rate. Using the basic relationship between value and the capitalization rate, the implied growth for the guideline company is as follows:

$$g = k - \frac{\text{benefit}}{\text{value}}$$

For example, if we know that the price-to-earnings multiple for a guideline company is 25.0, and the cost of equity ( $k$ ) is equal to 14.6 percent, then the implied perpetual growth rate is as follows:

$$g = 14.6\% - \frac{1}{25.0} = 10.6\% - 5.0\% = 5.6\%$$

This is a relatively simple calculation for price to earnings; however, it becomes much more complex when trying to determine growth for other income statement line items, such as EBIT, EBITDA, or revenues, when the discount rates may not be as easy to calculate. In chapter 13, I will discuss why the discount rate for EBIT, EBITDA, or revenues is different from the discount rate for net income. We may be able to sometimes assume that net income and net cash flow are close, but that too becomes a problem in this calculation. Who said this stuff was easy?

## Advantages of Using the Guideline Public Company Method

Different approaches and methods have distinct advantages and disadvantages in the valuation process. Not all methods will be appropriate every time, but it is up to the valuation analyst to determine the best methods to be used based on the facts and circumstances of each situation. The use of information from the public stock market is considered by many valuation analysts to be an objective source of data. The stock prices of public companies are set by many transactions involving many buyers and sellers. Therefore, the result is considered to be objective. However, there are some skeptics who believe that factors such as institutional computer trading remove a considerable amount of objectivity. Others believe that the public marketplace is efficient. For those of us who remember the “efficient market hypothesis” from our finance courses, one has to wonder if the creators of this hypothesis could have ever dreamed that computers would be trading stocks on Wall Street (there goes that theory!).

Many studies of the public marketplace have been performed, analyzing the activity that has taken place in the market. These studies assist the valuation analyst in the determination of risk and value. Control premium studies, restricted stock studies, initial public offering studies, and a group of proprietary studies have been performed and published as a basis of empirical data that can be used by a valuation analyst. These items are discussed in chapters 14 and 15.

Valuations of larger closely held companies can be performed using these methods because larger companies frequently take on many of the characteristics of their publicly traded counterparts. Therefore, comparing larger, closely held companies with publicly traded guideline companies is an effective method of valuation (remember: fair market value comes from the market).

## Disadvantages of Using the Guideline Public Company Method

Despite the fact that the public market affords certain advantages to a valuation analyst, many valuation analysts feel that there is a lack of comparability between publicly traded guideline companies and a closely held valuation subject. Although the concept of using publicly traded guideline companies as surrogates is intended to be based on comparability, no two companies are ever so closely alike that they make perfect comparables. Sometimes, particularly if the valuation subject is a small or midsize company, there are so many differences between the valuation subject and the publicly traded companies (for example, size, depth of management, capital structure, ability to borrow, product diversification, and geographical diversification) that a meaningful comparison cannot be made without making extraordinary leaps of faith.

In addition, the public stock market has an emotional aspect to it. This is evidenced by the fact that announcements made by companies, the government, or both create peaks and valleys in the stock market.

Another disadvantage of using publicly traded methods is that it is frequently difficult to interpret and understand the stock market data that is disseminated. Despite the amount of information available about public companies, there is often a considerable amount of information that is not available. This makes it difficult to truly compare the companies. The information that can be obtained about a public company appears in annual reports,

10-Ks, other SEC filings, and proxy statements, as well as information that is published in financial periodicals, trade publications, and the like. Because the valuation analyst is rarely given the opportunity to speak with the long-range planning group, management, or anyone else in the public company, the only information that can be obtained is what the public company wants the valuation analyst (and the public) to know.

For those valuation analysts who value entire companies, there is also the difficulty of translating the minority, marketable value that is derived using these methods into a control, nonmarketable value (you know, small portions of companies with almost instant liquidity versus full companies with no liquidity). Ten shares of IBM stock have very different characteristics from 100 percent of the stock of closely held XYZ Computer, Inc.

### So Let's Be Honest...

The guideline company method is as good as the data used to perform it. There are many analysts who are willing to live and die by the market, especially for a fair market value assignment. I have frequently been told that the income approach (which we will get to in a couple of chapters) is much more subjective because it involves a forecast and the selection of discount rates. Well, no offense, but the market approach is as subjective as, and possibly more so, than the income approach. If you do not feel comfortable with the fact that you have to analyze the valuation subject and then forecast its future performance, imagine the following:

1. Choose guideline companies that are a good enough fit to the subject company.
2. Understand which multiples are the most appropriate.
3. Be able to adjust the multiples for the public companies to make them applicable to the subject company.
4. Determine what income stream is the most representative for the subject company.

Give me a good forecast any day of the week! Although I agree that fair market value comes from the market, there are times when the market approach may be very difficult to apply. Sometimes, the market approach is not the best approach to use. This can especially be the case if you are trying to measure fair value based on what an owner is really giving up. In chapter 24, I have included a critique that addresses the market and income approaches as used in a litigation setting. It has many good references that will emphasize many of the issues that I have discussed in this chapter. Don't read it now because the chapter about the income approach has yet to be covered. Be patient, and the time will come.

### Let's Demo Pitchbook

PitchBook is a really neat product that I have reviewed, and I wanted to share it with the readers of this book. It is brought to us by, who else, Business Valuation Resources ([www.bvresources.com](http://www.bvresources.com)). Since the last edition of this book, there is now a plugin that allows the user to create Excel files and directly link cells within it to the PitchBook data.

Let me start off by giving you the only negative that I found about this product. My only objection to this database, and it is minor in the scheme of things, is that Pitchbook will not automatically populate my valuation model. This requires us to manually input the data into our own template for us to use it in the manner in which our firm operates.

Once you log in to the database, you get a screen that looks like figure 9.10.

Figure 9.10

SEARCH

(Source: PitchBook. Used with permission.)

The first screen allows you to set up your search criteria either by the name of the company or with various search criteria that I discussed in this chapter. So let's do a search. In this example, we will be valuing a small restaurant chain. So, we enter a check in *Retail Trade* under the SIC industries section, and we check the box for SIC 580 from the drop-down menu that appears after checking the retail box. We also enter a size restriction based on revenues so that we do not end up with very large companies in our search results. We can always redo our search and change the criteria if we find that we were too restrictive or, possibly, not restrictive enough. See figure 9.11.

SEARCH

(Source: PitchBook. Used with permission.)

Figures 9.12–9.18 illustrate the results of the search. It is much easier to view after you download this stuff into a spreadsheet because there are so many columns of data. That, however, is a really good thing.

**Figure 9.18 Search Results** (continued)

(Source: PitchBook. Used with permission.)

The search located 22 possible guideline companies based on our criteria. If you look at the headings of the various tabs in this figure, you will get an idea of what is coming. Figures 9.12–9.18 also provides us with a host of summary statistics, including some multiples (EV is *enterprise value*, which is similar to but not the same invested capital that I described previously. In this instance, it is invested capital less cash and short-term investments). In the right hand portion of the figure, you have the option of clicking on three buttons: (1) Modify Search, (2) Save Comparables, or (3) Download.

There are many different options for downloading the data, and you can actually customize it if you do not want the predetermined formats. All the way to the right of the screen in figure 9.18 is the website for the public company. You can click on it and go there for more information about the potential guideline company. This database makes your life easy in that regard.

Now let's look at the different tabs. The amount of data will blow your mind. Figure 9.19 illustrates the Key Metrics tab.

The Key Metrics tab provides the user with information about each of the possible guideline companies selected. If you have a large selection, this data will go all the way out to the right. A mean and median is calculated for each item based on the guideline companies. The data is broken down by income statement, balance sheet, cash flow, pricing multiples, financial ratios, audit information, and information about the data. For example, is the data audited or restated?

Because there is not a lot more to discuss about this, I am now going to provide the various figures that you can review by yourself. The following figures relate to the information contained in this database:

Figure No.	Tab
9.21 and 9.22	Income Statement
9.23, 9.24, and 9.25	Balance Sheet
9.26 and 9.27	Cash Flow
9.28	Multiples
9.29 and 9.30	Ratios

## Conclusion

By now, either valuation analysts should be very excited and ready to forge ahead, or they may be suffering from an anxiety attack. If it is the latter, take a Prozac! The guideline public company methodology can be overwhelming for the valuation analyst who has never done this stuff before. In fact, even if the analyst has done it before, it still can be overwhelming. We discussed the methodology, the selection of multiples, the assessment of risk, and the advantages and disadvantages of the method. I hope it has become apparent that the guideline public company method can be applied to small- and medium-sized companies. Sometimes, it may be difficult to apply, but that does not excuse the valuation analyst from considering it. In the next chapter, we get to apply the spirit of this same approach at the entity level. Let's do it!

## Chapter 10

# The Market Approach— Part II

### Learning Objectives

In this chapter, I will finish explaining the market approach. Because the last chapter discussed the theory behind the market approach, it will not be repeated (too much) here. This chapter will include the following:

- A discussion about the merger and acquisition (transaction) method
- Highlights of different private transaction databases
- The practical application of the merger and acquisition method
- Internal transactions
- Rules of thumb (the only thing that some folks use!)

### Introduction

After the last chapter, the general thought is probably that if the valuation analyst values small businesses, he or she will never use the market approach. And if that is not the general thought, it might be that if one is an accountant or thinking about becoming one, a job preparing income tax returns is starting to look better and better. So, now I am going to shift gears to show you how the market approach can be used even for small- and medium-sized businesses. The guideline public company method will not be applicable in all assignments, particularly if the subject company is very small, but the valuation analyst has alternatives. The merger and acquisition method allows the valuation analyst to locate sales of businesses in the same or a similar industry for the purpose of applying the market approach. Sometimes, transactions that are internal to the subject company are the best data to be used to determine value. Also, although rules of thumb should never be used as a valuation method, the valuation analyst needs to be aware of them. Just sit back, grab a drink, and let's discuss the market approach some more.

### Merger and Acquisition (Transaction) Method

The spirit of Revenue Ruling 59-60 is frequently applied through the use of the merger and acquisition method. With this method, transaction data is used in a manner similar to that in the guideline public company method previously described. Instead of selecting individual guideline companies, actual transactions involving companies similar to the valuation subject are used to determine pricing multiples. In this instance, the price is that of the entire company instead of a share of stock.

The merger and acquisition method can be applied by using either public company or private company data. Because the entire company has been sold, the transaction is considered to result in a control value. If public company transactions are used to develop the multiples, the results are control, marketable values. If private companies are used instead, the result is a control, nonmarketable value.

Because we never want this stuff to be easy, let's discuss a contradiction in the valuation theory. If minority shares from the public market are used in the guideline company method, the results of the application of this method are dependent on the normalization adjustments made to the benefit stream used in creating the market multiple. However, if all the shares of the same public company are purchased, regardless of the normalization adjustments made, the theory indicates that the result is a control value. How can that be? In reality, it should not be. As we will discuss in chapter 14, not all transactions in the public market take place at

the trading price of the shares. Some purchases take place at a premium (synergistic purchases) and others at a discount (these are not synergistic, but they are a form of negative control premium).

The use of public data for the transaction method requires more analysis to figure out whether it is truly synergistic or maybe control without synergies. The theory is pretty clear for the use of the private databases. These are control transactions.

Before we go too far, let's discuss this concept of control, nonmarketable value. This tends to confuse a lot of people. The control portion of that phrase should not be the problem. Obviously, if an entire company is sold, it represents a controlling interest. But how can it be nonmarketable if it has been sold? Here is where the confusion sets in. This stuff will be covered in more detail in chapter 15, but a preview is in order. An interest in a privately held company is often considered to be less marketable than an interest in a publicly traded company. If you own shares of a public company, you can call your broker, sell the stock, and usually receive cash in about three days. You cannot do that with closely held stock. That is why the private company is considered nonmarketable compared to the public stock. Perhaps a better term would be *illiquid*.

Because selling a privately held company takes more than three days, it, too, is considered nonmarketable. This does not mean that it cannot be sold. It only means that it lacks the liquidity of shares of publicly traded stock. There is a debate in the valuation profession that has been going on for a very long time about this entire topic, and I discuss it in much greater detail in chapter 15. However, for the purpose of this chapter, and until the valuation analyst decides which side of the battle he or she wants to defend, sales of closely held companies are considered nonmarketable. Sales of entire publicly traded companies are considered marketable. This should give you enough for the time being, but here's something to tuck away in the back of your head (if it isn't already spinning from this stuff): Can an entire company really be sold in three days, and if not, does the closely held company, taken as a whole, really have any less liquidity than the public company sold as an entire unit?

Sources of data about acquired or merged companies were discussed in chapter 5. At this point, the manner in which the valuation analyst will proceed depends on whether he or she is using transaction data from the public or private marketplace. Let's discuss each separately:

- *Public market.* Once the valuation analyst has identified transaction data from the public market, an analysis must be performed similar to what was suggested under the guideline public company method. Once the target companies are determined to be similar enough to the valuation subject, pricing multiples can be calculated for the transactions. These multiples can then be adjusted for the differences between the valuation subject and the target companies and then applied to the valuation subject's figures. If the target company is a public company, the valuation analyst can track down much of the same information that would be used in the application of the guideline public company method. Because this process is so closely related to the guideline public company method, there is little need to elaborate further.
- *Closely held market.* The real difference in the merger and acquisition method comes when the valuation analyst uses closely held company transaction data. This type of data is frequently available with limited amounts of details. Some authors believe that if the valuation analyst cannot verify each and every transaction, he or she cannot use this data. I believe that some data may be better than no data. As long as the valuation analyst recognizes the potential deficiencies in the application of this method, it remains a viable alternative. In fact, sometimes, I would rather use this method than any other for small businesses.

Getting away from the public sector moves our discussion to compilations of actual transactions in the closely held world. Our firm has found several sources to be somewhat useful in our quest for transaction data for the closely held business. These sources can be found in box 10.1. Needless to say, some are better than others.

The resources in box 10.1 are presented in no particular order, but the first few will be more useful for smaller businesses. Items 4–7 in box 10.1 contain both public and private transactions. The Mergerstat reference is actually to a control premium study as opposed to a transaction database. The control premia result from transactions and it is for this reason that I have included it in this list. One of the first things that the valuation analyst must do if these databases are going to be used is to learn the various definitions used by each one. The terminology used in these databases varies, therefore, if the valuation analyst is not careful, it is very easy to apply a multiple to the wrong level of earnings or other benefit stream. Some of the more important variations of the terminology will be detailed in this discussion. Recognizing that each of these sources of information has certain deficiencies, the valuation analyst is faced with using common sense and sanity tests to ensure the reasonableness of the results. This is not any different from everything else that we do in this business.

## IBA Market Database

Available from the Institute of Business Appraisers (IBA) or Key Value Data, this database is the largest known source of market transactions of small, closely held businesses. It is free to IBA members, but nonmembers require a subscription. It is available through the online resource Key Value Data ([keyvaluedata.com](http://keyvaluedata.com)) or through the IBA website ([go-iba.org](http://go-iba.org)). This database has been compiled over the years from IBA members and other professionals associated with the sales of businesses (mostly business brokers).

The IBA Market Database includes more than 39,000 transactions across a broad number of Standard Industrial Classification (SIC) codes. Many SIC categories have so many transactions that a highly supportable statistical inference can be drawn from this data. Most of the transactions included in the database are for businesses that had a sales volume below \$1 million. The database is geared toward transactions of the very small business. Small businesses typically are sold as asset sales as opposed to stock sales. An *asset sale* is a transaction in which only certain assets (and maybe liabilities) are transferred to a purchaser who will effectively become the new owner of the business. More often than not, only the operating assets (the assets that are needed to conduct the business operations) of the business are transferred to the buyer. This type of transaction is common for smaller businesses. It is also very different from a *stock sale*, which is typical of larger business transactions. In a stock sale, the stock (all assets and liabilities) is transferred to a buyer. This transfer represents the entire equity of the company. The transaction type is a critical point to understand when considering multiples, and it will be addressed at length later in this chapter.

Figure 10.1 depicts a sample of a search under SIC code 5812 (restaurants) when you request information from this database. It can be downloaded into an Excel spreadsheet.

3 Export Records  Data Only  Direct Market Data Method Report  Transaction Analysis

(Source: ValuSource IBA Market DataBase. Used with permission.)

If you highlight a particular line and click the “View Detail” button (not shown in figure 10.1), you see what appears in figure 10.2.

Figure 10.2 IBA Market Database Detail

The screenshot shows the KeyValueData IBA Market Data interface. At the top, it indicates the subscription expires on 9/1/2017 and exports are unlimited. The interface is divided into three main sections: A. Click on item(s) to search, B. Enter SIC Codes, and C. Search. Section A includes filters for SIC Codes, Description, Price, State, Sales, Price to Sales, and Date of Sale. Section B shows the SIC Code(s) entered as 5812, with 1,596 records and 1,596 values. Section C has a Search button. Below these sections is a 'Review Records (1596)' section with a 'Show record' indicator set to 11. The main table displays a detailed financial record for a business in Pennsylvania, including fields for location, financial metrics, and terms.

(Source: ValuSource IBA Market DataBase. Used with permission.)

Although this detailed record seems to contain a lot of information, it really does not. This is one of the major drawbacks of this database. It does not contain enough information for any transactions to be used with any confidence. I will discuss this again shortly.

Now that you have a feel for what the data looks like, you may want to know what the data represents. Box 10.2 lists the major fields contained in the IBA database, along with a definition of each item. I expect this to change over time, so please keep checking the information provided by the database to make sure that you use this information correctly.

In reviewing the information in box 10.2, there are a few things that may come to your attention. The first is that the database lists only the principal line of business, which is typically two or three words. Not much information is given about the target company (the one that was acquired) that will aid a valuation analyst in determining comparability. One of the major drawbacks of this database is that it contains little qualitative information about each business.

Annual earnings are reported as earnings before owner's compensation, interest, and taxes, which reflect the total compensation of an investor in a small business (assuming that the owner will be the operator of that business; it also assumes only one owner). As discussed throughout this book, a valuation analyst must take care to apply a multiple to the correct level of earnings. When applying an IBA multiple to earnings, make sure that the earnings stream is defined and calculated as indicated in box 10.2.

**BOX 10.2****IBA Data and Definitions**

Business description	Description of the primary business activity of the firm sold.
SIC code	Principal Standard Industrial Classification number applicable to the business sold
Sales	Year 1 Gross Sales (most recent year)
DE	Year 1 Discretionary Earnings. Annual earnings before owner's compensation, interest, and income tax expense
Owner's compensation	Year 1 owner's compensation
Price	Total reported consideration (that is, cash and liabilities assumed, among other items, but excluding real estate)
Price/sales	= Price / Year 1 gross sales
Price/DE	= Price / Year 1 DE
Date of Sale	Date the sale was completed

Another question that may arise when using this data is about the sales price, which is reported as a dollar figure. Terms of the deal (typically including some type of seller financing) are generally not disclosed. If the valuation analyst gets lucky, he or she may find it for a few transactions in the details. However, as every good student knows, a dollar today is more valuable than a dollar 10 years from now. Because fair market value is considered to be a cash or cash equivalent value, knowing the terms of the deal could make a difference. If the valuation analyst does not know the terms of a deal, the IBA listed price may not be its cash equivalent value.

In an attempt to better understand the significance of the transaction data included in the database, an empirical study was undertaken by Raymond Miles, the founder and past Executive Director of IBA, and his results were presented at an IBA national conference many years ago. Mr. Miles concluded the following:

The price-to-earnings<sup>1</sup> and price-to-gross revenue multiples are almost equally valid criteria for estimating the market value of businesses. This conflicts with the conventional wisdom that the price-to-earnings ratio is the most significant performance criterion of a business.

In practice, the price-to-gross revenue multiple is especially useful for appraising closely held businesses, because price-to-gross revenue multiples are available for all sales in the IBA Market Database, while price-to-earnings multiples are only available for some sales.<sup>2</sup>

Empirical data for all business categories, in aggregate, does not show any significant change in business value as a function of time. This is contrary to the conventional wisdom that only recent sales should be considered when choosing guideline (comparable) companies.

The data shows no significant correlation between the selling price and the percentage down payment. This differs from the conventional wisdom that a business sold for cash should bring a lower total price than one sold for terms.

As expected, business values, as measured by price-to-earnings and price-to-gross multiples, differ from one kind of business to another. However, this difference is not as large as one might expect. This suggests that the search for guideline transactions does not need to be limited to businesses in the same SIC category as the business being valued. Thus, the search for guideline transactions can reasonably include SIC categories other than the category assigned to the business being valued.

Empirical evidence indicates that the *most probable price* for a business is significantly different from the average price of businesses that have been sold. Thus, when the standard of value is *most probable price*, use of the average selling price of guideline transactions can lead to a value estimate that is in error by a significant

1 This is also considered to be the price-to-DE (discretionary earnings) ratio in today's materials.

2 *Ibid.*

amount.<sup>3</sup> Being the accountant that I am, and being suspicious of people who publish information that could be deemed self-serving, I was provided with the opportunity to review Mr. Miles' study in this area. His findings were accurate. In fact, what really blew my mind was the fact that transactions that were 10 and 15 years old, in most industries, were still valid. Now, don't get me wrong, using dated transactions can often be a difficult task, especially when certain industries have been fairly inconsistent over the years. With that said, certain industries have been extremely consistent from year to year. What I am really saying is analyze the data to see what the impact is for the particular situation.

Even geographically, the multiples were not materially different. In another study<sup>4</sup> published by Mr. Miles, he disclosed the data presented in table 10.1.

**TABLE 10.1 Miles' Price to Earnings and Price to Gross Revenue Difference Study**

Region	Price to Earnings Different From		Price to Gross Revenue Different From	
	Mean	Nat'l Avg.	Mean	Nat'l Avg.
Southwest	2.10	-11.00%	0.54	-4.00%
Northwest	2.60	11.00%	0.57	6.00%
Southeast	2.23	-7.00%	0.56	1.66%
Northeast	2.99	25.00%	0.54	1.66%
All Regions	2.39	—	0.54	—

As can be gleaned from the data included, the price-to-gross-revenue multiples were not materially different from one geographic region to another. Following completion of the study, the author determined that a major reason for the higher price-to-earnings multiples for the Northeast geographic region was submission of many business sales by one business broker who dealt with high-end businesses.<sup>5</sup>

Now, of course, the valuation analyst wants to test the data before he or she uses it, but this database gives the valuation analyst a methodology that can be applied to small businesses. The valuation analyst must be smart when using this or any other database to ensure that there are enough transactions to be statistically reasonable. As you can see, there are many things to consider when using this data. Answers to many of the issues discussed previously, as well as others that may not have been addressed, can be found in various publications available from IBA. In fact, IBA also has a variety of tutorials on its website to show how to use this data.

## BizComps

The BizComps<sup>®</sup> database includes sales information by SIC category as accumulated by Jack Sanders, a well-respected business broker. The most convenient manner in which to subscribe to this database is through Business Valuation Resources, LLC ([www.bvmarketdata.com](http://www.bvmarketdata.com)). It contains a lot of useful data, but the valuation analyst should be careful to understand what is included in each item. Much like the IBA database, BizComps reports seller's discretionary cash flow as a measure of earnings, but this definition includes depreciation, amortization, and all other noncash and non-operating expenses. According to Business Valuation

<sup>3</sup> Raymond C. Miles, "Business Appraising in the Real World: Evidence From the IBA Market Database" (paper presented at the IBA National Conference, Orlando, FL, February 7, 1992).

<sup>4</sup> Raymond C. Miles, "Business Values in the Real World: Evidence from the IBA Transaction Database" (paper presented at the American Society of Appraisers Business Valuation Conference, Houston, TX, October 23, 1993).

<sup>5</sup> *Ibid.*

Resources, BizComps contains transactional information on “Main Street” businesses (service station, restaurant, convenience store, print shop, travel agent, florist, coin laundry, beauty salon, auto repair shop, video rental, day care center, and so on) dating back to 2000.

Historically, transaction data about small business transfers had been virtually nonexistent, leaving the investor or adviser to speculate about the fair market value of the small business enterprise. This database removes the marketplace uncertainty and provides the user with detailed, meaningful financial information about these real-world transactions.

Subscribers to BizComps are granted access to all of the details in the database, including annual gross revenue, asset figures, operating ratios, and the price and terms of the sale. Additionally, sale price to gross revenues and sale price to seller’s discretionary earnings multiples are calculated for each transaction reported. And once you have found the information you need, you can effortlessly export it to a Microsoft Excel spreadsheet, print the individual transaction reports, or recalculate the summary financial statistics.

As of October 2016, BizComps contained 12,120+ transactions. Within the database, 57.2 percent of the deals have less than \$500,000 in annual gross revenues, whereas 19.4 percent of the deals have annual gross revenues over \$1 million. The entire database is searchable by various parameters, with transactions updated throughout the year.<sup>6</sup>

According to the *BizComps User Guide*, what was actually sold includes the following:

Only two elements are contained in either the BizComps Asking Price or the Sale Price. The items are Fixtures & Equipment (F&E) and Goodwill or the intangible value. Cash, accounts receivable, loans receivable, real estate, and other assets are not included, and all liabilities have been excluded. All licenses necessary to conduct business are generally included. This is nothing magical—just simply the way these businesses are sold. They are all asset sales or have been converted to an asset sale.

The sellers of these businesses rarely are willing to part with the cash and accounts receivable and the buyers are rarely willing to pay for it. And the businesses are considered to be debt-free at close even if there are new loans coming on board from the seller or others. Sellers usually are responsible for paying off all debt at the close of sale.<sup>7</sup>

To better illustrate the contents of this database, as well as what the contents include, I have included a listing of the BizComps fields as outlined in its user guide in box 10.3 on the following page.

There are many useful data points in the BizComps database that the IBA database does not have. BizComps has the asking price as well as the sales price, which can give a valuation analyst a better idea of what is really going on in the market. Two important pieces of information included in BizComps are the percent down payment and terms of financing. Although the Miles study claims that the down payment does not matter, the terms of financing certainly do. This will allow a valuation analyst to estimate the cash equivalent value of the transaction price.

When logging into this database, various search parameters can be entered in order to locate transactions that may be relevant to a particular valuation. For this example, a search was conducted based on SIC code 5813, Drinking Places, located in North America. We also limited the search to include only those transactions that took place after 2010. The search screen is presented in figure 10.3 on the following page.

**BOX 10.3**

**BizComps Field Definitions**

- SIC = Small Business Industry Classification Number (Standard Industrial Classification)
- NAICS = North American Industry Classification System
- BUS TYPE = Best Description of Subject Business
- ASK PRICE = Asking Price (000's). Does not include inventory
- ANN GROSS = Annual Gross Sales (Normally Net of State Sales Tax)
- SDE = Seller's Discretionary Earnings (Net Profit Before Taxes and any compensation to owner plus Amortization, Depreciation, Interest, Other Non-Cash Expense and Non-Business Related Expense) SDE Assumes One Working Owner
- SDE/GROSS SALES = Seller's Discretionary Earnings Divided by Gross Sales
- SALE DATE = Actual Date of Sale
- SALE PRICE = Actual Sale Price (in 000's). Inventory has been deducted if it was in Sale Price
- % DOWN = Down Payment as a Percent of Sale Price
- TERMS = Terms of New or Assumed Encumbrance
- SALE/GROSS = Sale Price Divided by Gross Sales
- SALE/SDE = Sale Price Divided by Seller's Discretionary Earnings
- INV = Inventory at The Time of Sale (in 000's) Inventory is not included in Sale Price
- FF&E = Estimate of Value of Furniture, Fixtures & Equipment
- RENT/SALES = Rent as a Percent of Sales
- DAYS ON MKT = Actual Number of Days Business Was on Market
- FRANCHISE ROYALTY = Actual Royalty Less Advertising Percentage
- AREA = Region or Geographical Location of Business

## BIZCOMPS

### Subscriber Search Results

BIZCOMPS FAQ Page | Subscriber Quick Reference Guide | Subscriber Services | Questions?

Total transactions found meeting criteria: 111

#### Search Criteria

Your search was executed: 11/1/2016 7:42:55 AM (PST)  
Your search results are based upon this criteria:

1. SIC Code ('5813')
2. Sale Date (mm/dd/yyyy) (1/1/2011 - 7/15/2016)

#### Transaction Summary

Financial values are (\$000).

Statistic	Count	Range	Mean	Median	Harmonic Mean	Coefficient of Variation
Sale Date	111	1/12/2011 - 2/29/2016	N/A	N/A	N/A	N/A
Annual Gross	111	\$60 - \$5,534	\$798	\$627	N/A	N/A
SDE	106	(\$38) - \$30,184	\$444	\$121	N/A	N/A
Sale Price (Excludes Inventory)	111	\$10 - \$1,150	\$266	\$200	N/A	N/A
SDE To Annual Gross	106	-0.14 - 54.39	0.73	0.20	N/A	N/A
Rent To Annual Gross	66	0.01 - 0.44	0.10	0.09	N/A	N/A
Sale Price To Annual Gross	111	0.04 - 1.34	0.40	0.33	0.26	0.62
Sale Price To SDE	102	0.01 - 17.59	2.27	1.68	0.44	1.06

(Source: BIZCOMPS®. Used with permission.)

The bottom portion of the initial search shows each transaction as reflected in figure 10.5.

Every transaction that meets the search criteria is listed in summary format. The valuation analyst can review the details of each transaction on his or her computer or print each one out for the working papers. By checking the box, you can print the detailed records for each transaction. The detailed listing is presented in figure 10.6.

The detail included in the transaction provides the analyst with a little more information than was included in the IBA database. More information is a good thing in our business. It provides you with the opportunity to do more analysis of the data.

Having transaction details can allow the analyst to calculate a cash equivalent value for each transaction. Let's do an example. Assume that this particular transaction was closed at a sales price of \$550,000, with a 15 percent down payment and the remainder financed over seven years at an interest rate of 8.5 percent. As of the date of the sale, the prime rate was 7.5 percent. For argument's sake, let's assume that a typical buyer of this type of business could only get financing at the prime rate plus 3 percent, or 10.5 percent. What this means is that this buyer was able to obtain below-market-rate financing, which adds value for the buyer, but the price listed is not indicative of a cash equivalent value. To calculate the cash equivalent value, the analyst must forecast all cash flows from the loan and discount them to the present value at the date of the transaction using the market rate of debt as the discount factor. For illustration purposes, let's assume that the loan is paid out in equal installments over a seven-year period (see table 10.2).

Sale price	\$550,000						
Down payment	82,500						
Amount financed	\$467,500						
Financing period	77						
Interest rate	8.5						
Market interest rate	10.5						
Year	1	2	3	4	5	6	7
Loan balance	\$467,500	\$416,438	\$360,861	\$300,372	\$234,536	\$162,879	\$84,889
Principal payment	\$ 51,062	\$ 55,577	\$ 60,489	\$ 65,836	\$ 71,657	\$ 77,990	\$84,883
Interest payment	37,776	33,264	28,352	23,007	17,187	10,853	3,959
Total payment	\$ 88,838	\$ 88,841	\$ 88,841	\$ 88,843	\$ 88,844	\$ 88,843	\$88,842
Present value of total payment	\$ 80,396	\$ 72,759	\$ 65,846	\$ 59,590	\$ 53,928	\$ 48,803	\$44,165
Total present value	\$425,488						
Plus: down payment	82,500						
Cash value	\$507,988						

The data from table 10.2 indicates that the cash equivalent value of this deal was only \$507,988, almost \$42,000 below the reported transaction price. If the valuation analyst was to calculate the multiple of sales price to annual revenues using the adjusted sales price, the result calculated will be very different (see table 10.3). Table 10.3 indicates a relatively small difference, but imagine how far off you could be depending on the financing terms.

	As Reported	Cash Equivalent Value
Annual revenues	\$1,040,000	\$1,040,000
Deal value	550,000	507,988
Multiple	0.529	0.489

Also, stated separately in this database are inventory and fixed assets. As with the IBA Market Database, the BizComps transactions are asset sales, meaning that only the operating assets are transferred to the purchaser. The \$550,000 sales price, by definition in the database, excludes inventory, but in this case, there is none. However, it would include the fixed assets (these are the operating assets). Therefore, even though it is not given in the database, the intangible assets that were part of the transaction can be calculated by subtracting the value of the fixed assets from the transaction price ( $\$550,000 - \$10,000 = \$540,000$ ). By including the operating assets in the database, BizComps gives the user the ability to estimate the intangible value that was part of the deal.

BizComps lists rent and franchise royalties as a percent of sales so that a user of the database can get a better idea of the fixed costs of the business. It also provides the number of days that the business was on the market before the sale closed. This piece of information is very interesting. One of the issues that analysts encounter with every assignment is the level of marketability of the subject business and a corresponding discount for lack of marketability (discussed in chapter 15) if it is applicable. Although using a sales-price-to-earnings-stream multiple yields a control, nonmarketable value, this information gives the user some basis with which to support a discount for lack of marketability for an indication of value derived from another method (for example, capitalized earnings, which is discussed in chapter 12).

Overall, BizComps gives more data fields than the IBA Market Database, but as discussed, it contains much fewer transactions (12,000 as compared with 39,000). The desktop version of the database comes with software that enables quick and easy analysis of selected transactions and gives the user the ability to value subject companies based on sets of transaction multiples. The analysis performed is by no means all inclusive, but it provides an easy way to do a quick analysis. Analysis of transaction data will be discussed in more detail later in this chapter.

## Pratt's Stats

Pratt's Stats<sup>®</sup> is another resource for closely held company sale information. Pratt's Stats contains details on approximately 26,000 closely held business sales from 1990 to the present, ranging in target revenues from \$1,000 to \$17,178,097,000. The industries represented in Pratt's Stats are also pretty broad, as evidenced by the roughly 770 unique SIC codes. This database, started by Shannon Pratt, and now carried on by Business Valuation Resources, is an excellent source for transaction data, and it has taken small business transaction reporting to the next level. Pratt's Stats data is available online at [www.bvmarketdata.com](http://www.bvmarketdata.com).

Pratt's Stats search criteria includes the industry SIC or North American Industry Classification System (NAICS) code, company description, city and state location, revenue range, text searches, and many other key data fields for each transaction. The valuation analyst can also search by a secondary SIC code. The ability to further select specific deals from the initial search, recalculate the summary statistics, and print or export to Excel spreadsheet formats are some of the features found here. Currently, you can download up to 149 fields of information for each transaction from the database (although, as you may have noticed with IBA and BizComps, not all information is available for each transaction). Figure 10.7 displays a Pratt's Stats search for SIC code 5813.

Even the search capabilities are much greater for this database. The valuation analyst can base a search on date ranges, financial metrics, and even the source of the data. This provides a much greater ability to focus on those metrics that are important to the particular valuation assignment.

After inputting the search criteria and pressing the search button, the valuation analyst gets a summary report, illustrated in figures 10.9 and 10.10.

(Source: Pratt's Stats. Used with permission.)

Summary data is provided in figures 10.9 and 10.10. By the way, remember the statistics that we discussed in chapter 7? Look at the statistical data provided in this summary. There is a reason that I included statistics in this book. The detail shown in these figures appears to be similar to the detailed report from BizComps, but look at the illustration more closely and notice a drop-down menu that allows you to choose which multiples you want to include for this report. Once you select the transactions, a detailed report for each transaction can be printed. A transaction report for one of the drinking establishments that was sold is illustrated in figures 10.11 and 10.12.

The detailed transaction reports illustrated in figures 10.11 and 10.12 contain many more data points for each transaction than IBA or BizComps. For instance, look at the item on the page, titled “Broker Firm Name.” As previously discussed, the first two databases had limited data that could be used to determine comparability, whereas Pratt’s Stats has taken the next step and given the user the name of the intermediary who participated in the transaction. Just from this one field, you have the opportunity to verify the listed transaction with the broker.

(Source: Pratt's Stats. Used with permission.)

In addition to the multiples and financial information about the target and the deal, additional information about whether there was an employment contract or a covenant not to compete is also provided. The more information available to the valuation analyst, the better his or her ability will be to determine comparability.

There are many other useful data points included in Pratt's Stats, and full definitions for all fields are available on the website under Pratt's Stats FAQs (frequently asked questions).

Each transaction does not have information in every data field, but this database does a good job of increasing the amount of information that is available for small company transactions. The more information that is available, the better the decision-making process will be. This will lead to better valuation opinions. Pratt's Stats provides up to six different valuation multiples based on invested capital (deal price). These include the following:

- MVIC / Net Sales
- MVIC / Gross Profit
- MVIC / EBITDA
- MVIC / EBIT
- MVIC / Discretionary Earnings
- MVIC / Book Value of Invested Capital

In addition, the database gives the user information to calculate other multiples (for example, equity-price-to-book value). With so much data available, the possibilities are endless, but the valuation analyst has to be careful to make sure that he or she understands what is listed in each field before making up multiples.

Another important item that the valuation analyst must consider is that Pratt's Stats reports two different transaction types. BizComps and IBA report only asset sales. In addition to asset sales, Pratt's Stats also reports stock sales. Stock sales are transactions in which a business transfers its equity to the acquirer, or in other words, transfers all of its assets and liabilities. Based on the transaction type, price will most likely reflect different assets or liabilities, or both, that were transferred as part of the deal. This becomes very important in comparing and applying multiples. I will demonstrate this shortly.

Pratt's Stats automatically calculates statistics on selected transaction data, and these are displayed on the subscriber results page. Users can limit the data set to include certain transactions and may recalculate statistics such as count, range, mean, median, harmonic mean, and coefficient of variation for each data set. These statistics can be useful in performing transaction searches, as well as multiple selections. Another very useful tool that comes out of Pratt's Stats is the ability to calculate multiples for S corporations versus C corporations. This can further support the valuation analyst's analysis when it comes time to address the question of whether to tax affect the earnings of an S corporation. This topic is discussed in greater detail in chapter 18.

Finally, one more useful tool that comes out of this database is the ability to calculate the relationship of the value of non-compete agreements to the total transaction price of the deal. This is really handy when the valuation analyst has to address the issue of personal goodwill allocations. This topic will be discussed in much greater detail in chapters 20 and 22.

## DoneDeals Database

The DoneDeals® database, now published by Thomson Reuters, as part of PPC (Practitioners Publishing Company), contains slightly larger transactions than the databases discussed previously, with purchase prices ranging between \$1 million and \$1 billion. According to its website, DoneDeals indicated that there are approximately 8,800 deals as of November 2016. The company says that they add new transactions weekly, up to 250 new transactions each quarter depending upon merger and acquisition activity among mid-market companies and the number of deals for which they are able to obtain full financials, but the number of deals has actually gone down since the last edition of this book was published.

Over 79 percent of the companies sold in the DoneDeals database were privately owned. Another 11 percent of the companies sold were subsidiaries of public companies. Most of the DoneDeals data comes from company financial reports filed with the SEC with financial data subject to generally accepted accounting principles. Other sources provide supplemental information. DoneDeals focuses on the smallest acquisitions reported to the SEC.

As time has passed, I have found that many of the transactions found in this database can be obtained through other databases. You may find many of the transactions to be duplicative and probably too large for the small- to mid-size valuations that you do. However, with that said, it is another resource that you should consider.

## Public Stats

Public Stats® is offered by Business Valuation Resources, the same organization that brings us Pratt's Stats. Public Stats is a database of public company purchases of 100 percent of public companies. Some of the transactions are international. Public Stats compiles and reports information on 64 data points, highlighting the financial and transactional details of the sales of publicly held companies.

According to its website, benefits enjoyed by Public Stats' users include the following:

- An easy-to-use search engine that quickly identifies comparable transactions based on criteria specified by the user
- Hard-to-find data on how deals are structured, including payment terms, employment agreements, and non-compete agreements
- Deal details with five valuation multiples and 13 financial ratios sorted by profitability, leverage, and activity ratios (getting close to size, growth, leverage, profitability, turnover ratio, and liquidity [SGLPTL]?) calculated for each transaction found in Public Stats, making the identification of value drivers with the greatest market reliance transparent to the user
- The ability to track market pricing trends via the Public Stats' timely deal updates

As of November 2016, Public Stats had compiled details on more than 3,795 public company business sales from 1995 to the present. Public Stats collects its data from SEC filings submitted to the SEC by the business buyer. Public Stats data is updated online monthly with several transactions added per month.

## Factset Mergerstat/BVR Control Premium Study

Another database that we search when looking for larger transactions is another brought to us by, who else, Business Valuation Resources. Any valuation analyst who has been working in this field for a number of years should recognize the name Mergerstat. We have been using *Mergerstat Review*<sup>8</sup> for as long as I have been in this business (you know, when the dinosaurs roamed the earth). Shannon Pratt teamed up with Mergerstat to create this database, and it is now being continued by the folks at BV Resources. The Mergerstat database is offered through other resellers as well, such as Alacra, Lexis-Nexis, and Dialog, and should not be confused with the FactSet Mergerstat/BVR Control Premium Study.<sup>TM</sup>

FactSet Mergerstat, LLC, located in Santa Monica, California, publishes this study, which is mainly used to quantify minority discounts and control premiums used in the business valuation, venture capital, and merger and acquisition professions. However, this database also allows you to find transactions. This database can be searched by specifying any of the following variables:

- Individual four-digit SIC code or NAICS code
- An industry (a range of SIC codes)
- Financial performance ratios (operating profit margin and net profit margin)
- Keyword from a business description
- Range of control premiums
- Financial data (including net sales, EBITDA, earnings before income and taxes [EBIT], net income, and invested capital)
- Sale details (including sale date, deal value, attitude, form, and consideration and transaction purpose)

Subscribers to the FactSet Mergerstat/BVR Control Premium Study are granted access to all the details in the database, including the control premium, five valuation multiples, and the available information to calculate the return on equity (Net Income / [book value per share × number of shares outstanding]). The database contains more than 10,490 transactions that detail up to 57 data points for each transaction. The differences between *Mergerstat Review* and FactSet Mergerstat/BVR Control Premium Study are highlighted in figure 10.13.

**Figure 10.13 Difference Between Mergerstat Review and the Database**

Control Premium Study Online	Mergerstat Review <sup>1</sup>
Used to calculate controls premiums and implied minority discounts	Used to stay current with deals by size or industry sector
Quarterly updates of controlling acquisitions	Monthly updates of major deal activity
Greater focus on individual transactions	Focus on aggregate data (plus individual)
Updated quarterly	Updated annually
Only includes deals that are closed	Includes deals that are announced and closed
Uses unaffected date price to calculate Control Premium (could be difference of days or weeks)	Uses five days before the acquisition announcement date to calculate Premium - but it's not a Control Premium (see below Review note)
Includes only controlling purchases	Includes controlling and NON-controlling purchases
Details on individual transactions are available	Details on transactions are available but not quite as much detail
Contains information only on public targets	Contains public, private, divestitures, and cross-border deals
Contains information from non-US companies - both sides can be non-US based companies	Contains information from non-US companies - one side MUST be US based company
Allows for inclusion of negative premiums	Excludes negative premiums
Includes transaction codes for Vertical Integration (V), Horizontal Integration (H), Conglomerate (C) and Financial transactions (F)	Does not include transaction codes

<sup>1</sup> Also includes monthly emailed Factset Mergerstat Monthly Review in PDF format

Review note - for the Review, there is the premium you pay for the right to control an entity but there is also the premium you may have to pay over the current share price to get the piece of the company you want to own. The moment your demand for the shares is realized in the market - the price of those shares are going to adjust (usually up in price) - almost as quickly as you can buy (especially if you are looking for a large piece). That differential between the share price (unaffected by your demand) and what you may actually have to pay to get the share is the "premium". It may be zero, negative, a small amount or a considerable amount depending on the market's reaction to your demand.

**General Comments:**

There are advantages for any firm to owning both publications because there is little overlap. The Mergerstat Review covers a much broader spectrum of overall M&A market & industry statistics and analysis plus details of the underlying transactions, whereas the Factset Mergerstat/BVR Control Premium Study focuses on transactions where a controlling interest is being exchanged and the associated control premiums.

## Thomson Financial Mergers & Acquisitions (TF Mergers & Acquisitions)

The Thomas Financial (TF) Mergers & Acquisitions database contains information about public company mergers and acquisitions of public and private companies. This database will be overkill for the valuation analyst who only values small companies. However, I think that a valuation analyst should be aware of it because you never know when that gas station valuation will turn into Shell Oil.

We access the TF Mergers & Acquisitions database through Alacra ([www.alacra.com](http://www.alacra.com)), which is a fee-based service. The database contains information about U.S. transactions from 1979 to the present. Non-U.S. transactions have been included since 1985. The exact number of transactions is unknown because the figures on the website continue to show that there are 121,300 U.S. transactions and 157,350 non-U.S. transactions included in this database. These numbers have not changed in years, but we do know that the total number is big!

Included in this database are all corporate transactions involving at least 5 percent of the ownership of a company in which the transaction was valued at \$1 million or more (after 1992, deals of any value are covered) or the value of the transaction was undisclosed. Public and private transactions are covered. Transactions include the following:

- Mergers and acquisitions
- Stake purchases
- Stock swaps
- Real estate investment trust acquisitions
- Asset sales and divestitures
- Rumored and seeking buyer transactions
- Leveraged buyouts
- Tender offers
- Privatizations
- Spinoffs and splitoffs
- Bankruptcy liquidations

This database boasts that there are 1,400 data elements available, but the reality is that many of the transactions have many blank fields. In some databases, when downloading reports, the cost is “per field” regardless of whether there is data. This database can become very expensive to use. A more in-depth discussion about this database is beyond the scope of this book.

## Business Brokers

Business brokers can also be an excellent source of market transaction data. The local business broker is frequently involved in many transactions and has access to information about businesses that have been bought and sold in the geographical region of the valuation subject. The major problem with business broker information is twofold: First, the broker may not have access to fully reliable financial information about the company that was sold because the seller frequently provides the figures to the broker without any verification. Second, the seller or the buyer, or both, are generally going to require the broker to respect their confidentiality, which would prohibit the broker from opening the file to the valuation analyst.

On occasion, enough data can be obtained from a business broker to allow some empirical data to be used in applying the market approach. There may be times when a reliable broker will be allowed to verify the transactions and the other party, assuming a litigation, will stipulate to confidentiality, because his or her expert will want to do the same. This is exactly what happened in the report excerpted in exhibit 10.1.

To help get data from business brokers, the valuation analyst may find it helpful to offer the broker compensation for his or her time. (Brokers just love me!) Another excellent way to gain cooperation is to refer some sales to the broker. Because brokers are involved in the market, it is only natural that they should be able to provide good market information in the valuation analyst's local area.

### EXHIBIT 10.1 Business Broker Information

This valuation method uses information that comes from the actual sales transactions of similar properties to determine a ratio of the sales price to the net profit from the property (commonly known as a *multiple*), which is then applied against the appraisal subject's net profit. This is probably the most widely used ratio in valuation methodologies today. Two important components of this method are the net profit (for this appraisal, net profit is defined as the amount available to the owner after normal business expenses but before taxes, loan payments, and owner's compensation; this is sometimes called *seller's discretionary cash flow*) and the appropriate multiple to be used.

XYZ Products, Inc. had an average net profit for the past three years of \$110,500. The multiple applied to the net profit must reflect the appropriate amount of risk that is associated with the net profit as calculated. In this instance, a multiple of 1.81 has been deemed appropriate, as explained in a later section of this report.

Therefore, the value of the intangible assets of XYZ Products, Inc. is calculated as follows:

Average net profit	\$110,500
Multiple	× 1.81
Estimate of value	<u>\$200,005</u>
Rounded	<u>\$200,000</u>

#### THE MARKET PRICE OF THE SALES OF CLOSELY HELD FOOD ROUTES

To assess the market price of sales of routes comparable to XYZ Products, Inc., we consulted with John Smith, President of Busbroke Inc. and a business broker who specializes in the sale of food route businesses. Mr. Smith provided us with the actual sales transactions of 10 routes that were used as guidelines for sales of similar types of businesses to the subject company. Table 1 provides financial data regarding the 10 guideline companies. All 10 routes relate to either dairy, cheese, or yogurt product lines. Table 1 provides ratios based on the relationship of the purchase price of the route to the net profits of the selling company.

**TABLE 1 Summary of Food Route Sales\***

Rout	Type	Net Sales (\$)	Purchase Profit (\$)	Gross Profit (\$)	Price/Net Price (R)	Profit (\$)	Multiple**
1465	Cheese	390,000	50,700	44,200	100,000	13.00	2.26
1474	Dairy	520,000	78,000	68,380	125,000	15.00	1.83
1514	Yogurt	650,000	110,500	85,800	248,000	17.00	2.89
1543	Yogurt	610,000	118,950	85,700	200,000	19.50	2.33
1546	Yogurt	478,400	119,600	91,780	205,000	25.00	2.23
1571	Yogurt	442,000	88,400	80,600	165,000	20.00	2.05
1726	Yogurt	338,000	60,840	54,860	155,000	18.00	2.83
1773	Cheese	936,000	112,320	90,740	200,000	12.00	2.20
1784	Dairy	327,600	88,400	82,160	120,000	26.98	1.46
1818	Dairy	468,000	93,600	70,980	85,000	20.00	1.20
						Average	2.13

\* Supplied by Busbroke, Inc.

\*\* Calculated by the valuation analyst.

## EXHIBIT 10.1 Business Broker Information

Some additional information should be highlighted about these transactions. The sale of food routes generally involves an individual purchasing a food route with the intention of working the route; in essence, the individual is purchasing his employment. This is in contrast to the potential investor, who would buy a route and then pay someone to service the route. As a result, an individual purchasing these food routes tends to be motivated and frequently bases the amount that he or she is willing to pay on a figure that is considered to be net profit but, in fact, excludes owner's compensation.

The cash flow generated by the food route must be adequate not only to allow the owner to make a living, but also to pay down the debt service that comes about as a result of the purchasing of the route itself. To determine the fair market value of a food route business, reasonable compensation should be considered to avoid confusing a true return on investment with the owner receiving compensation for working the business. Logically, value is generally measured by the return received in excess of reasonable compensation; otherwise, employees would be paying their employer for the opportunity to work.

In comparing XYZ Dairy Products, Inc. with the routes listed in Table 1, we noted that the guideline companies reflect a gross profit (sales less direct cost of sales) of 12 percent to 26.98 percent, whereas XYZ Dairy Products, Inc. has averaged only 10.35 percent over the last five years. Many of the guideline companies reflect a net profit to the owners of \$85,000–\$90,000 based on sales of \$300,000–\$600,000, whereas XYZ Dairy Products, Inc. reflects an average net profit of \$105,771 based on average net sales of approximately \$3,373,000.

In addition to the preceding, a price-to-net profit ratio was calculated by the valuation analyst for each actual transaction, resulting in ratios of 1.20–2.89, with an average ratio actually paid of 2.13 times the net profit. In fact, a multiple of 2.13 is equivalent to a capitalization rate of 46.9 percent, indicating an extremely high rate of return required by the buyers in the food route marketplace. This is the same as saying that the willing buyers expect to recoup their investments in a little over two years, in addition to their labor.

Another important factor that must be considered in reaching a value conclusion about intangible assets is risk. The level of risk associated with an investment generally determines the required rate of return for an investor.

This is why, for example, certificates of deposit may pay 5 percent, whereas corporate bonds pay 8 percent and junk bonds pay 16 percent. The higher the level of risk, the higher the required rate of return must be in order to attract an investor.

Almost every closely held business is extremely risky. XYZ Dairy Products, Inc. is certainly no exception. The willing buyer of a customer list is not assured that customers will continue with that company. In fact, unless there were contracts guaranteeing volume, a substantial discount would normally be applied in the value of the company. In the real world, buyers and sellers address this contingency through sales contracts because if a customer were lost, no payment would be required. This is almost like buying a business on a royalty basis. If the business volume continues as anticipated, the willing buyer will pay the willing seller.

Some of the more pertinent risk factors that a willing buyer would consider are the following:

- Brand X represented approximately 90 percent of XYZ Dairy Products, Inc.'s business.
- XYZ Dairy Products, Inc. had no contract with Brand X indicating that business would continue at any point in the future. The fact that the company had been delivering Brand X products for a number of years could not, by itself, be relied upon for continuity to take place in the future.

In the early 2000s, PQZ became a broker for Brand X. PQZ represented Brand X in stores and supermarket headquarters and actively worked with the supermarkets through central billing. At that point XYZ Dairy Products, Inc. started billing with Brand X invoices, and Brand X collected the money directly. PQZ also began handling the promotional aspects with the supermarket to further change the role of the company.

In approximately 2004, Cheese, Inc. purchased Brand X. According to the deposition of Sam Jones, when Cheese, Inc. took over Brand X, many distributors were concerned about Brand X "going warehouse" (that is, distributing through a central warehouse instead of directly to the supermarkets).

Compared to the guideline companies, XYZ Dairy Products, Inc. was considerably less profitable despite a larger sales volume. The company's gross profit on sales was lower than all 10 guideline companies. XYZ Dairy Products, Inc. had no control over the billing, distribution, and collections associated with Brand X products. The company was primarily a one-company distribution agent with little diversification.

In addition to the preceding, a financial analysis was performed by the analyst using Integra's Business Profiler. This database contains statistical data broken down by Standard Industrial Classification (SIC). In this instance, SIC code 5143, "Wholesalers of Dairy Products," was used.

In our opinion, XYZ Dairy Products, Inc. appears to be weaker than the industry group, due primarily to its lower profitability. As a result, we believe that a 15 percent discount is appropriate from the average guideline company multiple. This indicates that an appropriate multiple to be used for XYZ Dairy Products, Inc. is 1.81, to be applied against the net profit available to the owner.

## Transaction Analysis

Get ready, here comes the good stuff! Now that the valuation analyst knows where to find transaction data, I will shed some light on how to use it. The fact of the matter is that the merger and acquisition method has some major limitations because most of the transactions retrieved through database services cannot be independently verified, and there is a limited amount of information for each transaction. Real estate appraisers verify each transaction, whereas valuation analysts must rely on someone else's work, which comprises limited information about the target companies.

However, fear not! Although a valuation analyst may have limited data, it can still be used. Actually, this method is often the most direct and applicable method for valuing a small company (just don't use it by itself as the only method). There is a wide array of tools and techniques that can help you analyze transaction data. Before we start in on the analysis, I want to clearly define what the valuation analyst is really trying to do. A valuation analyst needs to fully understand the purpose of this exercise to perform the task correctly. When we get a data set (transaction data), be it from IBA, BizComps, Pratt's Stats, or any other transaction information, we attempt to determine

- if the transactions appear to be usable transactions (qualitative analysis) and
- what multiple, if any, should be applied to the subject company (quantitative analysis).

A valuation analyst can utilize qualitative and quantitative analysis, much the same as was done in applying the guideline public company method to build a meaningful and supportable indication of value for the subject company.

## Qualitative Analysis

*Qualitative analysis* refers to the soft stuff, or the nonnumerical information, known about the transactions. As discussed, we know very little about the transactions as compared to real estate appraisers, who can get all sorts of information about their comparables. However, we have to work with what we've got. For instance, the business descriptions listed in the IBA and BizComps databases may be brief (often one or two words), but they still serve as a good indicator of what a business does. Analyzing business descriptions, particularly in large data sets, can prove to be invaluable to an analyst. An analysis of IBA transactions performed for an Italian restaurant and pizzeria located in a mall is shown in exhibit 10.2. Even though the dates are older, the analysis would continue to be the same, so I did not update this exhibit from the last edition.

### EXHIBIT 10.2 Institute of Business Appraisers' Transactions Analysis

This database was searched for transactions involving companies in SIC code 5812: Retail Trade, Eating Places. Our search located approximately 1,500 transactions in this SIC code that contained all types of restaurants whose revenues ranged from \$13,000 to in excess of \$200,000,000. In order to more appropriately utilize this information, we stratified this data into several more applicable categories.

The first category consisted of small Italian restaurants and pizzerias. This data is presented in table 1.

**EXHIBIT 10.2 Institute of Business Appraisers' Transactions Analysis****TABLE 1 Institute of Business Appraisers Market Data Italian Restaurants/Pizzerias**

Business Type	Annual Gross \$000's	Sales Price \$000's	Price / Gross	Geographic	Year/ Month of Sale
Deli with pizza	89	28	0.31	CA	1986/04
Fast Food, Pizza	227	55	0.24	GA	1993/07
Fast Food, Pizza	230	49	0.21	CA	1994/12
Restaurant, Pizza	306	120	0.39	CA	1990/05
Restaurant, Italian	310	29	0.09	CA	1995/08
Restaurant, Pizza	317	81	0.26	TX	1991/04
Restaurant, Italian	324	75	0.23	FL	1994/05
Restaurant, Italian	390	53	0.14	CA	1995/07
Restaurant, Pizza	477	397	0.83	ID	1995/04
Restaurant, Italian	516	212	0.41	CA	1995/08
Restaurant, Italian	653	89	0.14	CA	1995/02
<b>Mean</b>			<b>0.30</b>		
<b>Median</b>			<b>0.24</b>		

As indicated, there were 11 transactions in this category, indicating an average price-to-revenue multiple of 0.30 and a median of 0.24. The second category consisted of 55 restaurants categorized as fast food restaurants. This information is shown in table 2.

### EXHIBIT 10.2 Institute of Business Appraisers' Transactions Analysis *(continued)*

#### TABLE 2 Institute of Business Appraisers Market Data Fast Food Restaurants *(continued)*

Business Type	Annual Gross \$000's	Sales Price \$000's	Price / Gross	Geographic	Year/ Month of Sale
Fast Food, Dairy Queen	312	117	0.38	NM	1991/07
Fast Food, Dairy Queen	324	40	0.12	Midwest	1994/01
Fast Food, Coffee Shop	346	150	0.43	FL	1995/03
Fast Food, Coffee Shop	346	100	0.29	FL	1995/06
Fast Food, Sandwich Shop	354	205	0.58	IL	1989/
Fast Food, Ice Cream	354	185	0.52	CA	1995/07
Fast Food, Roast Beef	398	93	0.23	CA	1994/11
Fast Food, Fried Chicken	540	248	0.46	TX	1994/08
Fast Food, Coffee Shop	832	200	0.24	FL	1994/11
Fast Food, Hamburgers	832	200	0.24	FL	1994/10
Fast Food, Hamburger	936	665	0.71	NV	1990/07
<b>Mean</b>			<b>0.39</b>		
<b>Median</b>			<b>0.40</b>		

This category indicated an average multiple of 0.39 and a median of 0.40. The final category consisted of restaurants with sales in the range of \$400,000 to \$700,000, regardless of type, because this range more appropriately reflects the revenues of the subject company. There were 168 transactions in this category as shown in table 3.

#### TABLE 3 Institute of Business Appraisers Market Data Revenues of \$400,000 to \$700,000

Business Type	Annual Gross \$000's	Sales Price \$000's	Price / Gross	Geographic	Year/ Month of Sale

### EXHIBIT 10.2 Institute of Business Appraisers' Transactions Analysis *(continued)*

**TABLE 3 Institute of Business Appraisers Market Data Revenues of \$400,000 To \$700,000 *(continued)***

Business Type	Annual Gross \$000's	Sales Price \$000's	Price / Gross	Geographic	Year/ Month of Sale
Restaurant, Full Line	680	325	0.48	NC	1993/
Restaurant	693	205	0.30	WA	1990/
Restaurant, Dinner Only	700	140	0.20	MA	1992/10
Donut Shop	700	400	0.57	East	1990/01
Diner	700	235	0.34	FL	1993/12
<b>Mean</b>			<b>0.36</b>		
<b>Median</b>			<b>0.34</b>		

This category indicates an average price-to-revenue multiple of 0.36 and a median multiple of 0.34. The price-to-revenue multiple was analyzed because this is typically the way that small businesses sell. This is because owners of very small companies tend to adjust expenses in order to minimize taxes; therefore, a willing buyer looks at the revenues he or she will be able to generate, believing that there will be certain costs that will be eliminated when he or she takes over the running of the business.

For each category, a mean and median price-to-revenue multiple was calculated. Statistically, the median is more appropriate than the mean because an average can be skewed by data that are outliers in the sample. The median is the point of central tendency when all the values are arranged by size. Therefore, the median multiple was utilized.

The three median multiples derived result in an average price-to-revenues multiple of 0.33. This is the multiple that will be applied to the appropriate revenue stream.

An analysis of historic and adjusted revenues was performed in the financial analysis section of the report. This analysis indicated that revenues increased over the past few years but declined in the most recent year. Because there appears to be no consistent growth pattern over the last five years, it appears that average adjusted revenues over the period should be used to reflect the future. This amounts to \$703,067. The values derived using the Institute of Business Appraisers (IBA) database include any assets that the buyer will receive, such as equipment, but do not include the assets that the seller will keep, such as cash, accounts receivable, and accounts payable. Therefore, the value of these assets and liabilities must be added or subtracted from the sales value to determine the value of the operating entity.

Therefore, the calculation of value on a control, nonmarketable basis utilizing the data from the IBA database is as follows:

Average revenues	\$703,067
Price-to-revenue multiple	× 0.33
Value	\$232,012
Plus: Inventory	6,250
Less: Current liabilities	(63,460)
Value of operating entity	\$174,802
Rounded	\$175,000

## EXHIBIT 10.2 Institute of Business Appraisers' Transactions Analysis

### Author's Note

The IBA suggests that when a valuation analyst uses its database, he or she uses the most recent year's data and not an average of the past. However, there are times that I believe we need to be a little subjective by applying more of a common-sense type of analysis. Be especially careful in a litigation engagement because it will provide the cross-examining attorney with material for attack.

The analysis shown in exhibit 10.2 illustrates how the valuation analyst can “slice and dice” the transaction data to attempt to get various cross-sections of data that may be considered similar enough to provide guidance about pricing multiples. Other useful analysis can be done considering geography or any of the other descriptive factors found in the different databases. Stratification analysis based on qualitative factors can be an extremely useful tool in understanding how businesses are sold.

If more data is available, then why not use it? As I mentioned before, the Pratt's Stats database has many more data points, many of which can be very useful. Pratt's Stats provides the valuation analyst with a business name and location, which can add a little meat to any analysis. Knowing this information allows the valuation analyst to perform additional research about the company and the transaction itself. You can use search engines, such as Google, to find out much more information about a particular target company or transaction. Don't be afraid to do the necessary research to truly determine if you are using good data. If you don't, the expert on the other side of a litigation engagement probably will. The end result is that you will be embarrassed.

## Quantitative Analysis

Once the valuation analyst has performed a qualitative analysis of a transaction set and is comfortable (ha ha!) with the remaining transactions, then it is time to figure out how to use the selected transactions to indicate values. There are important questions to answer, including the following:

- Are multiples calculated from a transaction set meaningful?
- Which multiple(s) should be used to indicate value?
- What multiple should be applied to the subject company?

These three questions should come to mind when looking at any set of pricing multiples, but the final, and often confusing, question is how to go about answering them. As indicated previously, all the databases offer some type of statistical toolbox to analyze transactions. The reason for this is because statistics are one of the few means that we have to glean information from a transaction data set. In chapter 7, I touched on the topic of statistics. I'm going to try again. Personally, the word *statistics* alone is enough to put me to sleep. Numbers and graphs and natural logarithms—it can be overwhelming. Like it or not, statistics provide an analytical toolbox that does what we need to do, which, as indicated in the transaction data described previously, is to pull significant information out of a data set. It is easy enough to take an average of multiples and not think about it anymore, but that can get you into a lot of trouble.

Years ago, many of us did just that. If we really got crazy, we would use a median instead. However, to properly apply these ideas and techniques, the valuation analyst must be somewhat comfortable with the theory. A course in statistics is beyond the scope of this book, but I am going to try to provide you with some additional stuff that you need to know. Think of some of this as a refresher and other parts that may have been forgotten from chapter 7 as new material.

According to *Webster's New World Dictionary*, *statistics* is defined as follows:

**Statistics.** Facts or data of a numerical kind, assembled, classified and tabulated so as to present significant information about a given subject.<sup>9</sup>

The mean and the median reflect measures of central tendency. These are proxies for the most probable observation in a data set. If the valuation analyst has a set of multiples and he or she wants to figure out what multiple to use, means and medians approximate the most likely one. Whether he or she uses a mean or median is based on professional judgment. Some prefer one over the other. Means can be skewed dramatically by outliers, whereas medians have less reliability as the size of a data set decreases. Like everything else, the one to use is based on the facts and circumstances of the assignment.

Using statistics to assist in the selection process for the various multiples can make the valuation analyst's conclusion stronger. Regardless of statistics, let's try to keep in mind that businesses often sell based on operating performance (profitability). Revenues, assets, and book value, although used to calculate multiples, do not reflect a level of operating performance. To compensate for this, we plot price to revenues and asset and equity multiples with their corresponding returns (return on revenues, among others). Several of these charts are shown in figure 10.14.

In my experience, these charts tend to be more meaningful for larger companies. Small companies are often bought based on sales, regardless of profitability. People buy jobs. Some of us also believe in the bigger fool theory. Some bigger fool will come along and overpay for a business, thinking that he or she will do a better job of running the business than the seller. Sometimes, the bigger fool can even be a large company. Think about Wall Street! Many of these public companies are the bigger fools.

We have built charts such as those found in figure 10.14 into our statistical analysis templates, so they come up automatically. Once the valuation analyst has constructed such spreadsheets, it does not take any additional time to perform these statistical exercises because the calculations are done automatically as new data is added. The charts give us an idea of which multiples are similar, but how do you choose a single multiple to apply to an earnings stream? One intuitive comment is, "If you have a regression through a good data set with high correlation, then use the equation of the line to estimate price." This seems very logical, and sometimes it may be the best way, but think about what you are doing. A chart reflects how price varies with one variable. Thinking back to the SGLPTL analysis in chapter 9, there are many factors that affect the value of a business. For example, let's suppose that there is a high correlation between price and revenues in the selected data set. Now, consider that the subject company has very high debt and is having problems meeting its obligations. Can the valuation analyst simply apply a revenue multiple to it? He or she must consider other pertinent factors, including the SGLPTL factors when performing a merger and acquisition method. In the case of IBA or BizComps, the valuation analyst will not get enough information to do much analysis, but he or she does have price-to-revenues information. BizComps has a little more information, but when the analyst gets to Pratt's Stats, there is a lot of financial information. There is no reason not to perform SGLPTL analysis for data derived from the larger databases.

<sup>9</sup> *Webster's New World Dictionary of the American Language*, college ed. (New York: World Publishing Company, 1968), 1425.

**Figure 10.14 Price to Revenues to Return on Sales**

In addition to the charts, we calculate means, medians, standard deviations, and percentiles from the price-to-multiple data sets. All of these terms were defined in chapter 7. Most of the readers of this book should already have some familiarity with these terms. If not, it is important to become familiar with them. This gives us a basis from which to estimate an applicable multiple. We base our analysis on all information available for the subject company, as well as what is available for the transactions. Weighing the strengths and weaknesses of each transaction and the guideline transactions can prove to be an invaluable tool for developing a meaningful and supportable analysis. An analysis of Pratt's Stats transactions for an insurance agency is presented in exhibit 10.3.

### EXHIBIT 10.3 Pratt's Stats

The Pratt's Stats database yielded 55 transactions. Of these transactions, 19 involved acquisitions of companies outside of the state of Florida and another 19 companies with revenues less than \$230,000. After eliminating these companies, 17 transactions remained. All 17 of these transactions were asset sales.

Because Pratt's Stats provides invested capital multiples, we looked at those. We focused on the MVIC-to-revenues multiple because it was determined that the subject company's historic earnings streams and profit margins are not reflective of probable future earnings.

A summary of the 17 transactions from the Pratt's Stats database is presented in table 22.

(continued)

### EXHIBIT 10.3 Pratt's Stats (continued)

#### TABLE 22 Pratt's Stats Data

Business Description	Sale State	Net Sales	Sale Date	MVIC Price	Discretionary Earnings	Discretionary Earnings Margin	MVIC to Sales
Auto Insurance Agency	FL	\$ 248,618	10/15/2010	\$ 225,000	\$ 54,503	21.9%	0.91
Insurance Agency (homeowner property and casualty)	FL	250,000	5/2/2011	420,000	132,871	53.1%	1.68
General Insurance Agent (homeowner and auto policies)	FL	250,000	4/29/2010	475,000	170,488	68.2%	1.90
Insurance Agency	FL	270,003	4/1/2010	250,000	160,999	59.6%	0.93
General Insurance	FL	287,430	7/31/2009	500,000	39,807	13.8%	1.74
Insurance Agency	FL	311,968	10/7/2009	400,000	188,160	60.3%	1.28
Auto and Homeowner's Insurance Agency	FL	367,781	9/1/2010	699,000	176,740	48.1%	1.90
Insurance Agency	FL	380,070	2/5/2009	590,000	188,051	49.5%	1.55
Health Insurance Agency	FL	476,035	11/19/2010	250,000	135,037	28.4%	0.53
Insurance Agency (property and casualty)	FL	495,617	11/12/2010	850,000	204,183	41.2%	1.72
Insurance Agency	FL	587,037	12/22/2010	735,000	253,204	43.1%	1.25
General Insurance	FL	670,347	9/25/2008	265,000	143,185	21.4%	0.40
Insurance Agency – Allstate® franchise	FL	730,976	1/21/2011	100,000	80,103	11.0%	0.14
Auto Insurance Agency	FL	818,216	10/8/2010	240,000	127,906	15.6%	0.29
Property and Casualty Insurance Agency	FL	880,337	3/17/2010	1,500,000	413,235	46.9%	1.70
Insurance Agency (personal property and casualty)	FL	1,533,110	12/31/2010	3,870,000	852,294	55.6%	2.52
Automotive Insurance	FL	3,296,441	10/15/2008	850,000	300,276	9.1%	0.26

**EXHIBIT 10.3 Pratt's Stats**

Net sales for the 17 companies located in the Pratt's Stats database ranged from \$248,618 to \$3,296,441. The discretionary earnings profit margins of these companies ranged from 9.1 percent to 68.2 percent. In comparison to the 17 companies, the subject company is larger than all but one in terms of revenues and its discretionary earnings margin of 15.3 percent<sup>1</sup> is higher than only four of the companies.

A statistical summary of the 17 MVIC-to-revenues transactions is presented in table 23.

<b>TABLE 23 Pratt's Stats—Statistical Analysis</b>	
	<b>MVIC to Revenues</b>
Statistical Analysis:	
Count	17
Mean	1.22
Standard Deviation	0.71
Coefficient of Variation	0.58
90th Percentile	1.90
75th Percentile	1.72
60th Percentile	1.65
Median	1.28
40th Percentile	0.99
25th Percentile	0.53
10th Percentile	0.28

The average and median MVIC-to-revenues multiple for the 17 transactions were 1.22 and 1.28, respectively. The subject company is less profitable than most of the acquired companies but is larger than all but one of the companies in terms of revenues. Based on these factors, the 40th percentile multiple of 0.99 was selected, which falls just below the median. Therefore, the indication of value using the Pratt's Stats transactions appears in table 24.

<sup>1</sup> Discretionary earnings was calculated as follows:

EBITDA	\$216,105
1/3 of Reasonable Comp.	127,053
Shareholder Health Insurance	<u>14,555</u>
	<u>\$357,713</u>

(continued)

**EXHIBIT 10.3 Pratt's Stats** *(continued)***TABLE 24 Pratt's Stats Indication of Value MVIC to Revenues**

Selected Multiple	0.99
Subject Company Earnings Stream	× 2,333,855
Indication of Value	<b>\$ 2,310,516</b>
Calculation of Retained Assets	
Cash	\$ 34,492
Accounts Receivable	64,840
Total Liabilities	(271,063)
Plus Net Retained Assets	\$ (171,731)
Market Value of Operating Invested Capital	\$ 2,138,735
Less: Interest-Bearing Debt	79,326
Indication of Operating Value Before Working Capital Adjustment	\$ 2,059,459
Working Capital Adjustment*	(177,585)
<b>Indication of Operating Value</b>	<b>\$ 1,881,874</b>

\* See section of report entitled "Working Capital Deficiency."

## Let's Get Back to Valuation Theory

As with any valuation methodology, the merger and acquisition method has both advantages and disadvantages. Let's discuss them in case they aren't readily apparent.

### Advantages of Using the Merger and Acquisition Method

Merger and acquisition methods are those that value a company based on transactions involving a large portion of the company or its entirety. The most readily determinable advantage of using this methodology is that the valuation analyst is able to estimate the value of the valuation subject based on the prices of entire companies that changed hands. Because most closely held transactions involve entire companies, this method is a logical application of the market approach.

The merger and acquisition transactions used in this method are considered to be an objective source of information because they come from the market. Market transactions are assumed to be between informed buyers and sellers; therefore, a good representation of fair market value occurs if there are enough transactions to be statistically meaningful. The problem becomes how to determine the number of transactions required for them to be statistically valid. Now that you are an expert on statistics, who said it would be easy?

## Disadvantages of Using the Merger and Acquisition Method

Although the merger and acquisition method is logical and inherently makes sense, it is difficult to find similar companies that have been acquired. It would be great if we had access to the same type of data that the real estate appraisers have, but unfortunately, we do not. Although public company information is sometimes available, there are generally not enough of these transactions to adequately help the valuation analyst. For a meaningful analysis to be performed, there should be enough transactions to enable the valuation analyst to reach a conclusion. (If you just asked yourself, “how many is enough?” you are getting the hang of this stuff!)

An experienced valuation analyst recognizes that valuation analysts do not work in a perfect world and, frequently, are forced to use less-than-perfect information. Although a greater amount of detail is generally available about public companies that are acquired, frequently, there are times when a valuation analyst turns to closely held data. Private company transactions are difficult to locate, particularly because the owners of these businesses do not feel that they are anyone’s business, and if a transaction is located, the details of the transaction are rarely available. For the deal to be consummated, the terms of the deal are frequently an important part of small company transactions. Hearing about 2 businesses that sold for \$200,000 could lead you to believe that they were of similar value if you did not know the terms of the transaction. If one sold for all cash and the other sold for \$20,000 down, with the balance due over 10 years, with no interest, the value of these 2 transactions would be very different. This is because of the time value of money.

Another problem with this method is that once the transaction is located, it is generally difficult to find out anything other than the financial terms of the transaction. Of considerable importance would be whether the transaction was an asset or a stock sale. Acquisitions frequently involve specific buyers who pay a premium for special or unique considerations, such as the synergies between the two companies. This also makes it difficult to know if the price paid for the business truly represents the value of the business.

Another disadvantage of this method is that because the values derived under these methods result in a control value, it is difficult to translate the estimated value into a minority interest value. If the valuation subject is a minority interest in a closely held business, the results of the merger and acquisition method will have to be discounted for the minority interest. The problems with these discounts will be discussed later.

### Author's Note

Before we conclude our discussion of the merger and acquisition method, I need to provide a few words of caution. First and foremost, know as much about the provided information as possible. If the valuation analyst is working in a litigation environment, he or she can expect that the other side will do their homework. The valuation analyst must know how each data point is defined so that he or she can properly apply multiples to the subject company.

Second, the valuation analyst should not mix and match data from different databases. Even though the analyst may know how information is defined, it may not be input under the same assumptions or using the same conventions. Combining the information from the different databases is not a good idea.

Third, beware of duplicates. Duplicate transactions appear in some of these databases. If it looks like a flower and smells like a flower, it's probably a flower. Duplicates will mess up any statistical analysis.

Finally, combine suggestions 2 and 3. If you bite the bullet and decide to combine databases, be very, very careful of duplicates. The databases get their data from business brokers, who may submit the same data to more than one database. It's not uncommon to find very similar deals in the previously referenced databases, so carefully review the transaction data.

One final point worth noting is the fact that some of the “errors” in the databases have already been corrected, and others are being corrected on a regular basis. This means that the valuation analyst really must understand the data that is being used and not just populate a field in a computer program and assume that it is correct. As I was writing this chapter for the last edition, I had just finished reviewing another valuation analyst’s report; he used a computer software program and its report writer that so totally destroyed the market

approach using BizComps data that I wanted to tar and feather him. But somehow, I felt that tarring and feathering was too light a punishment for the job that was done. Instead, I got to see him in court! It was ugly.

## Internal Transactions

Another variation of the market approach comes from Revenue Ruling 59-60. This ruling suggests that the valuation analyst consider any sales of the company's own stock. These internal transactions may provide the valuation analyst with information for use in the market approach. If internal transactions are located, the next step will be to determine whether these transactions were consummated at arm's length. Arm's length means that the transaction should not be longer than your arm. Actually, it is important to make sure that the transaction is a properly negotiated transaction between parties who have their own best interest in mind. The closer the relationship between the parties, the closer you need to look at that relationship to see if it was truly a negotiation as if between strangers.

Internal transactions are very useful if the valuation analyst has many transactions, rather than just a few. Professional practices, which sometimes have partners coming and going on a regular basis, may be a good example of when to use this data. In these instances, partnership agreements often are used as a road map showing how partners come and go. This concept is discussed further and illustrated in chapter 23.

## Industry Method

Sometimes called "rules of thumb," the industry method can prove to be a valuable tool but should never be relied on by itself in a valuation assignment. Industry methods are an important part of the valuation process. If an industry uses a particular method to determine the value of a business, the valuation analyst should pay close attention to that method. If enough transactions take place using a particular method, then there is market data that will support the use of that method. However, if these formulas are the only methods used, an inappropriate valuation may result.

Sources of rules of thumb include published compilations, industry sources, business brokers, trade associations, and industry members. The advantage of the industry method is that it generally provides a sanity check on other valuation methods. The disadvantages of the industry method are as follows:

- Different sources may provide different rules of thumb for the same industry.
- The application of an uninformed rule of thumb may result in an incorrect estimate of value.
- Although they are simplistic in their applications, rules of thumb may ignore the economic reality of the situation.
- Information (profit margins and capital structure, among others) about the companies that made up the rule of thumb transactions is not known.

Rules of thumb are sometimes used in the application of the market approach, but the valuation analyst must exercise care. Rules of thumb should not be used alone because valuation analysts frequently lack the information required to adjust the rule of thumb for particular questions, such as the following:

- Was the transaction based on an asset or equity purchase?
- Did the buyer pay cash, or were there terms that would affect the purchase price?
- Was there a continuation of employment by the seller or a covenant not to compete?
- Was the business profitable?

Clearly, if used incorrectly, a rule of thumb can be dangerous. However, it serves a useful purpose in some smaller appraisals when all else fails. Just be careful! In exhibit 10.4, the potential uses and dangers of rules of thumbs are discussed. This exhibit is based on excerpts from actual reports.

## EXHIBIT 10.4 Rules of Thumb

A very popular but often abused method of valuation for professional practices is the multiple-of-revenue method.

This method is also referred to as the “industry rule of thumb” method. There are many disadvantages to this method, but the major disadvantage is the number of different multiples that are used for the same type of practice. A classic example of the danger in applying this method is the rule of thumb for an accounting practice. Over the years, accounting practices are said to have been sold for an amount that ranges between 50 percent and 150 percent of gross billings. This means that an accounting practice with gross billings of \$1 million could be valued anywhere from \$500,000 to \$1.5 million. This is clearly too wide a spread to be meaningful. Disparities such as this take place all of the time and must be considered before applying unsupported rules of thumb.

The major advantage of this method is that it is easily understood by all parties: buyer, seller, financier, and valuation analyst. According to Ronald Klein, CPA, “a particular multiplier may, in fact, be self-serving, used because it is so widely quoted.” In New Jersey, the multiplier of three became popular because of its application in *Dugan v. Dugan*. Since 1983, this multiplier has been used over and over again, regardless of the facts and circumstances of the current appraisal subject.

Some valuation analysts have extended the use of Dugan and have applied the Dugan multiplier to different types of professional practices. Mr. Dugan was an attorney. Even an appraisal of another law practice may not result in an appropriate multiple of three. Qualitative factors (such as the type of practice, the type of clients, and profitability) must be considered in the development of an appropriate multiplier.

Looking for rules of thumb for our valuation subject (a dental practice), we found several methods. In *Valuing Professional Practices*, published by CCH International, James L. Horvath, CA, CBV, ASA, suggests two different methods: (1) fair market value of furniture, fixtures, and equipment plus 20–60 percent of annual revenues; and (2) net asset value plus one year’s pretax earnings before owner’s compensation. Using method 1 results in a range of values from \$307,655 to \$802,615, whereas method 2 yields a value of \$730,489.

The *Business Reference Guide*<sup>1</sup> lists four different methods. These methods, with their calculated range of values, are as follows:

- 1 to 1.5 times annual adjusted earnings plus fixtures, equipment, and inventory: \$212,073 to \$286,272
- Net assets plus 25 to 30 percent of gross annual revenues: \$567,935 to \$629,805
- 20–60 percent of annual fee revenues plus fixtures, equipment, and inventory: \$311,155 to \$806,115
- One year’s pretax earnings before owners’ salary, plus fixtures, equipment, and inventory: \$535,579

In *Handbook of Small Business Valuation Formulas and Rules of Thumb*,<sup>2</sup> Glenn M. Desmond, ASA, MAI, suggests two additional methods: (1) monthly revenues times 8 to 12, plus net asset value, less fixed assets, which yields values of \$1,023,343 to \$1,435,810; and (2) monthly revenues times 2.5 to 5, plus net asset value, yielding a range of \$516,377 to \$774,168.

Finally, in *Valuing Small Businesses and Professional Practices*,<sup>3</sup> Shannon P. Pratt mentions two additional methods: (1) equipment and fixtures plus 25 to 35 percent of revenue, resulting in a range of \$369,525 to \$493,263; or (2) equipment and fixtures plus 50 to 100 percent of earnings available to the doctor, yielding values of \$291,270 to \$532,079.

Although some of the methods discussed previously are similar, there are 10 different methods that yield values for the practice ranging from \$212,000 to \$1.4 million.

## Conclusion

By now, either you should be very excited and ready to forge ahead, or your anxiety attack has gotten worse. The market approach chapters contained a lot of stuff. We discussed methodologies, the selection of multiples, the assessment of risk, and the advantages and disadvantages of these methods. We even discussed statistics. Wow, if my mother could see me now! I hope it has become more apparent that the market approach can be applied to all sized companies. Sometimes, it may be difficult to apply, but that is not an excuse not to use it.

# Chapter 11

## The Asset-Based Approach

### Learning Objectives

In this chapter, I will attempt to explain the following:

- When to use the asset-based approach
- The advantages and disadvantages of the asset-based approach
- The adjusted book value method
- How to communicate with other appraisers
- Economic obsolescence
- How to find other appraisers
- The liquidation value method
- The cost to create method

### Introduction

The asset-based approach is also commonly known as the *cost approach* or the *replacement cost approach*. Sometimes, you may even see this approach called the *asset accumulation approach*. In this approach, each component of the balance sheet is valued separately, including liabilities. The asset values are totaled, and the total of the liabilities is subtracted to derive the value of the enterprise.

The valuation analyst estimates value by adjusting the asset values of the individual assets and liabilities of the business to fair market value. Some valuation analysts will use this approach for the tangible assets only and consider it to be complete. In fact, I used to do this. However, as we get older, we get wiser; or maybe I should say that if we make enough mistakes, we eventually get it right. This approach, like the market and income approaches, is intended to value the entire company. This means that the tangible assets, as well as the intangible assets, should be valued and the liabilities subtracted. You may have to use other approaches to value the intangible assets, but I will discuss that later. If the valuation analyst only uses this approach to value a company, he or she could overstate the value of the business as a going concern because if there are insufficient earnings to support the asset base, he or she will end up with a higher value under this approach than the other approaches. This could be due to a concept known as *economic obsolescence*, which I will discuss in considerable detail later in this chapter.

I used to think that valuing the tangible assets and liabilities would result in a “floor” value for an enterprise being valued as a going concern. I hate to admit it, but I was wrong. The purpose and function of the assignment (remember that from the beginning of this book?) has a lot to do with whether it can truly be a floor value.

### Common Applications of the Asset-Based Approach

The asset-based approach is most commonly applied to the following types of business valuations:

- Not-for-profit organizations
- Holding companies
- Manufacturing companies
- Asset-intensive companies
- Controlling interests that have the ability to liquidate assets

In all of these instances, the valuation subject will have most, if not all, of its value in its tangible assets or identifiable intangible assets, such as copyrights, patents, or trademarks. Intangible assets, such as goodwill, will not play an important role in the value of this type of enterprise. If goodwill or another type of intangible value exists, it will be added to the value of the other assets.

This approach is generally not used for the following types of business valuation assignments:

- Service businesses
- Asset-light businesses
- Operating companies with intangible value
- Minority interests, which have no control over the sale of the assets

Service businesses and asset-light businesses generally get the bulk of their value from intangible assets. Therefore, it seems logical that the asset-based approach would not be an effective means of valuing these types of entities. Operating companies are generally valued based on the ability of the company to generate earnings and cash flow; therefore, they rely on a market or income approach for the determination of their value. If you recall, Revenue Ruling 59-60 states the following in Section 5:

**Weight to Be Accorded Various Factors.** The valuation of closely held corporate stock entails the consideration of all relevant factors as stated in section 4. Depending upon the circumstances in each case, certain factors may carry more weight than others because of the nature of the company's business. To illustrate:

- (a) Earnings may be the most important criterion of value in some cases whereas asset value will receive primary consideration in others. In general, the appraiser will accord primary consideration to earnings when valuing stocks of companies that sell products or services to the public; conversely, in the investment or holding type of company, the appraiser may accord the greatest weight to the assets underlying the security to be valued.
- (b) The value of the stock of a closely held investment or real estate holding company, whether or not family owned, is closely related to the value of the assets underlying the stock. For companies of this type, the appraiser should determine the fair market values of the assets of the company. Operating expenses of such a company and the cost of liquidating it, if any, merit consideration when appraising the relative values of the stock and the underlying assets. The market values of the underlying assets give due weight to potential earnings and dividends of the particular items of property underlying the stock, capitalized at rates deemed proper by the investing public at the date of appraisal.

A current appraisal by the investing public should be superior to the retrospective opinion of an individual. For these reasons, adjusted net worth should be accorded greater weight in valuing the stock of a closely held investment or real estate holding company, whether or not family owned, than any of the other customary yardsticks of appraisal, such as earnings and dividend paying capacity.

Minority interests will usually not be valued using an asset-based approach because the minority shareholder does not have the ability to liquidate the assets. However, do not take this as a hard and fast rule. In chapter 21, I discuss valuing minority interests in family limited partnerships, which are frequently valued using an asset-based approach. If you have not yet figured it out, business valuation is full of contradictions. All of this stuff will be explained further later in this chapter in my discussion about adjusting the balance sheet. Meanwhile, as a general rule, if the ownership interest cannot get to the cash flow that will be generated by selling off the assets, this approach will not get to the value of the cash flow to the minority owner. After all, value is based on the future benefits stream that will flow to the investor.

## Advantages and Disadvantages of the Asset-Based Approach

The asset-based approach has both advantages and disadvantages. Included in box 11.1 are some of the advantages and disadvantages to consider when using an asset-based approach.

The asset values derived using this approach allow a valuation analyst to test the reasonableness of the concept of highest and best use when he or she compares the results with other methodologies in the income or market approach. If these other approaches yield a value considerably less than the value of the entity's assets, liquidation may be a viable alternative if the interest being valued has the ability to effect a liquidation.

**BOX 11.1****Advantages and Disadvantages of the Asset-Based Approach****Advantages**

- Net tangible assets can be valued more reliably under this approach than under the other two approaches.
- This approach creates a better reflection of the economic balance sheet of the valuation subject.
- Net tangible assets can generally be seen and felt, giving the user of the valuation a “warmer” feeling about the value.

**Disadvantages**

- The asset-based approach provides the valuation analyst with the cost of duplicating the business being valued.
- This approach is frequently more time consuming (and sometimes more costly) to apply than the other approaches.

## Valuation Methods

Included in the asset-based approach are the following valuation methods: (1) the adjusted book value method, (2) the liquidation value method<sup>1</sup>, and (3) the cost to create method.

### Adjusted Book Value Method

The adjusted book value method finds its theoretical basis in the principle of substitution, which was discussed in chapter 4. In the adjusted book value method, all the assets and liabilities (including all intangible assets) are adjusted to reflect their fair market values. The fair market value of the subject company's equity will be the fair market values of the assets less the fair market values of the liabilities. It is important to recognize that certain assets and liabilities may not be reflected on the books of the subject company, but these items need to be included in the valuation of the equity of the company. For example, goodwill that is internally generated, as opposed to purchased, would not be on the balance sheet under “generally accepted accounting principles.” However, this is an asset of the company that needs to be valued. The same could apply to a contractual right.

The adjusted book value method is primarily used in the valuation of asset-intensive businesses when valuing a controlling interest. Just as a reminder, a control valuation is one in which the owner of the interest being valued has the ability to throw his or her weight around. This is to be distinguished from a minority interest valuation or an interest that lacks control.

The mechanics of the adjusted book value method are to convert the book values of the assets and liabilities shown or not shown on the valuation subject's balance sheet to a market-oriented basis. This will generally involve adjusting the valuation subject's balance sheet to fair market value. Certain values are easily ascertained by the business valuation analyst, but others are not. There will be times when the business valuation analyst will look to other appraisers (such as real estate or machinery and equipment) to provide the values of certain assets. As a reminder, when the valuation analyst relies on the work of others, he or she needs to pay attention to the standards regarding his or her responsibilities.

<sup>1</sup> Liquidation is actually a premise of value as opposed to a valuation method. Later in this chapter, I am going to discuss the machinery and equipment concepts of fair market value in continued use (going concern) and fair market value in liquidation. Similar concepts can be applied here as well.

## Adjusting the Balance Sheet

The adjustments made to the balance sheet will depend on the purpose and function of the valuation assignment. If the assignment is to value the equity of the company, every asset and liability should be reviewed for possible adjustment to fair market value. If specific assets, liabilities, or both, are the subject of the valuation, only those assets or liabilities should be valued.

Balance sheet adjustments should generally be made only if the interest being valued has the ability to liquidate the assets and liabilities of the company. If a minority interest does not have the ability to sell off the assets to realize the fair market values of these assets, it makes little sense to revalue them when the standard of value is fair market value. Sometimes, valuation analysts will adjust the values to fair market value and then apply a discount for lack of control. I find this to be a time-consuming and costly exercise. However, if fair value is the definition of value being used, the minority owner is sometimes put in a position to receive the benefit of the appreciated net assets of the company.

In the *U.S. News & World Report* case,<sup>2</sup> this point was a much-disputed part of the litigation. Retiring employee shareholders were being bought out based on an annual valuation performed by one of the large valuation firms.

The stock was valued on a minority, nonmarketable basis (as if closely held). The company had amassed a large portfolio of highly appreciated real estate that was not valued at fair market value because the assignment called for a minority valuation. A short while after a buyout of some employee shareholders, the company was sold for a considerably larger amount than the amount that appeared in the valuation. Disgruntled former employees sued the valuation firm and the company, claiming that their shares had been undervalued at the time that they were bought out. The court found otherwise. In the opinion, Judge Barrington D. Parker stated the following:

In a minority valuation...assets may or may not play an important part in arriving at a per share figure, because a minority shareholder cannot reach those assets....Generally speaking, if the valuation being undertaken is of a business, such as *U.S. News*, that produces goods or services, primary consideration will be given to the earnings of the company and the resultant return on a shareholder's investment.

This was a good opinion and can be used as instruction for all valuation analysts. Get a copy of this case! It is worth having in your library.

Generally, the balance sheet should be adjusted as follows:

- *Cash and equivalents.* Cash and equivalents usually require no adjustment. On occasion, excess cash may be considered non-operating and should be segregated from what is used for working capital. This is done for analysis purposes only because it will not affect the value when using an asset-based approach. However, segregating excess cash will be useful to the valuation analyst when applying the income and market approaches because the excess would be added to the value of the operating enterprise.
- *Marketable securities.* Marketable securities should be adjusted to their fair market value. Usually, an average of the high and low prices on the valuation date will be used to accomplish this. There are times, however, when the closing price of the securities may be used instead.
- *Accounts receivable.* Accounts receivable should be reviewed to see what portion of the receivables is collectible. There are many companies that carry accounts receivable without writing off the uncollectible amounts hoping that they will be collected (eventually). Older receivables may require a present value adjustment because of the time value of money. A comparison of the ratio of receivables to revenues with industry composite data should be made to determine if there are any significant differences. In certain valuation assignments, such as medical practices, in which the entity reports its

<sup>2</sup> *Charles S. Foltz et al. v. U.S. News & World Report, Inc., et al., and David B. Richardson et al. v. U.S. News & World Report, Inc., et al.*, U.S. District Court, District of Columbia, Civil Actions Nos. 84-0447 and 85-2195 (June 22, 1987).

results using the cash method of accounting, it may make sense to treat the accounts receivable as a non-operating (or really an excess) asset. Medical practices that report their financial statements on an accrual basis must be analyzed to determine whether the amount being carried on the books is the amount billed, the amount allowable for reimbursement, or some other variation of these. I will discuss this in greater detail in chapter 23. Professional practices, such as law firms and accounting firms, frequently have an additional subset of accounts receivable, namely, work in progress. Work in progress in these types of professional practices represents unbilled work as of a particular date. If an accounting firm bills its clients at the end of each month, there will be billable hours that the staff worked throughout the month that would be considered to be work in progress.

- **Inventory.** Inventory should be adjusted to reflect fair market value, which is generally the current cost to replace salable inventory. However, inventory valuations for income tax purposes must consider Revenue Procedure 77-12. A valuation analyst may want to consider the following procedures with respect to inventory:
  - Determine the method used to value the inventory carried on the books of the valuation subject (first in, first out [FIFO] or last in, first out [LIFO], among others).
  - Determine if the inventory can be sold, and if it cannot, adjust the book value accordingly.
  - If the company uses the LIFO method, adjust the value to reflect the current cost to replace the inventory. Although LIFO provides better matching on the income statement, FIFO provides a better balance sheet valuation.
  - If the company does not maintain proper inventory records, consider if there are any necessary adjustments to management's estimate to compensate for possible errors in the valuation of the inventory. If the effective date of the valuation is relatively recent, suggest a physical inventory. A physical inventory that was taken long ago may prove to be meaningless (but, what's "long ago"?). Exhibit 11.1 illustrates a portion of a rebuttal report addressing the other side's adjustment to inventory and some of the types of issues that come up in these assignments. The valuation date was in 2010.

### EXHIBIT 11.1 Inventory Adjustment Rebuttal

On page 25, the valuation analyst begins discussing his application of the adjusted book value method. The valuation analyst begins by discussing its adjustment to "Material Inventory." The report reads as follows:

- 1.) **Material Inventory:** Our initial inquiries found that the stated inventories for ABC Company as reported on its financial statements may have been understated. ABC Company's inventory was reported as \$263,791 in 2000. However, a large company paid ABC Company \$2.7 million to move its inventory and other assets to its new location in 2000 when the large company purchased the property from which ABC Company was then operating. Management confirmed that over 1,400 truckloads of material were moved from the original yard to the new yard. It is unlikely that such activities were undertaken to move only roughly \$260,000 of inventory. In addition, there was an inventory count taken in 2001, and again in 2010, which showed very significant discrepancies in the ABC Company inventory. We requested Counsel seek a more complete survey of ABC Company inventories.

This section should be read again and again to see how adversarial it is. First of all, ABC Company was not paid \$2.7 million to move its inventory. It was paid this amount to move the entire business from its old location to a new location. The payment was also to compensate the company for the period of time that it would be "out of business" due to the move. The payment was for approximately 1,300 truckloads (dump truck, tractor trailer loads, and so on) that were used to move all of the company's fixed assets from the original location, the entire office, garage, equipment, and inventory. There is absolutely no way to determine how much of the move was for inventory. Furthermore, construction of a new office building also took place from these proceeds, and each of the owners had to recognize \$750,000 apiece as taxable income according to John Smith, CPA, in his testimony of May 16, 2014. Therefore, the entire underlying premise is false and cannot be trusted.

Besides, the valuation analyst is referring to inventory values as of the year 2000, 10 years prior to the valuation date. Other than his client telling him to include this, how is it relevant for a 2010 valuation? We recognize that there are frequently discrepancies on the books of small companies between what is considered to be useable inventory and recorded inventory on the books, but this statement is nothing more than unsupported conjecture.

(continued)

### EXHIBIT 11.1 Inventory Adjustment Rebuttal *(continued)*

The valuation analyst then proceeds to mention an inventory count that took place in 2001 (which is nine years prior to the valuation date) and another in 2010. The valuation analyst obtained these “inventory counts” from the documents that were produced during the discovery phase of this litigation. First, it should be noted that the inventory count, according to these documents, was as of 2011 not 2010 as the valuation analyst indicates in the report. Therefore, once again, the valuation analyst is relying on data that was not *known or knowable* as of the valuation date.

The valuation analyst continues on the topic of its “material inventory” adjustment by stating the following:

The requested appraisal of inventories stored at the current site confirmed our expectation that the inventories owned and stored by ABC Company had a value far in excess of amounts reported on the financial statements for ABC Company. We note that generally accepted accounting principles do not require assets such as inventory to be stated at full market value. However, the difference in this case between market value and the value reported on financial statements is extremely significant. The independent inventory appraiser presented a range of inventory value of \$6,886,390 (minimum) to \$9,582,303 (maximum) as of the valuation date. For purposes of this analysis, we used the average of the minimum/maximum ranges, that is, \$8,234,347.

The inventory valuation report that the valuation analyst is relying on is problematic and cannot be relied upon for the purpose of this valuation. The problem with this valuation report is that the inventory appraiser performed his inspection over six days during April and May 2013, three years after the valuation date. Using this inventory count as of 2013, the appraiser then adjusts the prices using 2010 pricing data to estimate the value of these items as of the valuation date. This assumes that the exact same inventory is maintained by ABC Company at all times, which is absolutely false. Furthermore, it is our understanding that several of the pictures that were included in the inventory appraisal were either stock photos or photos from a property not belonging to ABC Company because of the manner in which the inventory was organized and bound. That raises another question entirely that is beyond the scope of this critique.

The valuation analyst uses the 2013 inventory count that was adjusted using 2010 pricing data and simply averages the minimum and maximum values that were determined by the inventory appraiser. He ignores the fact that over this time period, ABC Company purchased additional inventory required to support its business, and as a result, inventory grew on its balance sheet as well. A summary of the company’s purchases<sup>1</sup> and end-of-year inventory balances<sup>2</sup> reflect the changes and are presented as follows:

	2009	2010	2011	2012
Materials Purchases	\$2,544,660	\$5,327,973	\$1,097,096	\$1,763,108
% Change		109.4%	-79.4%	60.7%
Inventory Balance	\$ 362,837	\$ 637,786	\$1,075,231	\$1,502,048
% Change		75.8%	68.6%	39.7%

From 2009–2012, ABC Company’s materials purchases totaled \$10,732,837, and the company’s ending inventory balance more than quadrupled from \$362,837 to \$1,502,048. This further demonstrates why an inventory count as of 2013 cannot be relied on for a 2010 valuation. This, by itself, explains the fact that the inventory was growing and that a post-valuation date inventory could easily be in error unless proper cut-off procedures were applied, which they were not, in this situation.

The appropriate procedure that should have been followed would have been to take the physical inventory, and then trace all purchases and uses of that inventory, in order to backtrack to the valuation date. However, with that being said, with the amount of time that passed from the valuation date to the physical inventory, this would have been a monumental assignment. But, what the valuation analyst relied on does not work as a surrogate for doing it the correct way. This causes the entire calculation under the adjusted book value method to be incorrect and should be completely disregarded.

<sup>1</sup> Purchases are reflected at cost.

<sup>2</sup> Inventory is reflected at lower of cost or market and is not expected to be at fair value.

- *Prepaid expenses.* Prepaid expenses should be reviewed to determine whether the balance included on the balance sheet reflects fair market value. Prepaid insurance may be subject to short ratings by the insurance company and, as such, may be worth less than its face value. Many cash-basis professional practices write off insurance when it is paid, although it may have value on the balance sheet as a prepaid asset. This is particularly true with medical practices, for which the malpractice insurance premiums can be substantial. These days, it seems like we all have malpractice premiums that are substantial. I do not remember the last time one of my valuations killed someone!
- *Land.* Land should be appraised at fair market value and adjusted accordingly. This will generally require the services of a real estate appraiser. If the standard of value is not fair market value, the valuation analyst may be faced with an interesting challenge. Real estate appraisers use a concept called *market value*. This may not always fit the assignment.
- *Buildings.* Buildings should also be valued at fair market value, which is generally considered to be the estimated depreciated replacement cost, considering such factors as age and economic depreciation. The alternative is to value the property using an income or market approach. This will also require the services of a real estate appraiser and may have the same issues as land when it comes to the standard of value.
- *Machinery and equipment.* Machinery and equipment should be adjusted to reflect their estimated fair market value consistent with the premise being used by the business valuation analyst. This may be much more difficult than it seems because of the need for the valuation analyst to be in communication with the machinery appraiser. Assets owned by the business that are not being used can be valued as if those assets will be sold. We will discuss some definitions later in this chapter.
- A visit to the business premises will often disclose assets that may be fully depreciated or expensed, or both, and do not appear on fixed asset schedules. These assets may have significant value to the enterprise and must be considered in the valuation. The services of a machinery and equipment appraiser will frequently be required.
- *Leasehold improvements.* Leasehold improvements may have a fair market value greater than what is shown on the balance sheet, if the expected life of the improvements is greater than the term of the lease and if the probability of a renewal of the lease is high. In certain situations, the value of the leasehold improvements may be practically nil, particularly when these improvements will shortly revert to the property owner.
- *Leasehold interests.* Leasehold interests may have value to the lessee if the lease is transferable and calls for favorable rental payments based on the current market conditions for that type of property. The fair market value of the lease is usually determined as the discounted present value of the future benefits to the lessee. This is the difference between the market rent and the actual rent being paid. An unfavorable lease could be a liability for the company, and if it is not treated in that manner, it will affect profitability and make the company worth less.
- *Identifiable intangible assets.* Identifiable intangible assets may require the services of a specialist in the valuation of a particular type of asset. Regardless of whether a specialist is employed, an estimate of the remaining useful economic life of the asset is essential. All three approaches to value may be used depending on the type of asset being valued. A market approach may be difficult to apply in many cases due to the lack of information about comparable sales of similar intangible assets, but it should not be overlooked. It may be applicable for such assets as customer lists. A cost approach may be used for such assets as an assembled workforce, architectural drawings, or computer software, whereas an income approach may be appropriate for patents, copyrights, and trademarks. These types of assets are discussed in chapter 20.
- *Contracts.* Contracts that provide future income to the business, such as royalty agreements, often have a determinable value. Other types of contracts may require the business to actually make payments, but by the very nature of the contract (for example, a covenant not to compete), these contracts may also have value. However, there may also be the need to recognize a corresponding liability in some instances.
- *Accounts payable.* Accounts payable should be reviewed to determine if these items would actually be paid. If the payable has been on the company's books for a long time, the valuation analyst may want to discount the liability based on when it might actually be paid. Cash-basis taxpayers may need to have accounts payable added to the balance sheet because this item is frequently omitted. This is similar to accounts receivable.

- *Notes payable.* Notes payable, particularly the current portion, should be reviewed to determine not only whether the liability is valid but also whether it is properly classified as short term. The valuation analyst uses this information in the financial analysis portion of the assignment. Therefore, incorrect classification will result in the use of incorrect ratios when comparison is made with guideline company data or industry composite data.
- *Credit lines.* Working capital credit lines must be carefully analyzed to determine whether this form of debt is temporary or permanent in nature. A credit line that is used and paid down on a regular basis should be considered as short-term debt. However, some companies use the credit line as a form of permanent financing that keeps growing as the company grows, with no principal reductions taking place. This may be considered long-term financing or a form of invested capital.
- *Long-term debt.* Long-term debt should be analyzed similarly to the current portion. All notes payable should be adjusted to fair market value if the interest rate does not reflect the market rate of interest.
- *Deferred taxes.* Deferred taxes can be valued by estimating their market value and adjusting the book value of the deferred taxes account to its market value. Deferred taxes caused by temporary timing differences are similar to zero percent government financing, and as such, they are essentially the same as an interest-free loan. The valuation analyst should calculate the present value using a discount rate based on the current market rate of interest. If the liability can be permanently deferred (this may be possible if the company is growing and the asset base grows while the tax rates do not change), the valuation analyst may be able to exclude this item from the economic balance sheet.
- *Other deferred liabilities.* There may be other deferred liabilities (or assets) on a company's balance sheet due to the manner in which they are recorded under generally accepted accounting principles. We had one valuation that had a large deferred rent liability on the books, and we addressed the valuation issue as appears in exhibit 11.2.
- *Stockholder loans.* Stockholder loans frequently show up on the company's books and records. More often than not, the subject company, particularly a smaller business, is undercapitalized, and the "loans" are actually a form of paid-in capital. In these instances, the loans should not be considered a valid liability of the business but, rather, equity. In other situations, the stockholder loan shows up as a receivable because the stockholder is either disguising compensation in this manner or because the stockholder is using the company's checkbook as his or her personal checkbook. Because the likelihood of repayment is slim, the value of these loans would be zero. If the loan is legitimate and in lieu of bank financing, it should be treated as a bank loan and valued accordingly.

The final acid test would be to determine if these loans would have to be repaid if the business was sold.

## EXHIBIT 11.2 Deferred Rent Liability

In addition to the restrictions on transfer for the remaining owners, an additional item that needs to be considered is the fact that all the owners have previously been able to take advantage of the favorable cash flow resulting from the accounting treatment of the deferred rent. While paying lower rent, the owners recognized a greater expense for accounting purposes, thus, reducing the amount of profit that has been passed through to the members, resulting in a lower tax and better cash flows. However, this will not continue into the future and the remaining owners will experience the reversing of timing differences of the accounting treatment resulting in a less favorable tax treatment in the future.

In order to quantify the impact of the deferred taxes relating to the deferred rent, the analyst asked management for their schedule of the deferred rent, and the changes thereto, and calculated the implied tax benefit and detriment (using the same 18.75 percent tax rate as calculated for the pass-through taxes<sup>1</sup>) over the life of the leases that are in place at the valuation date. The results of the analysis are shown in table 73.

<sup>1</sup> The analyst used the same 18.75 percent tax rate, which is believed to be extremely conservative because it is more likely than not that the tax rates will change before the year 2036, which is how long the deferred rent is scheduled for at the valuation date. It would be speculative for the analyst to use a higher rate in this valuation but The Court might want to consider the equity of such an adjustment. The analyst will gladly assist The Court with other calculations.

**EXHIBIT 11.2 Deferred Rent Liability****TABLE 73 Unfavorable Tax Impact of Deferred Rent**

Month	Change in Deferred Rent	Tax 18.75%	P.V. Period	P.V. Factor	Present Value

					<u><u>\$(3,763,280)</u></u>

The discount rate used to discount the taxes to present value is 6 percent, the cost of debt capital for the subject company. Because this is a timing difference, the present value factors used should reflect the lower risk. Having a \$3.7 million tax detriment would indicate a discount of about 39 percent based on the overall value of \$9.6 million. This detriment will be considered in the selection of the discount for lack of marketability.

**Author's Note**

In this particular valuation assignment, it was decided to use the unfavorable tax impact of the deferred rent to support the discount for lack of marketability of 35 percent that we ultimately ended up with at the end of our valuation. We used an income approach to value the company and used this unfavorable deferred rent to demonstrate that the company was less marketable because a buyer would be concerned about the lack of profitability in the future as the timing difference of the deferred rent reverses itself.

**Tax Affecting the Balance Sheet**

Since the last edition of this book, I have received more questions about this section of my book than any other section. Tax affecting of the balance sheet adjustments will often depend on the purpose and function of the valuation assignment. The Treasury Department indicated in Private Letter Ruling 91-50001 that capital gains taxes should not be considered when the valuation analyst determines fair market value if there is no plan of liquidation. However, since that time, the Tax Court has allowed built-in gains taxes to be considered as part of the discount for lack of marketability. I will discuss this in greater detail in chapter 15.

Before the Tax Reform Act of 1986 (I just realized that some of the students reading this book were not born when this tax act was passed. Man, I feel old!), a tax-free liquidation of a corporation could have been accomplished under what was known as the General Utilities Doctrine.<sup>3</sup> The former position of the Tax Court was that if there was no plan of liquidation, the taxpayer should not be allowed to value an asset as if it were going to be liquidated. However, as the tax law changed, the prevailing wisdom presented to the Tax Court by an IRS valuation analyst was that the willing buyer and the willing seller would consider taxes, even if there was no plan of liquidation. Quite frankly, a willing buyer is not going to pay market value for an asset without considering the impact of a large built-in gains tax on the asset.

<sup>3</sup> See previous IRC Sections 336 and 337, as amended by Section 631 of the Tax Reform Act of 1986. The General Utilities Doctrine allowed a tax-free liquidation under certain circumstances. This provision was removed in the 1986 tax act.

In the first edition of this book (1998), I said that in my opinion, Private Letter Ruling 91-50001 was problematic. At that time, I said

It defies the concept of what a willing buyer would pay a willing seller if all of the facts are known. In some instances, the potential built-in gains tax could be so great that the purchaser would not purchase the corporate stock at all. The real estate would be sold as an asset sale, and the taxes would be paid at the corporate level. In the *Estate of William Luton*,<sup>4</sup> the Tax Court did not permit a discount for the costs in selling the stock in a real estate holding company, nor was the potential capital gains tax at the corporate level taken into account. The Internal Revenue Service has recently settled several cases that have allowed some discount for the built-in taxes.

Do not think that built-in gains taxes are an automatic deduction from the value of the assets. The case law has not always allowed a full deduction for the amount of taxes that would be paid by the purchaser of these assets. In fact, as you read the case law, the rationale in which the taxes were calculated is unclear in some cases because the taxes were buried into the discount for lack of marketability. However, the valuation analyst must be aware of the circuit in which the valuation will be filed because the different circuit courts have ruled very differently on this point. I will discuss that in greater detail in chapter 15. Tax affecting the balance sheet is being done inconsistently, but most experienced valuation analysts believe that accounts receivable and accounts payable (also known as the *accrual assets and liabilities*) should be tax affected when going from cash basis to accrual basis, if there is a likelihood that taxes would be paid or saved by the entity. The valuation analyst must be careful not to get caught in the trap of automatically tax affecting these items. The purpose and function of the assignment must be considered here. If the accounts receivable are the same at the beginning and end of the accounting period and revenues have been flat, taxes will probably not be paid in the immediate future. In addition, many professional practices bonus out profits, eliminating any tax. If it is assumed that the hypothetical willing buyer will do the same, there may not be tax.

If an asset, such as inventory, is sold as a normal part of the business, the adjustment should be tax affected if there is a likelihood that taxes would be paid by the entity. This relates to income taxes, as opposed to capital gains taxes. Therefore, it appears that a reasonable argument can be made for making this type of adjustment.

Changes from LIFO to FIFO will frequently require a tax adjustment. Here also, the income tax implications must be considered. Clearly, there are no hard and fast rules about tax affecting. Why should this be any different from everything else that we have discussed? Common sense must be used to justify tax affecting. There is no substitute for the valuation analyst using his or her head to support his or her position.

It is now time to address the many questions that I get about tax affecting the receivables and payables when valuing a professional practice. Very often, professional practices are sold based on cash basis financial statements. Let's think about a simple dental practice. A purchaser pays some multiple of revenues that are determined based on actual collections. More often than not, the seller keeps the receivables and has to pay all the payables because the transaction is an asset sale, rather than a stock sale. If you recall, I discussed this in chapter 10 not that long ago. So, what happens when the seller collects the receivables and pays the payables? Taxes are paid on the monies collected, net of the expenses paid for. Therefore, isn't it logical that these accrual assets and liabilities should be tax affected if the valuation analyst is valuing the practice based on amounts that exclude these items? This only works if the practice is valued on a cash basis.

One more point for clarification: Any accrual assets or liabilities (accounts receivable or accounts payable) would flow through to the income statement affecting revenues, expenses, and profits. For example, if accounts receivable is recorded on the balance sheet, the corresponding entry would be to record sales or revenues on the income statement. Accounts payable would result in an expense being recorded on the income statement. Therefore, if the valuation analyst uses the income or market approach and applies these other approaches to revenues, earnings, or cash flows that already consider the accrual assets and liabilities, there would be a double-counting of these items. Got it?

4 T.C. Memo. 1994-539, RIA T.C. Memo. 94539, 68 CCH T.C.M. 1044 (1994).

## When All Adjustments Have Been Made

After all the adjustments have been made, the difference between the value of the adjusted assets and the value of the adjusted liabilities equals the value of the adjusted equity of the enterprise. If all assets, both tangible and intangible, have been considered, the value should be in the same ballpark as the value estimates reached in the other approaches. However, if the unidentifiable intangible assets (that is, goodwill) are excluded, the result may or may not be considered the “floor” value in a valuation of a controlling interest (without any discounts at this point). This “floor” value is probably greater than what the company would realize in liquidation but may be less than the values derived under the income and market approaches if the company is not strong. That is when the fun really begins!

Most likely, the valuation analyst will have to value the unidentifiable intangible assets using a different methodology and add the result to the adjusted book value estimate of all the other assets and liabilities. A frequently used method to accomplish this is the excess earnings method. The problem with this method is that it should not be used unless there is no better basis for determining the value of the intangibles. If you don't believe me, reread Revenue Ruling 68-609. I will discuss the mechanics of the excess earnings method in the next chapter, so be patient.

## Communication Among Appraisers and Valuation Analysts

Communication among appraisers and valuation analysts is an important component of the valuation process. The business valuation analyst should be thought of as the team's quarterback. This individual will be responsible for making sure that the other appraisers provide information that will be useful in the business valuation. This means that the valuation analyst must have a clear understanding of the terminology used by appraisers in other disciplines (for example, real estate and machinery, among others) to ensure that the same standard of value and premise of value (going concern or liquidation) is consistently applied throughout the valuation. This is more of a problem when the client or attorney hands you a valuation that was done for a different purpose than the assignment that you are involved in. For example, an insurance appraisal may use a very different standard of value than an appraisal for estate tax purposes. A really bad situation exists when the valuation analyst is given a machinery and equipment appraisal that was done for bank financing and is now being used for a business valuation using a going concern premise of value. Chances are that the machinery and equipment appraisal was originally done using some form of liquidation, which is not compatible with a going concern valuation. Think about it: If the loan goes bad, the bank wants to know how much its collateral may be worth if it has to sell it off. That is not a going concern.

To keep the lines of communication open and clear, the valuation analyst should be familiar with certain terminology used by these other professional appraisers. One way to accomplish this is to take the introductory courses in machinery and equipment and real estate offered by the American Society of Appraisers (ASA). Some of the important terms are outlined in box 11.2.

## The Adjusted Book Value Method Illustrated

Following box 11.2 is exhibit 11.3, which illustrates the adjusted book value method. The example in exhibit 11.3 was part of a valuation that was being used by a client for a divorce litigation. This same example will be used to demonstrate economic obsolescence (soon to be explained) and liquidation value (also coming soon).

### BOX 11.2

#### Professional Appraiser Terminology

##### Definitions of Value Relating to Machinery Assets

The underlying theme and elements of the definitions presented here are based in standard appraisal theory. Many terms are used to describe various thoughts or premises of value. These definitions are offered to provide the fundamental value concepts; they are not the only acceptable definitions, since contracts or jurisdictions may dictate somewhat different philosophies. Therefore, these definitions may be expanded or refined as the purpose and function of an appraisal dictate, as long as the fundamental concepts are not altered. In other cases, the laws of a country, state, region, or regulatory agency may require other terms, which, therefore, would take precedence over the definitions shown here.

1. *Reproduction Cost New* is the cost of reproducing a new replica of a property on the basis of current prices with the same or closely similar materials, as of a specific date.
2. *Replacement Cost New* is the current cost of a similar new property having the nearest equivalent utility as the property being appraised, as of a specific date.

**BOX 11.2****Professional Appraiser Terminology**

3. *Fair Market Value* is an opinion expressed in terms of money, at which the property would change hands between a willing buyer and a willing seller, neither being under any compulsion to buy or to sell and both having reasonable knowledge of relevant facts, as of a specific date.
4. *Fair Market Value in Continued Use with Assumed Earnings* is an opinion, expressed in terms of money, at which the property would change hands between a willing buyer and a willing seller, neither being under any compulsion to buy or to sell and both having reasonable knowledge of relevant facts, as of a specific date and assuming that the business earnings support the value reported, without verification.
5. *Fair Market Value in Continued Use with an Earnings Analysis* is an opinion, expressed in terms of money, at which the property would change hands between a willing buyer and a willing seller, neither being under any compulsion to buy or to sell and both having reasonable knowledge of relevant facts, as of a specific date and supported by the earnings of the business.
6. *Fair Market Value Installed* is an opinion, expressed in terms of money, at which the property would change hands between a willing buyer and a willing seller, neither being under any compulsion to buy or to sell and both having reasonable knowledge of relevant facts, considering market conditions for the asset being valued, independent of earnings generated by the business in which the property is or will be installed, as of a specific date.
7. *Fair Market Value Removed* is an opinion, expressed in terms of money, at which the property would change hands between a willing buyer and a willing seller, neither being under any compulsion to buy or to sell and both having reasonable knowledge of relevant facts, considering removal of the property to another location, as of a specific date.
8. *Liquidation Value in Place* is an opinion of the gross amount, expressed in terms of money, that typically could be realized from a properly advertised transaction, with the seller being compelled to sell, as of a specific date, for a failed, non-operating facility, assuming that the entire facility is sold intact.
9. *Orderly Liquidation* is an opinion of the gross amount, expressed in terms of money, that typically could be realized from a liquidation sale, given a reasonable period of time to find a purchaser (or purchasers), with the seller being compelled to sell on an as-is, where-is basis, as of a specific date.
10. *Forced Liquidation Value* is an opinion of the gross amount, expressed in terms of money, that typically could be realized from a properly advertised and conducted public auction, with the seller being compelled to sell with a sense of immediacy on an as-is, where-is basis, as of a specific date.
11. *Salvage Value* is an opinion of the amount, expressed in terms of money, that may be expected for the whole property or a component of the whole property that is retired from service for possible use elsewhere, as of a specific date.
12. *Scrap Value* is an opinion of the amount, expressed in terms of money that could be realized for the property if it were sold for its material content, not for a productive use, as of a specific date.

**EXHIBIT 11.3 Adjusted Book Value Method**

*To help you understand this exhibit, an explanation is in order. This exhibit comes from a real valuation in which the company had been losing money for years. The asset-based approach was the only approach that made any sense. We had a hunch that liquidation would eventually be used, but we had to satisfy The Court that valuing the business as a going concern would not result in a higher value than valuing the business as if in liquidation. This is the beginning of our analysis. There will be more to come later.*

Of the three approaches to value, the asset-based approach is generally the least used for the valuation of a business enterprise. This is explained in the valuation literature.

In Section 5 of Revenue Ruling 59-60, it states:

The valuation of a closely-held corporate stock entails the consideration of all relevant factors as stated in section 4. Depending upon the circumstances in each case, certain factors may carry more weight than others because of the nature of the company's business. To illustrate:

- (a) Earnings may be the most important criterion of value in some cases whereas asset value will receive primary consideration in others. In general, the appraiser will accord primary consideration to earnings when valuing stocks of companies which sell products or services to the public; conversely, in the investment or holding type of company, the appraiser may accord the greatest weight to the assets underlying the security to be valued.

(continued)

### EXHIBIT 11.3 Adjusted Book Value Method *(continued)*

(b) The value of the stock of a closely-held investment or real estate holding company, whether or not family owned, is closely related to the value of the assets underlying the stock. For companies of this type the appraiser should determine the fair market values of the assets of the company. Operating expenses of such a company and the cost of liquidating it, if any, merit consideration when appraising the relative values of the stock and the underlying assets. The market values of the underlying assets give due weight to potential earnings and dividends of the particular items of property underlying the stock, capitalized at rates deemed proper by the investing public at the date of appraisal. A current appraisal by the investing public should be superior to the retrospective opinion of an individual. For these reasons, adjusted net worth should be accorded greater weight in valuing the stock of a closely-held investment or real estate holding company, whether or not family owned, than any of the other customary yardsticks of appraisal, such as earnings and dividend paying capacity.

In essence, Revenue Ruling 59-60 indicates that a business enterprise is valued based on “earnings” rather than on “assets.”

The value of the intangible assets, if any, are captured more readily using an income or market approach. According to *Financial Valuation*

Although the asset approach can be used in almost any valuation, it is seldom used in the valuation of operating companies. The time and costs involved in valuing individual tangible and intangible assets typically is not justified, because there is little, if any, increase in the accuracy of the valuation. The value of all tangible and intangible assets is captured, in aggregate, in the proper application of the income and market approaches. In many valuations there is no real need to break out the amount of value associated with individual assets, including goodwill. However, it is sometimes used as a floor value. **Other times it may be a value that is too high if the net asset values do not have income support as a going concern.**<sup>1</sup> (Emphasis added)

The major disadvantage to using an asset-based approach is that merely valuing the assets as if they were going to be sold individually fails to consider the true economics of the business enterprise. Using only an asset-based valuation for the individual assets does not consider the value that these assets contribute to the existing business enterprise.

According to *Going Concern Valuation*,

*Use Value* and *Value in Use*—If you look up *Value in Use* in the Dictionary of Real Estate Terms, you will find that it refers to *Use Value*. It defines *Use Value* as, “The Value a specific property has for a specific use.” The 13th Edition has that definition, but goes into a lengthier definition and states it is:

‘a concept based on the productivity of an economic good.’ ‘In estimating use value, the appraiser focuses on the value the real estate contributes to the enterprise of which it is a part, without regard to the highest and best use of the property or the monetary amount that might be realized from its sale.’<sup>23, 2</sup>

(Footnote to Quote 23: *The Appraisal of Real Estate*, 13th Edition, The Appraisal Institute 2008: 27).

We applied the asset-based approach in this valuation assignment on a going concern and a liquidation basis. As indicated early in this report, valuation standards require us to consider the highest and best use of the property.

For the going concern valuation, we adjusted the balance sheet at December 31, 2014, as reported by The Company to fair market value as shown in table 39.

(continued)

**EXHIBIT 11.3 Adjusted Book Value Method** *(continued)*

1. Accounts receivable was adjusted to reduce the book value by the receivable from China Co. because this was determined to be uncollectible. The balance represents several years' worth of sales that have not been paid for. The forecast for China Co. does not indicate an ability to pay this item.
2. Fixed assets were adjusted to reflect the following:

	Going Concern Values
<b>Real Estate:</b>	
East Building – State 1	\$ 1,600,000
West Building – State 1	900,000
State 2	
1234 ABC Drive	525,000
5678 ABC Drive	750,000
7890 ABC Drive	753,684
State 3	400,000
Belgium	4,011,678
<b>Total Real Estate</b>	<b>\$ 8,940,362</b>
<b>Machinery &amp; Equipment</b>	
Belgium	\$ 2,632,712
Less: Equipment Sold From 7/14–12/14	(115,000)
State 1	722,235
Less: Equipment Sold From 7/14–12/14	(1,348)
State 2	3,676,800
State 3	25,410
<b>Total Machinery &amp; Equipment</b>	<b>\$ 6,940,809</b>
<b>TOTAL FIXED ASSETS</b>	<b>\$15,881,171</b>
<b>ROUNDED</b>	<b>\$15,880,000</b>

The real estate values were obtained from appraisals performed by XYZ Real Estate Appraisal Co. as of various dates in May 2014. The machinery and equipment was appraised by Plants Valuation Services, LLC as of December 31, 2014.

Several items must be noted about these appraisals. First, the real estate appraisals use a market value concept. This means that these values assume a sale of the properties, as opposed to valuing them based on their contributions to the business enterprise.

### EXHIBIT 11.3 Adjusted Book Value Method

As for the machinery and equipment, the appraisers valued these assets under a “market value in place” concept, which they define as

*Market Value In-Place:*

The estimated gross amount expressed in terms of money that the subject property would most likely realize in its most common market. The transaction must be between a willing buyer and willing seller with neither party being under any compulsion to buy or sell and with both parties in full knowledge of all relevant facts. Consideration is given to costs of moving and installation in order to arrive at an ‘In-Place’ value.

Once again, this does not consider the economic obsolescence that is specific to the valuation subject’s use of these assets. According to the definition of *economic obsolescence* contained in the machinery and equipment appraisal:

**Economic Obsolescence:**

A form of depreciation, or loss in value, caused by unfavorable external conditions. These can include such things as the economics of the industry, availability of financing, loss of material and labor sources, passage of new legislation, and changes in ordinance. **(Economic Obsolescence, as it pertains directly to the current financial condition of the subject company, has not been considered in the valuation of the subject assets).**<sup>3</sup> (Emphasis Added)

The valuation analyst spoke to the machinery appraiser who confirmed that the underlying assumption behind the valuation is that the economics of the valuation subject would support the values as they have determined them. However, based on the under-capacity and continued losses, we know that this is not the case. A further adjustment will be made by the valuation analyst to support the economic obsolescence built into the balance sheet of The Company.

3. Intangible assets were removed as the earnings do not support the balance sheet values.
4. The Investment in China Co. is explained, in detail, in a later section of this report.
5. The Investment in Mexico Co. is explained in detail in a later section of this report.
6. The Investment in Real Co. is explained in detail in a later section of this report.
7. Economic obsolescence is explained in a separate section of this report.
8. Accounts payable was adjusted to indicate the amount owed to China Co. that will be offset against the uncollectible accounts receivable. It is anticipated that if the valuation subject cannot collect the receivable, it will not pay the payable.
9. Accrued expenses were adjusted to reflect only those expenses that The Company is still liable for. Our review of the detailed accrued expenses indicated that there were items carried by The Company that would most likely not have to be paid in the foreseeable future.
10. Stockholder’s equity has been adjusted for the net of all other adjustments.

As a result of the various adjustments, the stockholder’s equity, on a going concern basis, has been determined to be approximately \$952,000.

<sup>3</sup> Plants Valuation Services Appraisal Report effective December 31, 2014 under cover letter dated June 22, 2015: 6.

## Economic Obsolescence

The example provided in exhibit 11.3 has an adjustment for economic obsolescence. This adjustment is frequently overlooked by valuation analysts because we generally do not see much written about this important concept in business valuation publications. In fact, this concept is being introduced for the first time in this edition of my book despite the fact that it is not a new concept. It just did not seem as important before as it does now. Let me start this discussion by laying out a set of facts. Suppose a valuation analyst determines the value of a company as a going concern as follows:

	Value
Income approach	\$1,000,000
Market approach	\$1,200,000
Asset-based approach	\$4,000,000

The first question that needs to be addressed is why is the net value of the assets so much higher than the values reached under the income and market approaches? There are several possible answers. First, there may be assets that do not contribute to the value of the company's earnings or cash flow. Maybe it has an airplane on the books that is only used to shuttle the CEO around without a significant cost savings. But let's assume that this is not the case. Instead, what if the company has many underutilized assets in its factories that do not make enough of an economic contribution to the company to have as much value to this company as it might have to another company that can fully utilize these assets? This is the concept of economic obsolescence. The assets may be worth more to someone else if sold in the market than they are worth to the company when valued as a going concern.

Let's continue this discussion about a company that had been losing money for many years but appeared to have a significant balance sheet, assuming everything was valued as a going concern. This was the case for the company whose adjusted book value was demonstrated in exhibit 11.3. I previously explained that one factor that must be considered in any business valuation is the highest and best use of the subject business. In this instance, we determined that liquidation ended up being the premise of value that would return the greatest amount to the hypothetical willing buyer. During the course of this assignment, we requested that a machinery and equipment appraisal<sup>5</sup> be performed, and that the machinery and equipment appraiser provide a "market value in-place" and "orderly liquidation value" for each of the assets.

As for the machinery and equipment, the appraiser valued these assets under a "market value in-place" concept, which was defined as follows:

The estimated gross amount expressed in terms of money that the subject property would most likely realize in its most common market. The transaction must be between a willing buyer and willing seller with neither party being under any compulsion to buy or sell and with both parties in full knowledge of all relevant facts. Consideration is given to costs of moving and installation in order to arrive at an 'In-Place' value.

This definition did not consider the economic obsolescence that was specific to the subject company's use of these assets. However, the machinery and equipment appraisal defined *economic obsolescence* as follows:

A form of depreciation, or loss in value, caused by unfavorable external conditions. These can include such things as the economics of the industry, availability of financing, loss of material and labor sources, passage of new legislation, and changes in ordinance. **(Economic Obsolescence, as it pertains directly to the current financial condition of the subject company, has not been considered in the valuation of the subject assets).** (Emphasis added)

As part of this assignment, we consulted with the machinery appraiser who confirmed that the underlying assumption behind the machinery and equipment appraisal is that the economics of the subject company would support the values as they have determined them. However, based on the under-capacity and continued losses of the subject company, we knew that this could not be the case. As a result, a further adjustment was required to be made by the valuation analyst to support the economic obsolescence built into the balance sheet of the subject company.

<sup>5</sup> Economic obsolescence may be applicable to various types of fixed assets, inventory, and so on, including certain types of real estate.

A fundamental requirement of fair market value is the assumption of a willing buyer and a willing seller. However, according to the American Society of Appraisers (ASA), the term *fair market value* needs to be refined with respect to machinery and equipment appraisals to fit the purpose and function of the particular appraisal. As a result, it is necessary to recognize different premises of value that are distinguished based on the anticipated use of the particular asset. These premises of value can be broadly classified into the following categories:

- Sale or removal for a similar or alternate use
- Continued (or installed) use of the asset for the purpose for which it was designed and acquired
- Liquidation<sup>6</sup>

As a result, the term *fair market value* as it pertains to machinery and equipment appraisal is modified to create special definitions to fit the needs of a particular appraisal. These same definitions can be applied to many business assets, not merely the machinery and equipment. Course materials offered by the ASA contain the following definitions of fair market value:

**Fair Market Value** is the amount expressed in terms of money that may reasonably be expected for property in exchange between a willing buyer and a willing seller with equity to both, neither under any compulsion to buy or sell and both fully aware of all relevant facts. (In the valuation of installed personal property with the intent for it to remain installed, this definition must be further defined based on the function and purpose of the appraisal.)

**Fair Market Value in Continued Use** is the estimated amount expressed in terms of money that may reasonably be expected for a property in exchange between a willing buyer and a willing seller with equity to both, neither under any compulsion to buy or sell and both fully aware of all relevant facts and including installation and **assuming that the earnings support the value reported**.

**Fair Market Value—Installed** is the estimated amount of an installed property expressed in terms of money that may reasonably be expected in exchange between a willing buyer and a willing seller with equity to both, neither under any compulsion to buy or sell and both fully aware of all the relevant facts.

**Fair Market Value—Removal** is the estimated amount expressed in terms of money that may reasonably be expected for an item of property between a willing buyer and a willing seller with equity to both, neither under any compulsion to buy or sell and both fully aware of all relevant facts, considering removal of the property to another location<sup>7</sup>. (Emphasis Added)

The definitions of fair market value are refined to reflect the intended use of the assets. The concept of value can assume removal, installation, or continued use of the assets. The removal concept considers the removal of the particular assets to a new location. However, certain assets require large installation costs, and any removal concept tends to incur large discounts for all items that are not economical to remove. According to the ASA, the difference between the installed concept and the continued use concept is the application of what is referred to as *economic obsolescence*.

Economic obsolescence is defined as the “loss in value of a property caused by factors external to the property.” These factors can include the economics of the industry; availability of financing; loss of material or labor sources, or both; passage of new legislation; changes in ordinances; increased cost of raw materials, labor, or utilities; reduced demand for the product; increased competition; inflation or high interest rates; or other similar factors<sup>8</sup>. One author suggests “to determine if economic obsolescence is present, a review must be made of the economics of the subject property and the industry in which it competes, as of the valuation date. The review can be made by examining the earnings history of the subject property and any local or other

6 American Society of Appraisers, *Valuing Machinery and Equipment: The Fundamentals of Appraising Machinery and Technical Assets*, Second Edition (Washington, DC, 2000, 2005): 2.

7 American Society of Appraisers, Course Materials for ME207: *The Advanced Cost Approach*.

8 *Valuing Machinery and Equipment*: 67.

influences that may affect the economic performance of the subject and its assets.” This author goes on to state the following:

EO (Economic obsolescence) may exist in any industry or property where the following attributes are found:

- Reduced demand for the company’s products
- Overcapacity in the industry
- Dislocation of raw material supplies
- Increasing cost of raw materials, labor, utilities, or transportation, while the selling price of the product remains fixed or increases at a much lower rate
- Government regulations that require capital expenditures to be made with little or no return on the new investment
- Environmental considerations that require capital expenditures to be made with little or no return on investment.<sup>9</sup>

The ASA teaches “words of art” to assist practitioners in distinguishing between different types of economic obsolescence. These are referred to as *item-specific*, *industry-specific*, and *business-specific economic obsolescence*. These terms are intended to help eliminate confusion as it relates to economic obsolescence. The ASA’s course materials discuss the definitions of the three types of economic obsolescence as follows:

**Item specific** economic obsolescence is defined as the reactions of purchasers after the deduction of physical and functional depreciation factors. It is measured from the market as items similar to the subject that are sold.

**Industry specific** economic obsolescence is related to the industry in which the equipment works. If a machine were operating in the textile industry and the economics of that industry are good, the appraiser could possibly conclude that the industry is standard and has no economic obsolescence factor. On the other hand, if the textile industry was considered as less than standard, there may be an economic penalty that may be assessed that relates to other companies that must compete for like products or operations.

**Business specific** economic obsolescence is usually provided by the valuation analyst. It is that factor for which the subject is measured, as a business, in order to demonstrate whether the earnings can support the values provided by the personal property appraiser and any other capital asset appraisers. In referencing the definition of fair market value in continued use, there is a statement of an assumption that the earnings can support the values reported. If the business indicates that the earnings do not support the values reported, that economic obsolescence factor as a percentage of that difference is the business specific economic obsolescence. Business specific economic obsolescence is only important as it relates to Fair Market Value-In Continued Use as applied to the current business.<sup>10</sup> (Underlined for emphasis).

Item-specific and industry-specific economic obsolescence are typically accounted for by machinery and equipment appraisers through use of a cost approach or a sales comparison approach. However, the values derived by machinery and equipment appraisers assume that the earnings of the business are sufficient enough to support the values derived. It is up to the valuation analyst to determine whether this assumption is applicable to the valuation subject. This business-specific economic obsolescence is the primary factor that distinguishes the installed concept versus the continued use concept. According to ASA course materials:

The difference between Fair Market Value-Installed and Fair Market Value-In Continued Use is the application of economic obsolescence as explained earlier.

<sup>9</sup> Michael J. Remsha, P.E., ASA, CMI, Vice President Managing Director, American Appraisal, *Identifying and Quantifying Economic Obsolescence* (2010):1–2.

<sup>10</sup> Course materials for ME207.

For Fair Market Value-Installed, the concept considers that the buyer is not concerned with the business and its management but rather what new management could create or accomplish with the subject equipment. The new management would consider each machine as a stand-alone piece with some credit for installation. For Fair Market Value-In Continued Use, the concept considers that the buyer appreciates the business for what it can accomplish with the combination of all equipment. **The Fair Market Value-In Continued Use is normally applied to a profitable business and substantiated through a business value appraisal in order to determine if there is any business specific economic penalty. When a business value is accomplished, it is many times stated as an “overlay” that indicates whether the subject business can support the values indicated. The machinery and technical specialties appraiser must understand that the business valuer could discover an additional economic penalty for the subject over and above any that might be determined for the industry.** If the business value appraiser finds additional economic penalty, it may be necessary for the machinery and equipment appraiser to be consulted. Under the internal revenue tax code, an allocation of purchase price applied to the equipment should not have a value lower than that for which the equipment can be liquidated. **It is always possible that prorating the equipment values downward in order to meet this allocation requirement could bring them below a number in which they could sell in the market place. If this were true for all equipment, the recommendation would be to liquidate the company rather than continue the operation.**<sup>11</sup> (Emphasis Added).

So, what are we supposed to do as valuation analysts? The analyst must deal with the economic realities of the subject company. In the business valuation that was partially shown in exhibit 11.3, the valuation subject was a company that had not generated a profit for the past decade. A financial analysis of the subject company's historic financial statements revealed that on a combined basis, the company was legally insolvent (more liabilities than assets), had underutilized assets, and had a high likelihood of going bankrupt in the near future. All of the subject company's facilities were operating well below capacity, and no individual facility had been operating at capacity for the past decade. An analysis of the subject company's forecasts indicated that the company was expected to continue to lose money in at least each of the next five years, with no turnaround in sight. All of these factors suggested that there was a significant amount of business-specific economic obsolescence related to the subject company's assets because the business enterprise was not generating any profits to support the fair market values of the equipment, real estate, or any of the other assets that had been valued.

In order to quantify economic obsolescence, we used the same five-year forecast that we had assisted management in putting together in an attempt to perform a discounted cash flow analysis (this is part of the income approach discussed in chapter 12) taking the subject's projected losses over the next five years into consideration. The fair market value balance sheet reflected the values of the subject company's assets as of the valuation date. However, if the company were to continue to operate as a going concern, it would have continued to incur losses that would further deplete its cash reserves, resulting in diminishing shareholder's equity over the next several years. Therefore, in order to value the subject company's assets as a going concern as of the valuation date, we had to consider the impact that these continued losses would have on the company's balance sheet going forward. This is the economic obsolescence that relates specifically to the company. In reality, this subject company could not possibly survive for the five-year period being forecast without exhausting all of its reserves. The calculation is shown in exhibit 11.4.

11 *Ibid.*

### EXHIBIT 11.4 Calculation of Economic Obsolescence

The valuation analyst performed a discounted net earnings analysis over a five-year period. Because the going concern concept is perpetual in nature, a five-year period was determined to be conservative. In order to discount these losses to present value, the analyst must determine an appropriate discount rate. In this instance, the analyst determined that the subject company's total combined cost of debt was the appropriate rate to use in the analysis.

Based on the average cost of debt of 6.93 percent, economic obsolescence was calculated as shown in the table that follows.

Calculation of Economic Obsolescence					
	2015	2016	2017	2018	2019
Forecasted Losses	\$( 9,269,579)	\$(8,263,054)	\$(7,434,658)	\$(7,434,658)	\$(7,434,658)
Discount Rate 6.93%					
PV Factors	0.9671	0.9044	0.8458	0.7910	0.7397
PV of Losses	\$( 8,964,610)	\$(7,437,106)	\$(6,288,234)	\$(5,880,815)	\$(5,499,417)
<b>Total Present Value of Losses</b>	<b>\$(34,106,182)</b>				

Note: Figures may not add due to rounding.

Although economic obsolescence had been calculated to be \$34,106,182, it must be noted that this amount can only pertain to the tangible business assets owned by The Company, namely inventory and fixed assets. There would be no writedown relating to the financial assets of The Company. Therefore, the amount of economic obsolescence was limited as follows:

Inventory	\$10,722,898
Fixed Assets	15,880,000
<b>Economic Obsolescence</b>	<b>\$26,602,898</b>

The \$26,602,898 would be recorded on the fair market value balance sheet as a going concern adjustment to reduce the value of the assets. This results in bringing the asset-based approach back to a more realistic level if the business is valued as a going concern.

Had we not adjusted for economic obsolescence, the going concern balance sheet would have been more than \$26 million greater. This would not have made sense when we considered the subject company's current financial status. This is an important adjustment that is needed to reconcile values and make the going concern valuation more realistic. Although this is not the only manner in which economic obsolescence could be calculated, it seemed logical when we did it. In fact, I actually called several of my well-respected colleagues to explain what I was thinking about doing to calculate the economic obsolescence and they all agreed that it seemed logical and supportable. Keep in mind that if the asset-based approach value is higher than the other values as a going concern, there must be a reason. Hopefully, that reason is not because the valuation analyst made a mistake. However, the valuation analyst must do everything possible to reconcile the values and understand why the values are not similar. In a perfect world, which I acknowledge does not exist, the values should be in the same ballpark.

## Liquidation Value Method

Before we can discuss the liquidation value method, let's first define *liquidation value*. Liquidation value is the net amount expected to be left over after the assets are sold off and the proceeds are used to satisfy existing liabilities. The types of liquidation value are *orderly liquidation* and *forced liquidation*. Orderly liquidation value is defined as the value given a reasonable amount of time to find a purchaser of the assets. The reasonable amount of time will differ based on the facts and circumstances at the time of the valuation, as well as on the type of assets involved; in general, the time is three to six months or longer. The values used in an orderly liquidation are based on the price that the market would pay for an asset in a similar, depreciated condition.

In a forced liquidation, there is generally a lack of adequate time to find a purchaser for the assets, and a fire sale value will generally apply. This is the case when the assets are disposed of as quickly as possible, usually in less than three months. A forced liquidation will take place primarily when someone other than the owners of the business force the liquidation. Obviously, an owner will want to maximize the amount derived from a liquidation. Thus, a plan of liquidation, combined with an adequate amount of time to get the best price in the market, will accomplish this task. This does not happen in a forced liquidation.

When considering the liquidation value method, all costs of liquidation should be deducted. Some of the following liquidation costs may apply:

- Commissions
- Administrative costs and losses that may continue during the period of liquidation
- Legal and accounting costs
- Taxes on the disposal of assets as a result of the liquidation

The time value of money should also be considered because it may take time to liquidate the company. It is rare that a business owner can liquidate the assets quickly. For example, if the company is no longer servicing its customers, it may take longer to collect the accounts receivable. Furthermore, during the winding-down stage of the business, the company may not be able to dispose of certain assets that may be required until the very end. Depending on the time frame involved, the valuation analyst may feel that a present value adjustment is in order.

When would the valuation analyst use the liquidation value method? The most obvious use of the liquidation method is when an actual liquidation of the business is contemplated. In this situation, the valuation analyst is aware that a liquidation will take place and will generally have the ability to discuss the plan of liquidation with the management of the company. This is the cleanest manner in which to deal with liquidation.

What does the valuation analyst do, however, if a liquidation is not actually planned? The liquidation methodology should also be considered when the highest and best use of the property is to liquidate and if the interest being valued has the right to liquidate.

Let's make sure that you are clear on what I just stated. Even though a business may not plan to liquidate, the valuation analyst may be required to value the company on a liquidation basis if the value estimate is higher than it would be as a going concern. This is especially true if the standard of value is fair market value.

At a minimum, this method may be used to set the lower limit of the range of possible fair market values of a controlling interest in a going concern. However, that may not always be the case. Exhibit 11.5 comes from the same valuation that we discussed earlier in this chapter in which the standard of value was fair market value, indicating that the highest and best use of the property should be considered.

**EXHIBIT 11.5 Liquidation Value**

The analyst has determined that the valuation subject has little value as a going concern. Attempts to value The Company under the income approach and the market approach resulted in no value. Furthermore, The Company was also determined to be worth little under the adjusted book value method under the asset-based approach. As a result, the analyst tested the value under a liquidation value method.

*Liquidation value* is the net amount that would be realized if the business is terminated and the assets are sold piecemeal. There are two types of liquidation value: orderly liquidation and forced liquidation. *Orderly liquidation value* is defined as the liquidation value at which the assets are sold over a reasonable period of time to maximize the proceeds received. *Forced liquidation value* is the liquidation value at which the assets are sold as quickly as possible, such as at an auction.<sup>1</sup> In this instance, the analyst proceeded to calculate the orderly liquidation value of The Company. The orderly liquidation value balance sheet is presented in table 69.

**TABLE 69 Orderly Liquidation Value Balance Sheet**

	Fair Market Value	Liquidation Adjustments	Orderly Liquidation Value
<b>Current Assets</b>			
Cash	\$ 604,915	\$ —	\$ 604,915
Marketable Securities	2,432,532	—	2,432,532
Accounts Receivable <sup>1</sup>	8,226,477	(2,056,619)	6,169,858

1. In the event of liquidation, the valuation subject would likely not collect 100 percent of its accounts receivable because customers would feel less urgency to pay a distressed business. In order to substantiate this claim, the analyst reviewed several liquidation analyses that were located on Bankrupt.com, a website that is co-produced by The Beard Group and Bankruptcy Creditors' Services, Inc. to provide information for restructuring professionals. For each of these liquidation analyses, the analyst reviewed the estimated recovery rates for accounts receivable for the liquidating business. A summary of the recovery rates for a sample of 20 liquidation analyses is presented in table 70.

*(continued)*

**EXHIBIT 11.5 Liquidation Value** *(continued)***TABLE 70 Hypothetical Recovery Rates**

		Low	High	Midpoint
1	Dura Auto Systems	60.7%	70.0%	65.35%
2	Tronix, Inc.			58.00%

	<b>Average</b>	<b>61.1%</b>	<b>75.7%</b>	<b>68.8%</b>

(Source: Bankrupt.com Beard Group: Restructuring Company.)

As indicated previously, recovery rates ranged from 61.1 percent to 75.7 percent, on average. Therefore, as a conservative estimate, the analyst selected a recovery rate of 75 percent for this valuation. This results in the following adjustment to accounts receivable.

Accounts Receivable – Trade	\$8,226,477
Collection Percentage	75%
Accounts Receivable, Net	<u>\$6,169,858</u>

**EXHIBIT 11.5 Liquidation Value**

2. The analyst requested that management prepare, and we received liquidation values for, the valuation subject's inventory from The Company, which we reviewed for reasonableness. A breakdown of this inventory valuation, along with the assumptions used in arriving at the liquidation values is presented in table 71.

*(continued)*

**EXHIBIT 11.5 Liquidation Value** *(continued)*

The inventory values were determined based on sales, pricing data, and demand trends that were in effect as of the valuation date. The Company also looked at liquidation inventory pricing information from Action Industries and Westlake, two companies that had recently filed for bankruptcy. With respect to Europe, The Company indicated that it had been trying to sell certain goods over the past nine months but had little success given poor business conditions and market saturation for particular items. In order to move these goods within a six- to nine-month period, The Company would have to slash the prices by a significant margin.

3. Fixed assets were adjusted to reflect their liquidation values as determined in the appraisals performed as discussed previously in this report, with the exception of the real estate located at 7890 ABC, which was valued at its going concern value. This property is owned in common with 2468 ABC, which is owned by Real Co. We have assumed that because it would take approximately 9 months to liquidate the equipment located at this property, the general partners would choose to hold the property to maximize its value (see further explanation in the section of this report for the valuation of Real Co.). These values are presented in table 72.

**TABLE 72 Liquidation Values**

<b>Real Estate:</b>	
East Building—State 1	\$ 1,280,000
West Building—State 1	720,000
State 2	
1234 ABC Drive	340,000
5678 ABC Drive	490,000
7890 ABC Drive	753,684
State 3	
Belgium*	2,660,105
<b>Total Real Estate</b>	<b>\$ 6,543,789</b>
<b>Machinery &amp; Equipment</b>	
Belgium	\$ 1,960,587
Less: Equipment Sold From 7/14–12/14	(115,000)
State 1	417,160
Less: Equipment Sold From 7/14–12/14	(1,348)
State 2	2,033,439
State 3	14,180
<b>Total Machinery &amp; Equipment</b>	<b>\$ 4,309,018</b>
<b>TOTAL FIXED ASSETS</b>	<b>\$10,852,806</b>
<b>ROUNDED</b>	<b>\$10,850,000</b>

\* Because it is anticipated that this property could not be sold before the nine months required to liquidate the machinery and equipment, the analyst used a forward-looking exchange rate to convert the amount to U.S. dollars.

Note: Figures may not add due to rounding.

### EXHIBIT 11.5 Liquidation Value

With respect to the real estate, the assumed liquidation periods for the properties were 6 months for each. For the U.S. properties, the appraisers applied a liquidation discount to the market values of the property. The liquidation discount is used solely to compensate for the reduced time period for the sale. After applying the liquidation discount, the appraisers calculated the gross liquidation values for the properties. The figures presented in table 72 reflect the gross liquidation values (as opposed to the net realizable liquidation values) and do not include sales commissions, closing costs, and other carrying costs. These expenses will be accounted for separately in this valuation.

The Belgium property, however, was appraised using a different methodology. For this property, the appraiser valued the property on a residual basis given its current condition. This value implicitly reflects a purchaser's view of the carrying costs for the property. Therefore, in order to be consistent, the valuation analyst added back the carrying costs and sales commissions associated with the Belgium property to arrive at a gross liquidation value. This adjustment is as follows:

Liquidation Value per Appraisal	\$1,930,400
Plus: Taxes and Fees	300,522
Plus Carrying Costs	429,183
Gross Liquidation Value of Property	<u>\$2,660,105</u>

The analyst took the appraised value of \$1,930,400 (€1,600,000) and added back transfer taxes and other fees, as well as carrying costs, to arrive at a gross liquidation value for the property. Taxes and fees were contained in the real estate appraisal, whereas the carrying costs for the property were obtained from management.

The machinery and equipment appraisal also assumed a six- to nine-month sale period. The values are expressed as gross amounts and do not include sales costs.

4. The investment in China Co. is explained in detail in a later section of this report.
5. The investment in Mexico Co. is explained in detail in a later section of this report.
6. The investment in Real Co. is explained in detail in a later section of this report.
7. Economic obsolescence was removed from the balance sheet because this is not applicable under a liquidation scenario.
8. Stockholder's equity was adjusted to include all the adjustments made to the orderly liquidation value balance sheet.
9. In order to determine the value of the equity, the analyst must account for The Company's non-operating assets and liabilities. In the financial analysis section of this report, the analyst identified three items that were determined to be non-operating: a \$100,000 note receivable due from Mr. and Mrs. Smith, current and long-term notes receivable due from Real Co. in the amounts of \$465,566 and \$251,423, respectively, for a total of \$716,989, and a payable due to Real Co. in the amount of \$1,623,999. These items were netted against the net book value on a liquidation basis to arrive at the value of the equity of The Company before liquidation costs.
10. Liquidation costs will be discussed in the text that follows.

Based on the adjustments to the balance sheet, the fair market value of the valuation subject was determined to be \$6,657,508, or \$6.7 million on a rounded basis under the liquidation value method. Because the going concern value is less than this amount, the analyst has concluded that the highest and best use of this property is on a liquidation basis.

#### LIQUIDATION COSTS

The *International Glossary of Business Valuation Terms* defines *liquidation value* as the net amount that would be realized if the business is terminated and the assets are sold in piecemeal. In order to properly perform the liquidation method, valuation analysts are required to account for the liquidation costs associated with shutting down the business operation to arrive at the net realizable value. According to paragraph .34 of Statement on Standards for Valuation Service No. 1 promulgated by the AICPA:

(continued)

## EXHIBIT 11.5 Liquidation Value *(continued)*

### Asset Approach and Cost Approach

34. A frequently used method under the asset approach is the adjusted net asset method. When using the adjusted net asset method in valuing a business, business ownership interest, or security, the valuation analyst should consider, as appropriate, the following information related to the premise of value:

Identification of the assets and liabilities

Value of the assets and liabilities (individually or in the aggregate)

Liquidation costs (if applicable)

In this instance, because the highest and best use of the business enterprise was determined to be in liquidation, liquidation costs must be deducted from the book value on a liquidation basis to arrive at the net amount that a willing buyer would receive in the event of a sale. PPC's *Guide to Business Valuation* outlines a step-by-step process that can be used as a guide to properly perform the liquidation value method. Step 5 of this publication states the following:

#### Step 5—Reduce Gross Proceeds for Direct and Indirect Expenses

703.7 The gross proceeds in Step 4 should be reduced for direct and indirect expenses. Examples include:

- a. *Direct Expenses.* Selling commissions and other fees or taxes related to the specific sales.
- b. *Indirect Expenses.* Legal expenses, other professional fees, and any holding costs (interest, taxes, insurance, repairs and maintenance, etc.) not included in the interim results of operations (Step 6 below).<sup>81</sup>

<sup>81</sup> Jay E. Fishman, et. al., *PPC's Guide to Business Valuations*, Volume 2 (Carrollton, TX: Thomson Reuters, February 2015): 703.5.

Furthermore, according to *Financial Valuation: Applications and Models*

#### Liquidation Value

*Black's Law Dictionary* defines *liquidation* as "the value of a business or of an asset when it is sold in liquidation, as opposed to being sold in the ordinary course of business." This definition broadly encompasses the idea of liquidation value, that is, that assets and liabilities are valued individually. However, there may be additional refinements to the assumptions under liquidation value, mostly dealing with the time and circumstances surrounding the disposal of the assets and extinguishment of liabilities. **Methodologically, liquidation value not only considers the proceeds from selling the assets of a business but also takes into consideration any associated expenses.**<sup>82</sup> (Footnotes Omitted) (Emphasis added).

<sup>82</sup> *Financial Valuation: Applications and Models*, 37.

In addition, according to *Understanding Business Valuation* published by the AICPA

When considering the liquidation value method, all costs of liquidation should be deducted. Some of the following liquidation costs may apply:

- Commissions
- Administrative costs and losses that may continue during the period of liquidation
- Legal and accounting costs
- Taxes on the disposal of assets as a result of the liquidation

The time value of money should also be considered because it may take time to liquidate the company. It is rare that a business owner can liquidate the assets quickly. For example, if the company is no longer servicing its customers, it may take longer to collect the accounts receivable. Furthermore, during the winding-down stage of the business, the company may not be able to dispose of certain assets that may be required until the very end. Depending on the time frame involved, the valuation analyst may feel that a present value adjustment is in order.<sup>83</sup>

<sup>83</sup> Gary R. Trugman, CPA/ABV, MCBA, ASA, MVS, *Understanding Business Valuation*, Fourth Edition (New York, NY: AICPA, 2012): 401.

The excerpts from the valuation treatises and the business valuation standards support the notion that it is proper procedure to deduct liquidation expenses when performing the liquidation value method.

Liquidation costs for each location were discussed in detail in an earlier section of this report. Because these costs will be incurred in the future, the next step in the analysis is to discount these costs to present value as of December 31, 2014. Using The Company's average debt rate, this calculation is presented in table 73.

## EXHIBIT 11.5 Liquidation Value

TABLE 73 Liquidation Expenses

	1	2	3	4	5	6	7	8	9

<b>TOTAL PRESENT VALUE— LIQUIDATION EXPENSES</b>									<b>\$8,225,050</b>

Note: Figures may not add due to rounding.

Based on the calculations in table 73, the present value of liquidation expenses was determined to be \$8,225,050.

## Author's Note

I spared you from the discussion of the liquidation expenses. It went on for about 20 pages in our report. Hopefully, you get the idea.

Remember, the valuation analyst does not want to use this method if the interest that is being valued does not have the ability to liquidate the company (for example, a minority interest). The rights of the interest being valued must be taken into consideration during the valuation process. If the valuation analyst is not sure what those rights are, he or she should reread the articles of incorporation, the bylaws, shareholder agreements, or ask an attorney.

If the valuation is for tax purposes, the valuation analyst might want to consider the case law. The IRS and, particularly, the tax courts have frowned on a liquidation methodology unless a plan of liquidation is in place.

## Cost-to-Create Method

The cost-to-create method is similar to the adjusted book value method. The main difference is that under this method, in addition to valuing the net tangible assets, the valuation analyst values the intangible assets as well. This method requires the valuation analyst to estimate how much it would cost to recreate the enterprise being valued. This would also include trying to estimate the time, effort, and monetary contribution necessary to recreate the intangible assets of the business.

The cost-to-create method will often result in a value estimate that is higher than the cost to reestablish a business enterprise, in much the same manner as I discussed earlier in this chapter when I defined *reproduction cost new*. There is rarely a situation in which the business would be rebuilt from scratch in the same fashion as had been done previously. However, the cost to create method can be useful for valuing intangibles such as customer lists, engineering drawings, and music libraries, among others. For example, let's assume that the valuation analyst is valuing an architectural firm that has a significant library of architectural drawings. Think about the number of hours that it would take to recreate them. These drawings could possibly be valued by determining which drawings have a recurring useful life, how many hours and at what cost per hour would it take to recreate each drawing, and how often might each drawing be used in the future. A forecast could be prepared based on this data that could be discounted to present value (because the monies would be expended in the future) to determine the cost to recreate the drawings.

## Working With Other Appraisers

One of the first steps in working with other appraisers is to properly define the standard of value that will be required as part of the business valuation. Very often, and in my earlier example, the valuation analyst may ask a machinery and equipment appraiser to give two or more estimates of value for the equipment. This may include the value in place, the value if sold, and a liquidation value. The valuation analyst should not leave it up to the other appraiser to give the analyst a value because the result may be totally inconsistent with the valuation approaches and methodologies that are chosen to value the equity of the company. More often than not, the machinery appraiser is used to valuing the assets for a bank loan, meaning that the bank wants to know if the loan goes bad, how much can they get for their collateral. This is often a liquidation value, rather than a going concern value. Sometimes, it may be necessary to have the machinery valued using two or more concepts. We frequently do not know if the highest and best use of the company will be as a going concern or as if in liquidation. Therefore, asking for both of these concepts at the same time is often more cost effective than having to go back to the equipment appraiser and ask for another report. It is also important that the valuation analyst understand the language of the other appraisers. For example, real estate appraisers frequently use *market value* as opposed to *fair market value*. However, if the standard of value for the business valuation is *fair value*, the valuation analyst must determine if the *market value* of the real estate will work in that situation.

## How to Locate and Recognize Specialists

There are various organizations that designate appraisers. Some of the more common designations in real estate are granted by the ASA, the Appraisal Institute, and the National Association of Independent Fee Appraisers. These designations are as follows:

- The ASA
  - *AM*. This designation is granted in various disciplines to individuals who have qualified with at least two years of experience.
  - *ASA*. This designation is granted in various disciplines to individuals who have qualified with at least five years of experience.

The various disciplines of the ASA include business valuation (with a specialty in intangible assets), gems and jewelry (with subspecialties in diamonds and unmounted colored gemstones, contemporary jewelry, art and designer jewelry, Native American or other collectible ethnic jewelry, antique and period jewelry, rough gemstones, gemstone carvings, and mineral specimens), machinery and technical valuation (with subspecialties in agricultural chattels, aircraft, arboriculture, computers and high-tech personal property, cost surveys, industrials, machinery and equipment, marine survey, mines and quarries, natural resources, oil and gas, and public utilities), personal property (with subspecialties in antique and collectible glass, antique and decorative arts, antique firearms, armor and militaria, antique furniture, Asian art, automatic musical instruments, automotive specialties, books, equines, ethnographic art, fine arts, fine arts photography, furs, Native American art, numismatics, oriental rugs, pre-Columbian art, residential contents, silver and metal ware, stamps, violins, and fine and rare wines), and real property (with subspecialties in urban real property, residential real property, rural real property, ad valorem real property, and timber and timberlands).

- The Appraisal Institute
  - *MAI*. The MAI membership designation is held by professionals who can provide a wide range of services relating to all types of real property, such as providing opinions of value, evaluations, review, consulting, and advice regarding investment decisions, among others. Property types may include commercial, industrial, agricultural, residential, vacant land, and others.
  - *SRPA*. The SRPA membership designation is held by professionals who can provide a wide range of services relating to all types of real property, such as providing opinions of value and review, among others. Property types may include valuation of commercial, industrial, agricultural, residential, vacant land, and others.
  - *SRA*. The SRA membership designation is held by professionals who can provide a wide range of services relating to residential properties, including providing opinions of value, evaluations, reviews, consulting, and advice regarding investment decisions, among others.
- The National Association of Independent Fee Appraisers
  - *IFA*. This designation represents a member.
  - *IFAA*. This designation represents an agricultural member.
  - *IFAS*. This designation represents a senior member.
  - *IFAC*. This designation represents an appraiser-counselor.

By now, you must feel like alphabet soup; however, box 11.3 summarizes the various professional designations nicely. The Internet will assist you in finding many of these types of individuals. Most of the appraisal organizations also have directories, which you can obtain by calling them or going online to their websites. Another alternative is to call equipment dealers, but be careful about using the information that you get from them. Problems similar to those discussed earlier when getting information from business brokers can arise. Some pieces of information are going to be better than others.

### BOX 11.3 Professional Appraisal Designations

#### American Society of Appraisers

AM—qualified with 2+ years of experience

ASA—qualified with 5+ years of experience

#### Appraisal Institute

MAI—highest level designator qualified to advise clients in commercial, industrial, and residential real estate valuation

SRPA—next level designator qualified to provide opinions of value and review in commercial, industrial, agricultural, residential, vacant land, and others

SRA—experienced in single family homes, townhomes, and residential income real estate valuation

#### National Association of Independent Fee Appraisers

IFA—member

IFAA—agricultural member

IFAS—senior member

IFAC—appraiser-counselor

## Conclusion

Fortunately, this chapter was easier than the last one. By now, you should know when to use the asset-based approach, how to apply the methods, and the advantages and disadvantages of each of them. So, let's move on.

# Chapter 12

## The Income Approach

### Learning Objectives

In this chapter, I will attempt to explain the following:

- When to use the income approach
- Advantages and disadvantages of using the income approach
- Using pretax or after-tax information
- Valuing invested capital instead of equity
- The capitalization of benefits method
- The discounted future benefits method
- The excess earnings method

### Introduction

Revenue Ruling 59-60 suggests that a valuation analyst should consider the earning capacity of the business in the determination of fair market value. *Earning capacity*, as applied in the methods about to be discussed, may be defined in a number of different ways. Some of the more common definitions include the following:

- Net income after tax
- Net income before tax (pretax income)
- Net cash flow to equity
- Net income to invested capital (aka Net Operating Profit After Tax or NOPAT)
- Net cash flow to invested capital
- Earnings before interest and taxes (EBIT)
- Earnings before interest, taxes, depreciation, and amortization (EBITDA)

These income streams, also known as *benefit streams*, are converted into estimates of the value of the valuation subject. The two processes that are used in the income approach are known as *capitalization* and *discounting*. They are defined as follows:

**Capitalization.** A single period valuation model that converts a benefits stream into value by dividing the benefits stream by a rate of return that is adjusted for growth. A common variation of this theme is the reciprocal of the market multiple price/earnings, which would be earnings/price. An earnings/price ratio is a capitalization rate.

**Discounting.** A multiple period valuation model that converts a future series of benefit streams into value by discounting them to present value at a rate of return that reflects the risk inherent in the benefits stream.

Some of the definitions from the *International Glossary of Business Valuation Terms* regarding these two processes can be found in box 12.1.

Believe it or not, a capitalization model is a shortcut for a discounting model. I will explain this in more detail shortly.

**BOX 12.1****Key Terms Related to Capitalization and Discounting Valuation Methods**

**Capitalization.** A conversion of a single period of economic benefits into value.

**Capitalization factor.** Any multiple or divisor used to convert anticipated economic benefits of a single period into value.

**Capitalization of earnings method.** A method within the income approach whereby economic benefits for a representative single period are converted to value through division by a capitalization rate.

**Capitalization rate.** Any divisor (usually expressed as a percentage) used to convert anticipated economic benefits of a single period into value.

**Discount rate.** A rate of return used to convert a future monetary sum into present value.

**Discounted cash flow method.** A method within the income approach whereby the present value of future expected net cash flows is calculated using a discount rate.

**Discounted future earnings method.** A method within the income approach whereby the present value of future expected economic benefits is calculated using a discount rate.

A capitalization model uses a current benefit stream and assumes that the particular stream of income will be received into perpetuity. A discounting model uses a forecasted benefit stream and discounts that stream back to present value.

In general, the capitalization rates and discount rates used for various benefit streams will be different in each situation. Capitalization and discount rates are discussed in chapter 13.

The fundamental theory behind the income approach to valuing a business interest is that the value of an investment is equal to the sum of the present values of the future benefits it is expected to produce for the owner of the interest. The present value of the future benefits is determined through the application of a rate of return (discount rate), which reflects the time value of money, the relevant investment characteristics, and the degree of risk perceived by the market. The application of the income approach results in an estimate of the value of the normalized net operating assets. In simple terms, the income stream that is capitalized or discounted is produced by using the net assets of the business. Therefore, the value that results from these net assets is included in the income of the company as a going concern. If the income being produced is lower than it should be, this may be a sign of economic obsolescence that is applicable to the value of the assets. The assets alone have value only if they can be sold or exchanged. (Does value in exchange sound familiar? Come on, it was in the last chapter. You could not have forgotten it already!). If the owner sold these assets, the business could no longer generate income, therefore, the value would be sold with the assets.

After the value of the net operating assets is determined, the value of the net non-operating assets is added to the result to obtain the value of the equity. In the invested capital versions of the income approach, the estimate of the value derived results in the value of the invested capital of the enterprise.

## Value Is From an Investor's Viewpoint

The income approach is generally used in determining the value of the valuation subject from the viewpoint of an investor. In many of the older textbooks, the income approach is referred to as the *investment value approach*. This can become confusing because investment value is a standard of value and not an approach to valuation. Although the valuation analyst will most likely understand the difference in these terms, he or she should avoid using the older terminology for the income approach so that users of this information will not be confused. See, you knew there was a reason that you bought the newest edition of this book. Terminology has, in fact, changed over the years, and it is a good idea to make sure that your library contains the current editions of the business valuation treatises.

The income approach is based on the assumption that an investor could invest in a property with similar investment characteristics but not necessarily the same business. This approach looks to the earnings power, or cash generation capabilities, of the enterprise being valued.

Very often, closely held businesses are so unique that the valuation analyst cannot find good information about market multiples or capitalization rates to apply to the company's benefit stream. Instead, the valuation analyst tries to compare the risk associated with the benefit stream to alternative types of investments in the marketplace. This becomes another form of the principle of substitution at work. The valuation analyst will go a long way by having knowledge about the rates of return available in the marketplace.

Although this approach can be difficult to apply at times, it is frequently the best approach to use for estimating the value of a business. Intuitively, if the valuation analyst can put together a reasonable forecast and determine a reasonable rate of return from other similar investment alternatives, this approach may be a much more reasonable approach than attempting to find guideline companies that may or may not be similar enough to the subject company to make a good comparison. If the valuation analyst is lucky enough to find good guideline companies, he or she then has the feat of subjectively choosing how to adjust the multiples that will be applied to the subject company. Although the income approach also has its own degree of subjectivity, a well-grounded forecast is sometimes easier to accomplish. Some valuation analysts reading this may not agree with me, but if they really start to think about companies that are acquiring other companies, most of these companies are using some form of discounting model (usually cash flow) as a primary method of determining the value of the target company. Of course, they may not ignore the market multiples, but it will usually come down to the forecasted cash flow.

## Advantages and Disadvantages of the Income Approach

As to be expected, the income approach has both advantages and disadvantages. By now it should be obvious that this valuation stuff is not perfect. Let's discuss the good, the bad, and the ugly!

### Advantages

The income approach has some definite advantages, including the following:

- It values an enterprise based on its earnings or cash-flow-generating abilities. Therefore, there is a relationship between the value of the enterprise and the earnings or cash flow it produces.
- It requires a simple mathematical application that is frequently performed more quickly relative to the other approaches.
- At times, it is the only approach that can be used to value intangible assets.
- Financial markets frequently use the income approach in the decision-making process.

### Disadvantages

As you would expect, there are also disadvantages to the income approach:

- It is frequently difficult to determine the correct level of the sustainable benefits stream that will be used in the application of this approach. This is especially true for most smaller companies (some of our clients are lucky if they can file their current year's tax returns, let alone forecast the future!).
- It is extremely difficult to choose the correct capitalization or discount rate that will be used to capitalize or discount the benefit stream. This requires the valuation analyst to exercise judgment, which is subjective. At times, it is a difficult number to defend on its own merits.

## Selecting Benefit Streams

The benefit stream(s) to be used in the application of the income approach depends on many factors. These factors are somewhat similar to those factors that were discussed in chapter 9 in applying the market approach. Special attention should be paid to the following factors: (1) the nature of the business and its capital

structure, (2) the purpose and function of the valuation, and (3) the particular subject of the valuation (for example, whether the valuation involves a controlling interest or a minority interest).

## The Nature of the Business and Its Capital Structure

The benefit stream used by the valuation analyst will frequently depend on the nature of the business and its capital structure. For example, net income (after tax) may be the appropriate income stream in certain valuation assignments involving larger companies. Net income may be used to achieve comparability with the guideline companies that report their earnings on an after-tax basis. A pretax income stream may be warranted for smaller valuation subjects that operate the business to minimize taxes. Chances are that the willing buyer will operate the business in a manner similar to that of the willing seller.

The capital structure of the subject business will also be a factor in the determination of the benefit stream to be used by the valuation analyst. Companies that are heavily leveraged, compared with guideline companies or industry composite figures, may be more appropriately valued on an invested capital basis. EBIT may prove to be a more meaningful comparison than net income. Of course, if the goal is to value equity, then the liabilities will be subtracted from the value of the invested capital.

## The Purpose and Function of the Valuation

The purpose and function of the valuation assignment will also play a role in the benefit stream that the valuation analyst will select. As a refresher, the purpose and function of the valuation relates to why you are doing the job and what the valuation will be used for. A valuation assignment for a merger or acquisition will most likely have more of an emphasis on pro forma earnings than on historic earnings. If the valuation analyst is representing the buyer, the investment value to that buyer may require certain adjustments to be made that would not normally exist in a fair market value assignment (for example, removal of certain expenses that will go away because of the synergies between the companies).

In certain jurisdictions, particularly for divorce assignments, future earnings are not allowed to be used in valuations submitted to the courts. In these jurisdictions, the primary emphasis becomes the historic figures. Since when does a willing buyer purchase history? These jurisdictions may be misguided, but I am not going to be the one to tell them that.

## The Particular Subject of the Valuation

The particular subject of the valuation makes a big difference in the benefit stream that can be used in a valuation. When a valuation analyst values a controlling interest, adjustments are commonly made (as discussed in chapter 6). For minority valuations, however, many of the adjustments that would have been made for control are not made. The valuation analyst will use a normalized benefit stream for both valuations, but the benefit stream for the minority valuation will most likely not contain the adjustments related to discretionary items.

Another consideration in this process is the fact that the minority shareholder cannot control the balance sheet of the company. Therefore, valuing the minority shares by assuming a normalized debt-to-equity relationship would not make sense. A small, closely held company with a considerable amount of debt on the balance sheet is going to be paying a lot of interest expense. Valuing this company for the minority shareholder on an invested capital basis would result in an overvaluation of the company's true worth to that individual. The fact that the controlling shareholder has elected to put the company in debt reduces the value of the company.

## Using Pretax or After-Tax Information

In general, it should not really matter whether the valuation analyst is working with pretax or after-tax information. The key is to be consistent. The use of either pretax or after-tax information has advantages and disadvantages. Remember that the valuation analyst is trying to perform an analysis using comparable information from either guideline companies or industry information. The valuation analyst must be able to compare similar information to reach a meaningful conclusion concerning value. The advantages of using pretax and after-tax information as key components in a valuation assessment are outlined in box 12.2.

**BOX 12.2****Advantages of Pretax and After-Tax Valuation Information****Pretax Advantages**

The form of ownership of the valuation subject will not make a difference. This will allow the analyst to compare C corporations with S corporations with partnerships with sole proprietorships. Varying tax rates will affect neither the analysis nor its conclusion.\*

Noncorporate entities can be valued without considering the tax effect of, for example, itemized deductions or personal exemptions.

Small businesses generally operate to minimize income taxes. The willing buyer would probably run the business in a similar manner as the willing seller in that regard. Because comparable data will rarely be found, the analyst will find himself or herself using industry composite data, which is often made up of companies such as the one being valued.

**After-Tax Advantages**

Most data derived from the public market is reported on an after-tax basis. This makes the comparison more meaningful if guideline companies from the public market are used.

After-tax information more appropriately reflects the amount that is available to the stockholders for dividends. Other items affecting cash flow are also considered.

Larger company valuations will frequently be performed this way for mergers and acquisitions, employee stock ownership plans, and initial public offerings because of the available information being reported in this manner.

\* It is also acceptable to tax affect pass-through entities and value these entities on an after-tax basis. In these circumstances, many valuation analysts will use the corporation tax rates for C corporations on the premise that the willing buyer could be a C corporation. This will also avoid getting involved with personal income tax rates, itemized deductions, personal exemptions, the self-employment tax, and other items that vary greatly between taxpayers.

The big controversy in the valuation field regarding the valuation of non-tax-paying entities, such as S corporations, and limited liability companies has been addressed frequently. There is a growing body of knowledge about this topic. The general consensus is that tax affecting depends on the facts and circumstances of each situation. There are no hard and fast rules. Now the valuation analyst must ask “to tax affect or not to tax affect,” that is the question. I feel like Shakespeare. Let’s save this discussion until chapter 18 because this topic deserves its own chapter.

For the nonaccountants reading this book, a C corporation is a typical, tax-paying corporation. An S corporation is a legal corporation that, for tax purposes, is treated like a partnership. This means that the shareholders pay personal taxes on the profit instead of corporate taxes being paid by the entity.

## Valuing Invested Capital Instead Of Equity

This is also like Shakespeare. “To be or not to be...” Should the valuation analyst consider using an invested capital or an equity benefit stream? The same rules apply as we discussed under the market approach (invested capital, remember?). Regardless of which one the valuation analyst uses, the answer should ultimately be the same. The choice of one over the other will frequently be based on comparability with the guideline companies, industry composite data, or the source of the capitalization or discount rates used in the application of this approach.

## Using Cash Flow Instead of Earnings

A valuation analyst will frequently find that using cash flow is a better measure of the company’s earnings capacity. This is particularly true when a more realistic picture is being sought of the amount of money that will be available to pay to the owners of the business as a return on their investment. Many profitable companies go out of business, but it is rare that we see a business with solid cash flow go under. Therefore, cash flow is the name of the game. Similar to pricing multiples (discussed in chapter 9), cash flow, as opposed to earnings, may be a better measure for the business when the net earnings are low compared with depreciation and amortization. The use of cash flow will depend on the facts and circumstances of each case. If the

valuation subject is a controlling interest, it can be assumed that the controlling interest is able to effect changes in the balance sheet of a company. Management must decide what they want to do with respect to the company's cash flow. They can distribute all the available cash and have no funds for growth, or they may reinvest all or part of the available cash into the company and provide for growth.

An operating business must have a sufficient amount of net working capital, a reasonable amount of fixed asset reinvestment, and available cash flow to pay its long-term obligations as they come due. The growth of the company results from investing more than is required to just maintain the existing assets. Growth is funded from internally generated cash flow, new equity, new debt, or a combination of these items.

## Defining Cash Flow

The definition of *cash flow*, as used in a valuation context, differs from the traditional accounting definitions as described in the FASB Statement No. 95, *Statement of Cash Flows* (codified in FASB Accounting Standards Codification 230, *Statement of Cash Flows*). Understanding valuation terminology is an important part of the education process so that the valuation analyst can be conversant in business valuation jargon. The following definitions of cash flow have been used by valuation analysts; therefore, users of business valuation services may already be familiar with the terminology. Even if the users are not terribly familiar with this terminology, there is no point in recreating the wheel with another set of terminology. The basic net cash flow model is depicted in figure 12.1. As you may recall, you also saw this in another chapter. It is worth repeating here.

The net cash flow illustrated in figure 12.1 would be the amount that is available to the equity<sup>1</sup> owners of the company. This could be thought of as the dividend-paying capacity. It is the amount that is left over after the company reinvests in itself to continue its operations while providing for growth. After investing in capital expenditures, reinvesting the amount of working capital to allow the company to grow, and taking care of changes in debt, the company is in a position to begin making distributions to the stockholders or owners. Granted, small businesses do not generally pay dividends, but this would be the amount that would be available if they did.

Gross cash flow is the measure of cash flow that we often see in the pricing multiples in the guideline company method. Net cash flow can't be used in that situation because it is rare that a valuation analyst will have access to the public company's working capital requirements, fixed asset requirements, and other assorted information needed to get from gross cash flow to net cash flow. However, the income approach concentrates on the subject company's cash-generating ability. The more information included in deriving the cash flow available to the stockholders, the less risky the cash flow is usually perceived as being because more factors went into its derivation. Of course, this could also result in more errors regarding these factors. It's not a perfect world!

The manner in which net cash flow is derived will depend on whether the valuation analyst is valuing the equity or the invested capital of the company. As a reminder, valuing the invested capital involves appraising the company on a debt-free basis. The net cash flow model illustrated previously is used by a valuation

**Figure 12.1 The Basic Net Cash Flow Model**

	<b>Normalized net income</b>
+	<b>Normalized noncash charges</b>
=	<b>Gross cash flow</b>
-	<b>Anticipated capital expenditures</b>
+ or -	<b>Working capital necessary to support growth (or generated due to negative growth)</b>
+ or -	<b>Debt borrowings or repayments</b>
-	<b>Preferred stock dividends</b>
=	<b>Net cash flow to common equity</b>

<sup>1</sup> Technically, the cash flow model in figure 12.1 relates to the net cash flow available to common stockholders because of the subtraction of preferred stock dividends. In noncorporate entities, this line item would not exist; therefore, the net cash flow would be to the equity owners that could be proprietors, partners, or members of a limited liability company. Obviously, this could also be applicable to corporations that do not have preferred stockholders.

analyst when he or she is valuing the equity of the company. If the goal is to value the invested capital of the company, certain modifications must be made to get there. Interest expense is added back, net of taxes, to restate the net income on a debt-free basis. Because interest expense gives rise to a tax benefit, the addback must be reduced by the corresponding tax benefit.

Another modification is that there will be no addition or subtraction for new borrowings or repayment of old borrowings. Logically, if we are attempting to derive a debt-free result, debt should be eliminated from the model. This results in the net cash flow model for invested capital (figure 12.2).

Let me take this opportunity to mention that if the company has substantial (long term) other assets or other liabilities on its balance sheet, it is possible that these items must also be considered in the determination of net cash flow, as well. These items could result in another line between gross cash flow and net cash flow in both models.

Now that we have discussed both equity and invested capital cash flows, let's look at these concepts side by side, as shown in figure 12.3.

### Figure 12.2 Net Cash Flow Model For Invested Capital

	<b>Normalized net income</b>

less	Capital expenditures	less	Capital expenditures
+ or -	Change in debt principal		
=	Equity Net Cash Flow	=	Invested Capital Net cash flow

The charts in figure 12.3 illustrate the flow of the income statement into the valuation determination of net cash flow to the investor. This is probably one of the most important illustrations that you will see in this book. You really must understand this concept if you want to be a valuation analyst.

There must be a clear distinction made between short-term cash flow, specific to a particular year, and long-term sustainable cash flow. It is the long-term sustainable cash flow that generally is of interest to the business valuation analyst. Short-term cash flows may be the result of peaks or valleys in the business cycle or the manner in which management operates the business. In fact, if a manager really wants to generate a lot of cash flow, he or she can sell inventory without replacing it. Of course, if he or she does not replace the inventory, the manager will have nothing to sell in the future, and the business will probably fail. But he or she certainly can generate short-term cash flow!

The forecasted net cash flow should be a normalized cash flow. It assumes a required reinvestment into the business each year in an amount sufficient to finance projected operations, as opposed to a discretionary short-term excess reinvestment or deficiency that is not sustainable in the long run. This also implies that the willing buyer would have control of the cash flow. If a minority valuation is being performed, the valuation analyst will generally not make changes to what the minority investor cannot control. By now, I have emphasized this point enough times that it's obvious now that it's important!

## Forecasting Future Benefit Streams

One of the most important parts of the valuation process is the forecast of the future benefits stream that will be used in the income approach. Because this topic is so important, I pulled it out of this chapter and placed it in chapter 8 so it could be reviewed sooner. The following is a small refresher.

The starting point of the forecasting process is that historical income statements must be analyzed and adjusted (normalized if the valuation analyst is valuing a controlling interest) to reflect the economic income of the business being valued. Some of the more common adjustments that have already been discussed are as follows:

- The inventory accounting method may be adjusted to conform to industry practice or expected future treatment. This could include a change in inventory accounting from last in, first out (LIFO) to first in, first out (FIFO).
- Depreciation may be adjusted to more accurately reflect current economic write-offs based on the value determined by the machinery and equipment appraisers or real estate appraisers.
- Nonrecurring items should be removed.
- Non-operating income or expense items may be eliminated, if appropriate.
- The effect of the non-operating assets on the income statement must be removed if a control position is being valued and the assets are to be separately treated in the valuation.
- Related party transactions may need to be adjusted if the results are other than those that would be negotiated at arm's length.

Some of the normalization adjustments will be made regardless of whether the valuation subject is a controlling interest or a minority interest. These types of adjustments would be those that affect the future benefit stream, particularly when the historical operations are expected to be different from the future operations. I discussed forecasting in chapter 8.

Historical operating results should also be analyzed to gain an understanding of the quality of the earnings reported. The valuation analyst will most likely use historical operating results to support the forecast. At a minimum, the valuation analyst will want to use it to double check what the client provided as a forecast. The valuation analyst should also look for trends that may help predict the future with respect to the direction in which the company is headed. These trends may indicate growing, declining, flat, or volatile income streams. If a company has been growing at an exceptionally high rate, the likelihood is slim that the same rate will continue into the future. Because this rate cannot be maintained, the valuation analyst must compensate in the forecast by reducing the growth going forward.

If the company is in a declining mode, the terminal value (TV) may be calculated on the basis of liquidation, as opposed to that of a going concern. If a decline is forecast indefinitely into the future, the valuation analyst should consider whether the highest and best use of the business is in liquidation. If so, the business should be valued in this manner.

If the company's future appears to be flat, there is no reason to use a multiperiod valuation model; in this situation, a single-period capitalization model will suffice. We will discuss this in the next sections. When a company's results are erratic, forecasts become extremely difficult and may have little value in the valuation process. An averaging of history may prove to be beneficial, but this should be done only as a last resort. The valuation analyst should not forget to use other information that was gathered from the company or through his or her own research. Customer contracts can help the valuation analyst forecast expected changes as a result of a customer's growth. The next question that the valuation analyst asks is how far out into the future the forecast should go. I already addressed this point, but the forecast should go out far enough into the future that it represents sustainable future levels of income for the company. If the company has been showing losses, the forecast should go out far enough to allow the company to return to a level of normal sustainable profitability. The same is true if the company has been making large profits. Go out far enough to reflect the normal conditions for the company. The overall idea is to go out beyond periods that contain the peaks and valleys that may be short term. The willing buyer is going to be looking for the income stream that he or she can count on beyond the near term.

Although I discussed forecasting in chapter 8, this is probably a good time to present a forecast that was prepared for a shareholder litigation assignment. Don't worry about the dates; concentrate on the methodology. Keep in mind that the goal was to ultimately get to the expected cash flow for the company being valued. The forecast from this assignment is explained in exhibit 12.1. The client was a trucking firm with large retail customers. Although this may be larger than some of the companies that you may value on a regular basis, the principles are the same.

### EXHIBIT 12.1 Sample Forecast Section

In this valuation, we will use an invested capital analysis because the capital structure of the company is considerably different from the industry peer group. By removing the effect of the debt from the balance sheet, this will allow a more meaningful analysis to be made when comparing the Smith Entities to the industry. After deriving the value of the total invested capital of the Smith Entities, actual debt will be subtracted to derive an estimate of the equity of the company.

Under normal circumstances, we would be provided with a forecast from a company the size of The Smith Entities. However, throughout this litigation, we have been told over and over again that the company does not forecast its financial results. In the absence of management's forecasts, it is appropriate for the appraiser to create his or her own forecast for use in a valuation. As a result, we have performed a forecast based on the extensive amount of information that was provided to us as part of the discovery in this matter, as well as the information that we researched about the Smith Entities' customers and its industry.

Valuation analysts have prepared forecasts for use in valuation analyses for many years. The fact that management does not provide a forecast does not relieve the valuation analyst of the responsibility to consider the necessity of preparing a forecast on his or her own. In fact, corroborating this practice, the American Society of Appraisers includes the following statement in its course materials:

Practitioner—If the subject company does not prepare forecasts or the prepared forecasts are unreliable, **the appraiser should prepare a forecast independently** or consider a capitalization model\* (emphasis added).

Using the adjusted historical financial statements as a starting point, the valuation analyst prepared a forecast based on the information that was known or knowable at the valuation date.

The forecasted income statement appears in table 1.

(continued)

**EXHIBIT 12.1 Sample Forecast Section** *(continued)***TABLE 1 Forecasted Invested Capital Income Statement**

	2011	2012	2013	2014	2015
Sales	\$175,278	\$186,040	\$196,802	\$207,564	\$218,326
Operating expenses	140,328	148,702	157,048	165,366	173,678
Earnings before depreciation, interest, and taxes	\$ 34,950	\$ 37,338	\$ 39,754	\$ 42,198	\$ 44,648
Depreciation and amortization	11,393	12,093	12,792	13,492	14,191
Debt-free income before taxes	\$ 23,557	\$ 25,245	\$ 26,962	\$ 28,706	\$ 30,457
Taxes	7,852	8,414	8,986	9,568	10,151
<b>Net Operating Profit After Taxes</b>	<b>\$ 15,705</b>	<b>\$ 16,831</b>	<b>\$ 17,975</b>	<b>\$ 19,139</b>	<b>\$ 20,306</b>

Assumptions entering into the forecasted income statement include the following:

- Sales: Sales were forecast based on the historical financial statement trends of the company, as well as the anticipated growth that The Smith Entities' major customers were forecasting on or before the valuation date. The industry section of this report contains a discussion about The Smith Entities' major customers. Anticipated growth rates were as follows:

K-Mart	0.0%
TJX Group	8.5%
Federated	2.0%
Best Buy	12.5%
Dayton (Target)	5.0%
Others	5.6%

Applying these growth rates to the amount of business generated by these customers to The Smith Entities results in a forecast for the following period as follows:

	2010 Sales	Growth	2011 Sales
K-Mart	\$ 42,807,075	0.00%	\$ 42,807,075
TJX Group	36,311,358	8.50%	39,397,823
Federated	30,116,268	2.00%	30,718,593
Best Buy	12,630,330	12.50%	14,209,121
Dayton Group	11,120,324	5.00%	11,676,340
Others	33,187,645	5.60%	35,046,153
<b>Total Sales</b>	<b>\$166,173,000</b>		<b>\$173,855,106</b>

\* BV202N: The Income Approach to Value, Chapter 5, "Forecasting Financial Statements," p. 29.

**EXHIBIT 12.1 Sample Forecast Section**

We also used a trend analysis to forecast the future sales based on the historical financial statements of the company. This trend analysis uses statistical techniques to forecast the future results based on the actual history of The Smith Entities. The customer analysis, shown previously, helps support the trend analysis and shows the reasonableness of the forecast.

The trend analysis results in the following level of revenues:

	Revenues	Growth
2005 (H)	\$109,812,000	—
2006 (H)	123,381,000	12.4%
2007 (H)	133,835,000	8.5%
2008 (H)	139,272,000	4.1%
2009 (H)	153,191,000	10.0%
2010 (H)	166,173,000	8.5%
2011 (F)	175,277,867	5.5%
2012 (F)	186,039,924	6.1%
2013 (F)	196,801,981	5.8%
2014 (F)	207,564,038	5.5%
2015 (F)	218,326,095	5.2%

(H) = Actual historical results  
(F) = Forecasted by valuation analyst

- Operating expenses: Through 2010, The Smith Entities were growing at a reasonable pace. As such, expenses started to grow as well. Total operating expenses, including depreciation expense, were as follows:

2006	90.15%
2007	84.96%
2008	84.60%
2009	86.02%
2010	88.98%
5-Year average	86.95%
Latest 3-year average	86.53%

Over the past three years, depreciation expense has been approximately 6.5 percent of revenues. Therefore, operating expenses will be reduced by this amount so that we can segregate depreciation from the operating expenses.

Although the operating expenses grew during 2010, certain expenses were also changing, partially due to the growth of the company but also due to the changing of the management of the company. There were some expenses that were duplicative in nature as a result of the management transition in the company. Therefore, the future operating expenses of the company would not be expected to rise with revenues at the same pace as during 2010.

*(continued)*

**EXHIBIT 12.1 Sample Forecast Section** *(continued)*

As a company grows, fixed costs, such as rent, are spread over more revenues. Also, administrative employees and management costs are spread over a greater revenue base until the need arises for additional personnel.

Taking The Smith Entities' historical expenses into consideration, as well as the manner in which fixed and variable expenses relate to sales growth, we believe that the historical trend can be forecast as follows:

	Operating expenses (with depreciation)	Growth
2006 (H)	90.15%	-5.8%
2007 (H)	84.96%	-0.4%
2008 (H)	84.60%	1.7%
2009 (H)	86.02%	3.4%
2010 (H)	88.98%	-2.7%
2011 (F)	86.56%	-0.1%
2012 (F)	86.43%	-0.1%
2013 (F)	86.30%	-0.1%
2014 (F)	86.17%	-0.1%
2015 (F)	86.05%	-0.1%

(H) = Actual historical results  
(F) = Forecasted by valuation analyst

Depreciation of 6.5 percent will be subtracted from operating expenses, with the 2010 expenses being maintained as a percentage of sales based on 2009.

- Depreciation: Historic depreciation has been approximately 6.5 percent of revenues. We are assuming that this trend will continue.
- Taxes: Assumed to be 33.33 percent. This is the same rate that was discussed earlier in the report. It is the S corporation equivalent tax rate.

The forecasted balance sheet appears in table 2.

Assumptions entering into the forecasted balance sheet include the following:

- Cash: Assumes the cash turnover ratio from 2010.
- Accounts receivable: Assumes the same day's receivables from 2010.
- Other current assets: Kept as a percent of the relationship of adjusted 2010 other current assets to sales.
- Fixed asset additions: Assumed to increase in a consistent manner with depreciation.
- Other assets: Kept as a percent of the relationship of adjusted 2010 other assets to sales.
- Accounts payable: Assumes the same relationship as adjusted 2010 accounts payable to operating expenses.
- Income taxes payable: Kept as the same percentage of the relationship of adjusted 2010 income tax payable to sales.
- Other current liabilities: Kept as a percent of the relationship of adjusted 2010 other current liabilities to sales.

**EXHIBIT 12.1 Sample Forecast Section****TABLE 2 Forecasted Balance Sheet**

	2011	2012	2013	2014	2015
<b>Current assets</b>					
Cash	\$ 15,042	\$ 15,965	\$ 16,889	\$ 17,812	\$ 18,736

**EXHIBIT 12.1 Sample Forecast Section** *(continued)*

As a result of the forecasted financial statements, the debt-free net cash flow is as follows:

**TABLE 3 Invested Capital Net Cash Flow**

	2011	2012	2013	2014	2015
Net income	\$ 15,705	\$ 16,831	\$ 17,975	\$ 19,139	\$ 20,306
+ Depreciation	11,393	12,093	12,792	13,492	14,191
– Capital expenditures	(11,393)	(12,093)	(12,792)	(13,492)	(14,191)
– Increase in working capital	829	(1,228)	(1,221)	(1,213)	(1,209)
– Increase in other assets/ (liabilities)	(136)	(162)	(162)	(162)	(163)
<b>NET CASH FLOW</b>	<b>\$ 16,398</b>	<b>\$ 15,441</b>	<b>\$ 16,592</b>	<b>\$ 17,764</b>	<b>\$ 18,934</b>

What if the forecast is incorrect? The valuation analyst can be absolutely certain that the valuation will be wrong. But don't worry; potential investors are frequently wrong also. If I were right every time that I made an investment, I would probably be retired and paying someone to write this book for me! The concept of fair market value, as well as other standards of value, requires the valuation analyst to put himself or herself in the position of the willing buyer on the valuation date and to make an informed judgment, based on all information known at that time, on what the future will be like. That is what is really being purchased. But don't forget about the willing seller also. Any knowledge that the willing seller has would also be known and factored into the selling price. So, if the forecast turns out to be wrong, the valuation may still be correct based on what was known at the time.

One of the real-world difficulties that will take place regarding the forecasts, especially if the valuation analyst is testifying in a court proceeding, is when the opposing attorney gives the valuation analyst financial data beyond the valuation date to prove that the forecast was wrong. This is where the cross-examining attorney watched too many episodes of *Law and Order* and expects to have a "gotcha" moment.

The valuation analyst should emphasize that the concept of fair market value would be violated if subsequent information was used. A willing buyer cannot know what is in store in the future, other than by performing the same level of due diligence that the valuation analyst attempts to perform. The analysis of the company's historical results, economy and industry forecasts, and other similar information should be used to project the future results of the valuation subject. All of the information gathered during this analysis will assist the valuation analyst in making reasonable forecasts. The valuation analyst should work with management to get the forecast to a reasonable level. He or she must understand, however, that what management wants to accomplish with the valuation may be a factor in the type of information that he or she will be given.

## Income Approach Methods

The value derived under the income approach represents the value of the operating assets less liabilities of the enterprise. The value of the non-operating assets less the non-operating liabilities is then added to the value of the operating entity to obtain the value of the total enterprise. The valuation methods included in the income approach are (1) the capitalization of benefits method and (2) the discounted future benefits method. Although not truly an income approach method, I am also going to cover the excess earnings method in this group of

methods. As you will see, the excess earnings method is really a method used to determine the value of the unidentifiable intangible assets (goodwill). When added to the adjusted book value method, the result is really closer to an asset-based approach than an income approach. However, because capitalization of a benefit stream is required in this method, I chose to cover it here. After all, it's my book!

### Capitalization of Benefits Method

The theoretical value of a business is the present value of all the benefits that can reasonably be expected to be generated to the owners in the future. This concept can be mathematically displayed. Personally, it makes me very unhappy trying to remember all the mathematics of finance that I took in school and forgot shortly thereafter. For students, thankfully, the material is more recent. But this stuff is important, so I am going to provide what I consider to be the minimum amount of math to demonstrate what we will be doing in the application of these models. The mathematical model to express this concept is as follows:

$$PV = \frac{E_1}{(1+k)^1} + \frac{E_2}{(1+k)^2} + \frac{E_3}{(1+k)^3} + \dots + \frac{E_\infty}{(1+k)^\infty}$$

$E$  = Benefit stream  
 $k$  = Discount rate

If you do not like long equations, this one can be reduced to the following:

$$PV = \sum_{n=1}^{n=\infty} \frac{E_n}{(1+k)^n}$$

$E$  = Benefit stream  
 $k$  = Discount rate  
 $n$  = Time period 1 to infinity

For those mathematical neophytes (like myself), the symbol  $\Sigma$  stands for *summation*. Therefore, this formula means the sum of the expected benefit streams from period 1 to period infinity, discounted to present value. Even more simply stated, it is the sum of the present values of the forecasted benefit streams going out for a long, long time (you can't get much longer than infinity; this is as long as perpetuity, and we know that this is a long time from now).

If the growth of the benefit stream (the numerator) is assumed to be constant over time, the equation can be reduced again to the following:

$$PV = \frac{E_1}{(k-g)}$$

$E$  = Benefit stream expected in the next period  
 $k$  = Discount rate  
 $g$  = Growth rate from time  $t = 0$  to time  $t = \text{infinity}$

Now that we got the math stuff out of the way, let's restate what we just did in English. The equation for the single period benefit stream capitalization method is as follows:

$$\text{Value} = \text{Benefit stream} \div \text{Capitalization rate}$$

If you think about what we just did, you will realize that we took the growth out of the numerator (we assumed it to be constant), and we removed the growth from the discount rate ( $k - g$ ). Because this capitalization model assumes a continued benefit stream into perpetuity, the growth that is removed from the discount rate must be the long-term sustainable growth. We will cover this in more detail in chapter 13. The mathematics, however, can be demonstrated with a simple example. Let's assume that the following information is available to you:

This year's cash flow	\$ 909
Next year's forecast cash flow	1,000
Forecast growth	10%
Required rate of return	35%

Forecasting the future cash flows and discounting them back to present value would result in the following calculation:

Forecast	Present value	Forecast	Present value
\$1,000	\$741	5,560	19
1,100	604	6,116	15
1,210	492	6,727	12
1,331	401	7,400	10
1,464	327	8,140	8
1,611	266	8,954	7
1,772	217	9,850	5
1,949	177	10,835	4
2,144	144	11,918	4
2,358	117	13,110	3
2,594	96	14,421	2
2,853	78	15,863	2
3,138	63	17,449	2
3,452	52	19,194	1
3,797	42	21,114	1
4,177	34	23,225	1
4,595	28	25,548	1
5,054	23	Total	<u>\$4,000 (Rounded)</u>

Instead of forecasting constant growth in each period and discounting it for the 35 periods in the preceding table, the mathematics of removing growth from the numerator and the denominator of the equation allows us to capitalize a single stream as follows:

$$\$1,000 \div (.35 - .10) = \$4,000$$

Much easier, isn't it? What this example actually proves is that the single-period capitalization model should derive the same answer as the multiperiod discounting model if you have constant growth. I will explain this further in a little while, but the reason for using one model as opposed to the other has to do with the stability of the income stream that is being forecast.

To apply the single-period capitalization of benefits model correctly, the benefit stream to be capitalized must be from stabilized operating conditions. Combining this with anticipated growth, the stabilized benefit stream should reflect the future expectations of the business or of the investment. Each benefit stream calls for a different capitalization rate. The risk associated with a particular benefit stream will cause the difference in the rates. This point is illustrated in exhibit 12.2.

### EXHIBIT 12.2 Matching the Benefit Stream With Capitalization Rates: An Example

Let's assume that Doodles, Inc. was valued as having an equity value of \$1 million. Based on Doodles's income statement used for the valuation, the following capitalization rates would apply:

	Benefit Stream		Cap. Rate		Value (\$)
Revenues	\$10,000,000	÷	1,000%	=	1,000,000
Cost of sales	9,000,000				
Gross profit	\$ 1,000,000	÷	100%	=	1,000,000
Operating expenses	600,000				
EBIT	\$ 400,000	÷	40%	=	1,000,000
Interest expense	50,000				
Pretax income	\$ 350,000	÷	35%	=	1,000,000
Taxes	100,000				
Net income	\$ 250,000	÷	25%	=	1,000,000

For right now, don't worry about how I calculated the capitalization rates. Obviously, a capitalization rate of 1,000 percent does not make sense. However, the point of this example is that regardless of the benefit stream that is capitalized, the answer should be the same. This does not mean that the valuation analyst can come up with the answer using one benefit stream and force all the other elements to fit. That would be cheating!

The benefit stream will be capitalized by a rate that reflects the risk of the benefit stream being capitalized. The valuation analyst should apply a sensitivity analysis to the capitalization process because relatively minor variations in either the benefit stream or the capitalization rate being considered can result in significant differences in the end result. This can be illustrated as follows:

Benefits Stream (\$)	Cap. Rate (%)	Value (\$)
100,000	20	500,000
100,000	25	400,000
100,000	30	333,333
100,000	35	285,714
100,000	40	250,000

Alternatively, this can be shown as follows:

Benefits Stream (\$)	Cap. Rate (%)	Value (\$)
100,000	25	400,000
120,000	25	480,000
140,000	25	560,000
160,000	25	640,000
180,000	25	720,000
200,000	25	800,000

Now, if the benefit stream is wrong and the capitalization rate is wrong but the valuation analyst got the right answer, he or she should count his or her blessings. Also, the analyst should pay his or her malpractice premiums because he or she may not be that lucky the next time.

The objective in a single-period capitalization method is to determine through analysis—and, if necessary, adjustments—the level of benefits that are reflective of a *sustainable* level for the valuation subject. As discussed previously, the purpose and function of the valuation influence the nature of the benefit stream to be capitalized.

In valuing a minority interest in a closely held business, the valuation analyst generally does not make discretionary adjustments to the benefit stream. Nonrecurring items and generally accepted accounting principles adjustments might be made when these items are considered to affect the benefit stream available to the minority interest in the future. Because the minority interest does not have the ability to effectuate change in the discretionary items, it is generally considered to be inappropriate to modify the benefit stream for items that cannot be changed by the minority.

In certain instances, adjustments to the benefit stream may be required, even in a minority situation. Adjustments may be appropriate when there are nonrecurring items or when the controlling party is abusing control to the detriment of the minority owner (in this instance, an oppressed shareholder action may be lurking in the wings). Another situation in which the valuation analyst may need to make certain adjustments is when he or she is valuing a family business, particularly for estate and gift tax purposes. Although the standard is the *hypothetical willing buyer and willing seller*, a reality check needs to be made when the parent is taking an above-market salary or perquisites in comparison to the minority interest being valued. The valuation analyst should use discretion and do the right thing. If the business is expected to be sold, pro forma earnings or cash flow will be more important to the willing buyer. Appropriate adjustments should be made to accommodate this situation.

Service businesses with few fixed assets are generally valued based on net income (pretax or after tax) or sometimes on a multiple of revenues. The multiple is another form of capitalization rate. Mathematically, a capitalization rate is the inverse of a multiple (a multiple of 5 equals a capitalization rate of 1/5, or 20 percent).

If a business tends to be cyclical in nature, an average of historical data is sometimes used to approximate the stable earnings base that can be capitalized. Once again, as a reminder, any time that historical data is used, it should represent probable future earnings. The valuation analyst should not rely purely on historical data! Willing buyers do not buy history!

When a business is growing, a multiperiod method (soon to be discussed) should be considered because the benefit stream is not expected to be stable. A weighted average of historical data—or, more preferably, forecasted data—should be used as a basis for discounting. When a business' operations have changed, the valuation analyst should ignore the historical data that is no longer representative of the current business. This means that even though the revenue rulings suggest that a period of five or more years be used as the basis of the valuation, it is perfectly acceptable to ignore the historical information if the future is expected to be different. (Don't worry about not following the revenue rulings. The analyst will still be in compliance with the intent of these rulings.)

Adjustments made to the benefit stream to be capitalized are generally made only when a majority (controlling) interest in the business is being valued. In the real world, just before the closing, willing sellers and willing buyers will adjust the sales or purchase price for certain items that may be known. Additional adjustments that can be made to the sale or purchase price are included in box 12.3.

On occasion, but not always, an adjustment will affect both the balance sheet and the income statement. For example, a balance sheet adjustment from LIFO to FIFO inventory does not necessarily require a corresponding adjustment to the cost of goods sold because a better matching has been accomplished in the income statement.

On the other hand, an adjustment to the value of the fixed assets on the balance sheet may require a corresponding adjustment to the depreciation expense on the income statement. This is the part that drives many accountants nuts! The debits do not equal the credits.

### BOX 12.3 Additional Items That May Require an Adjustment

- **An excess or deficiency of net working capital.** An abundance of working capital may be considered to be a non-operating asset and may be added to the ending value determined for the operations. In addition, if a willing buyer is aware that he or she will have to infuse additional capital into the business immediately, a reduction in the sales price is likely to occur. For example, assume that a willing buyer knows that the widget machine must immediately be replaced upon purchase to keep the business running. What is the likelihood that the price will not be adjusted if the cash flow used to calculate value did not have the replacement of this asset in it?
- **The existence of non-operating assets.** The value of these assets, net of non-operating liabilities, will be added to the operating value of the enterprise.
- **Evidence of underutilized capacity.** Underutilized capacity has value if the buyer has the ability to use it properly. For this reason, the business may be worth more in someone else's hands than in the hands of the current owner. Although a willing buyer will not want to pay for what he or she will bring to the company after the acquisition, the willing seller will want compensation for the ability to increase capacity. Negotiations will probably result in a compromise value. This is frequently a very tough adjustment to make because it requires the valuation of the company to be made based on a different set of assumptions than the business actually operates under. If the calculations are performed as if in the hands of a particular buyer, the result may be investment value and not fair market value. However, if all willing buyers would most likely make the same changes, it may be fair market value after all.
- **The need to invest in additional productive capacity to meet future operational demands.** This should be considered in the cash flow requirements of the business.
- **Insufficient management or employee skills or capacity.** Poor management increases the risk of the business and, therefore, decreases its value. More often, this is reflected in poor earnings capacity or a higher discount or capitalization rate due to the increased risk of having a buffoon run the company. Just don't double-count and put it in both places.

Revenue Ruling 59-60 states that “determination of the proper capitalization rate presents one of the most difficult problems in valuation.” No kidding! Capitalization of the total benefit stream results in an indication of value for the entire operating enterprise (shareholder’s equity or invested capital); partial benefit streams can also be capitalized to estimate the value of portions of the enterprise (excess earnings can be used to estimate the value of the intangibles).

The mechanics of the capitalization of benefits method without valuation discounts or premiums are shown in exhibit 12.3.

### EXHIBIT 12.3 Example Of Single-Period Capitalization Method

Adjusted net income	\$1,000,000
Forecasted growth	X 1.05
Estimated future income	\$1,050,000
Capitalization rate	÷ 25%
Indicated value from operations	\$4,200,000
Add: Net non-operating assets	350,000
Total enterprise value	\$4,550,000

In this example, you will notice that the estimated future income is being capitalized. Discount rates and capitalization rates that are determined from the market are considered to be prospective in nature. To match the income stream and the capitalization rate appropriately, both must be on a prospective basis. Historical income and rates could have been used as well, but it is not preferable. If historical data were used, the results would look like this:

Adjusted net income	\$1,000,000
Capitalization rate (25.0 ÷ 1.05 = 23.81)	÷ 23.81%
Indicated value from operations (rounded)	\$4,200,000
Add: Net non-operating assets	350,000
Total enterprise value	\$4,550,000

In this instance, the capitalization rate has been adjusted by the anticipated growth into the next year (5 percent). By removing the growth, a historical capitalization rate can be applied to the adjusted historical net income. Note that the answer is the same in both examples.

### Discounted Future Benefits Method

Founded on the principle of future benefits, the value of a business is the present value of all the benefits it can reasonably be expected to generate in the future. These benefits are generally considered to be the future cash flows available to the owners from the business or investment (dividends and ultimate sale). In theory, if the holding period is expected to continue into perpetuity, the future dividend stream discounted to the valuation date at an appropriate discount rate should represent the value of the investment. Because investments

rarely go to perpetuity, a long time horizon is generally substituted as the holding period for most investments in closely held businesses.

Although distributions to the owners are the main consideration, the application of this method can also be applied to earnings, cash flow (gross or net), and other benefit streams. Regardless of the benefit stream being discounted, the basic concept is the same. This methodology generally involves two steps. First, calculate the sum of the present values of the benefit stream for each of a number of periods (normally, years) in the future. Second, add the present value of TV to that amount.

The TV is generally calculated under a benefit stream residual method or an asset residual method (soon to be discussed). The benefit stream residual method assumes that the benefit stream being discounted will eventually stabilize; then, the stabilized benefit stream can be capitalized into perpetuity and discounted back to the valuation date. In some situations, an exit multiple is applied, instead, under the assumption that the business is being valued based on the multiple that it might sell for at that point in the future. The asset residual method assumes that the benefit stream being discounted will stop at some point in the future as a result of the business coming to an end and being disposed of either through a sale or a liquidation. This method tends to be popular if the business is expected to have a limited life.

What did I just say? The TV assumes that the benefit stream of the business will eventually stabilize. This is similar to the assumption about single-period capitalization models. Don't panic; later, I hope to clear this up with some examples.

Because we had so much fun with the last mathematical equations, I thought that we should do it again. The mathematical equation for multiperiod discounting is derived as follows:

$$\sum_{n=1}^{n=\infty} \frac{E_n}{(1+k)^n}$$

$E$  = Benefit stream  
 $k$  = Discount rate  
 $n$  = Time period 1 to infinity

The preceding equation can be changed. If we use a definite period of time instead of infinity, we can add another component to the equation that would represent the terminal value. Let's change "n" to a finite period of time ending with period "t." Let's also allow for the inclusion of all future value beyond the end of period "t" as a TV. The equation then appears as follows:

$$\sum_{n=1}^{n=t} \frac{E_n}{(1+k)^n} = \frac{FV_{t+1}}{(1+k)^n}$$

$E$  = Benefit stream  
 $k$  = Discount rate  
 $n$  = Time period 1 through time period  $t$   
 $FV$  = Future value or terminal period benefits stream

In simple language, value is estimated as the sum of the present values of the benefit stream for the forecast period plus the present value of the TV. The TV will be the present value of the stabilized benefit stream capitalized into the future. The TV may also be the present value of the sale or liquidation proceeds of the company. Use one or the other, but not both!

The mechanics of the discounted future benefits method are illustrated in table 12.1. In the example in table 12.1, it is assumed that the first five years of the forecast are unstable and that stability takes place at the end of year five. Two calculations require an explanation. The first is the calculation of the TV of \$350,000. This is achieved by starting with the year five forecasted net cash flow of \$70,000 and growing it by the next year's rate of growth that will result in the stable net cash flow stream of the company into the future (in this case, we assumed 5 percent). This means that the next year's (year six) net cash flow is assumed to be \$73,500 ( $\$70,000 \times 1.05$ ).

Year	Forecast Cash Flow	26% Present Value Factors	Present Value Cash Flows
2017	\$ 40,000	.79365	\$ 31,746
2018	49,000	.62988	30,864
2019	57,500	.49991	28,745
2020	64,300	.39675	25,511
2021	70,000	.31488	22,042
TV	350,000	.31488*	110,208
		Total	<u>\$249,116</u>

\* The terminal value is discounted at the same rate as in the final year of the projection.

The next step is to capitalize the stable benefit stream by using a capitalization rate equal to the discount rate used in the present value computations and subtracting the assumed long-term growth rate (in this case, 5 percent). Therefore, the capitalization rate in this example would be 21 percent (26 percent minus 5 percent). (**Note:** Don't worry yet about where these rates come from because we will spend more time on this subject in chapter 13.)

The TV is, therefore, calculated as follows:

$$\$73,500 \div 0.21 = \$350,000$$

The second item needing an explanation is the fact that the discount factor used to discount the TV is the same factor that was applied to the year five forecasted net cash flow. Because stability is reached at the end of year five, we are capitalizing the future cash flow (year five plus growth), but it is being done at the end of year five. Because year five is used for both the forecasted cash flow for that year and the TV, both years should be discounted by the same present value factor. This assumes that the cash flow stream is being received on the last day of the year during the forecast period, say December 31. Then, the terminal period begins on the first day of the next year, January 1. This is the reason why we use the same present value factor.

As previously stated, this example assumes that discounting is being performed at the end of each year because the net cash flow stream is received at the end of the year. If a mid-year convention is assumed (because the benefit stream is generated throughout the year), the present value factor that would be used for the TV would still be the same as the factor used for year five. There used to be a debate in the valuation profession on whether the year five factor should be used in a mid-year model. I believe that this debate has been decided by most valuation analysts. A mid-year convention would change the basic formula to the following:

$$V = \frac{E_1}{(1+k)^{0.5}} + \frac{E_2}{(1+k)^{1.5}} + \frac{E_3}{(1+k)^{2.5}} + \frac{E_4}{(1+k)^{3.5}} + \frac{E_5}{(1+k)^{4.5}} + \frac{E_5^*(1+g) \div (k-g)}{(1+k)^{4.5}}$$

$E$  = Benefit stream  
 $TV$  = Terminal value  
 $k$  = Discount rate  
 $g$  = Rate of growth

The difference between these 2 formulas is the period used to discount the benefit stream, including the TV, back to present value. The vast majority of valuation analysts agree that the same factor should be used for the final forecast period and the terminal period. The minority opinion says that because the terminal period is intended to begin on the first day after the forecast period, the factor should be as of the first day of that terminal period or, conversely, the last day of the forecast period. Using 4.5 instead of 5 in the preceding formula moves the income stream up 6 months. This results in a higher value. The income stream is considered to be a continuous stream, therefore, there really is no gap at the end of a forecast period and the beginning of the terminal period.

There may not be one correct answer for which model the valuation analyst should use, but the model chosen should be properly explained. Keep in mind that a mid-month convention could be used if you really want that income stream to be more representative of how the income stream is received throughout the year. This would close the gap to only one-half of one month.

Some additional considerations about the TV are worth pointing out. If no growth is anticipated after the projection period, the capitalization rate used will be the same as the discount rate. Many finance textbooks estimate that long-term growth for most businesses tends to be somewhat modest, generally in the 3 percent to 5 percent range (inflation plus population growth). Because capitalization into perpetuity is a long time into the future, sustainable growth may not reflect too much more than the rate of inflation. However, the facts of each valuation may warrant different growth rates to be used. If a company has a greater rate of growth in the near term, the present value of the future growth can easily exceed the 3 percent to 5 percent range. Just be careful because a higher growth rate into perpetuity can cause the business to grow beyond reality.

## Calculating the TV

In the discounted future benefits method, the TV can represent a significant portion of the overall value of the business; therefore, care must be exercised in its derivation. The TV should represent the value at the point in time in which the business is in a stabilized and sustainable condition. It is frequently calculated using a single-period capitalization methodology. The benefit stream capitalized is the projected stream for the year after stabilization (time period  $t + 1$ ). The capitalization rate used to convert the benefit stream into an indication of the value of the business at that point is calculated by subtracting the long-term sustainable growth rate from the discount rate used to discount the annual forecasts.

Other acceptable methods to determine a capitalization rate may also be used for the derivation of the TV, but there should be some correlation between the discount rate used and the capitalization rate applied to the terminal benefit stream. After the terminal benefit stream is capitalized, it must then be discounted to its present value (at the valuation date). The basic mechanics of this methodology are demonstrated in exhibit 12.4, which contains a portion of an actual valuation using this methodology. In this valuation, the subject company manufactured a product that started being marketed by two very large public companies that virtually took away that component of the subject company's sales. After our analysis of the historical financial information, we requested that management provide us with a forecast for the business. We actually received a pretty reasonable forecast. The exhibit illustrates what we did with it.

### EXHIBIT 12.4 Discounted Future Benefits Method—Report Excerpt

The next step in this analysis is to determine how the historic performance of the company will compare with what is expected in the future. At the request of the valuation analyst, management has provided an estimate of what it expects future sales to be. This forecast appears in the following table.

#### Management's Forecast (\$000)

	Historic		Forecast		
	2014	2015	2016	2017	2018
<b>Total company</b>					
Sales	\$2,498	\$1,614)	\$910	\$700	\$800
Cost of sales	1,174	697	320	196	224
Gross profit	\$1,324	\$ 917)	\$590	\$504	\$576
Expenses	1,206	934	500	500	500
Operating profit	\$ 118	\$ (17)	\$ 90	\$ 4	\$ 76
Normalized profit	\$ 767	\$ 341	\$ 90	\$ 4	\$ 76
<b>Product A</b>					
Sales	\$2,054	\$1,149	\$310	\$ 0	\$ 0
Cost of sales	1,050	567	152	0	0
Gross profit	\$1,004	\$ 582	\$158	\$ 0	\$ 0
<b>Other products</b>					
Sales	\$ 444	\$ 465	\$600	\$700	\$800
Cost of sales	124	130	168	196	224
Gross profit	\$ 320	\$ 335	\$432	\$504	\$576

The information in the table reflects the decreased sales in the product A business, whereas the sales of other products increase. Management recognizes the fact that it must make a concerted effort to increase the sales of the other products of the company to compensate for the loss of the product A business. Based on our discussions with management, this forecast appears reasonable. Although we cannot guarantee that the actual results will be achieved, the underlying assumptions are consistent and are well thought out. Projected income is significantly reduced from the 2014 and 2015 banner years. Even when allowing for a compound growth rate of about 20 percent in the continuing segment of the business, profits in 2016–2018 are projected to average \$57,000 per year. This forecast also includes a reduction in expenses, which appears to bring the company's historic expenses in line with those on a normalized basis.

A willing buyer will clearly be much more concerned with the expectation of future profitability than with historic results. Historic results are generally used as a basis of forecasting the future, but reliance purely on history will often result in an incorrect conclusion of value. Revenue Ruling 59-60 discusses the future in at least 15 different instances, and it is clear from the guidance provided in this treatise that the future is of greater importance than the past. This will be discussed further in the following section.

**EXHIBIT 12.4 Discounted Future Benefits Method—Report Excerpt****VALUATION CALCULATIONS—DISCOUNTED FUTURE EARNINGS METHOD**

The discounted future earnings method is one of the most theoretically correct methods of valuation. It is premised on the concept that value is based on the present value of all future benefits that flow to an owner of a property. These future benefits can consist of current income distributions, appreciation in the property, or a combination of the two. The formula for the discounted future earnings method is as follows:

$$\sum_{n=0}^{n=t} \frac{E_n}{(1+k)^n} = \frac{TV_{t+1}}{(1+k)^t}$$

$E$  = Forecasted benefit stream

$n$  = Year in which the benefit stream is achieved

$k$  = Required rate of return

$TV$  = Terminal value, which is the estimated benefit stream during a stabilized period

$t$  = Year of stabilization

The formula appears much more complicated than it is. In essence, this valuation method requires a forecast to be made of future earnings, going out far enough into the future until an assumed stabilization occurs for the property being appraised. In this instance, XYZ Company, Inc. is expected to incur a substantial fluctuation in its earnings over the short term due to the change in the company's product mix.

The previously discussed data shows an operating profit for this business estimated at \$90,000 in 2016, \$4,000 in 2017, and \$76,000 in 2018. When a fluctuation of this type takes place, a multiperiod model, such as this one, is generally deemed appropriate for valuing the entity. A single-period capitalization method would be appropriate only if projected earnings are relatively stable and predictable into the future.

The company should experience modest growth, but over the long term, the company is not expected to grow at much more than the rate of inflation. Factoring in the maturity of the company and the shifting of the product mix, the high end of inflation, or 6 percent, will be used for the calculation of the terminal value.

The earnings stream being discounted in this model represents the return on investment to the stockholders. In this instance, there are employment contracts with two nonowner employees that require the company to pay them each 2 percent of all dividends that are paid to the company's shareholders. In this valuation, we have assumed that the company will not be paying dividends; therefore, no reduction will be made to the earnings stream reflected in the table.

Once the earnings stream has been forecasted, the selection of a proper discount rate becomes necessary. Because the income being estimated will not occur until sometime in the future, the future income must be discounted to its present value. In this instance, a discount rate of 32 percent has been deemed applicable. This results in the value estimate of XYZ Company, Inc. being calculated as follows:

$$PV = \frac{90,000}{(1 + .32)^1} + \frac{4,000}{(1 + .32)^2} + \frac{76,000}{(1 + .32)^3} + \frac{TV}{(1 + .32)^3}$$

In this instance, the terminal value is determined by growing the last year's forecast income by a stabilized growth rate. The result is then capitalized and discounted to its present value. Once again, this appears to be much more complicated than necessary, but it is consistent with the Gordon Growth Model used in the securities market.

(continued)

**EXHIBIT 12.4 Discounted Future Benefits Method—Report Excerpt** *(continued)*

Although long-term growth is forecast to be no greater than the long-term rate of inflation, the growth from 2016–2018 is still expected to be a bit higher than that rate in the short term. Therefore, a 6 percent growth rate has been used to determine the stabilized income after 2018. The capitalization rate applied in this instance is based on the selected discount rate less long-term growth, as opposed to next year's growth. Therefore, the terminal value is calculated as follows:

$$TV = \frac{76,000 \times 1.06}{.32 - .06} = \frac{80,560}{.32 - .06}$$

$$TV = \$309,846$$

The insertion of the terminal value into the equation indicated results in the present value of the future earnings of XYZ Company, Inc. to be determined as follows:

$$PV = \frac{90,000}{(1 + .32)^1} + \frac{4,000}{(1 + .32)^2} + \frac{76,000}{(1 + .32)^3} + \frac{309,846}{(1 + .32)^3}$$

$$PV = 68,132 + 2,299 + 134,714$$

$$PV = \$238,238$$

The present value of the future benefits of XYZ Company, Inc. results in an estimate of value of \$238,238, or \$238,000 rounded.

## The Excess Earnings (Formula) Method

An argument can easily be made that the excess earnings method is more of an asset-based approach than it is an income approach. Actually, it is a hybrid of both approaches. The excess earnings method, which is also known as the *formula approach*, is probably the most widely used method of valuation, particularly for small businesses and professional practices. This hybrid of the asset-based approach and the income approach is based on Revenue Ruling 68-609, which provides a method for valuing intangible assets. Note that I said “valuing intangible assets” and not valuing entire companies.

A variation of this method has become popular among valuation analysts who perform allocations of purchase price for financial reporting. For many years, when I taught this method in courses, individuals from the large accounting firms used to wonder what this was and why was I teaching it. Today, they all are familiar with it and use it regularly. Boy, how times have changed!

The excess earnings method involves valuing the subject company's tangible assets and liabilities at fair market value using the adjusted book value method, which was discussed in chapter 11. The capitalization of excess earnings is used to value the intangibles. This is a single-period capitalization model that is similar to what was discussed at the beginning of this chapter.

Excess earnings—rather than net income, cash flow, EBIT, or EBITDA—becomes the numerator in the capitalization model. These excess earnings are derived by forecasting the normalized annual net income (after tax or pretax) for the entity in the same manner as in the other income approach methods. Then, a reasonable return on the net tangible assets is subtracted from the normalized net income to determine the excess earnings. These excess earnings are then capitalized to arrive at the intangible value of the enterprise.

The underlying theory behind this method is logical but is often misapplied. The theory is that a company's earnings stream results from the company's investment in both tangible and intangible assets. All of those machines that make widgets allow the company to have products to sell. Combined with the other operating

assets and liabilities, a return on investment is produced that is attributable to those net tangible assets. If you subtract this return on the net assets from the total earnings stream produced by the company, the balance would be attributable to the intangible assets of the company. Logical, isn't it? This concept is graphically depicted in figure 12.4.

**Figure 12.4 Excess Earnings Method Model**

The valuation analyst needs to understand the theoretical basis of this method to avoid many of the common errors that are made in practice. The following are important guidelines for using this method:

- Because valuation is a “prophecy of the future,” the valuation analyst should estimate the normalized future annual income. A common error is to calculate a weighted average net income for the five prior years or some measure of historical data. The revenue rulings emphasize that using a weighted average of history is incorrect unless it reasonably reflects *probable future earnings*.
- The reasonable return on the net tangible assets should be based on the level of risk associated with these assets, as well as on the returns available in the market. The theory behind this assumption is that if a business owner invested in an investment other than the business assets, a return would be received. Therefore, the investment in assets should also generate a return on investment that is unrelated to the intangible value of the enterprise.
- The return on the net tangible assets should be based on the market value of the net assets and not the book value. Frequently, I see valuation analysts use book value in the calculation. That is just plain wrong!
- The return on investment can be determined by reviewing what other investments are paying. For example, if an investor can buy government securities and receive a 4 percent return, the return on, for example, accounts receivable or fixed assets, should be higher to reflect the amount of risk related to an investment in these assets. Obviously, a balance sheet with all cash would be considerably less risky than a balance sheet that contains only highly technical specialty machinery.
- A common error is to consider the return of 8 percent to 10 percent given as an example in Revenue Ruling 68-609 as gospel. The rate must reflect risk and will generally differ from the rate in the revenue ruling, which was promulgated in 1968. Even the revenue ruling states that “the above rates are used as examples and are not appropriate in all cases. In applying the ‘formula’ approach, the average earnings period and the capitalization rates are dependent upon the facts pertinent thereto in each case.”
- The capitalization rate chosen must reflect the appropriate amount of risk relating to intangible assets. The example of 15 percent to 20 percent in Revenue Ruling 68-609 will, in most cases, be far too low for the average business’s unidentifiable intangible assets (for example, goodwill).

Recognizing the riskiness of the intangible assets will be one of the most difficult jobs for the valuation analyst. The capitalization rate chosen will depend on how much of the earnings stream is attributable to the tangibles versus the intangibles. This will be explained further in chapter 13.

- The excess earnings method should be used only if no better method is available to determine the value of the intangibles. The enterprise can frequently be valued using other methodologies. This is not just my opinion. Reread the revenue ruling!

The basic calculations of the excess earnings method are shown in exhibit 12.5. The mechanics are simple, which is probably why judges like this method so much. Unfortunately, this method is frequently applied incorrectly, and the result is a poor valuation.

### EXHIBIT 12.5 Capitalization of Excess Earnings

Estimated future income (normalized)	\$1,000,000
Less: Return on net tangible assets (\$800,000 × 15%)	(120,000)
Excess earnings	\$ 880,000
Capitalization rate	÷ 40%
Intangible value	\$2,200,000
Plus: Adjusted book value	800,000
Total entity value	<u>\$3,000,000</u>

Non-operating assets are usually excluded from this calculation so that the total entity value reflects the value of the operations of the subject company. Any net non-operating assets are added to the end result to value the total equity of the subject.

In using the excess earnings method, rules similar to those discussed in the single-period capitalization model apply. Because a single income stream is being used, that income stream should reflect stability. If the forecasted earnings are not expected to be relatively stable, a different method should be used. Furthermore, because the assets and liabilities are adjusted to their fair market values, this method implies a control valuation. This method may not be appropriate for minority interests because they cannot liquidate the assets. Of course, you can always subtract a discount for lack of control (discussed in chapter 14) from the control value to get to a minority value. Quite frankly, I would rather have a root canal, or at a minimum, use a different method.

There are frequently better methods to use in valuing businesses, therefore, the excess earnings method is not always appropriate. Still, it continues to be used by many valuation analysts. As mentioned previously, the excess earnings method is commonly applied in the valuation of professional practices and small, owner-operated businesses. In essence, the valuation of these entities is an asset-based approach, with the goodwill (unidentifiable intangibles) being valued this way and added to the adjusted book value of the net tangible assets.

To use the excess earnings method for intangibles, all the operating assets and liabilities of the business must first be appraised. There are many valuation analysts who believe that because small companies and professional practices are usually sold as asset sales as opposed to stock sales, a more appropriate way to apply this method is on an invested capital basis. This would change the rates of return used in the method from equity rates to weighted average costs of capital or invested capital rates (this will make more sense after you read the next chapter). Personally, I like to apply this method the old-fashioned way, which is based on equity. If the valuation analyst does it correctly, he or she should get similar answers (particularly if he or she is lucky!).

The next step is to calculate the normalized sustainable (stable) earnings of the business. Be careful to remove any non-operating income or expenses during the normalization process. Also, remove any items on the balance sheet that may be attributable to non-operating assets or liabilities. The valuation analyst must then determine the appropriate rates of return on the net operating tangible assets owned by the company.

## Required Rate of Return on Net Tangible Assets

There are several acceptable ways to determine the required rate of return on the net tangible assets of the business. There are no hard and fast rules, but there is no substitute for common sense in choosing appropriate rates. One method of determining the rate of return on the net tangible assets is to review the assets and liabilities that make up the balance sheet to assess the amount of risk attributable to these assets. I said it before, and I will say it again: A balance sheet with all cash will be considerably less risky than a balance sheet that is heavy in special technology equipment. The difference in the rates in this instance would be the difference between what a certificate of deposit pays, as opposed to the cost of leasing the equipment. The principle of substitution should be considered in weighing alternative returns.

Another method used to determine the rate of return on the net tangible assets is to calculate a weighted average rate based on the borrowing power of the company. This calculation appears in table 12.2. The idea behind this calculation is that the return should be based, in one part, as a return on the equity investment and, in another part, as a return on the borrowed funds. The return on the debt portion will generally be lower than the return on equity because the latter is considered riskier.

Another source of rates of return on net tangible assets is the market itself. The valuation analyst cannot necessarily use public companies because the returns measured also include intangible assets, but sources such as trade associations, Microbilt's *Integra Business Profiler*, and Risk Management Association's *Annual Statement Studies* may help provide information about returns on tangible net worth. The problem with using this data is that the returns

presented are based on book values and not fair market values. Regardless of which method is used to determine the reasonable return on the net tangible assets, it is generally accepted in the valuation community that this rate should not be below the subject company's cost of borrowing money.

The return on the net assets is then subtracted from the normalized earnings, resulting in excess earnings subject to capitalization. The capitalization rate applied to the excess earnings must be sufficiently high because the excess earnings represent the return from intangibles, which are considered riskier. Logically, if the rate of return on tangible assets is 15 percent, and the required rate of return on the company's earnings (which includes a return on the net tangible and intangible assets) was determined to be 33 percent, then the rate of return for only the intangibles has to be higher than 33 percent, so that on a weighted basis, the 15 percent plus the intangibles return equals 33 percent. This concept is illustrated in exhibit 12.6.

**TABLE 12.2 Return on Net Tangible Assets**

Tangible Assets	FMV	Loan %	Loan Amount
Accounts Receivable	\$150,000	× 80%	= \$120,000
Inventory	80,000	× 60%	= 48,000
Fixed assets	200,000	× 50%	= 100,000
Borrowing capacity	\$430,000	62.3%	\$268,000
Existing debt			100,000
Remaining capacity	\$430,000	39.0%	\$168,000
Market borrowing rate	10%		
1—Effective tax rate	65%		
After-tax borrowng rate	× 6.5%	39%	2.54%
Required equity rate of return on tangible assets	28%*	61%	17.08%
Required rate of return on net tangible assets			19.62%

\*Net earnings discount rate.

### EXHIBIT 12.6 Excess Earnings Method—Rates of Return Proof

Assume that the following calculation was deemed appropriate by the valuation analyst.

Estimated future income (normalized)	\$1,000,000
Less: Return on net tangible assets (\$800,000 × 15%)	120,000
Excess earnings	\$ 880,000
Capitalization rate	÷ 40%
Intangible value	\$2,200,000
Plus: Adjusted book value	800,000
Total entity value	\$3,000,000

The capitalization of benefits method applied to the estimated future income, instead of the excess earnings, would necessitate a capitalization rate as follows:

$$\$1,000,000 \text{ income} \div \$3,000,000 \text{ value} = 33.33\% \text{ capitalization rate}$$

This means that the valuation analyst would have had to determine a capitalization rate of 33.33 percent for a single-period model to be consistent with the results of the excess earnings method. The mathematical proof is the weighted average return on the tangible and intangible components of the value as follows:

Tangible component	$\$800,000/\$3,000,000 \times 15\% = 4.00\%$
Intangible component	$\$2,200,000/\$3,000,000 \times 40\% = 29.33\%$
Weighted average capitalization rate	<u>33.33%</u>

The example in exhibit 12.6 demonstrates that on a weighted average basis, the returns on the tangible and intangible portions of the income stream must result in the return for the entire income stream. This makes sense if you think about it. However, the proof requires circular logic because you need to know the value of the enterprise in order to perform the mathematical calculation. If we know the value, why would we go any further? This is an excellent sanity check on the soundness of the rates of return used in the various methods.

## Background and Drawbacks

If used correctly, the excess earnings method can be a good method to use. However, the answer is only as good as the information that the valuation analyst uses to calculate it. There are many negatives with regard to the excess earnings method. The discussion that follows is intended to provide more background about this method, as well as illustrate the problems that can result by using it incorrectly.

The excess earnings method was promulgated in Appellate Review Memorandum (ARM) 34 in 1920. The purpose of ARM 34 was to provide a formula to be used in determining the proper amount of compensation for the owners of breweries and distilleries for the loss of goodwill that resulted from prohibition. To assist in this task, ARM 34 included rates of return on the investment in assets employed in these types of businesses. This was supposed to allow a separation of the tangible and intangible portion of the taxpayer's income stream to be used in the formula. As the formula method became more popular and started being used for other types of businesses, it became apparent that the rates included in the memorandum may not have been appropriate in every situation or appropriate over time.

Revenue Ruling 68-609 was issued to correct the misinterpretations regarding the use of the excess earnings method in the valuation of goodwill. This revenue ruling suggested higher rates of return but also led valuation analysts to the belief that this methodology is appropriate for all types of businesses. As time went by, the IRS began to recognize that the excess earnings approach was being misapplied in practice. It was being used to value entire businesses when it was intended to value only the intangible assets.

In Revenue Ruling 68-609, the IRS has gone on record to state, "The (excess earnings) approach may be used only if there is no better basis available for estimating the value of intangible assets." There are frequently better methods to use in valuing businesses, therefore, the excess earnings method is not always appropriate. Still, it continues to be used by many valuation analysts.

The basic formula in applying this methodology is to restate the balance sheet at fair market value. The next step is to calculate the probable future earnings of the business. A reasonable return on the net tangible assets is subtracted from the probable future earnings, resulting in the excess earnings that are attributable to the intangible value of the entity. The excess earnings are then capitalized to determine the value of the intangibles. This is sometimes referred to as the *big pot theory*, when all intangible value is calculated as a single figure. I will discuss a multiperiod excess earnings model in chapter 20 in which the intangible value is also segregated into identifiable and unidentifiable intangible assets.

The problems with this methodology are plentiful. The most basic problem is the false assumption that the earnings of a business can easily be divided between the amounts attributable to the tangibles and intangibles. The valuation analyst must determine the appropriate rates of return on the net tangible assets and intangible assets (other than goodwill) owned by the company. There is no empirical data to support these rates of return.

Errors are also frequently committed because of a lack of understanding of the theoretical background and application of the method. Therefore, because this method is so easily misapplied, it is not widely favored by experienced valuation analysts.

In *Business Valuation News*, Shannon Pratt stated

The excess earnings method of valuation actually is another version of a capitalized earnings approach. It is the most widely used and misused of all methods for valuing small businesses and professional practices. It is widely written about, and more than half the business and professional practice brokers that I know use some version of it. It is widely used in divorce proceedings by courts for determining the value of goodwill in professional practices. Yet the Internal Revenue Service, who spawned the method back in 1920, now roundly denounces it.<sup>2</sup>

Discussing the methodology further, Pratt quoted *How to Buy or Sell a Business*:

Small Business Reporter Series, in which it is stated that because each business and sales transaction is different, the formula should be used only to indicate some of the major considerations in pricing a business.<sup>3</sup>

In an article titled "Closely Held Business Valuations: The Uninformed Use of the 'Excess Earnings/Formula' Method," Jeffrey Fox, ASA, indicated that "to mechanically cite the excess earnings/formula method as the authority for a closely held business valuation will leave an appraiser very vulnerable to criticism."<sup>4</sup>

2 Shannon Pratt, "The Excess Earnings Method," *Business Valuation News* (September 1985), 4-12 (now known as *Business Valuation Review*, published by the Business Valuation Committee of the American Society of Appraisers).

3 *Ibid.* (quoting Bank of America, *How to Buy or Sell a Small Business: Small Business Reporter Series* [San Francisco, CA: Bank of America, 1982], 8-9).

4 *Business Valuation News* (September 1984).

Fox indicated that this method should be used only as a last resort. All the difficulties in the application of this method are discussed in the article, but the author summed up the use of this method when he stated, “the utility of the excess earnings/formula method is definitely in doubt when the creator of the method has its own questions concerning its validity.” Despite the overall dislike of the excess earnings method, it has its use in business valuation. For professional practices and small, owner-operated businesses, information is difficult, if not impossible, to obtain, and the valuation analyst has no other choice of method. Care must be exercised in its application, however, because the end result does not always make sense. A blind application of this method without sanity checks and tests for reasonableness will frequently result in a serious misstatement of the value of the subject business.

Although there is wide acceptance of the excess earnings methodology, the mechanics of the method make it a method of last resort. First and foremost, among its many deficiencies is that unless the valuation analyst is extremely lucky, the excess earnings method will rarely reflect the market. In a fair market value valuation, there is nothing more important than the market.

Another problem with the excess earnings method is having to determine two rates of return (return on net tangibles and capitalization rate for excess earnings) instead of one. We have enough trouble supporting our capitalization rates for small businesses because of the lack of empirical data, and now, proponents of the excess earnings method have to determine a capitalization rate for excess earnings for which there is absolutely no empirical data.

As we will discuss in chapter 13, as valuation analysts we are taught to build up a capitalization rate by starting with a discount rate developed for cash flow. We add a subjective element called the specific company risk premium to reflect the added element of risk that is associated with the valuation subject as compared to other companies or with industry data that we obtain. Now we are being asked to add an additional subjective element for only the unidentifiable intangibles portion of the income stream. Where is this supposed to come from? Is this one of those “leaps of faith” that experienced valuation analysts refer to as a *common error* in many valuation reports?

Another reason to avoid the excess earnings method is that it violates the spirit of Revenue Ruling 59-60, in which the IRS has stated

In general, the appraiser will accord primary consideration to earnings when valuing stocks of companies which sell products or services to the public; conversely, in the investment or holding type of company, the appraiser may accord the greatest weight to the assets underlying the security to be valued.

It is commonly accepted in the valuation community that a business valued as a going concern will generally be appraised based on the earnings or cash flow capacity of the business. Only in limited circumstances would primary weight be afforded to an asset-based approach. The excess earnings method places a great emphasis on net asset values to determine the value of the intangibles. This is contradictory.

If a company had to be valued by separately stating the tangible and intangible assets, the excess earnings method could possibly be used in limited situations. However, the subtraction method can also be used to determine the value of the intangibles. Using this method, the company is valued in its entirety, and then the valuation analyst subtracts the value of the net tangibles to determine the value of the remainder, the intangibles.

The discussion about the capitalization method of valuing intangibles states the following:

The capitalization method supposes that the value of the business is based on its ability to generate profits.

This method is computed as follows:

1. Determine net value of tangible assets.
2. Determine a capitalization period and whether to use a straight line or weighted average.
3. Determine a capitalization rate and apply it to the average determined above.
4. If the earnings, once capitalized, are greater than the net tangible assets, the difference represents goodwill.

Because goodwill has generally been described in terms of earning capacity, one method to calculate its existence is based upon a capitalization of earnings method. One of the early attempts to arrive at the value of goodwill by capitalizing earnings was set forth by the IRS in ARM 34.

An example of the form of the computation prescribed by ARM 34 is as follows:

### Example

Welch Company, a low risk company, had net tangible assets as of the appraisal date of \$100,000. In addition, its earnings record was as follows:

Preceding Years Earnings	
1st yr. earnings	\$ 20,000
2nd yr. earnings	30,000
3rd yr. earnings	15,000
4th yr. earnings	40,000
5th yr. earnings	25,000
<b>Total</b>	<b>\$130,000</b>

Average annual earnings for 5 preceding years:

$$\frac{130,000}{5 \text{ years}} = \$26,000$$

ARM 34 uses a rate of return for low risk companies of 8 percent. In this case, the earnings attributable to tangible assets are 8 percent of the net tangible asset value:

$$\$100,000 \times .08 = \$8,000$$

The balance of earnings attributable to intangible assets is as follows:

Average earnings	\$26,000
Less earnings attributable to tangible assets	8,000
<b>Earnings attributable to intangible assets</b>	<b>\$18,000</b>

ARM 34 then recommends, for low risk companies, a capitalization rate of 15 percent. The value of the intangible assets is as follows:

Earnings attributable to intangible assets	\$ 18,000
Divided by capitalization rate	÷ .15
Equals value of intangible assets	<u>\$120,000</u>

Initially, this formula was interpreted as providing set rates of return on tangible and intangible assets. This resulted in many improper valuations because the use of arbitrary capitalization rates has no relationship to the financial marketplace at the time of valuation. *The IRS has clarified its position by stating that the appropriate average earnings period and capitalization rates are dependent upon pertinent facts of each case.*

In making the calculation, the following factors should be considered:

1. The period of past earnings should fairly represent probable future earnings. Ordinarily, this will not be less than five years.
2. Abnormal years, whether above or below average, should be eliminated.

Factors that influence the capitalization rate include the following:

- nature of the business
- risk involved
- stability or irregularity of earnings

*The formula approach may be used for determining the fair market value of intangible assets of a business only if there is not better basis [sic] available [emphasis added].* A recent Tax Court decision used the formula approach to calculate going concern value in a situation where it was determined that no goodwill existed.

The valuation guide indicates that even though the excess earnings method is discussed in Revenue Ruling 68-609

- the IRS has stated that a taxpayer may use the capitalization of excess earnings method only if there is no better basis for determining the value of intangibles;
- the Tax Court has, on occasion, rejected the taxpayer's use of the capitalization of excess earnings method for valuing intangible assets (for example, core deposit intangible in *Banc One*, 84 T.C. 506);
- The Court, in *Banc One*, criticized the basic assumptions made in the capitalization of excess earnings method, noting that the "[d]etermination of the 'normal' earnings of business, the 'average' return on the tangible assets, and the 'appropriate' capitalization rate is a highly subjective task."
- The Court even rejected the theory supporting the capitalization of excess earnings method, finding that "there is no goodwill unless there is also an expectancy of continuing excess earnings capacity," and noted also that goodwill may be present in the absence of excess earnings capacity.

To make a long story short, the promulgator of the methodology is not too thrilled with its own invention. Clearly, fair market value is supposed to come from the market. It is not to be conceived from formula methodologies that often fail to reflect the market value of a business. Because good valuation practice dictates that the valuation analyst should use multiple methods of valuation in any assignment, and there are other methods of valuation that can be used in any given assignment, we should learn from the IRS when they tell us, "The formula approach may be used for determining the fair market value of intangible assets of a business only if there is not a better basis available." Any experienced valuation analyst should understand that there is always a better basis for valuing an entire enterprise and almost always a better method for valuing only the intangibles.

By now it is probably understood that the foregoing discussion was extremely critical of the excess earnings method. I would have liked to highlight a positive side of this method, but I could not think of one. The excess earnings method should be used only if all else fails. The valuation analyst can use this method when he or she knows that he or she is going in front of a judge who will throw the report out of court if he or she does not use it. Whatever the valuation analyst does, it is not wise to use only this method. Use other methods that

may be applicable to the assignment at hand, so that a feeling of comfort can be had about the estimate of value that is determined.

Finally, with all of that being said, if you really think about this method for small closely held businesses, it may make sense. These small businesses probably do not have a lot of intangible value, which would necessitate or justify the use of an asset-based method to estimate the value. Therefore, the adjusted book value portion of the method might get close to the value of the overall enterprise. The excess earnings calculation may result in a small bump in the value for the little bit of intangible value that may exist. Therefore, in certain circumstances, this method can work. How is that for going full circle?

## Conclusion

I hope that you now understand the income approach. You should have learned various methodologies, the advantages and disadvantages of each method, various pretax or after-tax considerations, and the derivation of net cash flow from the valuation point of view. Be honest: You didn't really expect me to make it that easy for you, did you? If you thought this stuff was fun, let's go to the next chapter and discuss discount and capitalization rates. Before you do that, take your heart medication!

## Chapter 13

# Discount and Capitalization Rates

### Learning Objectives

In this chapter, I will attempt to explain the following:

- Discount and capitalization rates in general
- The use of pretax or after-tax rates
- Discount rates
- The factors that affect the selection of a discount rate
- The components of a discount rate
- The build-up method
- The capital asset pricing model (CAPM) (in English, no subtitles)
- Alternatives to the build-up method and CAPM
- Capitalization rates
- The factors that affect the selection of a capitalization rate
- The data sources for discount and capitalization rates

Pretty optimistic, huh?

### Introduction

Here comes the good stuff! This is the chapter that you have been waiting for. If you are dangling on the edge, this is the chapter that is sure to push you over. Hold on tight because here we go! One of the most difficult tasks that the valuation analyst faces is selecting an appropriate discount or capitalization rate. For many years, I went to seminars waiting for some business valuation guru to give me the formula for developing the “right” discount rate. When I realized that no one could do it, I started teaching and writing about this stuff myself. The theory behind discount rates is quite simple. The amount of risk that is perceived by the market must generally be balanced by the rate of return that is offered for the investment in order to entice investors to take the risk of making the investment. Stated differently, if a willing buyer wants to make an investment in a closely held company, the rate of return being offered, based on the price to be paid for the investment, must be high enough to justify taking the risk. This can be illustrated by figure 13.1, “The Rate of Return Department Store.”

As one goes from the ground floor to the roof of the rate of return department store, the risk of the investment increases. When you examine the rates of return in the market, you will find that the rates of return increase in the same direction. This shows the correlation between risk and reward. There is a positive relationship between these two items. This relationship is shown in figure 13.2 on the following page. It even looks like something that you would see in a finance textbook.

**Figure 13.1 The Rate of Return Department Store**

<b>Venture Capital</b>
<b>Junk Bonds</b>
<b>Small Cap Stocks</b>
<b>Large Cap Stocks</b>
<b>AAA Corporate Bonds</b>
<b>Certificates of Deposit</b>
<b>Treasury Bonds</b>
<b>Treasury Bills</b>

**Figure 13.2 Relationship of Risk and Return****Figure 13.3 Relationship of Return and Value**

The opposite relationship exists between returns and value. These are negatively related. Greater risk means lower value. This is illustrated in figure 13.3. If practicing in the field of business valuation, always remember that what the valuation analyst is really trying to do is figure out which floor in the rate of return department store he or she needs to get off on based on the risk of the benefit stream that is going to be discounted. The valuation analyst may even choose to get off between floors. What the valuation analyst is ultimately trying to do is use the principle of substitution that was mentioned in chapter 4. No reasonable investor would accept a lower rate of return, given the risk of the investment, than they could get in another investment in the market.

As long as we are still in the introduction section, let's get another goody out of the way. Discount and capitalization rates are not the same. A discount rate is a required rate of return—a yield rate used to convert expected future receipts into present value. The rate of return represents the total rate of return expected by the market—the rate necessary to attract capital to the subject investment.

A capitalization rate is not a rate of return; it is a divisor used to convert a future return into an indication of value. The capitalization rate plus the long-term sustainable rate of growth of the selected return combine to provide the rate of return. The rate of return is market-driven. It is the rate determined to be available on alternative investments of comparable risk and with similar characteristics—an opportunity cost. And, of course, risk represents uncertainty. If there is no uncertainty, there is no risk. Therefore, risk is the degree of uncertainty associated with a given investment.

The discount and capitalization rates used will depend on what is being discounted or capitalized. Some possibilities include the following:

- Net income (after tax)
- Net income (pretax)
- Gross cash flow
- Net cash flow
- Excess earnings
- Dividends or dividend paying capacity, or both
- Earnings before income and taxes (EBIT)
- Earnings before income, taxes, depreciation, and amortization (EBITDA)

The determination of which benefit stream will be discounted or capitalized will depend on various factors, including the availability and reliability of data. This data can relate either to market information about discount or capitalization rates or to the subject company's information. The valuation analyst may have better information to work with in certain assignments and may not feel comfortable with financial information in others (cash businesses). The amount of risk associated with the valuation subject's benefit stream should be a major consideration in determining an appropriate rate. The valuation analyst also considers alternative rates of return on comparable investments available to the willing buyer. This is the principle of substitution at work.

## Discount Rates

If this were a finance book, I would probably include a rather complex explanation of discount rates. Be grateful for little things because it's not one! In simple terms, a discount rate is the required rate of return that an investor would demand—based on the risks associated with the benefit stream under consideration—to induce him or her to make the investment. What do I mean by risk? Risk is uncertainty: the greater the amount of uncertainty, the greater the amount of risk. The greater the risk, the less someone is willing to pay for something. The lower purchase price is used to provide a greater potential return to the buyer. For example, assume that ABC Company has an expected income of \$100,000 that is sustainable into the future. To keep the example simple, let's assume there is no growth anticipated. This would make the discount rate and the capitalization rate equal to each other. If the required rate of return was 20 percent, the value of ABC would be calculated as follows:

$$\$100,000 \div 20\% = \$500,000$$

If the buyer's perceived risk was greater, the buyer might offer only \$400,000 for ABC. This would provide a 25 percent rate of return to the buyer, calculated as follows:

$$\$100,000 \div \$400,000 = 25\%$$

Lowering the price provides a greater return for the buyer. However, if the risk related to an investment in ABC is not really lower, the seller would insist on a greater price for the business. A \$600,000 price would provide the buyer with a lower rate of return. In the real world, a negotiation will go forward between the buyer and the seller based on the perceived risk of the investment. The buyer will think it is very risky, and the seller will tell the buyer that there is no risk. Who would ever figure this could happen?

The discount rate represents the rate of return that an investor requires to justify his or her investment in an asset, depending on the amount of risk associated with the investment. For example, an investor may expect a 2 percent return on a certificate of deposit from a bank, a 5 percent return on a corporate bond, and a 15 percent return on junk bonds. Usually, the higher the risk, the higher the required rate of return. That is the exact nature of the rate of return department store example provided in figure 13.1. The discount rate is the basis for present value factors, which are used to discount a stream of future benefits to their present value.

On occasion, valuation analysts use other terms of art (such as *opportunity cost of capital*, *alternative cost of capital*, or *weighted average cost of capital* [WACC]) instead of the term discount rate. Regardless of what term is used, discount rates are supposed to reflect the required rate of return related to the benefit stream being discounted, given the risks associated with the benefit stream. One such risk element is the investor's ability to receive the benefit stream that is being forecast as part of the valuation. A company with a steady track record of earnings and distributions will generally be considered less risky than a company that has had a volatile past.

Discount rates are determined by the market. They will vary with time, even for the same investment. This is easily illustrated through an explanation of why the interest rates paid on 30-year Treasury bonds vary. Discount rates take into consideration the inflationary expectations of the future benefit stream being used. If constant dollar projections are made, the discount rate should not include an inflationary element. The valuation analyst must be consistent!

Discount rates take into consideration the risks in the marketplace and must also include an element that is specific to the valuation subject. These rates are based on the yields available for alternative investments. If an investor can get a 16 percent rate of return on a type of investment that is less risky than the valuation subject, why would he or she accept less than 16 percent? Logically, the investor would not. The discount rate will also depend on the nature of the future benefit stream being reduced to the present value.

## Factors That Affect the Selection of a Discount Rate

Factors that affect the selection of a discount rate are considered to be external (noncontrollable) and internal (controllable) to the valuation subject. The external factors are those over which the owners or managers of the business have no control. For example, general economic conditions and the economic outlook at the valuation date are considered to be external factors that affect the selection of the appropriate rate. The nature and economic condition of the industry within which the business operates, as well as the market served by the enterprise, are also considered to be external factors.

Market perceptions regarding similar investment opportunities is another example of an external factor that is beyond the control of the owners. The sources and availability of capital to finance operations is yet another example. These items are important to the willing buyer and should be considered by the valuation analyst.

Internal factors are those that the owner or owners of the business have some control over. The financial condition of the valuation subject is one example. The earning capacity of the company is another. This includes the level and quality of the earnings or cash flow of the company. The ability of the company to obtain the goods and services it needs to produce its products is also considered an internal factor; this is clearly within management's control. The ability to bring the products to an available market is also a burden that rests with management. The quality of the management team running the company is another factor that the valuation analyst should consider.

Another internal factor is the quality of the available data. High quality data is usually the result of a good accounting system with proper controls. The ability of management to meet its budgets, forecasts, and projections reflects on the quality of management.

Regardless of the internal or external factors, discount rates are driven by risk. In the discussion that is about to take place, I will be telling you more about discount rates. Keep one important point in mind—discount rates are derived from the market based on the risk associated with comparable types of investments. Apply all the fancy formulas or methodologies that I will discuss, and even others, but the bottom line is that the result has to make sense. If the analyst is a finance nerd, he or she may choose to use some extravagant formulas from a finance textbook to properly calculate the discount rate but end up with the wrong answer. The valuation analyst should not try to impress the client, the attorney, or the judge with his or her ability to develop discount rates. It's the value that counts!

## Components of a Discount Rate

There are many different ways to derive a discount rate. In this book, I will attempt to address several of them, but you must recognize that these are not all inclusive. The most common methods used to develop discount rates include the following basic components: (1) the risk-free rate of return, (2) the equity risk premium (ERP), (3) the size premium, and (4) the company-specific risk premium. Sometimes, the size premium is considered to be part of the company-specific risk premium. Another component that is sometime shown separately is an industry risk premium (IRP). The use of a premium is often seen when a build-up method (soon to be discussed) is used. An example of the components of a discount rate is provided in table 13.1.

**TABLE 13.1 Components of a Discount Rate**

Risk-free rate	5.0%
ERP	7.0%
Size premium	6.0%
Company-specific risk premium	3.0%
<b>Discount rate</b>	<b>21.0%</b>

Each of these components will be discussed. It is important to recognize the concepts that are being discussed and not get caught up on plugging numbers into a formula. Each of the following components will be used to build up to the required rate of return that is applicable for the benefit stream that is going to be discounted to present value.

## Risk-Free Rate of Return

The risk-free rate of return is sometimes known as the *safe rate* or the *cost of money*. In theory, this is the minimum return that an investor would accept for an investment that is virtually risk free. It is the pure cost of money plus the rate of inflation anticipated by those who deal in these types of transactions. What this really represents is the minimum rate of return that an investor should accept because he or she can earn this amount with reasonable safety instead of risking an investment in a closely held company.

The risk-free rate and the ERP are interrelated concepts. All ERP estimates are, by definition, developed in relation to the risk-free rate. The first step in developing a discount rate is to estimate a benchmark rate of return on equity capital; that is, a risk-free rate plus ERP. The practice developed to separate the expected return on equity capital into two inputs because data was typically used from prior periods to estimate the ERP. That data was derived from observed returns on stocks during differing periods of inflation. The practice developed to subtract the then current risk-free rate from the observed returns on stocks to adjust for the different inflationary environments over time. This historic ERP data became the basis for estimating a current discount rate by adding the current risk-free rate. The risk-free rate plus ERP estimate, in theory, serves as the basis for a benchmark rate of return on equity capital, given the current inflation environment embedded in the risk-free rate. Thus, the ERP is the extra return investors expect as compensation for assuming the additional risk associated with an investment in a diversified portfolio of common stocks, compared to the return they would expect from an investment in risk-free securities as of the valuation date where the risk-free securities serve as the mechanism to adjust for the current inflation expectations.

Sources of risk free rates of return include U.S. Treasury securities. The theory is that U.S. Treasury securities are about as close as we can get to an investment that is risk free. Obviously, there is no such thing as a risk-free security, but the chance of a default by the U.S. government has historically been pretty slim. If our government defaults, we are in more trouble than just understanding business valuation theory!

The alternatives available in Treasury securities are short-term, intermediate term, and long-term securities. The longer term bonds are considered to have an inflationary risk built into them, which explains why long-term bonds pay a higher rate of interest than short-term investments. So, in a perfect world, we might want to use short-term Treasury bills for a risk-free security. However, as I have stated numerous times throughout this book already, this is not a perfect world. The problem with using short-term Treasury bills is that over the long term, the rate of return that an investor would get is unknown because of the constantly changing interest rates. Therefore, we tend not to use short-term bills as the proxy for the risk-free rate in a business valuation assignment.

More often than not, long-term rates are used to simulate the long-term holding period of a closely held business. The 20-year bond (actually, it is a composite rate for bonds that have 20 years until maturity) is frequently used, although the 30-year bond has been used as well. Although the difference between the 20- and 30-year bond yields has been pretty small, the 20-year bond yield is most often used. The 20-year bond has become popular among valuation analysts because of the fact that many valuation analysts have used the ERP data published by Duff & Phelps (D&P) (published by Morningstar/Ibbotson Associates before 2014), and these are based on 20-year bonds. I will explain more about this in a little while.

Other sources of risk-free rates can be used as well, although few can give the true feeling of being risk free. Assuming that our government is risk free is as much of a leap of faith as I am generally willing to take. Some valuation analysts believe that they can use high quality corporate bonds as a risk-free rate, but they are usually not considered to be as good as Treasury bonds.

Intermediate term rates (from 1–10 years) are sometimes used when the expected holding period of the investment is short. Treasury notes can be used in this instance. Others prefer short-term rates (1 year or less), such as those on U.S. Treasury bills. These are considered to be the safest of the investments because the nature of a short-term vehicle is that it is less affected by inflationary expectations and the risk associated with the investment. However, short-term rates tend to have a greater degree of volatility than long-term investments. If more of an explanation is required about this stuff, read a finance textbook. It is guaranteed to put

anyone to sleep at night (unless, of course, one has a finance background)! Another application in which the valuation analyst may determine a discount rate using an intermediate term rate is when calculating the present value of lost profits in an economic damage analysis. This will be discussed more in chapter 26.

The selection of a long-term, intermediate term, or short-term rate will depend on the investment horizon implicit in the asset being valued. Closely held businesses are generally purchased with the intent of a longer holding period and should involve longer term rates in deriving the discount rate. On the other hand, a contract right with a life of three years must be properly matched with the proper risk-free rate.

Fluctuations in U.S. treasury rates have caused valuation analysts to rethink the manner in which risk-free rates should be assessed in recent years. The general thought process is that the recent lower rates are an aberration; therefore, the valuation analyst should deviate from the conventional theory and use something other than the yield on Treasury securities. Since the financial crisis of 2008, the market saw a broad movement of capital from riskier equity and debt investments to higher quality U.S. Treasury securities. The so-called “Great Recession” and subsequent period of weak recovery were marked with high volatility in the stock market, a very high level of uncertainty regarding future economic growth, and a low interest rate environment. As investors flocked to U.S. Treasury securities, yields on these securities declined significantly. A decline in Treasury yields would result in a lower discount rate, right? Wrong. A lower discount rate equates to a lower level of perceived risk associated with an investment and, thus, a higher value. Intuitively, given the high risk associated with equity investments at the time, discount rates should have increased!

Many valuation analysts argue that the risk-free rate should be adjusted to a more “normal” yield, whereas others argue that the proper adjustment for increased risk outside of each component of the build up is in the company-specific risk premium. Just remember that by building up to an equity discount rate, we are not attempting to measure each separate component on a stand-alone basis. Ultimately, it is the aggregate cost of equity capital that needs to be right and make sense.

With that being said, there are certain individuals who believe that the adjustment for the increased risk during periods of abnormal risk-free rates should be an adjustment to the ERP, not the company-specific risk premium.

The feeling is that this risk affects all stocks. The valuation analyst must decide how he or she wants to deal with this issue. There is no single way that the valuation profession deals with it.

Personally, because I perform most of my valuation work in a litigation context, I am a fan of using the rates that are published by credible sources that use the more traditional methodologies, rather than changing the rates to an unsupported rate that could have my opinion challenged in court. However, the much lower rates require me to make an adjustment somewhere in my rate.

## Equity Risk Premium

The equity risk premium (ERP) is the rate of return investors receive as compensation for the risk of common stocks *in excess of* the rate of return received on the risk-free security. The general formula for the ERP is as follows:

$$ERP = E(R_m) - R_f$$

Where

$$\begin{aligned} R_m &= \text{Return on the stock market} \\ E(R_m) &= \text{Expected return on the stock market} \\ R_f &= \text{Risk-free rate of return} \end{aligned}$$

The ERP is supposed to be forward-looking. However, the most commonly used methods to determine the ERP rely on historical data. Using historical data, as compared to forecasted data, has certain advantages and disadvantages. This is also true about forecasted data. Some of the more obvious advantages and disadvantages of each are included in box 13.1.

**BOX 13.1****Advantages and Disadvantages of Historical and Forecasted Data****Historical Data:**

- *Advantage:* The data is objective and easy to find.
- *Disadvantage:* The past may not reflect the future. Different measurement periods produce significantly different results. Research suggests that what actually happened in the past differed from the expectations at the starting point.

**Forecasted Data:**

- *Advantage:* Theoretically, this is closer to what we are actually trying to determine, investment expectations as of a particular point in time.
- *Disadvantage:* Forecasts are clearly more subjective. Different forecasters and different models produce a wide range for the ERP.

The ERP takes into consideration market perceptions and the expectations of a broad measure of the market. For example, if the valuation subject's industry is returning 17 percent on equity, an investor in the subject company would expect to receive the same 17 percent, all other factors being equal. After all, why would someone be willing to accept less than what they could get from an equally desirable substitute? We have already discussed this point, so let's keep going.

Valuation analysts have been attempting to develop alternative ways to determine the ERP. Some methods look at the entire market, but others look at only segments of the market. Standard & Poor's (S&P's) industry studies include indexes that show how different industries have performed. These and other studies are being used to differentiate between returns on equity, which are calculated based on the book value of companies (primarily tangible assets), and hypothetical returns, as if the intangible values of the companies were included in the calculation. Direct market comparison methods are used to suggest that other investments in the marketplace may provide an indication of the risk associated with a closely held business. Some valuation analysts believe that comparing low quality bonds with stocks may better equate to the risk of a closely held stock.

The ERP for corporate equity securities can be obtained from various sources. D&P publishes several estimates of ERP in the annual *Valuation Handbook—U.S. Guide to Cost of Capital*.<sup>1</sup> Before 2014, a commonly referenced source was the *Stock, Bonds, Bills and Inflation (SBBI®) Annual Yearbook, Valuation Edition* (Morningstar/Ibbotson). The *Valuation Handbook—U.S. Guide to Cost of Capital* continues and expands on the data series formerly published in the *SBBI® Valuation Edition*, replicating that methodology. D&P will continue providing ERP data in 2018 and in future years.

The *Valuation Handbook* includes two sets of data: the data previously published in SBBI, which consists of investment returns for several types of financial assets since 1926, as well as the data formerly available in the *D&P Risk Premium Report*. To try to make this less confusing, I will primarily be discussing the *Valuation Handbook* and not SBBI. Keep in mind that the *Valuation Handbook* is a continuation of SBBI, with some differences that I will address. The *Valuation Handbook* also incorporates the *Risk Premium Report*, and I will discuss this further, as well. If you feel the need to learn about SBBI, read an older edition of my book. Business valuation analysts are generally interested in the information relating to risk-free returns, market equity returns, small company stock premiums, and the calculated differentials among them. The *Valuation Handbook* provides this data for the valuation profession.

It is worth noting that Morningstar continues to publish its *Ibbotson SBBI Classic Yearbook* (SBBI Classic), which contains much of the same rate-of-return data that the valuation edition provided. However, SBBI Classic is geared towards a much broader range of professionals, including institutional investors, financial planners, portfolio managers, economists, and corporate executives. It provides an in-depth analysis of how Morningstar calculates the ERP and provides some good insight into economic and market trends that have

<sup>1</sup> Duff & Phelps, *Valuation Handbook—U.S. Guide to Cost of Capital*. As we were going to press with this edition of the textbook, I was informed that this publication and a computerized calculator, soon to be discussed, will be changing the manner in which this data will be delivered beginning in 2018.

affected market rates of return over time. Although I will focus primarily on the *Valuation Handbook* in this chapter, SBBI Classic is certainly worth reading.

The *Valuation Handbook* contains a comprehensive compilation of data relating to the ERP. The historical, or unconditional, ERP is measured as the arithmetic mean of the total historical return on stocks less the arithmetic mean of the income only return on long-term government bonds. So, what does this mean? One of the differences between the *Valuation Handbook* and SBBI is that the *Valuation Handbook* presents this data from 1926, as SBBI did, as well as from 1963. For example, the 2016 edition of the *Valuation Handbook* measures the returns through the end of 2015. So, in this case, the average returns will be calculated for a 90-year and a 53-year period, respectively.

The *Valuation Handbook* uses the S&P 500 as a basis for the return on the entire market. The general feeling is that these large cap stocks make up the bulk of the market and serve as a good proxy for the overall market. Historically, these returns have been about 11.5 percent. However, the S&P 500 is not the only basis for this return. Morningstar provides alternative measures of the ERP in SBBI Classic using the Total Value Weighted NYSE and the NYSE Deciles 1-2 as alternatives for the S&P 500. To put this into perspective, the 2014 edition of SBBI Classic reflects long horizon ERPs of approximately 7.0 percent, 6.8 percent, and 6.2 percent, depending on which index is used. The S&P 500 provides the highest. The income returns from long-term Treasury bonds for the same 88-year period have been about 5.1 percent. Therefore, the calculation of the ERP would be  $12.1\% - 5.1\% = 7.0\%$ . This is another reason for possibly purchasing the SBBI Classic in addition to the *Valuation Handbook*.

Although the historical data was once considered to be the greatest source of information on the ERP, it has also been the target of criticism. First, the ERP has come under attack as being too high. I do not plan to go into the various articles that have been written on this subject, but the valuation analyst needs to be aware of the controversy. Even Roger Ibbotson, the founder of Ibbotson Associates (past publisher of SBBI) has written articles stating that the historical ERP data is overstated. Imagine that, Ibbotson criticizing Ibbotson data! Ibbotson wrote an article<sup>2</sup> with Peng Chen in which the authors applied a new methodology that divided the returns into various economic components, including inflation, earnings, dividends, price-to-earnings ratios, dividend pay-out rates, book value, return on equity, and per capita gross domestic product. What they determined is that a portion of the historical returns on the stocks was attributable to price-to-earnings ratios, which was unlikely to recur in the future. This is referred to as the *supply side ERP*. To make a long story short, the most recent calculation of the supply side ERP is 6.03 percent, compared to 6.90 percent, based on the historical ERP. These rates cover the period 1926–2015.<sup>3</sup>

Okay, so what does this mean to us? Not much! So, let's get this stuff straight. Ibbotson woke up one morning, coauthored an article, and decided that the ERP was overstated. Therefore, the discount rate would be lower because the valuation analyst lowered one of the component parts of it. As a result, the value of businesses just went up. I don't think so. With all of the academics dancing around the issue that the ERP is overstated on a historical basis, the rates of return in the market for a particular investment have not changed. Earlier, I told you to stay focused on what we are really trying to achieve. The principle of substitution and alternative rates of return for similar types of investments are what we are trying to get to. Did that hardware store's value change because the academics have decided that the ERP should be lower? No. Something else would have had to go up to offset this component of the discount rate.

In addition to the supply side ERP reflecting a lower ERP, other controversies have also arisen about this component of the discount rate. Several individuals have questioned whether the use of a geometric mean instead of the arithmetic mean would be more appropriate in determining the ERP. The arithmetic mean tends to be higher than the geometric mean. The *Valuation Handbook* uses the arithmetic mean for calculating the unconditional ERP. Some folks think that this is significant, but I keep going back to the question of what the required rate of return is, given alternatives in the market. Again, who cares?

2 "Long Run Stock Returns, Participating in the Real Economy," *Financial Analysts Journal* (January/February 2003): 88–98.

3 *Valuation Handbook—U.S. Guide to Cost of Capital*, Chicago, 2016.

Another debate is which time period should be used to best measure the ERP. Following the SBBI calculation, the *Valuation Handbook* data begins at 1926, and every year the average returns have been recalculated by adding another year of data. So, the 2016 *Valuation Handbook* contains returns from 1926–2015. Ironically, using shorter or longer time periods results in lower ERPs than the current premium based on 90 years. The range is about 5 percent to 6 percent, rather than approximately 7 percent. Numerous articles support this range. Therefore, many analysts are using the lower range in their valuations. The *Valuation Handbook* uses the 90-year range because the highest quality data is available from the Center of Research in Security Prices (CRSP) at the University of Chicago beginning in 1926.

D&P points out another consideration with respect to the historical time period. Interest rates in the 1940s and the years following World War II may have been abnormally high due to manipulation by the Federal Reserve. From 1942–1951, the U.S. Treasury decreased interest rates to reduce the government's borrowing rates. As expected, the decreased interest rates inflated the realized ERPs during this time period. D&P calculates the average long-term ERP from 1926–2015 (excluding the impact of the ERP from 1942–1951) to be 5.84 percent, rather than 6.96 percent for all years. D&P recommends considering the impact of these years on the ERP.

As if all of this wasn't enough to think about, D&P also provides what they call a "conditional" ERP, which takes into consideration current market conditions and is intended to be a forward-looking rate of return on equity. The *Valuation Handbook* describes these conditions as follows:

[...] both the risk of investments as viewed through the collective eyes of the marginal investors (those investors moving money into and out of investments at a particular date; i.e., those investors setting prices) and the collective risk aversion as viewed through those same marginal investors. For example, the ERP should be greater when uncertainty is greater and smaller when uncertainty is smaller.<sup>4</sup>

Without going into specifics, D&P starts with the historical ERP and adjusts for current economic and market conditions, among other quantitative indicators to estimate the conditional ERP. Because a forward-looking ERP is based on subjective assumptions and adjustments, additional models are considered to corroborate D&P's conclusions. As of the writing of this book, D&P recommended a conditional ERP of 5.5 percent. If you want to read more about how the conditional ERP is estimated, you can refer to the 5th edition of *Cost of Capital* written by Shannon Pratt and Roger Grabowski.

Whatever the valuation analyst ultimately chooses as the ERP in his or her valuations, it needs to make sense. Remember that valuation is a forward-looking process and that this concept does not exclude the cost of capital. The use of historical rates of return essentially assumes that history will repeat itself in the future. Clearly, this is not always the case, so it is helpful to consider more than one approach to determining the cost of capital.

One more very important point should be added here. The ERP does not represent a minority or control position. I continue to see valuation reports that state because the rates of return come from the public market, the results are on a minority basis. This has been a consistent error by those uninitiated in the field of business valuation. If you think back to chapter 9, I said that the market multiples used in the guideline public company method do not determine if the solution is control or minority. Rather, it is the normalized benefit stream that determines if the result is control or minority. The same market is being used for multiples and discount rates. Therefore, if the multiples do not represent minority positions, how can the discount rates? According to D&P:

Some valuation analysts argue that the income approach always produces a publicly-traded minority basis of value because the capital asset pricing model (CAPM) and the build up method develop discount and capitalization rates from minority transaction data in the public markets. This is not correct. The discount and capitalization rates as developed in this book do not include an

.....  
<sup>4</sup> *Ibid*, 3-33.

implied “minority interest” discount in them. There is little or no difference in the rate of return that most investors require for investing in a public, freely tradable minority interest versus a controlling interest.

The Delaware Court of Chancery recognizes that discount rates derived from public company data should not be adjusted for an implied minority discount. The Court of Chancery first rejected this adjustment in 1991 and, except for one anomalous exception, it has continued to reject adding a control premium to valuations where the valuation experts used the discounted cash flow method, a form of the income approach.

Before we go too much farther, you may also be interested in reading the court decision in *Global GT LP and Global GT LTD v. Golden Telecom, Inc.* (Del. Court of Chancery, April 23, 2010). In this dissenting shareholder litigation, Golden’s expert selected 7.1 percent, the long-term historical ERP from Morningstar’s 2008 edition of SBBI, which was based on the historical difference between the average annual return of the S&P 500 index (stocks) and the average annual income return of long-term U.S. government bonds (the risk-free rate) over the selected time period (in this case 1926–2007). The petitioners’ expert, on the other hand, selected an ERP of 6.0 percent “... based on his teaching experience, the relevant academic and empirical literature, and the ‘supply side’ ERP reported in the 2008 Ibbotson Yearbook.” Although this case discussed the use of SBBI, the same issues exist when using the *Valuation Handbook*.

The Court rejected the use of the historical ERP of 7.1 percent and, instead, chose the lower estimate of 6 percent. It cited the “... wealth of recent academic and professional writings that supports a lower ERP estimate...” that were put forth in the hearing. The Court went on to say that the “...relevant professional community has mined additional data and pondered the reliability of past practice and come, by a healthy weight of reasoned opinion, to believe that a different practice should become the norm...”

The Court continued:

... to cling to the Ibbotson Historic ERP blindly gives undue weight to Ibbotson’s use of a single data set. 1926 might have been a special year because, for example, that was the year when Marilyn Monroe was born, but it has no magic as a starting point for estimating long-term equity returns....

So, we now know that the ERP and, therefore, the discount rates, are neutral with respect to minority or control. Okay, enough of this techno-premium babble. It is killing me. The value of the local hardware store has still not changed because of the ERP, so let’s move on to other exciting stuff.

## Size Premium

In addition to the overall ERP, a type of premium that is generally considered by the valuation analyst is the size premium (also sometimes referred to as the small company risk premium). This is frequently considered to be part of company-specific risk but is very often separately stated. The *Valuation Handbook* provides information about returns for small company stocks and provides two methods to determine the size premium. First, it replicates the method formerly published in SBBI based on the market capitalization of the equity of public companies using the CRSP data. The second method is based on D&P’s *Risk Premium Report* (formerly a separate publication), which considers the market values of equity and invested capital, book value of assets and equity, number of employees, sales, net income, and EBITDA. We will address the *Risk Premium Report* in a little while.

The *Valuation Handbook* indicates that the returns for smaller companies have been greater than those of the larger companies. This means that an investor who makes an investment in a smaller company should look for a higher return based on this market data. Size may have something to do with it. Obviously, there are many other factors that cause smaller companies to be at greater risk than larger companies.

The *Valuation Handbook* breaks up the reported data into 10 deciles based on the market value of equity. The 9th and 10th deciles are used to measure the small companies in the market. The total market capitalization of public companies in these deciles through December 31, 2015, was \$256,235,720,000. With 1,290 companies included in this group, the average company market capitalization is \$198,632,342. Clearly, these companies are still much larger than many of the companies that we value on a routine basis.

In 2001, SBBI divided the 10th decile into a 10a and 10b category. Some valuation analysts prefer to use the 10th decile, whereas others have tried to use the 10b portion. In many informal polls (in which people such as Jim Hitchner or myself were giving speeches and asked a question of the audience—very informal and, as you should now know, not statistically valid), the vast majority of practitioners seem to agree that using the 10b data is not very good. These companies seem to be very volatile, and the returns may reflect many things besides size. The data does not exclude rate-of-return data for companies that are speculative or distressed.<sup>5</sup> These types of companies would certainly reflect premiums as part of their returns to account for risks other than size.

In the 2010 edition of SBBI, the 10a category was further subdivided into 10w and 10x and the 10b category into 10y and 10z. This is starting to become alphabet soup! According to SBBI, 10w, 10x, 10y, and 10z exhibit the same trends that the deciles 1–10 and 10a and 10b categories show: that size premiums increase as companies become smaller. However, the same issue that arises with the 10b size grouping also applies to the 10y and 10z categories. The *Valuation Handbook* identifies several of these issues:

- The betas used for calculating the size premium for subdecile 10y and subdecile 10z generally *understate* the beta and, therefore, *overstate* the size premium.
- Subdeciles 10y and 10z are populated by many large (measured by total assets) but highly leveraged companies with small market capitalizations that probably do not match the characteristics of financially healthy but small companies.
- There are companies with no sales included in the data (for example, speculative startups).
- Stocks of troubled companies included in the data (companies with negative returns on the latest fiscal-year book value) probably are trading like call options (unlimited upside, limited downside).<sup>6</sup>

Clearly, there are issues that exist with the 10b, 10y, and 10z size categories. When you consider the fact that many analysts do not rely on the 10b size premium, the valuation analyst should be extremely cautious about using the 10y and 10z data. D&P recommends that analysts ensure that the companies within the subdeciles are comparable to the subject company. D&P explains that the size premium measures *systematic* risk priced by the market. By developing a discount rate using the size premium, we assume that the subject company has the same systematic risk as the broad portfolio of small companies in the public market. (I have not explained systematic risk yet, so let's keep it simple at this point and say that it is the volatility of the company's stock in relationship to movements in the stock market overall.) This is highly unlikely because a particular company's industry alone may make that company more or less risky than the broad composite of small companies.

Another factor that could cause the return data for the small public companies to be skewed is a low trading volume. Remember a long time ago when you read Revenue Ruling 59-60 and the eighth factor had to do with using the market price of stocks that were actively traded? Thinly traded stocks may not provide good data for measuring stock market returns either.

One word of caution: If the valuation analyst uses the various deciles for calculating a size premium, he or she must make sure to read the materials in the book. The valuation analyst needs to make sure that he or she understands what data should be used. The *Valuation Handbook* provides size premiums that are beta-adjusted. D&P describes this as follows:

A “beta-adjusted” size premia has been adjusted to remove the portion of excess return that is attributable to beta, leaving only the size effect's contribution to excess return. The size premia in both studies are calculated in essentially the same way – as the difference in historical portfolio excess returns (i.e., what actually happened), and the excess returns that CAPM would have predicted. Excess returns are defined here as portfolio returns over and above the risk-free asset's returns.<sup>7</sup>

<sup>5</sup> Pratt and Grabowski, *Cost of Capital*, 5th Ed., Wiley, 2014: 337.

<sup>6</sup> *Valuation Handbook—U.S. Guide to Cost of Capital*, 2016: 44–15.

<sup>7</sup> *Ibid.*, 7–8.

This means that D&P has made an adjustment to the size premium to isolate the premium associated with size. The *Valuation Handbook* uses three beta-adjustments: ordinary least squares (OLS) regression, sum, and annual beta. The results are different depending on which data are used. D&P states the following:

First, we calculated sum betas. Smaller companies generally trade more infrequently and exhibit more of a lagged price reaction (relative to the market) than do larger companies. One of the ways of capturing this lag movement is called “sum” beta. Sum betas are designed to compensate for the more infrequent trading of smaller company stocks.

Second, we calculated betas based on annual return data (rather than monthly data).

Both of these methods appear to correct for the low beta estimates of smaller companies. The sum beta estimates are greater for smaller companies than OLS betas, which are derived using non-lagged market benchmark data. The annual betas are also greater for smaller companies than the betas derived using monthly return data. The net result of the *greater* sum betas (or greater annual betas) is *smaller* size premia.<sup>8</sup>

So, what does all this mean? I wish I knew! This is much more complicated than when I wrote the first edition of this book. In short, it means that the type of beta used to derive the size premium needs to be appropriate for the subject company and the methodology used by the valuation analyst. Whichever is chosen, the beta used with CAPM needs to be consistent with the size premium used in the build-up method. Be patient, and we will discuss CAPM and the build-up methods shortly. Hopefully, it will start to make a little more sense then.

You should also be aware that the selection of the size premium has been criticized in the courts. In *Re Sunbelt Beverage Corp.* (shareholder litigation decided in the Court of Chancery of the State of Delaware) in January 2010, two experts utilized the SBBI data to develop discount rates. The plaintiff’s expert elected to use the micro-cap (combined 9th and 10th deciles) category size premium, whereas the defendant’s expert used the 10th decile data. In this case, the selection of the size premiums resulted in differing values that placed Sunbelt Beverage Corporation within either the micro-cap grouping or the 10th decile. The court identified this circularity with the following statement:

...a discounted cash flow analysis both *values* the size of a company (and thus points to the appropriate Ibbotson premium to use) and *relies* on the appropriate Ibbotson premium to determine the value of the company. This process is circular; which should come first, the valuation of the company or the selection of the Ibbotson risk premium?<sup>9</sup>

The court continued

There must be some independent basis of value used for determining the propriety of applying a risk premium from the Ibbotson table, particularly when, as appears to be the situation here, the company’s valuation may actually place the company close to the line between deciles.<sup>10</sup>

This judge really got it. This was the first time that I saw a judge recognize the circular logic behind what we do. Although the defendant’s expert’s use of the 10th decile was selected through an independent determination of value (a transaction-based approach), the court had “several concerns about the methodology and factual information underlying the comparables analysis” and determined that the micro-cap grouping was more appropriate. The micro-cap grouping accounts for the fact that the company’s determined market value may place it within the 9th or 10th decile.

What does this tell us? Well, it tells us that when we select a size premium, we need to be able to support our conclusions. If the valuation analyst is able to determine market value through a market-based approach and have good guideline companies or transactions, he or she can likely use that value to assist in the selection of a size premium. However, the valuation analyst always needs to be prepared to defend the methods used.

8 *Ibid.*, 4–9.

9 Del. Ch. Consol C.A. No. 16089-CC, January 5, 2010: 29.

10 *Ibid.*, 30.

**Author's Note**

Although this case discussed SBBI, the concept applies to the deciles and portfolio groupings (in the *Risk Premium Report*) provided in the *Valuation Handbook*. Pay attention to the fact that the selection of the size premium may be circular because it could have a material impact on the valuation conclusions.

With all the discussion about the individual components of the discount rate, don't lose sight of what we are trying to accomplish. We are trying to determine the overall discount rate applicable to the subject company, not the individual components of a discount rate. The valuation analyst should not spend an exorbitant amount of time making sure that the components of a discount rate are defensible just to discover that the overall discount rate does not make sense. When we develop discount rates, we try to use as many alternate methodologies as possible to confirm that the overall discount rate is reasonable (we will discuss other methods to determine a discount rate in this chapter). At the end of the day, if the discount rate makes sense and the assumptions behind each

component tie together, the valuation analyst is probably on the right track. However, if the components are wrong but the discount rate is correct, the analyst got lucky.

## D&P Risk Premium Calculator—CRSP Deciles Data

**Author's Note**

Although I have referred to this tool as the D&P Risk Premium Calculator, the name of this product has actually changed to the Risk Premium Toolkit. However, this may be confusing if you already subscribe to the current Toolkit. Be aware that the name of the Risk Premium Calculator is now the Risk Premium Toolkit.

In 2014, D&P created a new Internet-based risk premium calculator that uses the CRSP decile data contained within the *Valuation Handbook*<sup>11</sup> and previously used by SBBI. This tool is available through Business Valuation Resources (surprise, surprise!) and essentially fills in the data needed for a traditional build-up method. It is simple to use and can be accessed at [www.bvmarketdata.com/DP.RPC.CRSP/](http://www.bvmarketdata.com/DP.RPC.CRSP/) by subscription. Let's walk through this calculator. The initial input screen is shown in figure 13.4.

**Figure 13.4**

CRSP Decile Size Study:

(Source: Duff & Phelps Risk Premium Calculator.)

This screen is simple because all that is needed is the company name and valuation date. If a valuation date earlier than January 1, 2014, is entered, the calculator will not function. Instead, the appropriate edition of SBBI should be used. We filled in our information and pressed “next” to arrive at the screen shown in figure 13.5.

<sup>11</sup> Duff & Phelps has been providing U.S. cost of capital data through the data exhibits published in the *Valuation Handbook—U.S. Guide to Cost of Capital* and through the Risk Premium Toolkit (formerly the Risk Premium Calculator) since 2014 (data through year-end 2013). Duff & Phelps is planning on changing the way it distributes data beginning in 2018.

(Source: Duff & Phelps Risk Premium Calculator.)

Near the top, we can select the type of ERP. Although we have selected the long-term historical ERP for this example, you can also choose from the supply-side ERP, D&P's recommended ERP, or input your own. Next, input the risk-free rate, beta (if you have one), and select the pertinent industry. The IRP will automatically be pulled into the calculator from the *Valuation Handbook* and calculated. We will discuss industry risk as a separate section in this chapter. The second portion of the screen involves selecting the appropriate size decile based on the market value of equity. In this case, the subject company is very small, so we selected the 10th decile. We click "next" and see a confirmation screen. At this point, the valuation analyst should check his or her inputs and make any necessary changes. Then, click "next" and the calculator will provide you with the results, as shown in figure 13.6.

General Inputs: Values as of the January 1, 2014 valuation date.

Subject Company:	Valuation Date:	Equity Risk Premium (Rpm):	Risk-free Rate (RF):	Beta <sup>1</sup> (β):	Source of risk premia information in this report: <sup>2</sup>
Nursing Home	January 1, 2014	6.96%	4.00%	NA	2014 Valuation Handbook - Guide to Cost of Capital

Industry Risk Premium (RPI) Calculations:<sup>3</sup>

Selected SIC Code:	SIC Short Name:	Full Information Beta (FIB):	Industry Risk Premium (RPI):	RPI Calibration RPI = (FIB x Rpm) - Rpm
8051	Skilled Nursing Care Facilities	1.87	6.06%	6.06% = (1.87 x 6.96%) - 6.96%

Size Premium (RPs):

Selected CRSP Decile:	Market Capitalization of Smallest Company (in millions)	Market Capitalization of Largest Company (in millions)	Size Premium (RPs):
Decile 10-Smallest	\$2.395	\$338.829	5.99%

Summary of Cost of Equity (COE) Estimates:

COE subject company	Buildup COE Estimate	CAPM COE Estimate
Nursing Home	23.0%	Not Calculated

<sup>1</sup> NA = Value not entered by USER.  
<sup>2</sup> If Beta not entered, COE estimates using CAPM, which uses a Beta as an input, cannot be calculated.  
<sup>3</sup> If SIC Code not entered, COE estimates using Buildup, which uses an industry risk premium as an input, cannot be calculated.

(Source: Duff &amp; Phelps Risk Premium Calculator.)

The calculator provides the option to download the results into a Microsoft Excel or Word document or receive the results in an email.

In this instance, the CRSP calculator estimated the cost of equity at 23.0 percent. Notice in figure 13.6 that the IRP is calculated based on the ERP that was selected.

### D&P Risk Premium Report

As was previously mentioned, the *Valuation Handbook* contains another study: the *D&P Risk Premium Report*, which was previously a separate publication issued by D&P and has gained in popularity. This study has also been called the Grabowski- King Study (named after the original authors), the Pricewaterhouse Coopers (PWC) Study (because Grabowski and King worked for PWC), and the S&P Study. The *D&P Risk Premium Report* expands the ERP analysis into more subsets of the market.

This study has been a terrific addition to the cost of capital data used by valuation analysts. A comparison between the *Valuation Handbook* and the *Risk Premium Report* is contained in box 13.2.

**BOX 13.2****Comparison of the Valuation Handbook and *Risk Premium Report*****Valuation Handbook**

Addresses returns on investments in publicly traded securities based on size.

Segments NYSE securities<sup>1</sup> into deciles based on equity capitalization.

Analyzes arithmetic returns, betas, and real returns in excess of risk-free rate.

**Risk Premium Report**

Addresses returns on investments in publicly traded securities based on size.

25 size groups.

D&P utilizes NYSE, AMEX, and NASDAQ data<sup>2</sup> starting in 1963.

“High financial risk” securities analyzed in a separate portfolio.

Seven size metrics in addition to equity capitalization.

1 NYSE Companies back to 1926 excluding closed-end mutual funds, American Depository Notes, unit investment trusts, and Americus Trusts.

2 Excludes American Depository Notes and non-operating holding companies.

According to the *Risk Premium Report*, *high financial risk* has been defined as companies that

- are in bankruptcy or liquidation,
- have five-year average net income of less than zero,
- have five-year average operating income of less than zero,
- have negative book value of equity, or
- have debt to total capital greater than 80 percent.

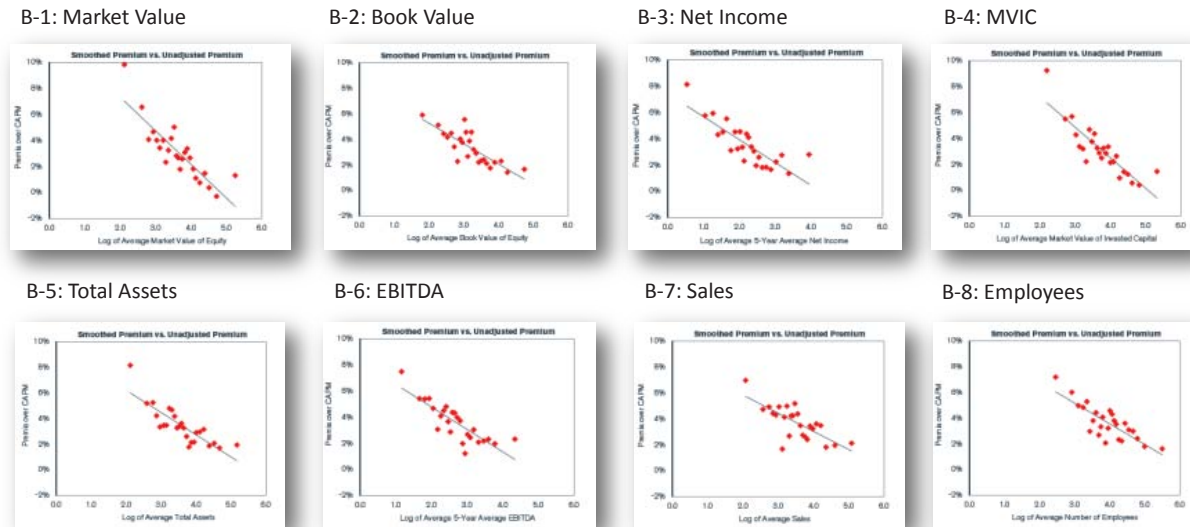

D&P segregates the returns from this group of companies in an attempt to better reflect the market.

Rather than solely relying on market capitalization, D&P breaks down its analysis by the following metrics:

- Market value of equity
- Book value of equity
- Five-year average net income
- Market value of invested capital
- Total assets
- Five-year average EBITDA
- Sales
- Number of employees

The trend line of the *Valuation Handbook* and *Risk Premium Report* ERPs look fairly similar. They clearly move in the same direction, indicating that smaller companies have larger premiums. Even if all the other metrics in the *Risk Premium Report* are graphed, the trend is in the same direction. This is shown on the following page.

The *Risk Premium Report* contains a variety of tables with data that can be used by the analyst in the application of the build-up method or the CAPM (both methods will be discussed in this chapter).

Back in the days when we didn't have access to an online calculator from D&P and Business Valuation Resources (to be discussed shortly), the risk premium had to be calculated in a spreadsheet program. Because it is important to understand the mechanics of the calculator, I will provide a brief background on how to use the *Risk Premium Report*. The authors of the *Risk Premium Report* recommend using the smoothed average ERP. The smoothing process uses the arithmetic ERP and, through mathematical regression, "takes the noise out." Using 25 data points in the smoothing process provides more statistically reliable results. With these results, we are able to run a regression analysis for companies smaller than the ones presented in the data. The tables included in exhibit A of this study allow us to calculate a size-adjusted ERP specifically for a subject company. With that being said, I want to make sure that the terminology does not get too confusing. Some readers may be confused by what is called the *risk premia over the risk-free rate* found in exhibit A (and used in the build-up method) and what I refer to as the

*Size-adjusted ERP* for possibly two reasons. First, when some folks hear something described as "XX-adjusted," they think that the effect of XX has been controlled (in other words, removed). The risk premia over the risk-free rate in exhibit A are designed to reflect size and market risk; size is included. Also, *ERP* is used to mean the traditional *equity risk premium* as discussed in other parts of the chapter.

The *Risk Premium Report* can be used in two ways. First, we can determine which of the 25 size portfolios for each size metric the subject company belongs in. We can also obtain the smoothed average ERP for as many of the metrics as possible and simply average them to determine the results. Recognizing that even those companies that are in the lowest 25th percentile of the market are still larger than the subject company in many instances, we are able to use this data and build on it to make it relevant to the subject of a particular valuation assignment. That brings us to the second method, which is to use the regression equation shown in the panel on the right side of the tables included in the *Risk Premium Report*. Each size metric provides a regression equation, which will calculate a size-adjusted ERP that is based on the size metric of the subject company. In other words, it is generally considered to get the valuation analyst closer to the size-adjusted ERP appropriate for the subject company.

The beauty of using the regression equations is that there will be no need to include an additional size adjustment in the company specific risk premium. The CSRPs are the one part of a discount rate that truly is challenged more than any other part, and I will discuss this in greater detail soon. For now, consider the fact that the *Risk Premium Report* allows us to derive a smaller company specific risk premium. That is an excellent thing!

Another part of the *Risk Premium Report* that I really like is the separation of the ERPs for high risk companies. This data can be used for valuations of troubled companies or companies that have filed for bankruptcy protection. The ERP ends up being about twice the range of the *Valuation Handbook* data for the overall market.

The *Risk Premium Report* exhibit A tables are applicable to the build-up method. The exhibit B tables are applicable to developing a size premium when using the CAPM. In the CAPM, the size premium is completely separated from the ERP. I will explain more about this when I discuss CAPM. Note, however, that in the build-up method a size-adjusted ERP is actually being calculated. In CAPM, the ERP and the size premium are separate and must remain that way.

A word of caution is needed before using the *Risk Premium Report* data. The *Risk Premium Report* uses historical risk premiums in its analysis. When using the exhibit A tables, an adjustment needs to be made to convert the determined ERP from a historical to a forward-looking basis. D&P suggests that this adjustment be completed using the following formula:

$$\text{ERP Adjustment} = \text{Expected ERP} - \text{Historical ERP}$$

D&P has recommended various levels of ERP over time. Estimated ERP for U.S. investors with returns in U.S. dollars are as follows:

November 15, 2016

December 1, 2009 – May 31, 2010	Spot 20-year U.S. Treasury yield	Spot	5.50	ERP
June 1, 2009 – November 30, 2009	Spot 20-year U.S. Treasury yield	Spot	6.00	$R_f$
<a href="#">December 31, 2008</a>	<a href="#">Normalized 20-year U.S. Treasury yield</a>	4.50	6.00	
November 1, 2008 – May 31, 2009	Normalized 20-year U.S. Treasury yield	4.50	6.00	$R_f$
October 27, 2008 – October 31, 2008	Spot 20-year U.S. Treasury yield	Spot	6.00	ERP
January 1, 2008 – October 26, 2008	Spot 20-year U.S. Treasury yield	Spot	5.00	Initialized

"Normalized" in this context means that in months where the risk-free rate is deemed to be abnormally low, a proxy for a longer-term sustainable risk-free rate is used.

(Source: Duff &amp; Phelps.)

In the preceding data, D&P recommends a 3.5 percent ERP from November 15, 2016, until further notice. It is important to note that this decision was made with data available as of that date.

However, the expected ERP can be substituted with the analyst's own forward-looking ERP. If the valuation analyst uses his or her own expected ERP, the analyst must make sure to be consistent in applying that ERP throughout the discount rate (in other words, IRP adjustment). This adjustment is recommended by D&P every time the exhibit A tables are used but should not be applied when using the exhibit B tables.

It is also important to note that the *Risk Premium Report* excludes financial services companies due to comparability issues between industrial companies and the financial sector. For example, banks traditionally derive a significant amount of “sales” from interest income (earned from loans to consumers), whereas in the case of industrial and other sectors, interest income is typically categorized as an “other income” item. In addition, companies within the financial sector often hold higher levels of debt compared to other industries. Finally, the study notes that early data on the financial sector from one of its primary data sources (Compustat) was of poor quality. Thus, D&P does not recommend using its study for financial services companies.

### D&P Risk Premium Report Online Calculator

In 2011, Roger Grabowski and James Harrington developed an Internet-based risk premium calculator (made available exclusively through Business Valuation Resources) that allows users to enter 1–18 total qualitative and quantitative inputs for a subject company. The calculator provides four estimates of the cost of equity considering industry-specific risk if input by the user. The calculator also calculates risk premiums for high financial risk companies (again, depending on inputs by the user). The data and analysis provided in the *Risk Premium Report* is used in the calculator. Thus, the derivation of a discount rate using the tables in the study and a discount rate generated by the calculator should be the same. The calculator is simple to use. Let’s walk through the use of this product. The calculator can be accessed at [www.bvmarketdata.com/DP.RPC/](http://www.bvmarketdata.com/DP.RPC/) (subscription is required). Figure 13.7 shows the initial input screen.

**Figure 13.7**

Duff & Phelps Risk Premium Report:

Is the Subject Company a financial services company (SIC Code 6)?

Financial service companies are excluded from the analysis used to develop the premiums used in the Duff & Phelps Risk Premium Online Calculator, and therefore using the results in the Duff & Phelps Risk Premium Online Calculator (or the accompanying Duff & Phelps Risk Premium Report) to estimate the cost of capital for a financial services company is not recommended.

I understand and wish to override the financial services restriction.

Please note that overriding the financial services restriction is not recommended.

(Source: Duff & Phelps Risk Premium Calculator.)

This screen requires the user to acknowledge if the subject company is a financial services company. As noted, the *Risk Premium Report* excludes all financial services companies from its analysis and is not recommended for use in valuing such entities. If you override the financial services restriction, be very careful in the application of the resulting rate of return. Because our subject company is not a financial services company, we leave the drop-down menu at “no” and click “next” to arrive at the screen shown in figure 13.8.

(Source: Duff & Phelps Risk Premium Calculator.)

In figure 13.9, we have input all the information we have. Under general inputs, the ERP can be left blank. The calculator will automatically fill in the appropriate ERP based on which study you selected in figure 13.7. We did not input a beta in this case because the four publicly traded nursing homes had widely varying betas in the 12 months ended December 31, 2013, and we thought that a resulting CAPM-based discount rate would not be meaningful. The IRP was populated by the calculator by selecting the appropriate SIC code, and we input the D&P normalized risk-free rate (20-year Treasury yield). The inputs for size and risk are actual figures from the subject company on an adjusted basis. These items should exclude any non-operating and nonrecurring items affecting the income statement and balance sheet. D&P recommends inputting as much information as possible. Because no market approach was applied in this particular valuation, we did not have a market value of equity or invested capital to input.

Clicking “next” will result in a confirmation screen. Check the inputs, make any necessary changes, and then click “next.” You should arrive at a screen similar to that shown in figure 13.10.

**Figure 13.10**

DUFF & PHELPS		Risk Premium Calculator			
<b>Cost of Equity Capital Estimates – Summary of all Size Study models</b>					
<b>Models: Buildup 1, Buildup 2, CAPM, and Unlevered COE Estimates</b>					
Subject Company: Nursing Home			A beta was not entered by the USER. A CAPM-based cost of equity estimate, which uses a beta as an input, can not be calculated.		
Valuation Date: 1/1/2014			NA		
Source of risk premia information:		ERP adjustment: an ERP adjustment of 0.1% is added to Buildup 1, Risk Study (Buildup 3), and Unlevered Risk premia to adjust for the difference in the historical ERP (1963–2013) and the ERP entered by the USER, as calculated below:		Adjusted Industry Risk Premium (IRP): an adjusted IRP of 4.4% is used in the 'Buildup 2' cost of equity estimate. The adjusted IRP is calculated by: (IRP entered by the USER) × (the ERP entered by the USER) / (historical ERP (1926–2013)), as shown below:	
Equity Risk Premium (ERP) entered by USER and used in all calculations:	Historical Equity Risk Premium (ERP) 1963–2013:	Long-term risk free rate as of January 1, 2014 (used in all calculations):	5.0%	4.9%	5.0% – 4.9% = 0.1%
			3.7%		6.1% × (5.0% / 7.0%) = 4.4%
Summary of Cost of Equity (COE) Estimates					
<b>Buildup 1 COE Estimates</b>			<b>CAPM COE Estimates</b>		
	$COE = (Risk\ Free\ Rate) + (Smoothed\ Risk\ Premium\ Over\ Risk\ Free\ Rate) + (Equity\ Risk\ Premium\ Adjustment)$			$COE = (Risk\ Free\ Rate) + (Beta \times Equity\ Risk\ Premium) + (Smoothed\ Risk\ Premium\ Over\ CAPM)$	
	Mean	Median		Mean	Median
Guideline Portfolio Method	16.9%	16.8%	Guideline Portfolio Method	No Beta	No Beta

Regression Equation Method	21.5%	22.1%	Regression Equation Method	18.3%	19.1%

(Source: Duff & Phelps Risk Premium Calculator.)

At the top of figure 13.10, the valuation analyst is given the option to download the results into a Microsoft Excel spreadsheet or a Word document or receive the results in an email.

In the middle of the page, a summary of the general inputs shown in figure 13.9 is provided. Note that the IRP was adjusted by the calculator for use with the D&P ERP. We will talk about the adjustment to the IRP later in this chapter.

At the bottom of figure 13.10, the calculator provides average and median costs of equity capital generated by four separate methodologies: build-up 1, build-up 2, CAPM, and the unlevered risk premium. Two different

types of measurement for the cost of equity are provided. The guideline company method ranks the subject company within 1 of the 25 size categories based on each of the 8 size measurements. The regression equation method forecasts the ERP based on a statistical regression of the 25 size categories. This is the same methodology described for the *Risk Premium Report* earlier in this chapter. Thus, the resulting cost of equity under the build-up 1 regression equation method should match the “manual” build up using the *Risk Premium Report’s* exhibit A tables. Build-up 2 incorporates the IRP (adjusted for use with the D&P ERP). The CAPM method, which was not used in our example, uses a beta-adjusted ERP and the exhibit B tables. Don’t worry, I will explain what this means in a little while. Finally, the unlevered risk premium uses the exhibit C tables of the *Risk Premium Report*. The *Risk Premium Report* reflects the existing capital structures of the companies within its data source. The unlevered risk premium assumes a capital structure of 100 percent equity and zero percent debt for all companies. This unlevering reduces risk to the equity holders and, thus, reduces the ERP. Effectively, this puts all the companies on the same playing field by eliminating the difference in debt that could affect risk.

If you recall, the D&P Risk Premium Calculator based on the CRSP deciles generated a discount rate of 23 percent. This compares to the 19 percent to 22 percent output by the calculator using the *Risk Premium Report* data. Why is this different? When considering the inputs, it is evident where the problem is: Our ERP input for the calculator using the CRSP decile data was 6.96 percent, or about 200 basis points higher than the 5 percent used in the *Risk Premium Report* calculator. We ran the calculator using the CRSP decile data again with a 5 percent ERP and ended up with a cost of equity of 19.3, which is within the range of the *Risk Premium Report* calculator. I purposefully input different ERPs into the two calculators to show what happens when the valuation analyst is inconsistent with his or her assumptions. The results did not make sense. Remember that the *Risk Premium Report’s* regression equation method provides us with a size-adjusted ERP that is “custom made” to the subject company’s size inputs. The size premium for decile 10 based on the CRSP data (in 2013) includes companies with market capitalizations up to \$338.8 million. Intuitively, the calculator using the *Risk Premium Report* data should derive a higher cost of equity because it better adjusts for the small size of the subject company.

Consistency is also important if the valuation analyst is completing two valuations as of two separate dates. The valuation analyst needs to understand the differences between the two data sets contained within the *Valuation Handbook* and their differences with previous publications of SBBI and the *Risk Premium Report*. Imagine using the historical ERP from SBBI for one date and then the recommended ERP per the *Valuation Handbook* at another date. “I don’t know” may not be the best answer when a cross-examining attorney is questioning the analyst on the witness stand about the differences in his or her results.

It is also important that the valuation analyst reads the *Risk Premium Report* in its entirety so that he or she understands how the calculator works. None of the four methodologies account for all the risk factors that need to be considered in developing a discount rate. Whatever the analyst does, he or she should not just buy a subscription and blindly plug numbers into the calculator to instantly calculate an ERP without making sure that he or she understands what it is doing. I could open up someone’s head and perform brain surgery, but I don’t think that person would want me to do that without knowing what I am doing.

## Does the Size Risk Premium Still Exist?

Now that I have just explained all there is to know about the size premium (well, maybe not all there is to know, but certainly enough for you to either understand it, be bored with it, or maybe both), let me throw in a new wrinkle to this topic. As with most other topics within the valuation profession, there has been some new research regarding the existence of the size risk premium. Michael Crain CPA/ABV, ASA, CFA, DBA, has suggested that there is no empirical evidence that size is the cause of higher returns. Crain’s research was performed as part of his doctorate program and involved an examination of a number of studies regarding size risk premiums conducted over the last 20 years. However, despite Crain’s research, Grabowski has argued against this. Who said this stuff was going to be easy?

The concept of a size risk premium integrated in discount rates was first introduced in 1981 by R.W. Banz. Banz’s study observed higher returns among smaller companies traded on the New York Stock Exchange between 1926 and 1975. However, subsequent studies have shown that premium returns generated by smaller

companies have either diminished or disappeared entirely. This trend is explained by various changes in the financial markets. First, investors now aware of the size risk premium have bid up the prices of small company stocks and have effectively reduced or negated the premium. Second, the popularity of passive investing in large cap mutual funds reduced capital available to smaller firms prior to 1981, which is no longer the case. Crain believes that these changes have affected the fundamental structure of the financial markets, so pre-1981 data is essentially unusable for justifying size risk premiums.

Some research into the size risk premium has indicated that any premiums related to size are concentrated in the stocks of the smallest companies and have minimal effect on larger firms. Because many small publicly traded companies are often somewhat illiquid, some have suggested that the “size effect” is actually related to illiquidity. Although Crain acknowledges that additional research must be completed in order to fully understand the impact of illiquidity on equity returns, his research raises interesting questions that an analyst should be thinking about when developing discount rates. Stay tuned, and I am sure it will get more confusing.

## Company-Specific Risk Premium

This component of the discount rate provides for the specific risk characteristics of the valuation subject that are not covered by the ERP. The company-specific risk premium can increase considerably depending on the risk associated with the valuation subject. The company-specific risk premium can also be negative. This occurs if the valuation subject is considered to be less risky than its peer group.

This is another part of this book that makes auditors cringe. There is no objective source of data to properly quantify the company-specific risk premium. It is a matter of judgment and experience. There are no mystical tables that a valuation analyst can turn to, nor can the valuation analyst be totally comfortable with this portion of the assignment.

Many of the risk factors that are considered in determining an appropriate discount rate are the same factors that a valuation analyst uses to adjust multiples from guideline companies under the market approach. Although they are a little different, a review is worthwhile. Once valuation multiples are determined for the guideline companies, it becomes necessary for the valuation analyst to adjust these multiples for the qualitative differences between the guideline companies and the valuation subject. These qualitative differences will most likely relate to factors such as expected growth and risks attributable to the valuation subject as compared with the guideline companies. Remember this stuff from a few chapters ago?

To briefly review, the different risk factors considered by the valuation analyst will generally include, but will not be limited to, the following:

- Economic risk
- Business risk
- Operating risk
- Financial risk
- Asset risk
- Product risk
- Market risk
- Technological risk
- Regulatory risk
- Legal risk

There are many other risk factors to be considered as well, but these are some of the more important items that a valuation analyst must think about in the application not only of the market approach but of the income approach. In the market approach, each of these risk factors should be analyzed from the point of view of how the valuation subject differs from the guideline companies. In the income approach, these factors are considered in relationship to the source of the market-derived rates. For example, because guideline companies tend to be in the same industry as the valuation subject, an economic risk, such as rising interest rates, will probably have the same impact on the valuation subject as the guideline companies. But if the valuation subject operates in a smaller geographic area, the risk could be different if that part of the country is doing better or worse than the rest of the country because a larger, more diversified company could reduce its risk by not being concentrated in one area.

## Comparing the Subject Company

Being a valuation analyst is similar to being a risk assessor. Because business valuation theory is so closely related to risk-reward theory, an analyst must spend a considerable amount of time analyzing the subject company to determine how much risk the income stream is subject to. Whether a single period capitalization model or a multi-period discounting model is going to be used in the valuation assignment, the valuation analyst must determine the degree of risk for the earnings, cash flow, or other income stream being analyzed.

How does the valuation analyst do this? The answer is simple. He or she compares the subject company to either guideline companies or, in their absence, other forms of industry or investment information. For example, trade association data or industry composite data, such as information available in MicroBilt Corporation's *Integra Financial Benchmarking Data* product, can be used for this comparison. Information in this type of product allows the analyst to perform a financial analysis of the subject company and compare the results against industry information. This comparison allows the analyst to determine whether the subject company is stronger or weaker than the industry group.

The financial analysis is probably the easier part of the analysis. Frequently, the nonfinancial analysis is the more difficult part of the assignment. Basic contributing factors to this difficulty are listed in box 13.3 and discussed further in the following paragraphs.

Most of these factors should not come as any great surprise. There must be a reason why every valuation textbook and educational course suggests that a valuation analyst look into these items. Revenue Ruling 59-60 addresses many of these items. If the analyst completed a Porter's Five Forces and SWOT analyses, most (if not all) of these factors and their impact on the subject company should already be known.

### BOX 13.3

#### Common Nonfinancial Factor Considerations for Analysis

The following are nonfinancial factor considerations common in risk analysis:

- Economic conditions
- Industry conditions
- Location of business
- Competition
- Depth of management
- Quality of management
- Barriers to entry into market
- Avoid Double Counting

## Economic Conditions

I previously discussed economic risk, so there is little reason to repeat the discussion. However, Revenue Ruling 59-60 emphasizes the economic conditions by discussing the risk associated with "boom" economies. The outlook for the economy should be considered because it will affect most businesses in one way or another.

## Industry Conditions

Industry conditions are also important because the subject company will probably be affected by changes in its industry. In some instances in which the subject company's customers are in another industry, they may be affected by the other industry, as well. We valued a printing company that specialized in the pharmaceutical industry. The printing industry was doing great at that time, but the pharmaceutical industry became our main focus because there was a reliance on this industry for business.

## Location of Business

In real estate appraisal, the value of property is greatly affected by the three Ls: location, location, location. Certain businesses are highly dependent on their location, whereas others are not. Imagine valuing a retail business that is located on a road about to undergo major construction and this construction is expected to last several years. Because of the construction, traffic flow will be diverted away from that road. How does the location of the business affect its value?

## Competition

At a management interview, valuation analysts always ask for information about the company's competitors. The reason for this is obvious. If a business suffers from the risk of competition, value is affected. If the valuation analyst was valuing a local hardware store and found out that The Home Depot was about to move in

less than a mile down the road, wouldn't this suggest that the valuation subject has a great risk of business loss?

## Depth of Management

Certainly, most smaller businesses have no depth in management. In fact, they are usually highly dependent on one key person. Revenue Ruling 59-60 discusses the possible loss of a key person as being a risk element. Several questions need to be considered by the valuation analyst. What is the likelihood of the loss of the key person?

Sometimes, the key person may not be the owner of the business. It may be a key salesperson. If the key person is lost, can a replacement be found? How long would it take to replace this person? At what cost? For many small businesses, the business may die with the owner. Frequently, we see businesses in which the owner is also the highly technical person whose knowledge is in his or her head.

## Quality of Management

Along with the depth in management, the analyst must consider the quality of management. Does the business have adequate management to properly achieve the business' goals, or does management have no control over its own destiny? What if the business is being run by a good technical person, but that individual cannot manage people? Or what if management cannot see what the future has in store for the company?

## Barriers to Entry Into Market

Another risk element is the difficulty that others may encounter in entering into the market. If the barriers to entry are nonexistent, competition may become fierce, creating serious risk. If it is difficult to enter the market, the company may be in a better position. This can hold true in situations in which the company holds patents, copyrights, and other types of intangibles.

## Avoid Double-Counting

In selecting the company-specific risk premium, it is important to consider that some risk factors may have already been accounted for with the selection of other premium data. For example, if the valuation analyst includes an IRP (discussed soon) as a separate risk element, he or she does not want to also include industry risk in the company-specific risk premium. Consider a company with limited management, debt, limited access to capital, high customer concentration, and little product and geographic diversification. These are factors that could increase the company-specific risk premium. However, these are all qualities of a small company. In considering all the qualitative factors that affect a company's risk, be mindful that the valuation analyst does not add premiums to the discount rate for factors that have already been considered in other components of the rate.

A certain amount of company-specific risk might also be accounted for in the forecast of future cash flows. Some company-specific factors have an impact on growth and profitability, which would be factored into a forecast or income normalization. For example, a company that lacks the ability to take advantage of certain opportunities available to the industry as a whole will likely experience lower growth relative to larger competitors. In selecting a company-specific risk premium, limited access to capital would only increase risk outside of its impact on the aforementioned growth.

The most important thing that the valuation analyst must remember is that when he or she is developing a discount rate, the following question is really being asked: What is the likelihood that the investor would receive the cash flows that are being forecast? That is what the valuation analyst is discounting. I often use our firm as an example. We are a small firm with very steady and predictable cash flows. Because the cash flow is relatively stable, this lowers the required rate of return for an investor. Do not penalize a company just because it is small. I have seen too many novice valuation analysts use an extraordinarily high discount rate because the company is small. If this rate is supposed to represent the risk of not receiving the cash flows, how risky is the cash flow if your forecast is only \$100 annually? How far off can you be? If the valuation analyst has a very conservative forecast, the risk will be much lower than if he or she has an aggressive forecast.

## The Bottom Line

The bottom line in the determination of the company-specific risk premium is to consider what the total rate of return would have to be, given the risk of the benefit stream being discounted. Though we use various methods to help quantify a discount rate, these are only tools in our toolbox; these methods do not help us quantify these rates. If nothing else, the final answer has to make sense. Remember, an analyst's responsibility is to determine an estimate of value that makes sense. It is not to develop rates of return.

A valuation analyst can look to market evidence to support the company-specific risk premium, but the process becomes somewhat circular in logic. For example, a number of years ago, we valued a business and determined that the discount rate should be 80 percent. Everyone involved in the litigation thought exactly what you are now thinking: We must be crazy. I began to testify at the trial and started describing all the factors that we have been discussing in this book. Obviously, I could not quantify every one of these factors, but I explained that the risk was substantial, and I felt that a rate higher than venture capital returns was appropriate. If venture capital was on the top floor of the rate of return department store, then my client was on the roof!

Over lunch, the client, the attorney, and I were discussing the testimony and preparing me to go back on the witness stand after lunch. The conversation led to the client telling me that business was really pretty tough. In fact, the only thing that was keeping him alive was the fact that his major supplier was financing his payables for 90 days at 19 percent interest. In fact, I think he called the guy a "shylock" (some of the other words could not be printed in this book). Because 19 percent for 90 days adds up to approximately 76 percent for the year, I went back to the courtroom feeling pretty good about my 80 percent rate. In this instance, the proof of the rate of return for an unsecured creditor justified the rate used in the valuation assignment. Thereafter, we regularly ask the business owner if there is any kind of financing other than the conventional type.

Logically, if we can determine a rate of return using outside empirical evidence, why would we need to determine a company-specific rate? Any time the analyst can avoid having to quantify the unquantifiable, I would suggest that he or she do so.

In an earlier edition of *Valuing a Business*, when discussing company-specific risk (*unsystematic risk*), Pratt, Reilly, and Schweih's stated the following:

The estimation of the effect of investment-specific (unsystematic) risk is often a matter for the analyst's professional judgment. These risk factors will be developed as part of the quantitative and qualitative analyses discussed in Part II of this book, and the significant positive and negative factors related to these analyses should be noted in the valuation report. These analyses will reveal many things that will affect the economic income projections, as well as the risk of achieving those projections. The analyst should be careful to distinguish between those factors that influence the *magnitude* of the projection (the numerator in the model) and those factors that affect the *degree of uncertainty* of achieving the mathematical expectation projection (that is, the *risk*, which determines the discount rate, the denominator in the model).

There is no specific model or formula for quantifying the exact effect of all the investment-specific risk factors on the discount rate. This is ultimately based on the analyst's experience and judgment.<sup>12</sup>

And, Jim Hitchner adds:

The final component of the discount rate is the risk specific to the company being valued and/or the industry in which it operates. This is one of the most subjective areas of business valuation.<sup>13</sup>

12 Shannon P. Pratt, Robert F. Reilly, and Robert P. Schweih's, *Valuing a Business: The Analysis and Appraisal of Closely Held Companies*, 4th ed. (New York: McGraw-Hill), 181.

13 James R. Hitchner, *Financial Valuation: Applications and Models*, 3rd ed. (New Jersey: John Wiley & Sons), 206.

Despite the agreement among these experts about the subjective nature of company-specific risk, several authors have discussed methods to quantify this aspect of the discount rate.

In the September 1999 issue of *Business Valuation Review*, Frank C. Evans wrote an article titled “How Do You Handle It?” In this article, Evans discusses assigning values to various risk factors, adding them up, and using the calculated number as an indication of the company-specific risk. A recreation of his company risk evaluation example in a chart format is illustrated in figure 13.11.

**Figure 13.11 Sample Risk Factor Value Chart to Indicate Company Specific Risk**

<b>Incremental Risk (Ex. Only)</b>		
<b>Company Specific Risk Factors for XYZ Corporation</b>		
1.	Operating history, volatility of revenues and earnings	3.5
2.	Lack of management depth	1.0
3.	Lack of access to capital resources	0.5
4.	Over reliance on key persons	1.0
5.	Lack of size and geographic diversification	0.5
6.	Lack of customer diversification	0.0
7.	Lack of marketing resources in light of competition	0.5
8.	Lack of purchasing power and other economies of scale	0.0
9.	Lack of product and market development resources	0.5
10.	Over reliance on vendors or suppliers	0.0
11.	Limitations on distribution systems	0.0
12.	Limitations on financial reporting and controls	0.5
<b>Positive Attributes</b>		
1.	Long term contracts with customers or unique product or market niche	0.0
2.	Patents, copyrights, franchise rights, proprietary products	-1.0
<b>Net increase to discount rate</b>		<b>7.0</b>

(Copyright © 1999, American Society of Appraisers. Used with permission.)

Although intuitively this process looks quantifiable and supportable, it is still highly subjective. First of all, anyone looking at figure 13.11 can probably think of at least another 6 items that could be added to it. In addition, there is no empirical support for any given number shown in the preceding chart. In a litigation environment, a good cross-examining attorney could spend hours leading the expert through an analysis of these factors. Before the expert was finished testifying, he or she would have explained the difference in value that would

be derived from a .25 or .50 point difference, either positive or negative, of any one of these factors, and what the addition of another 6 factors would have on the discount rate. Other writings on the subject of company-specific risk discuss the factors to be considered but do not assign a specific weight to them. Some authors discuss using a system of +, -, or neutral or high, low, neutral for each factor. In the working papers, there would be a list of factors that affect the discount rate. For each of these factors, the analyst would determine whether the factor would increase or decrease the discount rate, or whether it would have no effect, and how important the factor is. After going through all of these factors, though, it still takes professional judgment to convert these factors into a risk premium. No one has written anything that empirically describes the amount of additional risk (or the deduction from risk) that any factor should have in numeric terms.

One last comment about company-specific risk. Judges hate it. In a litigation setting, although it really does exist, judges do not like to see a valuation analyst add this risk premium into the derivation of a discount rate. The reason for this is because it is subjective, and many valuation analysts are doing a poor job in supporting it. I had a case in which I added a 2 percent company-specific risk premium in the build up of my discount rate. The judge was not happy with it until I was able to show him the specific industry rate of return from a reliable source of about 14 percent, and my overall discount rate for the riskier subject company ended up being about 16 percent. Once the valuation analyst determines the discount rate, it is a good idea to support the conclusion by finding other data to use as a sanity check that supports the overall rate. As I said before, don't worry as much about the components of the rate as the overall rate.

## Duff & Phelps Risk Study Revisited

We previously discussed the use of the *Risk Premium Report* to derive a forward-looking size-adjusted ERP. The *Risk Premium Report* also includes a risk study, which can be used to derive an overall cost of equity capital (inclusive of some company-specific risk). The risk study is based on three fundamental risk measures: five-year average operating margin, the coefficient of variation in operating income margin, and the coefficient of variation in return on book equity.<sup>14</sup> Based on research conducted by D&P, there is a strong correlation between returns and profitability and volatility of profitability and return on equity. In other words, as operating income margins decline and as volatility in profitability and return on equity increases, perceived risk (as measured by annual returns) increases. D&P calculates risk premiums in excess of the risk-free rate based on these three measures of risk and organizes the data into 25 portfolio rankings. This risk premium data can be found in the D exhibits of the *Risk Premium Report*.

We can use this data in much the same way we calculate a size-adjusted ERP. Either using the regression equations for each factor or ranking the subject company within the 25 portfolio groupings and applying the published risk premiums will provide an analyst with the ability to derive a risk premium applicable to the subject company.

There are some things to keep in mind if you use the *Risk Premium Report* for this purpose. First, this risk premium is based on historical data and will need to be converted to a forward-looking figure. You can use the formula provided previously in our discussion of the *Risk Premium Report*. Next, the risk premium derived from the risk study will not fully account for size or all company-specific risks. Remember that this calculation only takes into consideration profitability, the volatility of profitability, and return on equity. Finally, risk premiums based on the risk study do not take into consideration any industry specific risks.

One aspect of the *Risk Premium Report* that is useful is that it allows the valuation analyst to compare the three risk measures of the subject company to those of the companies that make up the 25th portfolio that are used to calculate the size risk premium. This is important because "smaller" does not necessarily mean "riskier." If the subject company is more profitable and has a more stable and predictable earnings stream than the companies that are included in the 25th portfolio, then an additional adjustment for company-specific risk may not be appropriate. In one instance, my firm valued a small managed services provider that generated approximately \$2.5 million in sales. Although the company was small, approximately 75 percent of the company's revenues were generated from 3- to 5-year contracts with customers. As a result, the company had a

14 The coefficients of variation of profitability and return on equity are measures of volatility in each financial metric.

predictable, recurring revenue stream. Therefore, in our cost of capital analysis, we utilized the *Risk Premium Report* as part of our determination of the amount of company-specific risk that was necessary for this company. The results appear in figure 13.12

**Figure 13.12 Duff & Phelps Risk Study Analysis**

Company-Specific Risk: Indication of Direction						
Relationship Between Fundamental Accounting Measures and Cost of Equity Capital						
Subject Company	Valuation date			ERP adjustment: an ERP adjustment of 0.6% is added to Buildup 1 Risk Study (Buildup 3), and Unlevered Risk premia to adjust for the difference in the historical ERP (1983-2015) and the ERP entered by the USER, as calculated below:	Long-term risk free rate as of June 30, 2016 (used in all calculations):	Source of risk premia information in this report
Advanced Networking Services, Inc.	June 30, 2016			5.5% - 4.3% + 0.6%	4.0%	2016 Duff & Phelps Risk Premium Report
Size Study: Exhibits C-1 through C-8						
Risk Premia Over Risk Free Rate (RP <sub>...</sub> ) for each of three risk measures	Size Measure	Subject Company Value (\$Millions)	Indicated Guideline Portfolio	Average Operating Margin (of Companies in Indicated Guideline Portfolio)	Average Coefficient of Variation: Operating Margin (of Companies in Indicated Guideline Portfolio)	Average Coefficient of Variation: ROE (of Companies in Indicated Guideline Portfolio)
Exhibit C-1	Market Value of Equity	\$4.00	25	6.2%	44.0%	64.0%
Exhibit C-2	Book Value of Equity	\$0.15	25	7.2%	40.2%	57.8%
Exhibit C-3	5-Year Average Net Income	\$0.34	25	6.0%	49.8%	78.4%
Exhibit C-4	MVIC	\$4.00	25	6.4%	43.7%	60.4%
Exhibit C-5	Total Assets	\$0.27	25	7.3%	40.2%	54.5%
Exhibit C-6	5-Year Average EBITDA	\$0.46	25	6.7%	44.3%	60.3%
Exhibit C-7	Sales	\$2.43	25	8.5%	41.7%	55.9%
Exhibit C-8	Number of Employees	18	25	9.1%	41.8%	56.0%
				Average operating margin of companies across Indicated Guideline Size Portfolios	Average coefficient of variation of operating margin of all companies in Indicated Size	Average coefficient of variation of ROE of all companies in Indicated Size Portfolios
				7.2%	43.2%	60.9%
				Operating margin of Subject Company	Coefficient of variation of operating margin of Subject Company	Average coefficient of variation of ROE of Subject Company
				18.4%	12.8%	25.2%
				Analysis	Analysis	Analysis
The operating margin of Advanced Networking Services, Inc. (18.4%) is HIGHER than the average operating margin of portfolios comprised of similarly-sized companies (7.2%), as reported in the Size Study of the 2016 Duff & Phelps Risk Premium Report. This suggests that Advanced Networking Services, Inc. is LESS RISKY than other companies of similar size, and that a DOWNWARD adjustment for company-specific risk may be indicated.				The coefficient of variation of operating margin of Advanced Networking Services, Inc. (12.8%) is LOWER than the average coefficient of variation of operating margin of portfolios comprised of similarly-sized companies (43.2%), as reported in the Size Study of the 2016 Duff & Phelps Risk Premium Report. This suggests that Advanced Networking Services, Inc. is LESS RISKY than other companies of similar size, and that a DOWNWARD adjustment for company-specific risk may be indicated.	The average coefficient of variation of return on equity (ROE) for Advanced Networking Services, Inc. (25.2%) is LOWER than the average coefficient of variation of return on equity (ROE) of portfolios comprised of similarly-sized companies (60.9%), as reported in the Size Study of the 2016 Duff & Phelps Risk Premium Report. This suggests that Advanced Networking Services, Inc. is LESS RISKY than other companies of similar size, and that a DOWNWARD adjustment for company-specific risk may be indicated.	

(Source: Duff & Phelps.)

In this instance, the subject company was small in size and ranked in the 25th portfolio in all 8 categories. However, the valuation subject's operating margin of 18.4 percent was more than double that of the companies in the 25th portfolio (7.2 percent). Furthermore, the coefficient of variation of the company's operating margin was only 12.8 percent compared to 43.2 percent for the companies in the 25th portfolio. In addition, the companies average coefficient of variation of return on equity was 25.2 percent compared to the 60.9 percent average for the guideline companies. Therefore, in this valuation, the subject company was considerably more profitable and had earnings streams and returns that were less volatile than the companies that were being used to calculate the size premium. Given this information, the analysis indicates that the subject company is less risky than the other companies of similar size and that a downward adjustment for company-specific risk may be warranted. This is an example of how "smaller" does not necessarily mean "riskier."

Therefore, for reasons listed in the preceding paragraphs, utilizing the *Risk Premium Report* data is not recommended without considering other methodologies. However, because the *Risk Premium Report* provides some additional insight into risks associated with profitability and returns on equity, it deserves some discussion and can be utilized as part of the analysis of company-specific risk. One can never have too many tools.

### Market-Derived Cost of Equity Models

Over the past several years, several new cost-of-capital models have emerged that attempt to use guideline public companies to derive rates of return for closely held businesses. The advantage of using guideline public companies to calculate rates of return is that investors' risk and return expectations are built into public company stock prices and, as a result, using this data can give a good indication of how the market is pricing risk

for companies that are comparable to the valuation subject. Assuming that the valuation analyst has a good group of guideline publicly traded companies, these models can serve as a secondary method to calculate the cost of equity. However, considering that many of these models are under an increased amount of scrutiny and still in the process of being peer reviewed, relying on them as a primary method to derive a discount rate is not recommended. Two models that will be discussed in this book include the Butler-Pinkerton Calculator and the Implied Cost of Capital model.

## Butler-Pinkerton Calculator

In the 2006–2007 time period, Peter Butler, ASA, CFA, and Keith Pinkerton, ASA, CFA, published two articles regarding the quantification of company specific risk.<sup>15, 16</sup> The abstract of the *Business Valuation Review* article read as follows:

Even though, according to traditional financial theory, public markets do not price company-specific risk, it does not mean that it does not exist or is not quantifiable for public comparables. In all instances, the company-specific risk premium for publicly traded companies is greater than 0%—yet appraisers start their benchmark analysis at 0% to determine an appropriate company-specific risk premium for privately held companies. Is this a flaw in our collective thinking?

In the article in *Business Valuation Update*, the editor states

In this article, the authors have refined their earlier work by providing a detailed example of how to select a company-specific risk premium (CSRP) for a privately held company using benchmark CSRPs derived from publicly traded companies.

The concept behind the analysis performed by Butler and Pinkerton is that although the marketplace does not price company-specific risk into its rates of return, every company has company-specific risk that can be quantified through the use of total beta. Total beta, which is a concept derived by Aswath Damadoran, PhD, measures a stock's riskiness relative to the market, which has a total beta of 1.0. It captures total risk, including systematic risk as well as size and company specific risk.

The two articles go on to discuss the quantification of company specific risk for a privately held company. The authors use publicly traded guideline companies and calculate their total betas in order to calculate the guideline companies' company-specific risk premium. This is followed by a comparison of the subject company to the guideline companies to determine the appropriate starting point for the company-specific risk premium. Once the analyst has determined the strengths and weaknesses of the analysis, he or she determines the starting point for the quantification of the company-specific risk for the subject company.

However, this appears to be similar to the use of the IRP (to be discussed) from the *Valuation Handbook*. It provides the analyst with a starting point for the company-specific risk premium but does not necessarily quantify all the company-specific risk. Therefore, some of the quantification will remain subjective. In support of this method, the authors state the following:

Moreover, if you do not consider any companies as appropriate guidelines, you must still perform some analysis (whether using this technique or the more subjective analyses) in quantifying company-specific risk. At least this method permits an appraiser to retrieve a Form 10-K from companies in the pertinent industry and analyze them for company-specific risk, since by definition, the risk is just that: company-specific and not incorporated in Beta (systematic risk) or the size premium. With this technique, we have created an empirical approach to benchmark company-specific risk.

15 Peter Butler and Keith Pinkerton, "Company-Specific Risk—A Different Paradigm: A New Benchmark," *Business Valuation Review* (Spring 2006): 22–28.

16 Peter Butler and Keith Pinkerton, "Quantifying Company-Specific Risk: A New, Empirical Framework With Practical Applications," *Business Valuation Update* (February 2007): 1.

Some of Butler and Pinkerton's conclusions from their analysis are as follows:

1. All companies have specific company risk (including large publicly traded companies, such as General Electric, that has a specific company risk premium in the range of 3 percent to 4 percent). Therefore, starting at a specific company risk premium of 0 percent underestimates a company's cost of capital. Due to their research indicating that companies such as Exxon Mobil and General Electric have specific company risk greater than 0 percent, Butler and Pinkerton believe that most valuation analysts have probably underestimated the discount rate and, therefore, overvalued the companies they have valued.
2. The methodology derived does not work for all industries or all companies.

It took me seeing this presentation a number of times before I finally figured out what Butler and Pinkerton were doing. They did a terrible job of explaining it. The Butler-Pinkerton Calculator, which is available from, who else, Business Valuation Resources, is not actually quantifying the company-specific risk but, rather, it is allowing the analyst to determine the rate of return that is applicable to companies in the public market as a starting benchmark for the determination of the discount rate. This calculator will allow us to determine the total cost of equity (TCOE) for our guideline companies. Similar to the application of the guideline company method, the analyst can then adjust the cost of equity for the differences between the subject company and the guideline companies. This is clearly a great addition to what we have done in the past.

It is important to know that there have been a number of criticisms about the Butler-Pinkerton Calculator. The primary criticism) is the calculator's subjective nature. An analyst must select guideline companies, choose a time period over which beta will be measured, and make adjustments to the TCOE figures that are calculated for risks specific to the subject company. There has also been criticism regarding the validity of the theoretical underpinnings of the Butler-Pinkerton Calculator, specifically total beta. Before the valuation analyst uses the Butler-Pinkerton Calculator, I highly encourage the analyst to read these criticisms and the responses from Butler and Pinkerton and other experts. Many of these articles can be accessed for free on the Business Valuation Resources website.

## Implied Cost of Equity Capital

In the summer 2016 edition of *Business Valuation Review*, Bradford Cornell, PhD and Rajiv Gokhale, MBA, published an article that discussed a valuation model based on the implied cost of capital (ICC).<sup>17</sup> The ICC model takes into account the analyst earnings forecasts of the guideline publicly traded companies. Because the market capitalization of the publicly traded companies is already known, the valuation analyst can perform a discounted cash flow calculation using analyst's forecasts to calculate the rate of return that equates the projected future cash flows to the market capitalization of the firm. A significant barrier to this methodology is the lack of data because certain publicly traded companies have little analyst coverage and may not have earnings forecasts available. Furthermore, the model is only as good as the publicly traded companies that are being used to value the subject under a market approach.

Ultimately, it is important to understand that these models are just tools that are available to estimate the cost of equity for a privately held company. These models do not provide analysts with a number that can be used in the income approach without further analysis or adjustment. Regardless of whether comparable guideline public companies exist, deriving the discount rate for a privately held company remains a very subjective procedure; analyst judgment and intuition still play primary roles. Thus, although the valuation analyst does not have to (and probably should not) rely on these models (or any model) as a stand-alone, it is always helpful to have access to another perspective with regard to something as subjective as a private company discount rate.

## Industry Risk—A Component of Company-Specific Risk in a Build-Up Method

Starting in 2000, SBBI started to include data on IRPs in its valuation edition and included them through its discontinuation in 2013. Starting in 2014, the *Valuation Handbook* began publishing this data for over 250 industries. Some are positive, and others are negative. In a build-up methodology, the industry risk is generally captured as part of the company-specific risk premium, whereas in the CAPM, the industry risk is captured in the beta (take my word for it until we discuss betas).

The manner in which the *Valuation Handbook* calculates the IRP transforms the build-up method into a modified CAPM. D&P uses the following formula to calculate the IRP:

$$IRP = (FIB \times ERP) - ERP$$

$IRP$  = Industry risk premium  
 $FIB$  = Full-information beta for the industry  
 $ERP$  = Equity risk premium

Many valuation analysts do not use this as a separate component because many industries have little data. In order to perform these calculations, D&P requires that (1) there be at least 10 companies in the industry with an aggregate beta between zero and 5 and full-information beta between zero and 3; (2) each company must have at least 36 months of contiguous return data; (3) sales for the company must be greater than \$100,000 in the most recent fiscal year; and (4) the market capitalization must be no less than \$10,000 in the most recent month. Some of these requirements differ from what Morningstar used in SBBI. Therefore, comparison between these two publications may be poor.

In order to calculate the IRP, D&P uses a full-information beta. Full-information beta is explained in the *Valuation Handbook* as follows:

The full-information beta methodology is based on the premise that a business can be thought of as a portfolio of assets. The full-information methodology is designed to capture the impact that the individual segments have upon the overall business beta. After identifying all companies having segment sales in an industry, the analyst calculates a beta estimate of those companies. The analyst then runs a multiple regression with betas as the dependent variables (applying a weight to each beta based on its relative market capitalization to the industry market capitalization) and sales of the segments of each of the companies in the industry as the independent variable. That is, one is measuring the relative impact on the betas of companies in an industry based on the relative contribution (as measured typically by sales) each company has within the industry<sup>18</sup>

The full-information beta methodology utilized in the *Valuation Handbook* is nearly identical with how it was calculated by Morningstar. The same database and data are used. D&P also attempted to improve the overall quality of the IRPs. Morningstar had previously required 36 months of return data in the previous 60 months and only 5 participants to publish an IRP for an industry. D&P's restrictions remove some of the "spotty" data for industries with few participants or high volatility, or both, from period to period.

D&P also provides IRPs using three different ERPs: long-term historical ERP (as was previously published in SBBI), long-term supply-side ERP (also published by Morningstar), and the D&P-recommended ERP. When using the IRP, you must be consistent with other assumptions made in the discount rate. For example, if you are using a build up using the historical ERP data, make sure you are using the IRP that uses the long-term historical ERP. The *Valuation Handbook* makes this easy for you because it provides you with multiple IRPs. Also, recall that the D&P calculators automatically adjust the IRP depending on the input ERP.

<sup>18</sup> *Valuation Handbook*, 5-11 and 5-12.

If you are performing a retrospective valuation and need to use SBBI to obtain the IRP, you may need to make this adjustment manually if you want to apply it to the *Risk Premium Report* data. The IRPs published in SBBI were based on the historical ERP, which differs from the forward-looking ERP estimated by D&P. Thus, we must adjust the IRP to use the ERP determined via the *Risk Premium Report* by applying the following equation:

$$\text{IRP}_{\text{Adjusted}} = \text{IRP}_{\text{SBBI}} * (\text{ERP}_{\text{D\&P}} / \text{ERP}_{\text{SBBI}})$$

As with everything else, the valuation analyst needs to make certain that he or she understands what he or she is using. There is a lot of data out there to be used in our profession. However, it is not always consistent and sometimes may overlap. Always be mindful to understand what the valuation analyst is working with.

Why is the IRP important? This separately calculated risk component addresses the risks associated with companies in a particular industry. It can be extracted from the company-specific risk premium as a separate element, which is always a good thing. As an example, my staff critiqued another analyst's report in which the analyst did not include an IRP and had a company-specific risk premium of only 0.5 percent. When we looked up the IRP in SBBI, it was 4.9 percent. This means that if we pulled the industry risk out of the company-specific risk premium, the analyst had a company risk of negative 4.4 percent. This was a company that was highly dependent on a key person, had significant customer concentration, had borrowings coming due shortly, had supplier issues, and had a host of other risk factors that made this company's cash flow pretty risky in the future. There was no way that the company-specific risk should have been negative. This is just one more example of using the information that we have available to us to test the reasonableness of a discount rate.

## Application of the Discount Rate

The rates of return appearing in the *Valuation Handbook* are after tax with respect to corporate entities but pretax to the investor. I am not sure why, but this seems to confuse a lot of people. Because public companies report their results on an after-tax basis, the *Valuation Handbook* data is logically after tax to the corporations. However, what should we consider the Treasury bonds to be? These returns are actually pretax to the government or after tax when you consider that the government does not pay taxes. A source of confusion is that the rates of return are pretax to the investor. Because we are normally being asked to value the business enterprise, personal taxes have no relevance. Total stock returns, as used in the *Valuation Handbook*, are defined as dividends plus unrecognized capital gains. The unrecognized capital gains are measured from the beginning of the year to the end of the year. Therefore, the returns reflected by these studies are considered to be cash returns, and the data used in determining discount rates from these studies should be applied to net cash flow and not earnings. An adjustment would be required to derive the appropriate discount rate to use for earnings. The reason for this adjustment is that earnings are considered riskier than cash flow because other factors (capital expenditures, working capital needs, and net borrowings) are not taken into consideration.

## When All Else Fails, Go Back to the Theory

When the valuation analyst gets to the point where he or she cannot get as lucky as I was when I found out that there was another way to determine a rate of return for the subject company, he or she needs to go back to good old valuation theory. Let's spend some time discussing some of the more popular methods for calculating discount rates. This discussion will include the following:

- The build-up method
- CAPM
- Price-to-earnings reciprocal plus growth
- Factor rating method
- WACC (a method of calculating a discount rate for invested capital, which may include the other methods in this list)

## The Build-Up Method

Many valuation analysts, especially those who work with smaller closely held companies, use the build-up method for developing a discount rate. The build-up method embodies all the elements of the discount rate previously described, including (1) a risk-free rate, (2) an ERP, and (3) a company-specific risk premium, which would also include a size premium, an industry premium, and anything else that will cause a premium, whether positive or negative. A demonstration of the build-up method is shown in table 13.2.

**TABLE 13.2 The Build-Up Method**

“Safe” rate	5.00%
ERP	7.20%
Size premium	4.20%
Company-specific risk premium	3.00%
Discount rate	19.40%

The *Risk Premium Report* contains several variations of the build-up method, which are discussed in the text that follows.

### Build-Up 1 Method

The build up 1 method consists of (1) a risk-free rate, (2) a size-adjusted ERP, and (3) an ERP adjustment. The difference between the build-up 1 method and the traditional build-Up method that appears in table 13.2 is the manner in which the ERP and the size premium are calculated. Instead of accounting for these two components of the discount rate individually, the build-up 1 method calculates a size-adjusted ERP that includes both the ERP and the size premium. The size-adjusted ERP is calculated as the average risk premium over the risk-free rate over the period 1963–2015 for each of the 25 size-ranked portfolios.

Also included in the build-up 1 method is an ERP adjustment. The ERP is necessary to reconcile the historical ERP that is calculated by D&P and the ERP that the valuation analyst utilizes in the valuation. For example, suppose the valuation analyst determines that a 5.5 percent ERP is appropriate. In this instance, the ERP adjustment would be 0.6 percent, which is calculated as the valuation analyst’s ERP of 5.5 percent minus the D&P historic ERP of 4.9 percent.

One drawback of the build-up 1 method is that it cannot be used in conjunction with an IRP or a beta to capture the risk associated with the industry in which the valuation subject operates. Because the risk premium is measuring the total risk premium over the risk-free rate, it captures the combined effect of both market (beta) risk and size risk. Therefore, utilizing an IRP or beta in addition to the size-adjusted risk premium would result in double-counting. When utilizing the build-up 1 method, the valuation analyst will have to perform a thorough qualitative analysis to incorporate industry risk and company-specific risk into the discount rate.

### Build-Up 2 Method

The build-up 2 method allows the valuation analyst to use the *Risk Premium Report* data in conjunction with the IRP. In this method, the components of the discount rate include (1) a risk-free rate, (2) an ERP, (3) a size premium, and (4) an adjusted IRP. The build-up 2 method closely resembles the modified CAPM model. The only difference is that an IRP is used as opposed to a beta. When utilizing the build-up 2 method, the valuation analyst must be prepared to explain why the guideline public companies might be good enough to be used as a measure of industry risk but were possibly not comparable enough to use in the market approach. We often see valuation analysts apply an IRP without knowing which companies are included in the composite data.

### Unlevered Model

The unlevered model allows the valuation analyst to estimate the cost of equity under the assumption that a company is financed with 100 percent equity and 0 percent debt. The components of the discount rate include (1) a risk-free rate, (2) an unlevered size-adjusted ERP over the risk-free rate, and (3) an ERP adjustment. The model is almost identical to the build-up 1 method. The only difference is that an unlevered size-adjusted ERP is being used as opposed to the levered size-adjusted ERP that is being used in the build-up 1 method. As is the case with the build-up 1 method, this method captures both market risk and size risk and, as a result, cannot be used in conjunction with an IRP or a beta.

## Modified CAPM

The *Risk Premium Report* also gives the valuation analyst the option to develop a discount rate using a modified CAPM model based on the *Risk Premium Report* rate-of-return data. A more detailed discussion of the CAPM model is contained in the next section.

## Capital Asset Pricing Model

The CAPM model was originally developed by William F. Sharpe. He published his theory in an article titled “Capital Asset Prices: A Theory of Market Equilibrium under Conditions of Risk.”<sup>19</sup> You are probably thinking that this is a real sleeper, but this guy won a Nobel Prize in Economics—now, have I gotten your attention? The model was originally developed in the context of portfolio theory as a way to measure the risk an individual stock contributes to a well-diversified portfolio. By now, I assume that everyone who has read this book is familiar with the efficient market hypothesis stuff from school? That is what this relates to. It actually suggests that the price of securities in the public markets will not depart from their true values for any real length of time (based on the economics).

So, why is this in a business valuation book? CAPM has been modified to be used as a method of determining a discount rate, commonly used in the valuation of larger companies. It has little, if any, applicability to small- and medium-sized businesses, but no discussion about discount rates would be complete without mentioning its existence. If the valuation analyst uses the CAPM to develop a discount rate to be used in the valuation of a smaller business, the valuation analyst has probably lost his or her mind. This last sentence is probably one of the most quoted sections of this book!

A valuation analyst should be familiar with all the tools available in the profession because there is a good possibility that CAPM will be seen in another analyst’s report at some point in the future. That’s how I found out about it! The discussion that follows is not intended to be a highly technical discussion about CAPM but, rather, it is intended to explain, in English, what this model is all about. Finance textbooks can be consulted if you want to learn more about this subject or doze off while reading.

The theoretical basis for the CAPM comes from the application of the *efficient market theory*. In short, this states that the expected returns on investment portfolios are related to the expected risk of the investments included in the portfolios. The relationship between risk and reward becomes apparent in its truest form under the efficient market theory. Because investors are said to be risk averse, portfolios are structured to diversify away the risk. Right away, you should realize the limited applicability of this method for smaller companies because the owners of these businesses do not have diversified portfolios and do not have the ability to diversify away the risk associated with owning the closely held business.

The theory behind the CAPM is that we assume there are a fixed number of securities in which we can invest in the marketplace. Each of the securities has its own expected return (based on its level of risk) and standard deviation. The investor will select the security that offers the highest return and the lowest standard deviation. What does this mean? Investors don’t like to take chances if they can avoid them! They look to minimize their risk and, at the same time, maximize the return available to them.

I hate to do this to you, but the mathematical equation for the CAPM is as follows:

$$k_e = R_f + \beta * (R_m - R_f)$$

$k_e$  = Expected return (also known as the discount rate for equity)  
 $R_f$  = Risk-free rate  
 $\beta$  = Systematic risk (volatility explained in the following section)  
 $R_m - R_f$  = Long-term average risk premium of the market as a whole  
 minus the long-term average risk-free rate (also known as the ERP)

19 William F. Sharpe, “Capital Asset Prices: A Theory of Market Equilibrium under Conditions of Risk,” *Journal of Finance* 19(3): 425–442.

The CAPM provides a discount rate that is applicable to the equity of the company (not invested capital). The formula looks a lot worse than it really is because the CAPM is similar to the build-up method, which is more commonly used by valuation analysts of smaller businesses. Always keep in mind that the three main components of a discount rate include a risk-free rate, an ERP, and a company-specific risk premium. If you notice, there is no company-specific risk in the formula. Therefore, it needs to be adapted for use in the valuation of a closely held company. In the discussion that follows, I will demonstrate that the CAPM has similarities with the much simpler build-up method.

## Components of the CAPM

There are two different methods that are commonly used to determine the risk-free rate. Long-term U.S. Treasury bond rates are generally used, as discussed previously in this chapter. The other method is more technically consistent with the CAPM assumption. In this approach, the risk-free rate is determined by taking the long-term Treasury bond rate minus Morningstar's horizon premium as defined and provided in *SBBi Classic*. The horizon premium represents maturity risk. This compensates for the fact that longer term Treasury securities are considered to be riskier because of their long-term nature.

Capital market theory segregates risk into two types: systematic and unsystematic. Systematic risk represents the uncertainty of future returns because of the sensitivity of the subject security to changes in the market as a whole. Unsystematic risk is a function of everything else. According to *Valuing a Business*, "The fundamental assumption of the capital asset pricing model is that the risk premium portion of the expected return of a security is a function of that security's systematic risk." In essence, because an underlying assumption of this model is that investors hold large, diversified portfolios, they are able to eliminate the unsystematic risk. Therefore, the CAPM only addresses systematic risk.

The systematic risk, beta, is the measure of the volatility of the stock market as a whole. It is a measurement that predicts how a stock will react to the movement of the stock market. The purpose of using a beta is to measure the expected return of the market based on the volatility that takes place when one uses guideline companies as a surrogate for the valuation subject. Because this is the expected return for a diversified portfolio, it is assumed that there is no specific risk relative to the company being valued. What this means is that a company's beta will predict what will happen to the price of the stock as the stock market goes up and down. A beta of 1.0 indicates that a company will move with the market (market up 10 percent, company up 10 percent). The use of public guideline data allows the valuation analyst to compare the median beta of these similar companies in order to predict the volatility of the valuation subject as if it were a public company.

Various sources can be used to determine betas. First of all, a beta can be calculated by the analyst (this procedure will not be discussed in this book, but more information can be found in Pratt's *Valuing a Business* or D&P's *Valuation Handbook*). The most common sources for finding betas are S&P's tear sheets, Value Line ([www.valueline.com](http://www.valueline.com)), and Wilshire Associates ([www.wilshire.com](http://www.wilshire.com)).

Because betas are calculated with respect to the entire market, the ERP ( $R_m - R_f$ ) should be calculated using an  $R_m$  that is representative of the return from the entire market. Some valuation analysts mistakenly use only the bottom part of the market to compensate for the size of the valuation subject. The fundamental assumption in the CAPM is that the risk premium portion of the expected return of a security is a function of that security's systematic risk. Capital market theory assumes that investors hold, or can hold, common stocks in large, well-diversified portfolios. Therefore, unsystematic risk is eliminated because of the diversification in the portfolio. (Can you believe this stuff?) *SBBi* was, and the *Valuation Handbook* (likely) is, the most commonly used sources for  $R_m$ . It is incorrect to include the return on small stocks in the  $R_m$  term in the CAPM equation. Because betas are calculated with regard to the entire market,  $R_m$  must be the return on the entire market, not just that portion in the bottom of the market. When beta equals 1.0 in the CAPM equation, the indicated return is the return on the market as a whole.

### Author's Note

Different sources of betas vary in the manner in which they are calculated. It is important that you be consistent when you use published betas. It is preferable to get them all from the same source or calculate your own.

It should also be noted that the  $R_f$  at the beginning of the equation is the risk-free rate at the valuation date, whereas the  $R_f$  in parentheses is a long-term average  $R_f$ . Although  $R_f$  is assumed to be the rate of return on a long-term U.S. Treasury bond, the rate on a short-term Treasury note might make more sense in certain instances. This may be the case when a shorter holding period (such as a self-liquidating investment of 10 years) is expected.

The ERP can be determined as discussed previously. However, you cannot use the *Risk Premium Report* to calculate a size-adjusted ERP for all the same reasons that I have been discussing. The entire market must be used. That does not mean, however, that a size premium from the *Risk Premium Report* cannot be used. In fact, it is a great resource. I will discuss this more shortly.

Another source is the *Valuation Handbook*, which contains some really good stuff. This publication provides industry-adjusted cost of capital using CAPM, the CRSP decile, and *Risk Premium Report* data included in the *Valuation Handbook, Valuation Edition*, as well as a plethora of other information by industry. This publication includes betas, financial ratios, historic return data, valuation multiples, and cost of capital estimates for numerous SIC codes. Within each industry, ICC calculates the median cost of capital for the companies included in a particular SIC code and also includes a SIC composite (which is weighted by the market capitalization of all the firms in the industry), large composite, small composite, and a high financial risk category. This allows the valuation analyst to compare the subject company to firms in the same industry that are of similar size. ICC calculates the cost of equity using various methodologies, including a CAPM plus-size premium and the build-up method based on data from either CRSP or the *Risk Premium Report*. This data is another useful tool for valuation analysts to incorporate into a discount and capitalization rate analysis.

There have been several articles written about the merits of using forward-looking ERPs over a reliance on the historical ERP. It seems logical to use forward-looking data because valuation is a prospective process. The real question to ask yourself over and over again is: How will this get us a more accurate valuation conclusion? If the valuation analyst believes that the forward-looking ERPs will allow him or her to do a better job, then he or she should use them. I have found that the small businesses that we value are relatively unaffected by all of this stuff. Rarely, if ever, will the CAPM be applicable to small companies. (Can you imagine trying to explain this stuff to a jury?) In reality, betas cannot be calculated for the small closely held company for which guideline company information is unavailable. The CAPM assumes that the market is efficient. (Talk about big assumptions!) An inefficient market will create distortions in the model. Computerized trading and insider information (among other factors) can cause the market to be less efficient than it could be. I have included an annotated list of underlying assumptions (box 13.4) that the model is largely based upon (my comments are in parentheses).

**BOX 13.4****CAPM Underlying Assumptions**

CAPM assumes the following:

- Investors are risk adverse. (No kidding!)
- Rational investors seek to hold efficient portfolios, that is, portfolios that are well diversified. (That's great, but how many of our clients have enough money to fully diversify? So, while they may want to diversify, they cannot.)
- All investors have identical investment time horizons, that is, expected holding periods. (All investors expect to hold their investments for the same time period. This means that there is no distinction among investors between day traders, short-term investors, or long-term investors.)
- All investors have identical expectations about such variables as expected rates of return and how capitalization factors are generated. (Every investor expects the same rate of return—give me a break!)
- There are no investment-related taxes or transaction costs. (Come on—Uncle Sam is not going to tax us, and Merrill Lynch is not going to charge for the transactions. Are you kidding?)
- Relative price volatility (beta) is a modifier of equity market risk and required return. (And this means what?)
- The rate received from lending money is the same as the cost of borrowing money. (Tell that to Big Tony on the Sopranos, or even more ridiculous, tell it to Chase Manhattan Bank!)
- The market has perfect divisibility and liquidity. (And I believe in the Tooth Fairy and Santa Claus.)

Obviously, the underlying assumptions that enter into CAPM can be considered somewhat silly. In a litigation situation, the valuation analyst can have his or her client's attorney cross examine the opposing expert about these assumptions. The judge or jury can always use a good laugh (assuming that they have any idea about what this stuff means).

The CAPM is used to derive an equity discount rate that is applicable to net cash flow. It is not intended to be applied to invested capital (debt and equity), nor is it intended to be applied to earnings. Because future returns and betas cannot be measured, historical data must be used as a surrogate.

To add a little bit more uncertainty to your life, betas can be unlevered and re-levered. Because public companies may have different capital structures than the private company being valued, better comparability can be achieved by jumping through hoops. This is done for reasons similar to why we value invested capital, rather than equity. In case withdrawal is setting in, here's a formula fix: A beta can be unlevered using several different methodologies. In this book, I am only going to provide two of them: the *Hamada formula* and the *Harris-Pringle formula*. The Hamada formula is probably the most widely known and frequently used for the purposes of levering and unlevering betas. The Harris-Pringle formula is an alternative to the Hamada formula and is used in the *Risk Premium Report* to unlever risk premiums. I will discuss both of these methods in the following paragraphs.

### The Hamada Formula

The Hamada formula is presented as follows:

$$\text{Unlevered Beta} = \frac{\text{Levered Beta}}{1 + [(\text{Debt/Equity}) * (1 - \text{Tax Rate})]}$$

The levered beta is the beta that the valuation analyst would look up. This means that it is based on the public company's actual capital structure, which includes both debt and equity. After the analyst unlevers the beta, he or she then gets to re-lever it using a different capital structure. The formula to re-lever the beta is as follows:

$$\text{Levered Beta} = \text{Unlevered Beta} * (1 + [\text{Debt/Equity}] * [1 - \text{Tax Rate}])$$

As with any theory, even the Hamada formula has come under scrutiny during the last bunch of years. According to Roger Grabowski and Shannon Pratt

The Hamada formulas are consistent with theory that:

- The discount rate used in calculating the tax shield equals the cost of debt capital (that is the tax shield has same risk as debt).
- The formulas imply that tax deductions on the interest expense will be realized in the periods in which the interest is paid.
- Value of the tax shield is proportionate to the value of the market value of debt capital (that is, value of tax shield =  $t \times W_d$ ).
- The amount of debt capital is fixed as of the valuation date and remains constant.<sup>20</sup>

This is starting to get too complicated. I suggest buying the 5th edition of *Cost of Capital: Applications and Examples* to read more about this topic.

Before we write off this method, it should be noted that many valuation analysts still use it in practice. Therefore, because little of this stuff makes sense without an example, let's do one.

<sup>20</sup> Shannon Pratt and Roger Grabowski. *Cost of Capital: Estimation and Applications*, 5th edition (New York: Wiley, 2014): 247.

XYZ Corp. has interest-bearing debt that represents 25 percent of its total capital structure (the market value of invested capital for the company). The primary competition in the public world has levered betas that average 1.2. Their average debt-to-equity relationship (considered optimal) is 0.6. The unlevered beta can be calculated as follows:

$$\begin{aligned}\beta_U &= \beta_L / (1 + ((\text{Debt/Equity}) * [1 - \text{Tax Rate}])) \\ \beta_U &= 1.2 / (1 + [0.6] * [1 - .40]) \\ \beta_U &= 0.88\end{aligned}$$

Now that we have unlevered the beta, the next step is to relevel the beta. Why do we do this? We relevel the beta to capture the debt-to-equity relationship of the subject company. This allows a better calculation of the volatility risk (beta) taken from the public guideline companies by incorporating the closely held company's capital structure into the determination of the discount rate. Re-levering the beta for the subject company is done as follows:

$$\begin{aligned}\beta_L &= \beta_U * (1 + [\text{Debt/Equity}] * [1 - \text{Tax Rate}]) \\ \beta_L &= 0.88 * (1 + [.25/.75] * [1 - 0.40]) \\ \beta_L &= 1.06\end{aligned}$$

### The Harris-Pringle Formula

For those of us who go to the grocery store, Pringles is a potato chip. I get hungry every time I think about this stuff. Anyway, the Harris-Pringle formula is as follows:

$$\text{Unlevered Beta} = \frac{\text{Levered Beta} + \text{Beta of Debt} * (\text{Debt/Equity})}{1 + (\text{Debt/Equity})}$$

Re-levering the beta is completed by using the following formula:

$$\text{Levered Beta} = \text{Unlevered Beta} + (\text{Unlevered Beta} - \text{Beta of Debt}) * (\text{Debt/Equity})$$

According to Grabowski and Pratt:

The Harris-Pringle formulas are consistent with the theory that:

- The discount rate used to calculate the tax shield equals the cost of equity calculated using the asset beta of the firm (i.e., the risk of the tax shield is comparable to the risk of the operating cash flows). That is, the risk of realizing the tax deductions is greater than assumed in the Hamada and Miles-Ezzell formulas.
- Debt capital bears the risk of variability of operating net cash flow in that interest payments and principal repayments may not be made when owed, which implies that tax deductions on the interest expense may not be realized in the period in which the interest is paid (i.e., beta of debt capital may be greater than zero).
- The market value of debt capital remains at a constant percentage of equity capital, which is equivalent to saying that debt increases in proportion to the net cash flow of the firm (net cash flow to invested capital) in every period.<sup>21</sup>

Again, reading Grabowski and Pratt's book will explain this method in more detail, as well as provide alternative methods to unlevering and levering betas. If the Harris-Pringle and Hamada formulas are compared, it appears that the key differences are the incorporation of a debt beta and tax rates. The Harris-Pringle formula accounts for a debt beta but assumes that the tax rates of the subject company are the same as those for publicly traded competitors.

<sup>21</sup> *Ibid.*, 252.

Before we move on, let's do an example. We will apply the same assumptions used in the discussion on the Hamada formula, as well as a debt beta of 0.3. Unlevering the guideline company beta is shown as follows:

$$\begin{aligned}\beta_U &= (\beta_L + \beta_D * [(Debt/Equity)]) / (1 + (Debt/Equity)) \\ \beta_U &= (1.2 + 0.3 * 0.6) / (1 + 0.6) \\ \beta_U &= 0.86\end{aligned}$$

Next, we will relever the beta using the subject company's debt-to-equity ratio:

$$\begin{aligned}\beta_L &= \beta_U + (\beta_U - \beta_D) * (Debt/Equity) \\ \beta_L &= 0.86 + (0.86 - 0.3) * (.25 - .75) \\ \beta_L &= 1.05\end{aligned}$$

Now, hold that thought because we will use this stuff some more when we talk about the WACC.

## Adapting CAPM for the Closely Held Business

Getting back to the real-world requires a valuation analyst to modify the CAPM if it is to be used for the valuation of a closely held company. Remember that this model was developed for use in portfolio analysis and not business valuation. The assumption of a well-diversified portfolio that eliminates unsystematic risk is a poor assumption when trying to address the value of a closely held business. The owner of a closely held company can rarely diversify away the risk element of the closely held business being the major investment in his or her portfolio. Therefore, the CAPM formula is generally modified for the valuation of closely held companies as follows:

$$\begin{aligned}k_e &= R_f + \beta (R_m - R_f) + \alpha \\ \alpha &= \text{Alpha, unsystematic risk (company specific)}\end{aligned}$$

The alpha may be a company-specific risk adjustment or an adjustment for size, or both. Because the CAPM assumes a diversified portfolio, an additional factor that is specific to the investor in a closely held company should be considered. For that investor, the closely held company may be the largest investment of his or her lifetime, and there may not be any diversification. Therefore, unsystematic risk, which was assumed to be diversified away in the original CAPM equation, may be a factor in the discount rates of closely held companies. The size premium should vary depending on the size of the valuation subject. The discount rates for small companies are generally higher than those for large ones, despite the fact that the betas of smaller companies are often lower than those of larger companies. Smaller companies tend to trade less often, which ultimately leads to lower betas. However, many smaller companies can have tremendous illiquidity premiums.

Before we go any farther, let's spend some time on the *Risk Premium Report*, particularly applying it to the size premium for use in CAPM.

The data included in the *Risk Premium Report* covers all 8 metrics and is broken down into 25 percentiles. The data provided includes average market value, sumBeta, arithmetic returns, arithmetic equity risk premiums, indicated CAPM premium, premium over CAPM, and smoothed premium over CAPM for each percentile. CAPM is used to help determine the size premium for each of the percentiles. This means that the size premium, as determined in this report, is the excess over the CAPM. D&P also provides data from Morningstar's *S&P 500 Classic* on these tables in the *Valuation Handbook* so that you can use them in applying CAPM. Let's do an example and try to make sense out of this stuff.

Let's assume the following:

$$\begin{aligned} R_f &= 5.00\% \text{ at valuation date} \\ \beta &= 0.90 \text{ (median of guideline companies)} \\ \text{ERP} &= 4.81\% \text{ (12.01\% - 7.20\% from D\&P table)} \\ \alpha &= 2.00\% \end{aligned}$$

Further, assume that the smoothed premium over CAPM for the 25th percentile for each of the 8 metrics results in an average of 7.30 percent. Calculate the cost of equity using CAPM:

$$\begin{aligned} k_e &= R_f + \beta (R_m - R_f) + \alpha \\ k_e &= 5.00\% + [0.90 * 4.81\%] + 7.30\% + 2.00\% \\ k_e &= 18.63\% \end{aligned}$$

What did we just do? We multiplied the ERP (calculated as the difference between the large company stocks and the income returns from long-term Treasury bonds) by the median beta (determined from guideline companies). We added the risk-free rate at the valuation date to that, the average size premium from the *Risk Premium Report*, and the company-specific risk premium. If the subject company is smaller than the 25th percentile, you can apply the same type of analysis as presented earlier in this chapter to get a more applicable size premium. Notice, however, that this is only applicable to size in this instance because the ERP is handled separately.

The company-specific adjustment is based on the valuation analyst's judgment. The factors used to make this adjustment are similar to those that are used for selecting market multiples. The difficulty with this adjustment is determining how much weight to put on the risk of achieving the forecasted growth. In the market approach, you can at least look at the guideline companies' earnings estimates to get an idea of short-term growth rates. In the derivation of a discount rate, particularly from the overall market, it is considerably more difficult.

## Other Methods for Estimating a Discount Rate

There are several alternatives to the build-up and CAPM methods. I like the dart board approach: Throw a dart and pick a discount rate. Although this book cannot possibly cover every alternative, I want to discuss some of the more common methods of deriving a discount rate. More often than not, the same methods are used to develop capitalization rates, which I will discuss. Remember that the difference between discount rates and capitalization rates is long-term sustainable growth. Some of the alternatives include the following:

- Price-to-earnings reciprocal plus growth
- Factor rating method
- WACC
- The private cost of capital (PCOC) model
- *International Valuation Handbook—Guide to Cost of Capital*

## Price-to-Earnings Reciprocal Plus Growth

One of the methods used to calculate a discount rate is to take the reciprocal of an industry-specific price-to-earnings multiple from the market (this provides a capitalization rate) and add the expected growth rate of the returns attributable to the guideline companies. This is said to be a market-derived rate because the price-to-earnings multiples will be determined from guideline companies. Because an earnings-to-price ratio is the same as a capitalization rate, long-term sustainable growth must be added to the result to convert from a capitalization rate to a discount rate.

Mathematically, the formula would look like this:

$$k - g = c$$

$$\begin{aligned} k &= \text{Discount rate} \\ g &= \text{Growth (long-term sustainable)} \\ c &= \text{Capitalization rate} \end{aligned}$$

Therefore, moving around the components of this formula results in the following:

$$c + g = k$$

If the valuation analyst uses this method, please remember that the result is a discount rate that is applicable to net income and not cash flow. Because the price-to-earnings multiple uses earnings and not cash flow, the result will be an earnings-based capitalization rate that is then converted to an earnings-based discount rate. Be careful to remain consistent (apples to apples, not apples to bananas—we do not want a fruit salad).

The difficulty in applying this method is figuring out what the market's expectations are for long-term sustainable growth. This growth is reflected in the market price of the stocks, but it is not published anywhere. Some valuation analysts will turn to industry data to come up with this expected growth rate. In practice, I have found that the rates published for industries are short term (maybe a few years), not long term. This makes this method difficult to use.

Let me give you an example. Let's assume you find public companies that are in the industry of the subject company. The average or median (for those who want to be more statistically correct) price-to-earnings multiple of these companies is 25 to 1. This means that these public companies are currently trading at 25 times earnings. The mathematical inverse, or capitalization rate, implied by the market can be stated as follows:

$$1/25 = .04 \text{ or } 4\%$$

If you refer to the *Valuation Handbook*, you can find out what they have reported as the median discount rate for the specific two- or three-digit SIC code based on the different methods they use to calculate it. More often than not, the discount rate for equity will fall in the range of +/- 15 percent. If this were the case, the implied growth rate, which would be the difference between the discount rate and the capitalization rate, would be about 11 percent. The problem with this picture is a simple one. A company's earnings cannot possibly grow at an 11 percent rate into perpetuity or it will eventually exceed the gross domestic product of the world. Long-term sustainable growth cannot exceed the rate of inflation and population growth. Even if short-term growth is high, the present value of this growth into perpetuity cannot be that high.

## Factor Rating Method

Another way of determining a discount rate is known as the *factor rating method*. This is very similar to what was described in the Frank Evans article. This method tends to be more popular among business brokers than among valuation analysts. However, this method is not much different from the build-up method. In the factor rating method, the company-specific risk premium is broken down into numerous factors. Each factor is given a weighting. These weightings will vary depending upon the valuation analyst, but they generally range from zero to three. The factors may include the location of the business, financial performance, management, liquidity, and so forth. In case these factors aren't apparent, they are all the items that the valuation analyst should be considering in the risk analysis of the company. Frequently, the use of this method is for the determination of a capitalization rate (not a discount rate) to be applied against seller's discretionary cash flow.

There is nothing empirical about the zero to three range for the factors. It is judgment. That's right, judgment. As a matter of fact, it is subjective judgment. As valuation analysts, it is our job to be objectively subjective. Be very careful if planning to use this method. I personally do not think that it is very good to use for anything more than factors to consider in determining company-specific risk.

## Weighted Average Cost of Capital

The next method for determining a discount rate is known as the WACC. (I used to think that this business was wacky! I don't think that anymore. Now I know it! But before you quote me out of context, this is a generally accepted methodology for determining a discount rate to be applied to invested capital net cash flow). The WACC is a combination of (1) the required rate of return on the equity of the company and (2) the required

rate of return on the debt of the company. The WACC is used when the valuation analyst values the invested capital of the valuation subject (invested capital = debt + equity).

The theory behind a WACC is simple. Because a company is financed partly with debt and partly with equity, the return on investment should consider the risk of each element. Because the business owner is not directly responsible for the debt (assume no personal guarantee), the bank, not the business owner, is the one that is at risk for that portion of the invested capital. Therefore, if the benefit stream comprises both debt and equity, it would seem logical that the risk is reduced on the overall capital for the investors.

However, the business owner is completely at risk for the money that he or she invests in the business. This money should command a higher return because of the increased risk associated with that portion of the invested capital. So, what does this all mean?

The WACC is determined using the following formula:

$$(k_e \times W_e) + (k_d [1 - t] \times W_d)$$

$k_e$  = Required rate of return for the company's equity capital (discount rate)  
 $k_d$  = Company's cost of debt capital (borrowing)  
 $W_e$  = Percentage of equity capital in the company's capital structure  
 $W_d$  = Percentage of debt capital in the company's capital structure  
 $t$  = Company's effective income tax rate

Pretty ugly, isn't it? Once again, this looks more complicated than it really is. A demonstration of the calculations is shown in exhibit 13.1.

### EXHIBIT 13.1 Application of the WACC

Assume that after the valuation analyst analyzes the company, its industry, and other pertinent factors, it is determined that the company's required rate of return on equity is 20 percent. The company is borrowing money from its bank at 9 percent. The company's effective tax rate is 40 percent. The company's condensed balance sheet looks like this:

Assets		Liabilities and Equity	
Current assets	\$ 500,000	Current liabilities	\$ 200,000
Fixed assets (net)	725,000	Long-term debt*	300,000
Other assets	175,000	Equity	900,000
<b>Total</b>	<b>\$1,400,000</b>	<b>Total</b>	<b>\$1,400,000</b>

\* Long-term debt contains all the debt on the balance sheet. The short-term portion of the long-term debt would also be included in the calculation below.

Based on these facts, the WACC would be calculated as follows:

$$\begin{aligned}
 &(k_e \times W_e) + (k_d [1 - t] \times W_d) \\
 &(.20 \times .75) + (.09 [1 - .40] \times .25) \\
 &.15 + .01 = .16
 \end{aligned}$$

Capital structure:

$$\text{Debt: } \$300,000 + \text{Equity: } \$900,000 = \text{Total: } \$1,200,000$$

Note that there is a technical error in exhibit 13.1. The WACC calculation is supposed to be based on the market value of the debt and equity. For closely held companies, we are generally valuing the equity. Therefore, this contains circular logic. We need to know the answer to get the answer! For the WACC to truly work, the theory indicates that we should allocate the cost of capital for the invested capital based on the market value of the debt and equity. If we knew the market value of the equity, why would we need to do any other calculations? We would already have the value of the subject company. For guideline companies, this works. For closely held companies, we make assumptions.

If the company has preferred stock, as well as common, the formula would be modified to include the preferred stock as part of the capital structure, and the formula would look like this:

$$(k_e \times W_e) + (k_p \times W_p) + (k_d [1 - t] \times W_d)$$

$k_p$  = Cost of capital for the preferred stock  
 $W_p$  = Weight of the preferred stock in the capital structure

Now imagine if you have class A common and class B common, among others. You can have one heck of an equation if you choose to!

Regardless of the number of classes and types of stock in the capital structure, the same question arises time and time again: What capital structure should be used in the WACC equation? Should it be the actual capital structure of the subject company, or should it be the normal capital structure of the industry? There are valid arguments for both alternatives if the interest being valued is a controlling interest. However, a minority interest cannot change the capital structure of the business, whereas the controlling interest can. This means that consideration should be given to the ability of the willing buyer to change things.

In a smaller business, it is not unusual to see much more debt as a percentage of the capital structure. This is usually because the small company is undercapitalized and depends on debt to make up the difference. However, the small business owner frequently guarantees this debt and uses his or her residence or other belongings as additional security for the lender. In this instance, the debt starts to take on the attributes of equity because of the risk of personal loss to the owner. This could be justification for using a discount rate that is higher than the WACC, but lower than the discount rate for pure equity. Once again, common sense and good judgment must be applied on a case-by-case basis.

Because I promised that we would use the levering and unlevering example again, let's do it. Note that depending on what data is used to derive the cost of equity, you should be consistent in applying either the Hamada or Harris-Pringle formula. If risk premiums from exhibit B of the *Risk Premium Report* are being used, then the Harris-Pringle formula should be used. We will apply the Hamada formula in our example.

Assume that the controlling stockholder of XYZ Corporation is planning to gift a minority interest to his child. Let's calculate a WACC using CAPM with the information from the previous example along with the following: 20-year risk-free rate = 6%; ERP = 7%; size premium = 5%; tax rate = 40%; borrowing rate = 10%; company-specific risk = 4%.

$$(k_e \times W_e) + (k_d [1 - t] \times W_d)$$

Let's calculate the discount rate:  $(k_e) = 6\% + (7\% \times 1.06) + 5\% + 4\% = 22.42\%$ . The 1.06 is the re-levered beta from the previous example. A minority interest cannot change the capital structure, so this beta is used along with the actual capital structure for XYZ Corporation, which provides a WACC as follows:

$$(22.42 \times 75\%) + (10.00 [1 - .40] \times 25\%)$$

$$16.82 + 1.5 = 18.32\%$$

The weights of 75 percent and 25 percent were based on the company's actual capital structure, which was given as 25 percent interest-bearing debt. If a control buyer came along, the WACC would be calculated as follows:

$$(22.42 \times 40\%) + (10.00 [1 - .40] \times 60\%) \\ 8.97 + 3.60 = 12.57\%$$

The weights given to the debt and equity are now based on the optimal capital structure that was given previously based on the guideline companies. The assumption for a control owner is that the capital structure will most likely resemble that of the industry (guideline companies) and will be aimed at lowering the cost of capital to the invested capital. Lowering the cost of capital will help maximize the value of the company.

### The Private Cost of Capital Model

All the methodologies to derive discount rates discussed thus far have relied on historical data available in the public market. However, the ultimate goal behind developing a discount rate is to reflect the rate of return expected by an investor in a particular company. The problem with using data from the public market is that it reflects the rates of return for companies in the public markets, rather than the private markets. Furthermore, this data is based on historical returns, rather than expected or required rates of return. In using this data, we make adjustments to the discount rate (often subjective; think company-specific risk premium) and through other analyses (for example, S corporation premium calculations) to account for company-specific risks that do not exist in the public market. Some differences between the public and private markets are shown in figure 13.13.<sup>22</sup>

**Figure 13.13**

<b>Public Markets (Wall St.)</b>	<b>Private Markets (Main St.)</b>
<b>Use of C corporation</b>	<b>Can be any type entity (S, LLC, etc)</b>
<b>Value is established by a market</b>	<b>Value is established at a point in time</b>
<b>Ready access to public capital markets</b>	<b>No access to public capital markets</b>
<b>Owners have limited liability</b>	<b>Owners may have unlimited liability</b>
<b>Owners are well diversified</b>	<b>Owners have one primary asset</b>
<b>Professional management</b>	<b>Owner management</b>
<b>Company has infinite life</b>	<b>Typical company life of one generation</b>
<b>Liquid securities efficiently traded</b>	<b>Illiquid securities inefficiently traded</b>
<b>Profit maximization as goal</b>	<b>Personal wealth creation as goal</b>

A newer model, developed by John Paglia of Pepperdine University and Robert Slee of the investment banking firm Robertson & Foley, surfaced within the last decade. In order to avoid making some of the subjective adjustments that compensate for the differences between public and private companies, Paglia and Slee developed the PCOC model. This model is based on the Pepperdine PCOC survey project, which was launched

<sup>22</sup> Slee, Robert T., *Private Capital Markets: Valuation, Capitalization, and Transfer of Private Business Interests* (Hoboken, NJ: Wiley, 2004).

in 2007 by Paglia. The PCOC surveys collect return expectations from various segments of the private capital markets, including various sources of debt financing and equity investors who provide detail regarding the various criteria that prospects must meet in order to qualify for an investment. The survey is administered online on an annual basis to financial professionals. Pepperdine University provides the results of the PCOC study for free at <http://bschool.pepperdine.edu/appliedresearch/research/pcmsurvey/reports.htm>.

Paglia and Slee collected 627 responses in the first survey (published in August 2009) and over 1,500 responses in the 2014 survey (taken in October 2013). The results of the 2014 PCOC study are shown in figure 13.14.<sup>23</sup>

**Figure 13.14 Private Capital Market Required Rates of Return**

	1st quartile	Median	3rd quartile
Bank (\$1M CF loan)	5.0%	5.5%	6.1%

<sup>23</sup> Pepperdine Private Capital Markets Project, 2014 Capital Markets Report.

Each source of financing has its own rules regarding capital access and expected returns. Thus, in order to understand the PCOC data, I will briefly define each form of financing (see figure 13.15).

When considering the risks associated with each form of financing, it will be apparent that the PCOC study organizes its survey data to reflect the lowest risk financing at the top of figure 13.14 and the highest risk financing towards the bottom. Does this format look familiar? If you recall The Rate of Return Department Store at the beginning of the chapter, the presentation of this data should make even more sense.

Looking at figure 13.14, also notice that the PCOC study provides the median expected returns for each type of financing, as well as the first and third quartiles of those returns. The PCOC study provides users with information regarding the level of importance of pertinent financial ratios for each source of financing. Further, it provides access to actual financial ratios for borrowers (as reported by survey respondents), organized into median, first quartile, and third quartile. In some cases, this data is even broken down by industry. With this data, you can benchmark the subject company against other recipients of certain types of financing to determine whether the median, first quartile, or third quartile expected returns should be used in developing a cost of capital. This comparative quantitative analysis should be coupled with a qualitative analysis (like SWOT or Porter).

**Figure 13.15**

<b>Source of Financing</b>	<b>Type of Financing (Debt or Equity)</b>	<b>Definition</b>
<b>Bank (Cash Flow Loan)</b>	<b>Debt</b>	<b>Senior cash flow lenders limit financing to businesses based on a function of a multiple on earnings before interest, taxes, depreciation, and amortization (EBITDA). Cash flow lenders typically hold senior positions in a debtor's capital structure. Lenders of this type of debt will require debtors to maintain certain debt coverage ratios and cash flow-to-debt ratios.</b>
<b>Asset-Based Lenders (ABL)</b>	<b>Debt</b>	<b>This class of debt includes asset-based lenders, which require collateral on certain assets held by the debtor. Businesses choose this financing when they cannot obtain a cash flow loan, the company's asset-backed borrowing capacity exceeds its cash-flow-based borrowing capacity, or if the cost of asset-based financing is cheaper than cash-flow-based debt. Since ABLs have collateral in debtors' assets, these lenders are somewhat less concerned than cash flow lenders about debt covenants.</b>

**Figure 13.15**

Source of Financing	Type of Financing (Debt or Equity)	Definition
Mezzanine Funds (Mezz)	Debt	Mezzanine funds provide financing to companies generating at least \$1 million in cash flow. Much mezzanine financing is placed in manufacturing, services, and health care businesses. The amount of mezzanine financing available to a business is typically based on a multiple of EBITDA and the debtor's senior debt-borrowing capacity. Debtors are required to maintain certain debt coverage ratios.
Private Equity Group (EG)	Equity	Private equity groups typically provide financing to companies that are generating at least \$1 million in EBITDA. Much of private equity funding is provided to manufacturing, service, and health care businesses. Private equity funds often consider the quality of management, customer concentration, historical operating performance, and future prospects as important investment factors.
Venture Capital (VC)	Equity	Venture capital firms invest in companies within a wide range of development stages. Venture capital is invested in companies with high growth prospects, quality management teams, and viable business plans and models.
Angel	Equity	Angel investors provide financing to high-growth companies primarily in their seed, start-up, and early stages. Companies that receive angel financing typically have quality management, high growth prospects, and viable business plans and models.

Special thanks to John P aglia for allowing me to use this material.

The overall point of the PCOC model is to select expected rates of return corresponding with the subject company's capital structure and adjusting from the median based on a comparative analysis. This is the same basic concept used in everything we do. Just as you would adjust multiples derived from publicly traded guideline companies up or down depending on the investment characteristics of the subject company, the PCOC data must be analyzed and adjusted to arrive at an appropriate discount rate for the subject company. The strength of this model lies in the fact that the valuation analyst does not need to make adjustments to account for the differences between larger publicly traded companies and the much smaller privately held firms that we value. The measurement applies directly to privately held businesses.

However, before the valuation analyst relies on this study for the basis of his or her discount rate, he or she should be aware of the issues surrounding the PCOC model. Kevin Yeanoplos CPA/ABV, ASA of Brueggeman and Johnson Yeanoplos, P.C. identifies that the primary weakness in the PCOC study is that it is based on a survey of expected rates of return. The problem with expected rates of return is that they are not always right! The expectations compiled by the PCOC survey are simply opinions. In the best of times, expectations may not be on point with actual results. In times of great uncertainty, as has been the case since 2008, expectations may be completely off track. On top of this, by nature, the accuracy of surveys can be reduced by lack of honesty and potential professional motivations of respondents to drive results in a certain direction. Furthermore, the latest survey received over 1,500 total responses, but individual types of financing, in some cases, received fewer than 100 responses. With this sample size, the results can easily be skewed by inaccurate responses.

As with every business valuation model and concept, there are strengths and weaknesses, and both should be considered before using the PCOC model. If the valuation analyst plans to use the PCOC model, he or she needs to understand the study, the model, and the issues surrounding both. Without a doubt, even with its weaknesses, this model is a great addition to the valuation toolbox and should not be ignored.

## Blended Methods

Another method of determining a discount rate is to create a blending of the rates of return that would be required on the various assets employed in the business (cash, accounts receivable, inventory, plant property and equipment, and intangible assets, among others). Liabilities would have to be considered in this analysis, as well. The concept is similar to the WACC.

Investment return requirements can also be used but generally by inference only. An example of this would be what a venture capitalist may require in a given situation. Venture capitalists base their rates on the risk associated with the venture capital, but they generally also consider an exit strategy in a reasonable number of years. This exit strategy may include a public offering or a management buyout.

Other methods that result in a discount rate for net cash flow include the arbitrage pricing model and the dividend yield plus growth model. Because neither of these models will be used in the valuation of small- and medium-sized businesses, this discussion ends here.

Regardless of the rate of return selected, it must be correlated with the risk inherent in the subject and, most important, produce a result that makes sense.

## *International Valuation Handbook—Guide to Cost of Capital*

In this global economy, valuation analysts will occasionally have to value a company based outside of the United States. One of the primary issues surrounding these types of engagements is how to measure the additional risk associated with a company operating in a foreign country (as opposed to the United States). For example, a company operating an oil pipeline in a country riddled with constant political turmoil and frequent civil war will be much riskier than a company operating a pipeline in the United States. D&P has a publication that can help with those types of assignments. *The International Valuation Handbook—Guide to Cost of Capital (International Valuation Handbook)*, published annually starting in 2014, provides country-level cost of capital analyses that were previously published in Morningstar's Ibbotson international cost of capital reports, which are now discontinued. The *International Valuation Handbook* expands on the former Morningstar data in a number of ways to enhance its usability. While I won't go into great depth on this publication, the *International Valuation Handbook* provides four indications of country risk:

1. Historical ERPs adjusted for country risk for 18 countries. These ERPs are derived using the MSCI Total Returns Indices, similar to how D&P calculates the historical ERP in the *Valuation Handbook*.
2. Country risk premia based on the spread between foreign country government bond yields and U.S. Treasury bond yields of the same maturity. This data is available for 188 countries.
3. Volatility-based adjustment to a beta-adjusted ERP for the United States or Germany. This data is available for 69 countries.
4. Country risk premia based on credit ratings for each country. This model is based on a survey of 55 investor perspectives and provides indications for 179 countries.

Before the valuation analyst uses this data, he or she really needs to read the entire publication (maybe twice) so he or she understands how the data is derived and how it should be applied. D&P acknowledges that no one model is perfect and that valuation analysts should consider all four methods contained in the *International Valuation Handbook*, if possible, and make a decision about whether the proper rate of return should be in the lower, middle, or upper end of the range (another example of how this stuff isn't an exact science).

## Capitalization Rates

A *capitalization rate* is the rate used to convert a benefit stream for a single period into an indication of the fair market value of the property that is its source. This rate is the required rate of return for an income-generating asset from which anticipated growth has been subtracted. As discussed previously, a capitalization rate is a discount rate minus growth. This is expressed as follows:

$$c = k - g$$

In this equation,  $g$  represents long-term sustainable growth (not next year's growth). This, by the way, is the growth of the benefit stream and not revenues. Capitalization rates, similar to discount rates, are determined by the market based on the duration and risk of the investment. They vary with time, even for the same investment, and are sensitive to, and incorporate, long-term inflationary expectations.

Capitalization rates consider the risk that generally resides in the market, and they must be adjusted for the risk that is specific to the valuation subject. Capitalization rates are founded on the principle of substitution because they are based on the yields available on alternative investments. They will also depend on the nature of the benefit stream being capitalized (operating income, income before taxes, net income after taxes, dividends, or cash flow).

A capitalization rate is frequently derived from the valuation subject's discount rate. It is used primarily as a divisor to determine value. The basis of the relationship between the discount rate and the capitalization rate is the assumption that the business has a perpetual life and its annual growth will be constant. The relationship is expressed as follows:

$$\text{Discount rate} - \text{Growth rate} = \text{Capitalization rate}$$

Mathematically, the discount and capitalization rates used in the multiperiod and single period models discussed in chapter 12 will result in the same conclusion. What is effectively being done in these models is the removal of growth from the numerator (top) and denominator (bottom) of the equations. I discussed this math stuff in the last chapter.

A simple mathematical proof follows. Assume that during a valuation, the forecast benefit stream for next year was \$110 and was expected to grow each year by 10 percent. Assume a 25 percent discount rate. A multiperiod model would result in the present value being calculated for the earlier years as follows:

$$\begin{aligned} PV &= \frac{110}{(1 + .25)^1} + \frac{[110 \times 1.10]}{(1 + .25)^1} \\ PV &= 88 + 645 \\ PV &= 733 \end{aligned}$$

As a reminder, the terminal value grows the last year of the forecast period to the following year ( $110 \times 1.10$ ). This result is then capitalized by the discount rate minus long-term sustainable growth ( $.25 - .10$ ). That result is then discounted to present value using the same present value factor as the last year of the forecast period  $(1 + .25)^1$  (assume end-of-year convention).

If the 10 percent sustainable growth was taken out of the numerator and the denominator, we would have a single period capitalization model, as follows:

$$PV = \frac{110}{.15}$$

$$PV = 733$$

Capitalization rates can also be directly derived from the market without calculating a discount rate. Methods of calculating this rate will be discussed in this chapter. For the time being, let's concentrate on the basic formula. The valuation analyst must use informed judgment in selecting the appropriate growth rate. The company's historical growth, the projected growth of the industry, and many other factors (including, but not limited to, management goals, the ability to achieve desired growth, and borrowing power) should be considered in the determination of the growth rate. The rate should reflect long-term sustainable growth, rather than what is projected for the short term.

An exceptionally high growth rate may not be achievable over the long run. Experts in finance generally expect the long-term growth of a company to average from 3 percent to 5 percent, generally not much more than the rate of inflation. A company can only grow so much. However, the long-term growth rate should reflect the present value of the growth. This means that if short-term growth is expected to be higher, the long-term growth rate's present value may be greater than the 3 percent to 5 percent mentioned in the books.

The selection of growth rates is a part of the valuation that requires the valuation analyst to tie several other parts of the valuation assignment together. The valuation analyst should consider the economic environment and industry outlook in determining the impact of the macroenvironment of the company on future growth in addition to historic growth and management's expectations of future growth. Finally, do not forget that a company can only grow so much before competitive forces enter to take advantage of the future growth.

### Factors Affecting the Selection of the Capitalization Rate

The factors considered for the determination of capitalization rates should be similar to those considered for the determination of discount rates. These include the external factors (those that management has no control over) and the internal factors (those that management has the ability to control). There is little need to go over these factors again. However, do not minimize their importance.

Because capitalization rates are used in a single period model, the rate of growth assumed must be one that could reasonably be expected to be sustained indefinitely. The investment horizon for a closely held business is generally presumed to be long term in nature, therefore, the assumption to be made is that the single benefit stream being capitalized will continue forever. What is the likelihood of a business growing at 25 percent per year indefinitely? Pretty slim! A small business would become a large business in no time at all if that were the case.

With such rapid growth, the local hardware store would become The Home Depot. I don't think so! All businesses are subject to cycles, as is life (rapid growth, slow growth, stagnation, and death). Therefore, the growth rate assumed in any valuation must take into consideration the existing state of maturity of the subject company.

## Sources of Data on Capitalization Rates

The ideal source of data for capitalization rates is the public (or private) market for corporate securities. However, if the valuation analyst is able to locate transactions that can be used in the determination of capitalization rates, the market approach (not the income approach) would be used. For example, assume that the following transactions were located from the public market:

Sales price	\$10,000,000	\$ 5,000,000	\$20,000,000
Net income	2,500,000	750,000	4,000,000
Cash flow (net)	2,000,000	500,000	3,000,000
Revenues	20,000,000	15,000,000	48,000,000

This information could be used to calculate the implied capitalization rates that were the results of actual transactions. This makes merger and acquisition data useful. The implied capitalization rates are as follows:

Net income	25%	15%	20%
Cash flow (net)	20%	10%	15%
Revenues	200%	300%	240%

In chapter 10, I discussed the calculation of pricing multiples using this data, which can also be used in the determination of capitalization rates for the income approach. However, merger and acquisition transaction data must be carefully scrutinized because it may embody elements of control as a result of the acquisition. The prices paid for the acquisition may also include a premium based on the expected synergies for the acquirer.

The transaction data derived from the public market is generally an indication of the value of stockholders' equity. This means that capitalization rates for use with invested capital benefit streams must incorporate assumptions regarding typical capital structures (debt and equity), not necessarily the actual structure of the subject company, because the public companies are more likely to have a better debt-to-equity relationship than the smaller, closely held company. This could require the valuation analyst to make certain adjustments to compensate for the different risk of the valuation subject because of its particular capital structure. This problem is reduced if the merger and acquisition data come from private company transactions of similarly sized companies.

On occasion, the valuation analyst will locate transactions in an industry that has a considerable amount of merger and acquisition activity. When transactions occur in an industry that is "hot," the capitalization rates reflected in the prices paid may have limited applicability. There may be so much anticipated growth in this industry that the capitalization rates may not make any sense. For example, if high price-to-earnings multiples are being paid for companies (say, 105 times the earnings), the implied capitalization rate would be less than 1 percent. We could rarely, if ever, use this type of information for a closely held company.

The opinions of authors, experts, and others with special insight into the market may be used to develop capitalization rates. This is a dangerous practice, however, because the rates referred to in the writings are usually based on the individuals' own experiences. Without knowing the facts and circumstances of the particular situations, it is impossible to rely on someone else's experience.

The valuation analyst should also be aware of current and evolving case law, particularly if the valuation will be used in a litigation. However, it is a common error to try to apply an old case to a current situation (sort of like putting a square peg in a round hole) because the times and facts are different.

The information maintained in the market data file of The Institute of Business Appraisers, BizComps, Pratt's Stats, Done Deals, and even possibly Thomson Financial M&A are other sources for determining capitalization rates. This information can allow the valuation analyst to determine the capitalization rates for various levels of benefit streams based on the information available in the databases. The same caution must be applied as was discussed in chapter 10, but this information is considerably better than trying to create your own capitalization rate from scratch.

Other, less sophisticated methods for determining capitalization rates include variations on the build-up method. These methods assign a factor to various risk elements in order to derive a capitalization rate. This is similar to the factor rating method discussed previously.

The capitalization rate must be derived by a method that matches it to the benefit stream being used. Depending upon the method used to derive the capitalization rate, the result will be applicable to a particular benefit stream. For example, if the CAPM is used, the discount rate is applicable to net cash flow. Subtracting long-term sustainable growth would result in a capitalization rate that is applicable to net cash flow.

The build-up method will result in either a discount rate or a capitalization rate for numerous benefit streams, depending upon the source of the information used to perform the build up. Other benefit streams (such as net income) may be used, but the discount rate must be adjusted from what was derived by the cash flow methods. This is accomplished by adding a premium (not to be confused with a control premium) to the rate derived for cash flow in order to compensate for the additional risk related to the other benefit stream. A capitalization rate for earnings does not equal a capitalization rate for net cash flow because earnings do not generally equal net cash flow.

The relationship of the discount rate derived for different benefit streams is based on the amount of risk that is implied in the benefit stream being used by the valuation analyst. In theory, net cash flow is the cash available to the stockholders; therefore, the analyst has taken into consideration items such as working capital needs, fixed asset requirements, and long-term debt repayments and borrowings. The more confidence the valuation analyst has after considering all of these factors, the lower the discount rate.

Many experienced valuation analysts have written that the range most often seen in practice between the rate used for net cash flow and net earnings is approximately 3 percent to 6 percent. This does not mean, however, that this range is an absolute and should always be used. In a master's thesis titled "Empirical Research Study of Rates of Return on Earnings and Cash Flow,"<sup>24</sup> Joseph A. Agiato, CPA, CBA, ASA, indicates that his study confirms the 3 percent to 6 percent rule of thumb.

In general, the higher the net cash flow discount rate, the higher the net income discount rate premium, assuming all other factors are the same. A high-cash-flow discount rate indicates that there is a degree of risk driving the rate up. Because earnings consider fewer factors than cash flow does, there is a normal tendency to believe that the rate for earnings should be higher. The higher the forecast growth rate, the higher the net income discount rate premium, assuming all other factors are the same.

High growth reflects its own element of risk in the subject company's ability to remain profitable as it incurs new levels of fixed and variable costs that are attributable to growth. If the valuation analyst has derived a high net cash flow discount rate at the same time that there is expected high growth, then the net income discount rate premium would be pushed higher than the 3 percent to 6 percent range mentioned previously (sometimes much higher). Low growth would keep the net income discount rate premium above zero but at the lower end of the 3 percent to 6 percent range.

.....  
24 This thesis is on file at Lindenwood College, St. Charles, MO.

## Deriving Discount and Capitalization Rates Applicable to Net Income Directly From the Market

The inverse of the price-to-earnings ratio is the earnings-to-price ratio, which is a capitalization rate applicable to net income (in which *earnings* are defined as net income). To get a discount rate, the valuation analyst must approximate growth and add that growth to the earnings-to-price ratio. The difficult part is establishing the proper amount of growth based on the market price-to-earnings multiples. Rarely in the financial information about the guideline companies selected do we find growth rates other than those being forecast by the analysts. We would need the actual growth implicit in the price of the stock in order to be more accurate. If we could figure out the long-term growth that is implied in the price-to-earnings multiples of the guideline companies, discount rates would be easier to calculate.

The earnings-to-price ratio is directly observable in the market, which provides the valuation analyst with solid empirical evidence about the capitalization rate, but we must still estimate the growth rates to achieve a discount rate for those same earnings. Expected growth rates for specific public companies appear in *Value Line Investment Survey* (available at [www.valueline.com](http://www.valueline.com)), but they are short-term growth rates. We need a long-term sustainable growth rate, which means that the Value Line growth rates will probably be of limited help.

A possible alternative to derive growth for the public companies requires us to assume that over the long term, the dividend payout equals the total cash return on an equity investment. This means that dividends would be growing at the same rate as earnings, indicating a constant payout ratio. In this instance, the capitalization rate for net cash flow would be equal to the dividend yield. If this were the case, the discount rate for net cash flow minus growth would equal dividend yield. Therefore, the discount rate for net cash flow based on the dividend yield would be available in newspapers.

## Back to the Real World

In case a touch of reality is necessary, capitalization rates, like discount rates, are market driven. However, there is very little information available to help valuation analysts determine the correct rate to use when valuing smaller companies. Let's keep in mind that our role as valuation analysts is not to determine discount and capitalization rates but, rather, to provide a conclusion about the value of the valuation subject. Regardless of the method used to derive these rates, the answer has to make sense. The principle of substitution alerts valuation analysts to the fact that the rates should be relevant to other rates in the marketplace, given the risk of the valuation subject. But there are no tables, charts, or gurus to help ensure a correct rate.

What we do know is that the discount or capitalization rate selected by the valuation analyst should match the benefit stream being discounted or capitalized. It is theoretically incorrect to use the same rate for different streams because each stream will have a different degree of risk. We also know that the rate will be risk driven. This means that a small closely held company with no depth in management, in poor financial condition, with no borrowing capacity, and with a high degree of dependence on a single customer has enough risk that the appropriate rate should be way up there.

Because I have examined transactions for smaller closely held companies, the general range of multiples that I have seen in the majority of cases is from one to three times owner's discretionary cash flow. Discretionary cash flow is the amount of money that the owner of the business has available for him or her before a deduction is made for owner's compensation. This equates to a capitalization rate ranging from 33⅓ percent to 100 percent for this income stream. Therefore, if this is the market, shouldn't we, as valuation analysts, use this information? Subtracting a reasonable level of owner's compensation (and possibly either depreciation or a reserve for the replacement of assets) would result in a pretax income stream. This pretax stream would be capitalized at a rate that is less than the rate used for owner's discretionary cash flow because the risk of the amount being capitalized is reduced by subtracting one or two additional items in deriving the pretax income. This is similar to the net cash flow model discussed in chapter 12. This concept is illustrated in exhibit 13.2.

A few observations can be made about the example in exhibit 13.2. The first observation is that there is supposed to be a relationship between the rates used for the benefit streams capitalized or discounted. In this example, the discount rate for net cash flow was used as a basis to calculate the discount rate for net income.

The mathematical relationship between these two elements was used to adjust the original rate that was determined. Wouldn't it be just grand if the world were this simple? Unfortunately, it is not.

The mathematical relationship does not always work in practice. If a multiperiod model is going to be used by the valuation analyst, each year's net income and cash flow would have to be used to calculate a different discount rate for each year. Imagine making a discounting model more complicated than it already is! This example also does not work for the calculation of a capitalization rate for excess earnings. I know this because I have tried to use it!

The second observation is that the capitalization rate for net income was calculated by multiplying the mathematical factor against the capitalization rate for net cash flow. Those who really read this book are probably wondering why I did not just subtract the 5 percent long-term growth from the discount rate for earnings (30 percent), resulting in a capitalization rate of 25 percent. This is because the long-term growth rate must also change based on which benefit stream is being used. The 5 percent growth rate is applied to net cash flow, not net income. This is why the capitalization rate for net income was 23.75 percent instead of 25 percent.

### EXHIBIT 13.2 Discount and Capitalization Rates

Assume that ABC Corporation has the following forecast net cash flow:

Normalized net income	\$150,000
Plus: Non-cash charges	+ 25,000
Minus: Fixed asset additions	– 65,000
Minus: Working capital additions	– 10,000
Plus: Change in debt	+ 20,000
Net cash flow	<u>\$120,000</u>

Now, assume that the discount rate for the equity of ABC Corporation was determined to be 24 percent using the build-up method, based on the *Valuation Handbook*. Also, assume that the long-term sustainable growth rate is assumed to be 5 percent. What is the discount rate for net cash flow? What is the capitalization rate for net cash flow? What about for net income?

Discount rate for net cash flow	24%*
Less: Long-term growth	5%
Capitalization rate for net cash flow	<u>19%</u>

To convert the discount and capitalization rates for use with earnings instead of cash flow, the following mathematical calculations can be performed:

$$\begin{aligned} \text{Normalized net income} \div \text{Net cash flow} & (150,000 \div 120,000) = 1.25 \\ \text{Discount rate for earnings} & (24\% \times 1.25 = 30\%) \\ \text{Capitalization rate for earnings} & (19\% \times 1.25 = 23.75\%) \end{aligned}$$

\* Using the *Valuation Handbook* results in a discount rate for net cash flow because the total return (dividends and capital appreciation) is measured in the ERP.

Once again, what I am saying is that the process is not perfect. There are only two factors that you can use to determine the appropriate rates in any valuation: common sense and good judgment.

## Using Pretax or After-Tax Rates

Although the issue of whether to use pretax or after-tax income streams and capitalization rates is one of the points that creates much confusion among lawyers and judges, the resulting value for the valuation subject should be the same regardless of whether pretax or after-tax income is used in the valuation. The capitalization rate will be adjusted depending on which income stream is used. An example that illustrates this point is contained in exhibit 13.3.

The example in exhibit 13.3 should clarify the fact that it does not matter if pretax or after-tax income is used as long as the capitalization rate correlates to the type of income being capitalized. This same premise holds true for cash flow, EBIT, EBITDA, or any other stream being capitalized or discounted. The capitalization rate or discount rate must correlate to the stream of income that is being capitalized or discounted.

### EXHIBIT 13.3 Pretax or After Tax?

Assume that the value of Smith Corporation is being determined using a capitalization of income method. Smith has a forecast pretax income of \$100,000 and an after-tax income of \$65,000 (assumes a 35 percent tax rate). If the valuation analyst has determined that the appropriate capitalization rate based on pretax information in the market was 20 percent, the valuation calculation would be as follows:

	Pretax	After Tax
Forecast income	\$100,000	\$ 65,000
Capitalization rate	÷ 20%	÷ 13%
Estimated value	\$500,000	\$500,000

If the value of the business was estimated to be \$500,000 using a 20 percent capitalization rate derived from the market on a pretax basis, then the value on an after-tax basis should be the same. If the numerator is changed from \$100,000 (pretax) to \$65,000 (after tax), the denominator (capitalization rate) must be changed by the same methodology. Mathematically, this can be explained by the following formula:

$$C_p \times (1 - t) = C_a$$

where

$C_p$  = Pretax capitalization rate

$t$  = Effective tax rate

$C_a$  = After-tax capitalization rate

This results in the following:

$$20\% \times (1 - 35\%) = 13\%$$

There will be times when the valuation analyst will capitalize a benefit stream other than cash flow or earnings. In fact, there are times when the analyst will use an income approach for a real estate holding company that makes distributions. The same may hold true when the analyst values family limited partnerships that own securities or real estate, or both. On occasion, he or she may even choose to capitalize dividends for a minority interest in an operating company when there is a record of payments being made.

## Discount Rates for Economic Damages

What I have provided thus far is the fundamental theory and methodology behind developing discount and capitalization rates. You can use all of this in pretty much every engagement you will ever see. Some

discussion is necessary, however, with regard to deriving discount rates for economic damage calculations. Although we haven't talked about economic damage calculations yet, I think this is the best place to start the discussion because discount and capitalization rates are probably top of mind at this point. We will talk about economic damage calculations in chapter 26.

In economic damage assignments, two rates of return are important to understand: interest rates and discount rates. You are likely familiar with both (if I have explained them well enough in this chapter). *Interest*, by definition, is the "amount of money that one party will pay for the temporary use of another's money."<sup>25</sup> As we have discussed thoroughly in this chapter, a discount rate reflects the rate of return to an investor for making an investment. Depending on the jurisdiction, the rate at which economic damages would be discounted can be very different. Based on legal precedent, this rate can be based on the rate of return on a safe investment, the injured party's rate of return expected from an investment, or the rate of return associated with the lost profit benefit stream given its risks.

The valuation analyst should always ask his or her client's attorney for the applicable case law or statutes when performing this type of work. The rates of return that the valuation analyst may use will vary by type of damages as well as by jurisdiction. For example, damages related to lost wages will most likely be based on some form of a safe rate. The question is which rate to use: short term, intermediate, or long term? However, there are few jurisdictions in which economic damages to a company are discounted using a rate of return on a safe investment. One such precedent was set by the Supreme Court of Pennsylvania in *Kaczkowski v. Bolubasz*<sup>26</sup> in 1980. A more recent case, *Helpin v. Trustees of University of Pennsylvania*<sup>27</sup> from 2010, described the use of a risk-free return in the context of a lost profits analysis for a dental practice:

To compensate for the competing effects of interest and inflation on a lump-sum damages award for lost future earnings, we adopted the "total offset" approach, which is based on the following assumption:

Under the total offset method, a court does not discount the award to its present value but assumes that the effect of the future inflation rate will completely offset the interest rate, thereby eliminating any need to discount the award to its present value.<sup>28</sup>

Essentially, this statement is saying that an investor in the dental practice would require compensation for interest returns and inflation, which doesn't make sense. We know from our discussion earlier in this chapter that there are many risks above and beyond inflation that apply to investments in privately held businesses. As noted, the application of a risk-free rate of return as the discount rate is typically seen in personal injury claims. However, because *Kaczkowski* set a precedent for the State of Pennsylvania, any economic damages cases in that state have to take this into consideration. But speak to the attorney before you apply the decision from this case!

The rate of return received from an investment in an economic damages assignment can be different depending on the circumstances of the case. If the injured firm would reinvest a court award back into its business, then the rate of return would likely be based on the injured firm's capital structure and return on capital. If a court award cannot be invested back into the firm because it ceased operations, then a rate of return for companies similar to the destroyed business may be applicable.

A discount rate based on the return associated with receiving lost profits must take into consideration the risk of not collecting. One way to think about this is a discount rate that has been further adjusted for collection risk. If there is risk in collecting future cash flows then, according to basic financial theory, the rate of return required from that cash flow should be higher to compensate for the additional risk. The risk adjustment is subjective and, just like everything else, must be well supported.

25 Crain, Michael, "Discounting Lost Profits in Damage Measurements," *The Comprehensive Guide to Lost Profits Damages for Experts and Attorneys*, Nancy J. Fannon, 2011 Edition (Portland, Oregon: Business Valuation Resources, 2010): 466.

26 *Kaczkowski v. Bolubasz*, 421 A.2d 1027 (Pa. 1980).

27 *Helpin v. Trustees of University of Pennsylvania*, 10 A.3d 267 (2010).

28 *Helpin v. Trustees of University of Pennsylvania*, 10 A.3d 267 (2010).

One other fact needs to be remembered by any valuation analyst who performs lost profits analyses. Lost profits only continue for a finite period of time and, therefore, are less risky than income streams that you may capitalize into perpetuity. Therefore, it is rare that an equity discount rate should be the starting point for a lost profits calculation that is discounted to present value. Five years of lost income is very different than a stream of income over the next 20 or 30 years. The longer time frame alone adds risk.

Much of the literature recommends keeping the selection of a discount rate simple. Remember who your audience is: jurors and a judge. An interest rate or rate of return on investment is likely easier to explain than a risk-adjusted discount rate applicable to a stream of lost profits.

## Conclusion

Wow. This chapter is finally done. If I didn't do a very good job, you are probably lost. If I did an okay job, you are still fumbling with your GPS system. I'm sorry. I never promised you a rose garden. In fact, this is a thorny topic. Okay, so I won't give up my day job anytime soon! I hope that despite the uncertainty, you now have more of an idea about discount and capitalization rates. What you have really learned is that these rates come from the market. If you stayed focused, as I suggested at the start of the chapter, you should have realized that no matter what method you use to develop these rates, and regardless of the components that make up that method, you have to measure the risk of what is being discounted or capitalized. Getting lucky is fine too, but don't solely rely on the luck factor. That can get you in trouble!

## Chapter 14

# Premiums and Discounts (Valuation Adjustments)— Part I

### Learning Objectives

In this chapter, I will attempt to explain the following:

- Valuation premiums and discounts, in general
- Control premiums
- Lack of control (minority) discounts
- Discounts from net asset value
- Discounts for embedded capital gains
- Nonvoting stock discount

### Introduction

The final value reached in the valuation of a closely held business may be more or less than the value that was calculated using the methods previously discussed in this book. Valuation discounts, premiums, or both, may or may not be appropriate in every business valuation. The type and size of the discount(s) or premium(s) will vary depending on the starting point. The starting point will depend on which methods of valuation were used during the valuation as well as other factors, such as the standard of value, normalization adjustments applied, and the sources of information used to derive multiples or discount rates.

The following are some of the common valuation adjustments that we see in business valuations:

- Control premium
- Lack of control (minority) discount
- Discount for lack of marketability (illiquidity)
- Private company discount
- Discount from net asset value
- Key person discount
- Embedded capital gains discount
- Blockage discount
- Non-homogenous assets (portfolio) discount
- Nonvoting stock discount

For a very long time, valuation premiums and discounts were called *premiums and discounts*. Recently, the terminology has begun to change. These items are now referred to as *valuation adjustments* by many valuation analysts. I am going to use these terms interchangeably, so do not get confused. Think about it this way—after the valuation analyst reaches a valuation indication, he or she then applies a valuation adjustment to reach the conclusion of value.

The type of value derived from the various methods discussed throughout this book are shown in table 14.1. The valuation analyst needs to understand the type of value estimate that each of these methods yields in order to know what type of valuation adjustments may be appropriate in any given situation. For example, if the guideline company method is used to value a controlling interest in a closely held company, and the benefit stream used is a minority benefit stream, the valuation analyst would consider the result from this method to be a minority, marketable interest. This means that a control premium may be added to convert the

minority value to a control value. Then, the valuation analyst might take a discount for lack of marketability to convert the value from a control, marketable value to a control nonmarketable value. It's not as bad as it seems! However, although the conventional wisdom has changed in recent times, as discussed in chapter 9, if you believe that the guideline company method results in a control value, adding a control premium would result in double counting. As explained in chapter 9, more and more valuation analysts now believe that the issue of control versus minority depends on the benefit stream being used. Just because the multiples come from the public market does not mean that the result is minority. This is the same principle as the one that discusses why discount rates that also come from the same public market do not result in a control or minority value. I discussed this point in chapter 13.

**TABLE 14.1 Types of Value**

Method	Control/Minority	Marketable/Nonmarketable
<i>Market approach</i>		
Guideline public company method	Control or minority*	Marketable
Acquisition method—public companies	Control	Marketable
Acquisition method—private companies	Control	Nonmarketable
<i>Asset-based approach</i>		
Adjusted book value method	Control	Marketable
Liquidation method	Control	Marketable
Cost to create method	Control	Marketable
<i>Income approach</i>		
Capitalization of benefits method	Control or minority*	Marketable or nonmarketable
Discounted future benefits method	Control or minority*	Marketable or nonmarketable
Excess earnings method	Control	Marketable or nonmarketable

\* Today's theory has changed from the past. Most of the current valuation literature indicates that the outcome of these methods depends on the normalization adjustments that are made to the benefit stream being used in the application of the method. If control adjustments are made, the resulting indication of value is considered to be on a control basis. If no control adjustments are made (and there could be), the indication of value is considered to be on a minority basis.

In addition to understanding the results from applying different valuation methodologies, there are other considerations that the valuation analyst must be aware of. For example, depending on the standard of value, as well as the jurisdiction that the business valuation will be used in, statutes or case law may dictate whether or not a business valuation should include valuation adjustments. For example, in a fair market value assignment, a discount for lack of control may be applicable for a minority interest. However, in a fair value assignment for an oppressed stockholder legal action, such a discount may not be appropriate. Guidance should be obtained from the client's attorney.

Many valuation analysts look to court decisions to support the premiums or discounts that are used in their valuations. These are not a form of market evidence. Court decisions are generally subjective decisions of a particular court in a particular case based on a particular set of facts. Valuation analysts must apply correct methodology, regardless of whether it is supported by court decisions. The benefit of looking at court decisions is to learn when the valuation analyst will have more of a burden of proof because the position being taken is outside the range of prior court decisions. Judge David Laro of the U.S. Tax Court has suggested to participants at various business valuation conferences that they read his opinions before coming into his court, so that they will understand what he expects from the valuation analyst. Court decisions generally

follow the conclusions that valuation analysts reach from their own valuation research, but often with time delay. Therefore, by using court decisions, we are generally following decisions that were made in the past. So, let's be clear about this. It is okay to know about the court decisions, but the valuation analyst does not want to quote opinions and use them to support his or her position. Quoting court cases in the valuation report can also result in the valuation analyst's opinion being rejected because he or she, in essence, was making a legal argument that the valuation expert is generally not qualified to do.

Court decisions are very useful in understanding how the courts have dealt with certain issues. If the valuation analyst plans to deviate from a position taken by The Court, I strongly suggest that he or she do the following:

- Acknowledge in the report (and testimony) the decision of The Court.
- Explain why the valuation analyst believes The Court's position is not applicable to the case at hand. Do not say that The Court made a mistake!
- Provide strong support for the valuation analyst's position in order to demonstrate why his or her position is more theoretically correct than The Court precedent.
- Make sure that the client's attorney is aware (and blesses) of the fact that the valuation analyst is deviating from the case law.
- Make certain that the client understands that the valuation analyst is taking a contrary position to the position in the case law and that he or she has the attorney's approval.
- Pray a lot. This could be a great time to find religion!

With this in mind, what if the case law does not establish precedent? For example, Tax Court Memorandums (that is, the *Mandelbaum* case, which will be discussed in chapter 15) does not establish precedent. Many valuation analysts do not understand this, or they choose to ignore it. This is an important reason to make certain that an attorney is consulted before a valuation analyst blindly starts citing case law in his or her report.

Don't get me wrong. I am not suggesting that the valuation analyst cannot deviate from case law. I am saying that the analyst needs a strong argument that is well supported because if a judge is going to go against legal precedent, the case may be appealed to a higher court. The higher court will need strong evidence (usually testimony because most reports are not admitted as evidence) on which to base its opinion.

It is a mistake to put court case references in a valuation report because the analyst is writing a valuation report and not a legal brief. There are some valuation analysts who start citing court cases, and I am willing to bet that they never read the case that they are citing. Either they paid someone to perform research for them, they have boilerplate from a computer software program, or they lifted the citations from a sample report included in a business valuation textbook. Don't do that. If the valuation analyst is questioned about the relevancy of the case, he or she better be able to answer the questions.

## Types of Discounts

Before I start to explain about the specific valuation adjustments, I want to take a short detour to discuss discounts, in general. There are two types of discounts that we see in business valuation. They are either at the entity level or the owner level.

*Entity-level* discounts are those taken at the control or "entity" level because they apply to any investor in the business, whether it is a control or minority position. Types of entity-level discounts include embedded capital gains, key person discounts, and discounts for environmental or legal issues. Sometimes, a discount for lack of marketability is also considered at the entity level (this will be discussed in the next chapter). Sometimes, these discounts are addressed by using a higher discount rate. However, this is not the recommended technique because a discount rate is different and serves a different purpose than a valuation adjustment. If the valuation analyst decides to do this anyway, and I am sure that someone reading this book will do it despite my saying not to, just be careful not to double-count by increasing the discount rate and then making a valuation adjustment, as well.

*Owner-level* discounts are those that are relevant only to one class of investors, usually at the minority level. Types of owner-level discounts include discounts for lack of control (DLOC), discounts for lack of marketability

(DLOM), discounts for nonvoting status, and blockage discounts. Once again, different types of owners have different sets of rights, and it is for this reason that the valuation analyst must get the attorney involved in this process. A minority shareholder may have very different rights than a minority partner or a minority member based on the state law.

## Levels of Value

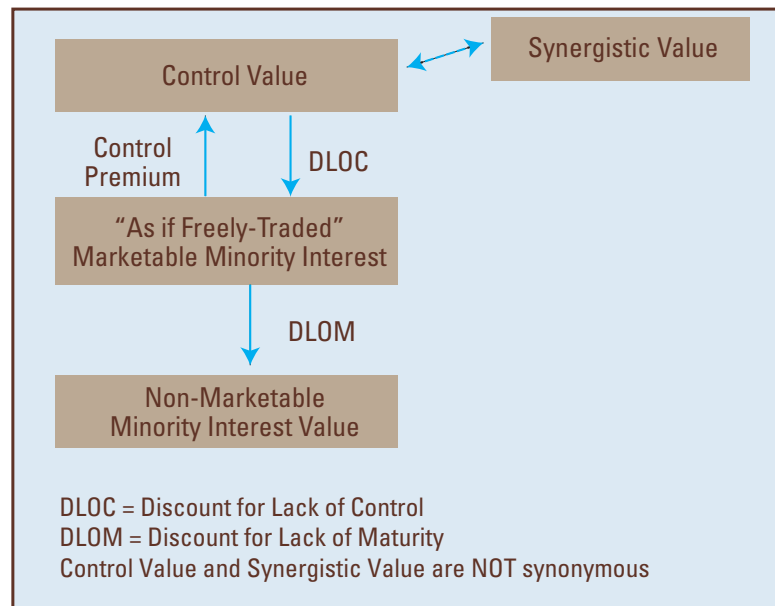

Depending on which valuation treatise you are reading, there are generally three or four levels of value relevant to the valuation of closely held businesses. The three main levels that are discussed include the following:

1. *Control*. The power to direct the management and policies of a business enterprise.
2. *Minority, marketable*. A minority interest in an enterprise that does not suffer from illiquidity—usually relevant to per share interests in publicly held equities that trade freely on an open market.
3. *Minority*. An ownership interest that is less than 50 percent of the voting interest in a business enterprise.

This level is sometimes called *minority, nonmarketable* to reflect the fact that it relates to a closely held interest and does not have the same level of liquidity or marketability as shares in a public company.

The fourth level of value that we frequently see is synergistic value. These levels of value are depicted in figure 14.1.

**Figure 14.1 Levels of Value Chart**

Synergistic value is sometimes also referred to as *investment value*, which is defined as the value to a particular investor based on individual investment requirements and expectations. It is not the equivalent of control value in the levels of value chart. Synergistic value is usually assumed to be a value higher than control value because it encompasses both the power to direct management and policies of a company, as well as the synergies that would be gained by combining two or more specific companies.

Unlike fair market value, synergistic value is not a hypothetical concept, therefore, its definition is different than that of fair market value. However, there may be times that an industry is in consolidation, and as a result, the willing buyers in the marketplace are all synergistic buyers. In this instance, fair market value, on a control basis, may reflect all the synergies, which results in fair market value being equivalent to synergistic value.

## Valuation Adjustment—Control Premium

The pro rata value of a controlling interest in a closely held company is said to be worth more than the value of a minority interest because of the prerogatives of control that generally follow the controlling shares. An investor will generally pay more (a premium) for the rights that are considered to be part of the controlling interest. These rights must be considered in assessing the size of the control premium, including the list of rights found in box 14.1.

A control premium is the opposite of the discount for lack of control (minority discount). The control premium is used to determine the control value of a closely held business when its freely traded minority value has been determined.

### BOX 14.1

#### Prerogatives of Control

- Appoint or change operational management
- Appoint or change members of the board of directors
- Determine management compensation and perquisites
- Set operational and strategic policy and change the course of the business
- Acquire, lease, or liquidate business assets, including plant, property, and equipment
- Select suppliers, vendors, and subcontractors to do business with and award contracts to
- Negotiate and consummate mergers and acquisitions
- Liquidate, dissolve, sell out, or recapitalize the company
- Sell or acquire treasury shares
- Register the company's equity securities for an initial or secondary public offering
- Register the company's debt securities for an initial or secondary public offering
- Declare and pay cash or stock dividends, or both
- Change the articles of incorporation or bylaws
- Set one's own compensation (and perquisites) and the compensation (and perquisites) of related party employees
- Select joint ventures and enter into joint venture and partnership agreements
- Decide what products or services, or both, to offer and how to price those products and services
- Decide what markets and locations to serve, to enter into, and to discontinue serving
- Decide which customer categories to market to and which not to market to
- Enter into inbound and outbound license or sharing agreements regarding intellectual properties
- Block any or all of the above actions\*

\* Shannon P. Pratt and Alina V. Niculita, *Valuing a Business*, 5th ed. (New York: McGraw-Hill, 2008): 385.

In most jurisdictions, majority control is not absolute. A majority owner may have certain duties to other owners, including a fiduciary responsibility to manage the company in a way that provides for the benefit of all owners. Officers and directors may have a duty of loyalty and, therefore, a duty not to deprive the business enterprise of favorable business opportunities. States also vary in the way they define control. In some supermajority states, certain decisions may require an ownership vote of more than 51 percent, greater than two-thirds, or even in some instances, 80 percent may be required to accomplish certain business actions. In California, 33⅓ percent may give a shareholder the right to some actions. In New York, it is only 20 percent.

## Protecting the Minority Owner With Rights and Restrictions Through Agreements

There are various ways to protect a minority owner from the risk of being in a minority position, thereby reducing the amount of the discount for lack of control. Protecting a minority owner can be accomplished through several avenues. Some of them include the following:

- Articles of incorporation (formation documents)
- Cumulative voting
- Preemptive rights
- Supermajority
- Ownership agreements
- Employment agreements
- Right of first refusal
- Other agreements<sup>1</sup>

### Articles of Incorporation

The articles of incorporation or other formation documents may include provisions that allocate certain rights, such as the creation of multiple classes of stock, with each class entitled to elect certain directors. Also, in certain transactions such as the sale of substantially all of the company's assets, a majority of each class of stock may be required to approve corporate actions. This is one of the reasons that we ask for this information in our basic information request. The valuation analyst needs to be aware of these provisions in order to do his or her job.

### Cumulative Voting

Bylaws may provide for cumulative voting that may allow minority shareholders to elect some of the board of directors. According to the SEC website:

Cumulative voting is a type of voting process that helps strengthen the ability of minority shareholders to elect a director. This method allows shareholders to cast all of their votes for a single nominee for the board of directors when the company has multiple openings on its board. In contrast, in "regular" or "statutory" voting, shareholders may not give more than one vote per share to any single nominee. For example, if the election is for four directors and you hold 500 shares (with one vote per share), under the regular method you could vote a maximum of 500 shares for any one candidate (giving you 2,000 votes total 500 votes per each of the four candidates). With cumulative voting, you could choose to vote all 2,000 votes for one candidate, 1,000 each to two candidates, or otherwise divide your votes whichever way you wanted.

### Preemptive Rights

Preemptive rights in the bylaws would allow all shareholders the opportunity to keep their pro rata share of the ownership upon the issuance of additional stock in the company, as opposed to having their interest diluted by the controlling shareholder(s) who may issue additional shares to himself or herself at a favorable price.

### Supermajority

There could be requirements for a supermajority for certain corporate actions. For example, instead of requiring a 51 percent approval to issue new shares in the company, an 80 percent approval might be required, thereby giving a 25 percent shareholder effective veto power in that situation. Some states have supermajority voting requirements for certain major corporate actions, such as mergers and liquidations.

### Ownership Agreements

Ownership agreements can set forth the rights and responsibilities of each of the owners under various circumstances. For example, a buy-sell agreement could require either the controlling owner or the business enterprise to buy back the minority owner's interest at a set price or set formula upon some triggering event,

<sup>1</sup> During this discussion, I refer to shareholders and various corporate situations, but many of these can also apply to partners, members of LLCs, and other types of ventures based on the state statutes. The valuation analyst should request the pertinent statutes so that the rights of the owners can be properly analyzed.

such as death or retirement of the owner. Another real example of this is when we merged with a friend of ours a number of years ago, and he was concerned that he would be outvoted “two to one” if we wanted to take a corporate action that he did not agree with. He did not think about the fact that my partner (my wife) would probably have voted with him more than me, so he really had little to worry about anyway. However, in order to protect him, we agreed that my wife and I would have one-half of a vote each and he would be entitled to a full vote on actions requiring a vote. This way he could block actions that he did not agree with.

## Employment Agreements

Employment agreements may give further protection to a minority owner who also works for the business to ensure that he or she will not be discharged and, therefore, lose the expectation of continued employment. Ironically, more often than not, an employee/owner who gets fired from a closely held business ends up with grounds for oppression (in many states). If it turns out that The Court finds that the owner was oppressed by being fired, the usual remedy is to have that owner bought out at fair value, which is often equal to a pro rata share of the control value.

## Right of First Refusal

If the controlling owner has a right of first refusal, minority owners are free to sell their interests to anyone they choose at any price they choose, but the controlling owner would have the right to match the price and buy the interests before the interests are sold to a third party. Be aware that sometimes the right of first refusal gives the existing owners the right to buy the offered interests at the offer price, but at special terms which are different than the original offer terms. However, a buy-sell agreement and right of first refusal also can give the minority owner an opportunity to buy out the controlling owner upon certain events, such as death or disability.

## Other Agreements

Other agreements can restrict or combine voting rights. For example, a group of shareholders, typically minority shareholders, may form a voting trust, agreeing to vote their stock as a block and thereby achieve a controlling position.

## Legal Remedies

There are certain legal remedies that are afforded to the minority owners of a closely held business. Although this is certainly not a legal treatise, valuation analysts sometimes have to consult with attorneys about the rights associated with the interest being valued. These should be taken into consideration by the analyst. This is discussed further in chapter 24.

## More Control Premium Issues

A control premium may be appropriate for an interest that is less than 100 percent. In this instance, the size of the premium will depend on various factors relating to the amount of control available to the controlling interest. Some of these factors include the following:

- Cumulative versus noncumulative voting rights
- Contractual restrictions (ownership agreements)
- The financial condition of the business
- State statutes
- The distribution of ownership

Let me give you an illustration of how less than a 50 percent interest could have a control premium associated with it. Although the dates in this real example are older, I really liked this assignment, and because this type of situation does not arise regularly in our practice, I am still going to use the dated example. The concepts are much more important than the dates. Part of this assignment required us to value a 47.3 percent block of a public company. We determined that this block should have a premium attached to it. A portion of our report is included in exhibit 14.1.

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion***(Footnotes Omitted From Exhibit)*

The valuation of John Q. Smith & Company, an investment holding company, is based on the value of the underlying assets held in the investment portfolio. The methodology employed will be similar to that used by Adam's Trust Company, as outlined in a memo dated January 14, 1993, from Chuck Jackson to Rebecca Harding. This memo outlined the procedure as follows:

To establish the fair market value of Smith & Company's stock holdings, we generally utilized the average price of the individual securities on December 16, 1992 (as determined by referencing *The Wall Street Journal*). An exception to this is the value established for the company's equity position in the Public Corporation.

According to the Jackson memo, the condensed balance sheet of John Q. Smith & Company as of November 30, 1992, was as follows:

John Q. Smith & Co. Condensed Balance Sheet as of November 30, 1992		
Assets		
Current assets		
Cash & equivalents	\$ 271,583	
Short-term investments	2,387,627	
Receivables	3,838	
Total current assets		\$2,663,048
Investments in capital stock		
Public corp.	\$ 876,726	
Others	2,157,886	
Total stock		3,034,612
Investments in oil & gas interests (net)		18,061
Total assets		\$5,715,721
Liabilities	\$ 218,266	
Stockholders' equity	5,497,455	
Total liabilities & stockholders' equity		\$5,715,721

According to the Jackson memo, the adjusted net asset value of John Q. Smith & Company as of December 16, 1992, was \$202,983,073. The other party to the litigation accepted the methodology used to value most of the underlying assets and, therefore, we will also accept the asset values that were agreed to by the parties as the starting point in our valuation. The major point of contention between the parties is the value of the interest in Public Corporation. We will value this asset separately. Accordingly, subtracting the value of this stock from the total results in the following:

Net asset value	\$202,983,073
Public corporation stock	160,721,253
All other assets & liabilities	\$ 42,261,820

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion**

*(Footnotes Omitted From Exhibit)*

On December 16, 1992, John Q. Smith & Company owned 5,337,360 shares of Public Corporation common stock. This represents approximately 47 percent of the outstanding shares of Public Corp. The underlying asset values did not present a problem for the valuation of the Public stock because the high and low valuation as of the valuation date is proper. However, consideration must be given to the fact that a 47 percent block of stock of a publicly traded corporation frequently constitutes a control position in the stock.

In our opinion, a 35 percent premium is appropriate in determining the value of the public holdings of John Q. Smith & Company. The pro rata value of a controlling interest in a company is said to be worth more than the value of a minority interest, due to the prerogatives of control that generally follow the controlling shares. An investor will generally pay more (a premium) for the rights that are considered to be part of the controlling interest. Valuation professionals recognize these prerogatives of control and consider them in the assessment of control premiums. Some of the prerogatives include the following:

- Elect the board of directors
- Appoint the management team
- Determine compensation and perquisites
- Set business policy
- Acquire or liquidate assets
- Make acquisitions or divestitures
- Sell or acquire treasury stock
- Declare dividends
- Change the articles of incorporation or bylaws of the corporation

Control is demonstrated in the public market as publicly traded companies are purchased at prices above the value at which the shares are trading in the open market. Empirical data is available about these transactions, and measuring the control premium allows the valuation analyst to use this data as a benchmark in the valuation of other companies.

Generally, the issue that the valuation analyst faces is the valuation of a closely held company. In this instance, the valuation subject is a controlling interest in a publicly traded company, Public Corp. Control premium data is tracked by several sources. The most widely used source is *Mergerstat Review*, which was published annually by Merrill Lynch Business Brokerage and Valuation, Schaumburg, IL (today, it is published by Factset, LLC). Another widely used source is the *Control Premium Study*, published by Houlihan, Lokey, Howard, and Zukin.

**Author's Note**

This is now known as the *Mergerstat Control Premium Study*.

A summary of the *Mergerstat Review* data appears in table 1 on the following page.

**TABLE 1 Percent Premium Paid Over Market Price**

Year of Buyout	Number of Transactions	Average Premium Paid Over Market (%)	Median Premium Paid (%)
1980	169	49.9	44.6
1981	166	48.0	41.9
1982	176	47.4	43.5
1983	168	37.7	34.0
1984	199	37.9	34.4
1985	331	37.1	27.7

*(table continued)*

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion***(Footnotes Omitted From Exhibit) (continued)***TABLE 1 Percent Premium Paid Over Market Price** *(continued)*

Year of Buyout	Number of Transactions	Average Premium Paid Over Market (%)	Median Premium Paid (%)
1986	333	38.2	29.9
1987	237	38.3	30.8
1988	410	41.9	30.9
1989	303	41.0	29.0
1990	175	42.0	32.0
1991	137	35.1	29.4
1992	142	41.0	34.7
Mean		41.2	34.1
Median		41.0	32.0

The mean and median premiums since 1980 have varied with the economy and stock market activity. In the early 1980s, interest rates were at an all-time high, possibly pushing the control premiums paid for companies even higher. As rates came down in the mid-1980s, the premiums followed. By 1992, the year of the valuation, the average and median control premiums were 41.0 percent and 34.7 percent, respectively, for the entire market.

In order to more closely assess the applicability of this data to the control premium that is warranted for the public holdings, we further analyzed the *Mergerstat Review* data. Information summarized from this publication appears below.

<b>Average premium offered</b>	<b>41.00%</b>
Controlling interest	41.30%
Minority interest	38.30%
Industry classification of seller	
Chemicals, paints, & coatings	34.00%
<b>Median premium offered</b>	<b>34.70%</b>
Purchase price \$100 million or more	39.00%
Method of payment	
Cash	29.60%
Stock	36.80%
Combination	41.90%
Seller's market price five days before announcement	
Over \$25.00 through \$50.00	25.80%
Seller's P/E ratio five days before announcement	
Over 15.0	34.00%

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion**

*(Footnotes Omitted From Exhibit)*

Dissecting the information included in *Mergerstat Review* illustrates that while the average control premium offered in 1992 was 41.0 percent, the average for controlling interests was slightly higher, at 41.3 percent. However, even minority interests were being bought at a premium of about 38.3 percent. Attempting to get more industry-specific, we reviewed the data for transactions in the chemicals, paints, and coatings category. The average control premium in this industry was 34.0 percent.

In addition to the averages, the median premiums paid were also reviewed. The median tends to provide a better indication than the average because the average can be skewed by extremely high or low data. The median is the central point when ranked by size.

The median premium offered was 34.7 percent during 1992. When the purchase price was \$100 million or more, the premium jumped to 39.0 percent. This is consistent with current studies that indicate larger companies frequently sell for higher multiples. Combination deals involving stock and cash resulted in a premium of 41.9 percent, but even when the deal was all cash, the premium was still 29.6 percent.

Reviewing this data based on the per share price of the public stock indicates that companies whose shares were trading between \$25 and \$50 sold at the lowest control premium of only 25.8 percent. Finally, companies whose price-to-earnings multiples were over 15 reflected premiums of 34.0 percent.

Additional analysis was performed of the data appearing in the Control Premium Study. The major difference in this study from *Mergerstat Review* is that the premiums are measured differently. Furthermore, this study only includes cash transactions. Data observed from this study includes the following:

By industry (SIC) (trailing 12 months)	
SIC 28 (Chemicals and Allied Products) (2 transactions)	
Median	70.50%
Mean	70.50%
SIC 38 (Controlling Instruments; etc.) (3 transactions)	
Median	27.00%
Mean	45.50%
Domestic transactions—4th quarter (18 total transactions)	
Median	44.50%
Mean	47.40%
12-month figures (1/1/92–12/31/92) (94 total transactions)	
Median	42.40%
Mean	50.40%
3-month median premium	
First quarter	34.60%
Second quarter	42.40%
Third quarter	49.20%
Fourth quarter	33.50%
12-month median premium	
First quarter	45.30%
Second quarter	45.10%
Third quarter	44.30%
Fourth quarter	42.40%

*(continued)*

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion***(Footnotes Omitted From Exhibit) (continued)*

The preceding data divides the control premiums differently than the data presented from *Mergerstat Review*. This information reflects that the control premiums paid within standard industrial classification (SIC) category 28 were 70.5 percent, whereas the mean and median premiums for SIC category 38 were 45.5 percent and 27.00 percent, respectively.

However, this data reflects considerably greater premiums for the transactions that are tracked. The specific data for the industry includes only two transactions; therefore, it is considered to be of little significance. These two transactions reflect control premiums of 12.9 percent and 128.1 percent, too large a spread to be meaningful.

A review of the additional control premium data broken down by domestic transactions and by time periods tends to provide premium data in the range of the mid-40s. During 1992, the median of the 94 transactions tracked by this study was 42.4 percent. Although slightly higher than the Mergerstat data, a conclusion can be reached that the median premium during 1992 was approximately 35 percent to 40 percent.

The question to be addressed by the valuation analyst concerns the appropriate level of premium to be applied to the public holdings. The economic and industry mood should also be considered when looking at this issue.

In the early 1990s, the U.S. economy was in the midst of a recession. The Persian Gulf War added to the problems, followed by the election of President Clinton. It was during this period that unemployment levels began to rise, consumer spending declined, and consumer confidence drifted downward. During 1992, the state of the economy in the nation began to show some signs of improvement, as the real Gross Domestic Product grew by 2.9 percent. However, the unemployment rate increased from 6.8 percent in 1991 to 7.5 percent in 1992. The sluggishness of the economy at the conclusion of the Bush administration's term was expected to improve in the year ahead with the election of a Democratic president. The feeling in the nation at the end of 1992 was that

1993, it seemed, could not come fast enough. Wall Street investors know the feeling well. For much of 1992, their sights have been fixed firmly on what the next 12 months may bring. There is, of course, nothing unusual about stock markets anticipating the future. But the presidential election, dominated by its cries of change and transition, and the turning point reached in the domestic economic cycle, have given investors a fixation with tomorrow's joys, obscuring the drearier realities of today.

America had been through tough economic times during the early stages of the decade, resulting in mixed feelings for the nation's consumers, employees, and investors. Optimism about the economy began to lift toward the end of 1992, with the consumer confidence index gaining 12.7 points in December, as reported by the New York-based Conference Board. The real estate market in the United States also began to show some signs of improvement, which indicated a positive attitude about the economy. However, fears of interest rate hikes were also apparent.

Investors, on the other hand, had mixed feelings about the future of the nation's economy.

This spate of encouraging economic data failed to translate into a traditional year-end rally on Wall Street, largely because investors were also trying to anticipate the tax changes which may take effect in 1993. The Clinton administration, which runs the thinking, will almost certainly increase the income tax burden on high-earning individuals. Accordingly, such investors had every incentive to lock into stock market profits before 1992 ended. Tax-centered concerns have already led to the early payments of bonuses by some Wall Street investment firms. Last week, these told on share prices, as dealers reported confusing "crosscurrents" in trading activity. Some investment clients, they suggested, were still buying on the economic news, but others were busily selling on tax fears.

Furthermore, the nation's unsettled economy had an effect on the mood of investors. *Chemical Week's* monthly stock report made the following statement regarding investors:

Investor confidence was also hurt by disappointing economic data, leading analysts to trim earnings projections for the second half of this year, and for 1993. Although selling pressure centered on industrial cyclical groups like autos, airlines, and steels, none of the S&P 500 composite's 88 industry groups eked out a gain. The S&P 500 fell 2.4% in August, giving back more than half its July rise, while the more cyclically oriented DJIA sank 4%.

Aside from reporting on the overall stock market, *Chemical Week* also reports on the performance of chemical stocks. During the third quarter of 1992, major chemical firms' earnings declined, while the outlook for specialty chemicals looked bright. Unlike the major chemical firms, specialty chemical companies do not depend on commodity chemicals because they generally produce "smaller batches of a wider variety of chemicals that command premium prices. These companies as a group are likely to see year-over-year quarterly earnings increases of about 10% to 15%," claims Jeffrey Cianci, a securities analyst with Bear, Stearns & Co.

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion***(Footnotes Omitted From Exhibit)*

Although there are some reports of a positive outlook for the specialty chemical industry, a market report of the specialties segment by *Chemical Week* magazine paints a contrasting picture.

In the specialties sector, losers outpaced winners by a three-to-one margin. Only the Dexter Corp. touched a new 12-month high. Seven issues advanced, with thinly traded LeaRonal, up 9%, posting the biggest rise. Among the biggest losers were Public, 210%; M.A. Hanna, 29%; and Ferro, 29%.

Overall, however, the specialty segment performed better than the large chemical companies. "The S&P chemicals and diversified chemicals indexes fell 6% and 5.8%, respectively, while the specialty chemicals index dropped only 1%." During the third quarter of 1992, specialty chemical makers saw higher returns, despite the weak U.S. economy.

Looking at the performance of specialty chemical firms during 1992, the industry displayed mixed results. During the first half of 1992, major chemical company stock prices increased 11 percent, whereas specialty chemical company prices fell 1 percent. Despite the differences in the performance of the two chemical sectors, specialty chemical stocks appear to be attractive investments.

The major, or commodity, chemical companies are highly sensitive to the economic cycle. To judge by the strong performance of these and other cyclical stocks, investors are expecting a sharp recovery. They are likely to be disappointed. Restructuring in the service sector, restrained fiscal policy, high real long-term interest rates, and the slowdown in Japan and Europe are all working against a strong recovery. Real growth of 5% to 6% has been typical of recoveries in the postwar period. The current cycle is more likely to show growth of 2.5% to 3%.

In this sluggish environment, specialty chemical companies look particularly attractive. They have some cyclical exposure but are not dependent on a strong recovery. In the best of times, the major chemical companies price their products on a cost-plus basis, expecting, or rather hoping, to cover production costs, with a little profit left over. These are highly competitive businesses in which price is virtually all that distinguishes one company's product from another's. Profit growth is dependent on sales increases and high capacity utilization rates.

The dynamics of the markets for specialty chemicals are quite different. Prices are driven by the added value each product brings to its customer. A significant amount of research goes into each product, and companies expend considerable resources on marketing.

Not surprisingly, specialty chemical firms tend to be smaller than commodity chemical companies. They typically dominate the markets in which they operate, and they enjoy wider profit margins, stronger growth, and higher returns on equity.

There are at least 70 good size, publicly traded specialty chemical companies. Broadly speaking, these firms produce chemical solutions to a host of different problems.

Public's primary business operations are in the specialty chemicals industry. The three major product groupings within this segment include oil field chemicals, industrial chemicals, and industrial polymers and waxes.

The chemical industry in the United States is highly competitive. During the early 1990s, the industry experienced market erosion.

Merger and acquisition activity has also become increasingly important in the oil field chemical industry in recent years due mainly to the declining U.S. market. Consolidation has continued to be a way that companies survive in the increasingly competitive industry. Baker Hughes became the leading U.S. producer and a major worldwide producer of oil field chemicals by making several important acquisitions in the early 1990s. These purchases, which also made Baker Hughes a more balanced chemical supplier, included ChemLink Incorporated (specialty production chemicals); BP's OFRIC business (UK oil field chemicals); the oil field chemical operations of CEDA Reactor in Canada, and the environmental chemical operations of Wen-Don Incorporated.

During the early 1990s, specialty chemical companies took steps toward increasing their market share. "For example, Public Corporation, a leading producer of specialty production chemicals, is working to increase the company's market share by emphasizing technology and value-added services." While Public was taking measures toward improving their market share and future position in the market during the early 1990s, the oil field chemical industry had been experiencing declining sales during the previous two years. "Due to industry consolidation there are also fewer customers for these products."

"Within the oil field chemical industry are numerous product segments. Public is concentrated in the area of production chemicals. There are five companies within this segment, which accounted for over 75 percent of the market share. The five companies are Public, Baker Performance Chemicals, Nalco, Exxon, and Champion Technologies."

*(continued)*

**EXHIBIT 14.1 Selected Portion of Control Premium Discussion***(Footnotes Omitted From Exhibit) (continued)*

Aside from the increase in competition, environmental concerns throughout the global economy placed even more pressure on the \$200 billion-per-year industry, which has “matured considerably during the past 10 years.” The increased awareness of the protection of the environment has resulted in increased costs of operations for specialty chemical producers. Due to the rising costs of operations, many of the industry’s small players have been acquired by larger companies. While environmental pressures have had an effect on the cost of doing business, some industry participants view the pressures as an opportunity to capitalize on a new environmentally conscious market.

The industry has seen many changes during the late 1980s and early 1990s, due in part to environmental pressures. The financial aspect of the industry has also changed. Chem Listner, senior V.P. at Kline, stated, “What has been described as a frenzy of purchases in the 1980s has settled down to a period of extreme caution. Deals are made strictly on the basis of strategic synergies with existing business units.” It is the consolidation that occurred during the 1980s that has increased competition so dramatically.

Toward the close of 1992 and looking forward to 1993, productivity appears to be the focus of chemical firms.

The economic chorus praises the U.S. chemical industry as well positioned for a productivity-driven future. The restructuring charges for layoffs and plant closures in the U.S. were taken in 1992, and the benefits will be seen on bottom lines in 1993, although some further charges are likely in Europe and will affect the profits of U.S. based multinationals in 1993. “The restructuring is over,” says Amoco’s Eck. “Everyone has done a tremendous job of cutting costs. We’re ready to grow, and grow profitably.” “The chemical industry has a very high value added,” Professor Smith concurs. “If the whole country were in the shape the chemical industry is in,” he says, “George Bush would be the one being inaugurated on Jan. 20.”

According to Form 10-K, filed with the SEC for the year ended October 31, 1992, Public was about to acquire Target, Inc., a subsidiary of AAA Chemical Company. This is a positive sign for the company. Making acquisitions of this type is one of the prerogatives of control discussed previously.

Public is a leader in their niche of the market. This factor, along with a favorable outlook for the specialty chemical industry, makes the company more likely to be acquired at a higher premium. In fact, because of the consolidation occurring in the industry, Public could be postured for a sale to an attractive suitor.

Considering the size of the premiums being paid in the marketplace, the industry outlook for Public, and the niche position that Public has filled in the industry, we believe that a control premium of 35 percent is appropriate.

By the way, the public company was acquired. It is definitely better to be lucky than good. In preparing to further explain why a control premium was applicable, we performed a simple analysis. Only 300,000 shares of stock were required for ownership greater than 50 percent. If management bought these shares at a reasonable premium, control of the entire company would have provided them with an asset that was worth much more money. Also, when a 47 percent shareholder shows up at the annual shareholder meeting, does anyone believe that he or she would not control the vote? What is the likelihood of all the other stockholders of this public company showing up at the annual meeting to vote? Not likely—the remaining shares were very small blocks in the hands of a lot of other shareholders.

Because I may not have made this statement enough already, be careful to avoid double-counting! Certain valuation methods result in a control value for the company. Adding a control premium in that situation would result in double-counting and should be avoided. For example, using merger and acquisition data would result in a control value because the merger and acquisition data generally comes from the sale of entire companies. The excess earnings method is also considered to be a control valuation method because the valuation analyst is required to adjust the balance sheet items to fair market value. Minority interests could not benefit from this because they cannot sell off these assets.

Control premium studies, such as the ones discussed in exhibit 14.1, are regularly used to assist the valuation analyst in determining the premium that is paid in the marketplace for control. I will discuss these studies in more detail shortly. However, are companies on Wall Street really buying control? Part of what they are buying is control, but there are many motivational factors that extend far beyond the control issue and cause acquirers to pay considerably more for a company. Let’s discuss a little history. When IBM purchased Lotus

Development Corp. for about \$66 per share, Lotus' shares were trading at \$33. This would be a 100 percent premium! What about when MFS Communications bought UU Net? The acquired company had \$94.5 million in revenues, a \$63 million net loss, and negative \$21 million in cash flow, but it sold for \$2 billion (that's right, billion—with a "b"). UU Net was one of the first companies that created an Internet platform at a time before everyone was spending their lives on the Internet (for students reading this book—believe it or not, there was a time when we did not text, tweet, Instagram, Facebook, or Google. We actually did a thing called "speaking with each other," and we shopped in those things called "stores").

Large companies purchase other companies for a variety of reasons besides control. Some of these reasons may include the synergies between the two companies, the ability of the acquirer to enter a new market without starting from scratch, or the ability of the acquirer to enter a completely new line of business that it had not been in before and that complements its existing business. Sometimes, it may just be to eliminate a competitor. In fact, if you examine many of the Wall Street megadeals, the acquirer frequently begins selling off parts of the target company immediately to help pay for the acquisition. How does this factor into the control premium studies? It doesn't! One more reason why the world is not perfect.

Assume that a company reports a deal for \$57 per share. However, after the acquisition is completed, certain subsidiaries are sold, and the acquirer gets back the equivalent of \$2 per share. The control premium studies would measure the premium as \$57 over the trading price. Wouldn't it be more accurate to reflect \$55 because that is the net number? Unfortunately, this is the best that we have to work with. It also explains why the courts are not willing to accept a blind application of these studies. The valuation analyst must think through and support the conclusions reached.

## Lack of Control (Minority) Discounts

There is little argument in the valuation profession that minority interests in a privately held company are worth less on a per share basis than controlling interests. A minority owner is usually unable to effectively influence the operations or results of the business. A lack of control discount is a reduction in the control value of the valuation subject that is intended to reflect the fact that a minority owner cannot control the daily activities or policy decisions of an enterprise, leading to a reduction in value. The size of the discount will depend on the size of the interest being valued, the amount of control, the owner's ability to liquidate the company, and other factors.

The benefits bestowed by control depend on the degree of control in the ownership interest. The degree of control is determined by various factors, including the relevant state law, corporate or operating agreements, and others that were discussed previously. But let's also not forget about the distribution of the ownership interests. Different ownership blocks can influence the degree of control. Let's use a 2 percent shareholder interest as an example. Do you think that it might matter if you are valuing a 2 percent interest and there are 49 other 2 percent interests as compared with there being two 49 percent interests that do not get along? The 2 percent interest, with 49 other similar interests, is probably not worth much. However, the 2 percent interest with the fighting 49 percent interests could be worth considerably more due to its swing vote, assuming a simple majority requirement.

Now, with the previous example being provided, let me save you from making a very common error that I see over and over again. Many new valuation analysts would see the 2 percent owner having significant value with the dueling 49 percent owners. Keep in mind that the 2 percent interest cannot be worth more than the amount that results from valuing the entire enterprise on a control basis after subtracting the value of the two 49 percent interests from it. I have seen analysts add a premium to the value of the 2 percent interest, resulting in the value of the entire company being greater than the whole. The sum of the parts can be less than the whole, but never more.

In many states, a decedent cannot cut a spouse out of a will. In fact, some states require the surviving spouse to get at least one-third of the estate. My firm was involved in a litigation where the surviving spouse (estranged at the time of death) sued the estate claiming she did not get her one-third of the entire estate. The

decedent had bequeathed 33 percent of the corporate stock to each, his service manager and bookkeeper, with the remaining 34 percent going to the estranged wife. The wife hired a valuation analyst who took the position that since 34 percent represented a minority interest, after discounts, the value was less than the one-third share required by state law (pretty creative, huh?). It turned out that the highest and best use of the company was as if in liquidation, entitling each interest to a pro rata share of the liquidation value; therefore, she got her one-third! It took the state appeals court to agree with me, but there were no discounts because the value was in liquidation. Each shareholder was entitled to the pro rata share of the whole under state law.

The degree of control will influence the magnitude of the discount for lack of control. While there is some empirical guidance available about discounts for lack of control, adjustments to reflect different degrees of control are made analytically on a case-by-case basis. A lack of control discount is basically the opposite of a premium for control. This type of valuation adjustment is used to obtain the value of a noncontrolling interest in the valuation subject when a control value is the starting point. Conversely, a control premium is used to determine the control value when the freely traded minority value is the starting point. Lack of control discounts can be mathematically determined using control premiums that are measured in the public market. The formula to determine the minority interest is as follows:

$$1 - \left( \frac{1}{1 + \text{Control Premium}} \right)$$

This concept is illustrated in box 14.2.

If you have ever done this stuff before, you probably know that a valuation analyst is supposed to be able to support the size of the discount taken. If you have never done this before, you now know. A discount does not get plucked from the air (or maybe I should say that the discount should not be plucked from the air). In addition to supporting discount rates, capitalization rates, and forecasts, the greatest problem that a valuation analyst faces is supporting the size of the valuation adjustments, whether they are discounts or premiums. I used to think that it was pretty humorous to see a valuation analyst write a 100-page valuation report in which he or she spends all of one paragraph to “whack” the value by 35 percent for various discounts. Now, it not only constitutes a violation of valuation standards, but it also makes for a really bad report. So, where does one go to look for support for the discount for lack of control?

Before we discuss specific sources that are used as a starting point in the process, let’s discuss what a discount for lack of control really is. This might best be shown with an example. This is also a good time to illustrate the concept of using the normalization adjustments to assist the valuation analyst in determining control or minority values. Let’s assume that ABC Company has a reported net income of \$100,000. Let’s also assume that the only normalization adjustment for control is excess rent paid to the stockholder, requiring a \$50,000 adjustment. To keep things simple, let’s ignore taxes. Assuming a capitalization rate of 20 percent, value can be estimated as follows:

#### BOX 14.2 Calculating the Lack of Control Discount

If the control value equals \$120 per share and the control premium equals 20 percent, the minority value would be calculated as follows:

$$1 - [1 \div (1 + 0.2)] = 16.67\% \text{ lack of control discount}$$

The 16.67 percent lack of control discount would be subtracted from the control value to derive the freely traded minority value. This is calculated as follows:

$$\begin{aligned} \$120 \times 16.67\% &= \$20 \text{ discount} \\ \$120 - \$20 &= \$100 \text{ freely traded minority value} \end{aligned}$$

The difference in value of \$250,000 is effectively the lack of control discount. By having control, an owner could create an additional \$250,000 of value by adjusting the excess rent to market levels. Conversely, the minority owner loses this value by not being able to change this.

The implied lack of control discount in this example is 33⅓ percent (\$250,000 ÷ \$750,000). The nice part about valuing the minority interest in this fashion is that the valuation analyst does not have to support a lack of control discount, which is difficult to do.

	Control	Minority
Reported net income	\$100,000	\$100,000
Normalization:		
Excess rent	50,000	—
Adjusted net income	\$150,000	\$100,000
Capitalization rate	÷ 20%	÷ 20%
Estimated value	\$750,000	\$500,000

There is a problem, however, in relying solely on the normalization adjustments to represent the difference in value between control and minority. There are certain attributes of control that may add value but may not affect measurable cash flow or earnings. For example, having the ability to sell the company is an attribute of control that adds value. However, just having a right, which intuitively should add value, may not be measurable. What about the well-run company with no normalization adjustments? Clearly, I would rather have control, even if the cash flow is the same. The question is how much is that right worth? Accordingly, in the preceding example, there may be an additional diminution in value to reflect the lack of other control rights not available to the minority shareholder. The problem is how do we quantify what they are worth?

The more common sources of information used to measure the lack of control discount include *Mergerstat*<sup>®</sup> *Review* and the *FactSetMergerstat*<sup>®</sup>/*BVR*<sup>™</sup> *Control Premium Study*, which is available from Business Valuation Resources, LLC (BV Resources).

These sources are referenced in chapter 5 and measure control premiums. Because control premiums are used to calculate the lack of control discount, these sources are the most widely used. Unfortunately, there are no sources that measure lack of control discounts directly. One of the problems that the valuation analyst faces is that these studies measure the control premiums differently; therefore, the implied lack of control discount may be different depending on the source used to calculate the discount. The other major problem is that it may be very difficult to use these references and associate them with a minority interest in a closely held business.

*Mergerstat*<sup>®</sup> *Review* is an annual publication that presents compiled statistics relating to mergers and acquisitions. Data on merger and acquisition announcements and purchase prices are presented annually and quarterly, for the current period and historically. Current transactions that are either completed or pending are also shown, as well as the prices offered and equity interest sought for companies that are in the \$100 million category.

The 100 largest announcements in history are featured, as are the largest by industry. The publication also has announcements on mergers and acquisitions for specific industries, including a ranking of the dollar value offered and the number of transactions in each industry. International transactions, divestitures, a transaction and cancellation roster by industry, and acquisitions of privately owned companies are other areas featured in the book. The information provided in *Mergerstat Review* can be used to identify industry guideline companies that were involved in actual transactions.

The *FactSet Mergerstat*<sup>®</sup>/*BVR Control Premium Study*<sup>™</sup> data contains more than 10,490 transactions in more than 700 standard industrial classification (SIC) codes. This database contains 19 years of data. Most transactions are mergers and acquisitions with 100 percent of the shares acquired and include controlling takeovers and buyouts. There are about 57 data points provided for each transaction. Control premiums are calculated as follows:

$$\text{(purchase price – “affected stock price”)} \div \text{“unaffected stock price”}$$

The “unaffected stock price” is determined by Mergerstat as the seller’s closing stock price five business days before the initial announcement of the transaction is made. The purpose of this is to arrive at a price for the target company before volatility due to acquisition or merger rumors.

The database is searchable by the following:

- Target company size (assets, revenues, and deal size)
- SIC code
- Profitability
- Trading market (New York Stock Exchange, NASDAQ, and so on)
- Transaction date
- Whether the deal is a tender offer or leveraged buyout

In addition to the preceding, the current database uses many of the same calculations that used to be available in another control premium study that is no longer published. Instead of calculating the unaffected price based on five business days before the initial announcement, as done in *Mergerstat Review*, this database provides the premium based on the following:

- One day before the transaction
- One week before the transaction
- One month before the transaction
- Two months before the transaction

In many instances, the further you get from the transaction, the higher the premium. This shows that once the news of the transaction leaks to the public, the market starts to bid up the price of the stock. By the time the valuation analyst gets close enough to the transaction, the premium is actually lower due to the price run up. (And you thought the public market was efficient!)

Many transactions are synergistic in nature. Thus, the premium paid probably measures the difference between minority, marketable level and investment value, not the control level. To address this, the database lists the transactions with the following codes:

- Horizontal integration
- Vertical integration
- Conglomerate
- Financial

Financial buyers would include private equity firms, which would not stand to gain from operational synergies. However, the premiums paid still may not directly measure the difference between private minority and control level value. *Mergerstat® Review* also defines *premium offered* as “calculated by dividing the offer price per share by the seller’s closing market price five business days prior to the announcement of the transaction. May include foreign sellers, publicly traded sellers, and divestitures. Excludes privately owned sellers.”<sup>2</sup> The benefit of this method is that it is a consistent and objective way of measuring the premium. The drawback of this method is that the public price may have already started to climb based on rumors of a deal, which may understate the premium. You also have to be careful if you use composite data because of the influence of foreign sellers.

Another problem that exists in using the control premium data is that we cannot determine if there is a true premium being paid for control or if the acquiring company is paying for synergies that cannot be separately measured. We also do not know how many of the Wall Street megadeals resulted in spin-offs after the acquisition. If a company makes an acquisition for \$100 million but intends to sell a subsidiary as soon after the acquisition as possible—for, let’s say, \$10 million—isn’t this really a \$90 million net acquisition? However, the control premium data used by the studies would be based on the \$100 million. Unfortunately, it is the best data that we have to work with. I discussed this before, so let’s not belabor this point here. In case this isn’t nerve-racking yet, one of the difficulties in properly measuring the control premium that was paid is that it must be in a cash equivalent price to help the valuation analyst determine the fair market value of the valuation subject. Business transactions are frequently consummated using various payment options, including all cash, cash and noncash, or all noncash considerations. Many times, these transactions also include some form of an earnout.

It is essential to know the value of the noncash consideration or the earnout, or both, in relation to the face amount of the consideration. Most control premium studies that include purchases using noncash consideration report only the price calculated using the face value of the noncash consideration, not its cash

.....  
 2 *Mergerstat® Review* (Norwalk, CT: FactSet Mergerstat, LLC, 2011): 322.

equivalent. Earnouts are calculated inconsistently between different sources, as witnessed in our review of the different transaction databases. I never said this stuff would be easy. I said understandable, but not easy!

Part of a typical table that appears in many valuation textbooks is illustrated in table 14.2. It demonstrates how the control premium data can be used in the calculation of the lack of control discount.

Year of Buyout	Number of Transactions	Average Premium Paid Over Market (%)	Median Premium Paid (%)	Implied Minority Interest Discount*
2009	239	58.7	39.8	28.5
2010	348	51.5	34.6	25.7
2011	321	54.1	37.8	27.4
2012	323	46.2	37.1	27.1
2013	257	44.0	29.7	22.9
2014	328	42.1	28.7	22.3
2015	362	48.1	29.6	22.8

\* Discount calculated by the author.

(Source: Financial data and analytics provider FactSet. Copyright 2017 FactSet. All rights reserved. Used with permission.)

Although many of us have seen this data over and over, what many of us ignore is the fact that the *Mergerstat* data includes only premiums. However, companies are not only purchased at a premium. Sometimes companies are purchased at a discount from the market price.

According to the *Control Premium Study*, during the fourth quarter of 2015, the difference in the data, with and without negative premiums, was as follows:

	Including Negative Premiums		Excluding Negative Premiums	
	No. of Deals	Premium	No. of Deals	Premium
Domestic average	61	52.4%	57	57.5%
Domestic median	61	37.6%	57	38.8%
International average	85	23.8%	65	42.4%
International median	85	19.6%	65	30.6%
Overall average	146	35.7%	122	49.4%
Overall median	146	30.4%	122	36.6%

Using the preceding data to calculate the discount for lack of control for the domestic average group, the discount would be 52.4 percent, including the negative premiums, and 57.5 percent, excluding the negative premiums. By overstating the control premiums, the discount for lack of control is also overstated. Putting this data into perspective, if a valuation analyst was to base the control premium or discount for lack of control merely on the data included in the table that we are used to seeing, the premium or discount, or both, could be significantly overstated. This means that the control premium that might be added to the minority value

could be too high. Conversely, if a discount for lack of control was calculated from the normally used data, the discount could be overstated, and the minority interest would be undervalued. Now, with that being said, those companies that sold at a negative premium may have issues associated with them that we may not see when valuing the subject company of our valuation. So, what does all of this mean? It means that we have to be aware of the data that we use and its impact on our conclusions. Merely accepting data without understanding what is included in it is a bad practice.

## Discount From Net Asset Value

A discount from net asset value is commonly applied in the valuation of holding companies, whether they own real estate, securities, oil and gas interests, or other types of investments. This discount is generally appropriate for the valuation of asset-intensive companies and is used to derive a freely traded value. In essence, this discount is similar to a discount for lack of control.

In many asset-holding companies, a discount from the net asset value is commonly applied to take into consideration the fact that a minority investor does not have the ability to get to the underlying value of the assets until such time that the investments are liquidated and distributed to the owners.

Obviously, another reason to take a discount from net asset value is if you are performing a liquidation value, in which case, it is more likely the investor will not receive the full book value for inventory or accounts receivable, for example. However, the reduction in value is better off being taken, as I demonstrated in chapter 11, as a reduction in the balance sheet, rather than as a valuation adjustment. This way, the reader of the report will not think that the analyst is taking a discount for lack of control in a liquidation scenario.

The sources used to support a discount from net asset value are generally different from the sources that were discussed earlier in this chapter. An example of an actual report that explained this discount is included in the sample Family Limited Partnership Report that is included as a downloadable file included with this book. We address the discount from net asset value in that report as the equivalent of a discount for lack of control.

## Discount for Embedded Capital Gains

A long time ago, way back in chapter 11, when discussing the asset-based approach, I discussed the concept of tax affecting the appreciation in the write up of assets on the balance sheet. Although some valuation analysts add a tax liability to the adjusted balance sheet, many address the embedded capital gains tax that would result from a sale of the assets as a discount. Because it is a form of discount from net asset value, and this is my book, I decided to address this subject here.

What seems like ages ago, the 1986 Tax Reform Act repealed the General Utilities Doctrine with the result that C corporation shareholders could be taxed at both the corporate level and shareholder level upon liquidation. This created an inequity between C corporations and pass-through entities (for example, S corporations) in terms of taxation. Valuation analysts had to find a way to address this issue because the tax that would be paid, in some cases, was pretty substantial.

For example, assume that an investor purchased the stock of a corporation that owns only one asset, real estate, for \$5 million in 2015. The real estate had been purchased by the corporation in 2010 for \$2 million. The investor sells the corporation for \$10 million in 2017. The following analysis compares the tax implications of the sale based on the corporation being a C corporation versus an S corporation.

<b>Tax Implications of Sale in a C Corporation</b>		
1 Sales price of C corporation	\$10,000,000	
2 Shareholder basis	5,000,000	
3 FMV of real estate in C corp	10,000,000	
4 Inside tax basis of real estate	2,000,000	
5 Capital gain in C corp (line 3 – 4)	8,000,000	
6 Capital gain tax in C corp (40% × line 5)		\$3,200,000
7 Distribution to shareholders before personal tax (line 1 – 6)	6,800,000	
8 Capital gain to shareholders (line 7 – 2)	1,800,000	
9 Personal tax to shareholders (20% × line 8)		360,000
10 Net distribution to C corp shareholders (line 7 – 9)	6,530,000	
11 Total corporate and personal tax paid		\$3,560,000
<b>Tax Implications of Sale in a Pass-Through Entity</b>		
1 Sales price of C corporation	\$10,000,000	
2 Shareholder basis	5,000,000	
3 FMV of real estate in S corp	10,000,000	
4 Inside tax basis of real estate	2,000,000	
5 Capital gain in S corp	N/A	
6 Capital gain tax in S corp		N/A
7 Distribution to shareholders before tax (line 3 – 4)	8,000,000	
8 Personal tax to shareholders (20% × line 7)		\$1,600,000
9 Total corporate and personal tax paid		\$1,600,000

As can be seen from the data in the preceding table, the investor pays much more tax if the appreciated real estate is owned by a C corporation. Therefore, why would any prudent buyer pay as much for the stock of the C corporation if there is an embedded capital gains tax lurking in the future? Logic says “he or she wouldn’t.” Be careful though; personally, logic has gotten me in trouble in the past. So, let’s talk about the problem.

### The Embedded Capital Gain Problem

Since 1986, valuation analysts, other than those who work for the IRS, argued that embedded capital gain tax liabilities in both C and S corporations deserve a discount separate from minority or marketability discounts.<sup>3</sup> The IRS argued that such a discount is invalid for at least the following 2 reasons. First, in the case of a C corporation, the entity can change to an S corporation and, if sold after 10 years, avoid the double tax. The second reason was that liquidation of both types of corporations in the context of an estate or gift tax

<sup>3</sup> S corporation tax affecting is discussed in chapter 18.

assessment is not imminent. Therefore, it would be inappropriate to discount the value by a capital gains tax liability that may not be paid for years, if ever.

Some analysts addressed the IRS's second argument by projecting a holding period for the stock and calculating a present value of the capital gains from the date of sale back to the valuation date. However, this approach proved to be a problem for several reasons. First, the analysis usually did not also address a change in value of the investment between the valuation date and the assumed sale date. It was one thing to state that the investment would be sold 6.338 years from now, but the analyst often forgot that there might be appreciation in the value of the investment during the holding period. Even when the analyst did not forget this, it appeared to be highly speculative and, therefore, not readily accepted by anyone other than the analyst who thinks his or her opinion is the only opinion.

M. Mark Lee and Gilbert Matthews presented research that showed that the present value calculation must consider several factors:<sup>4</sup>

1. The dividend paying capacity and tax basis of the entity.
2. The relationship between the assumed growth rate of the assets and the required rate of return. If the assets are growing in value but the entity does not pay dividends, an increasing amount of the growth will be consumed by taxes.
3. If the company pays dividends, the present value of capital gains tax may be less than a dollar-for-dollar calculation due to the tax rules for excluded corporate dividends from companies owned less than 20 percent.

Nobody said that this would be easy! One thing that I can absolutely tell you about this matter is that the treatment has been consistently inconsistent. Let's look at what the courts have done with it.

## Court Case Precedents on Embedded Capital Gains Tax With C Corporations

In the *Estate of Davis v. Commissioner*,<sup>5</sup> the Tax Court allowed a combined discount of 50 percent in the valuation of this C corporation, implicitly including a discount for capital gains, which equaled approximately one-third of the actual dollar-for-dollar capital gains tax liability. Although The Court offered no reasoning, this was the first Tax Court case in which the embedded capital gains tax issue was accepted as a separate element of marketability.

Having friends in this business provides me with some great insight about what happens sometimes when stuff is not published. In this case, a very reputable valuation firm was working for the IRS. In their opinion, a discount was warranted because of very highly appreciated property being owned by the C corporation. So, they calculated a discount and built it into their report. Here is the real kicker—the attorneys for the IRS were asleep and did not realize what they had done until it was too late. This discount got past them and precedent was born!

In *Eisenberg v. Commissioner*,<sup>6</sup> the company in question was a personal holding company set up as a C corporation. The Tax Court agreed with the IRS and rejected a discount for embedded capital gains, but this decision was overturned by the U.S. Court of Appeals, 2nd Circuit. Although both *Eisenberg* and *Davis* accepted at least partial discounts for capital gains, neither court provided reasoning for how they measured the amount.

Then came the case of *Estate of Dunn v. Commissioner*,<sup>7</sup> where the U.S. Appeals Court overturned the Tax Court's decision and, for the first time, determined that a dollar-for-dollar discount for capital gains tax liability was appropriate for a C corporation. The Court concluded that an asset approach is the same as a liquidation approach therefore, under this theory, The Court explicitly rejected the IRS position that the discount was

4 M. Mark Lee and Gilbert Matthews, "How Should Trapped-in Capital Gains Taxes be Valued?," *Business Valuation Update* 10, No. 8 (August 2004).

5 *Estate of Davis v. Commissioner*, 110 T.C. 530 (1998).

6 *Eisenberg v. Commissioner*, No. 97-4331 U.S. Appeals (2nd Circuit, Aug. 18, 1998).

7 *Estate of Dunn v. Commissioner*, No. 00-60614, U.S. Appeals (5th Circuit, August 1, 2002).

inappropriate because an actual liquidation was imminent (in reality, the subject company never liquidated and never intended to). The Court stated that because fair market value assumed a hypothetical transaction, the discount had to be considered.

Probably one of the more controversial opinions of recent years came in the *Estate of Frazier Jelke v. Commissioner*.<sup>8</sup> Of course, this is in the Federal District where our main office is located. The estate's expert took a dollar-for-dollar discount for capital gains in a closely held C corporation. The IRS's expert projected a liquidation date in the future and discounted the capital gains tax liability to present value. The Tax Court sided with the IRS. The fact is that the IRS's expert did a pretty good job in this case (and no, it was not our firm).

The Court of Appeals rejected the Tax Court's findings using the reasoning from *Dunn* that the fair market value standard requires that a transaction be assumed on the valuation date and accepted the dollar-for-dollar discount. The Appeals Court decision came on November 15, 2007. The IRS appealed the case to the Supreme Court, which denied the *writ of certiorari* on October 6, 2008, meaning the high court would not hear the case. I cannot understand why the Supreme Court does not want to get involved in tax disputes! This could have been the perfect case to take on in which the different circuit courts had varying opinions on the same subject.

In the *Estate of Marie J. Jensen v. Commissioner*,<sup>9</sup> the estate's expert took a dollar-for-dollar discount for capital gains in a closely held C Corporation. The IRS's expert analyzed closed-end funds to determine the discount. The Tax Court rejected the IRS expert's analysis indicating that closed-end funds were not relevant to this analysis under the circumstances of the case. Instead, the Tax Court followed a methodology that was reasonably similar to what the IRS expert did in *Jelke* (which was rejected in that circuit). If this case had been appealed, it would have been to the 2nd Circuit, not the 11th.

The *Davis*, *Eisenberg*, *Dunn*, *Jelke*, and *Jensen* cases all deal with C corporations; the decisions do not apply to pass-through entities (S corporations, partnerships, limited liability corporations, and limited liability partnerships). The dollar-for-dollar discounts for capital gains have only been accepted in the 5th and 11th circuits, and given different facts and circumstances, decisions can differ in other cases and circuits. Not only do you have to understand the rules, but they vary depending upon the circuit court in which it will be argued. Don't you just love this stuff? And they want to know why we only get it right sometimes?

## Embedded Capital Gains In Pass-Through Entities

The IRS has successfully argued that pass-through entities can avoid capital gains tax by structuring a transaction to obtain a step up in the basis of the asset. I'm no tax guy anymore, but my understanding is that partnerships can opt for an IRC Section 754 election in which the inside basis of the partnership's asset is raised to match the cost basis of the buyer; the buyer, therefore, will only incur capital gains tax if the asset appreciates after the transaction. The 754 election, though, is not always selected for several reasons:

- A 754 election is only possible with the consent of each of the existing partners.
- The election cannot be revoked without the permission of the IRS.
- The election normally causes additional administrative overhead in the partnership because each partner's basis must be tracked.

The shareholders of an S corporation can opt for an IRC Section 338(h)(10) election. (I just love it when I talk code sections. I feel like an accountant. Oops, I am one!). This election occurs when a stock sale is treated as an asset sale and the depreciated asset is written up to current value. Both, the buyer and the seller must agree to this election. From a buyer's perspective, an asset sale is preferable because the embedded capital gains are avoided in the future and depreciation expense would be higher over the life of the assets, providing a tax shelter. From the seller's perspective, the 338(h)(10) election usually has no effect, although there is a possibility that the deal could be taxed as ordinary income, rather than a capital gain. Most practitioners agree that a seller would not agree to a 338(h)(10) election without negotiating at least some of the cash value of the benefits enjoyed by the buyer. This could affect the price that is paid in the transaction.

<sup>9</sup> *Estate of Marie J. Jensen v. Commissioner*, T.C. Memo, 2010-182 (filed August 10, 2010).

## Court Decisions on Embedded Capital Gains in Pass-Through Entities

We have seen court cases regarding pass-through entities as well as for C corporations. In the *Estate of Jones v. Commissioner*,<sup>10</sup> two family limited partnerships (FLPs) were formed. FLP-A transferred an 83.03 percent limited partner (LP) interest to the decedent's son, who was the FLP's general partner (GP). The assets in the partnership had a basis of \$500,000 and a fair market value of \$11.6 million. FLP-B transferred four, 16.915 percent LP interests to each of decedent's four daughters. The assets had a basis of \$1.8 million and a fair market value of \$7.7 million. (I want to be adopted by these folks.)

The Court disallowed discounts for embedded capital gains for a few different reasons. The interest transferred in FLP-A constituted a controlling interest and a controlling interest could force a 754 election. Although the interests transferred in FLP-B were minority, The Court decided the partnership and its assets were small enough that a 754 election would not be a detriment to the remaining partners. The Court implicitly weighted the potential of a 754 burden on the existing partners but provided no detail on what constitutes a burden. Also, The Court assumed that the existing partners would vote for a 754 election without negotiating any return for themselves. Chances are, if we had done that, The Court would have said that it was too speculative.

In the *Estate of Dailey v. Commissioner*,<sup>11</sup> the decedent made two gifts of LP interests in an FLP that held appreciated securities. The taxpayer's expert took a 40 percent discount, whereas the IRS took discounts of 14 percent and 16 percent on the two partnerships. At trial, the IRS expert admitted that he never read the FLP partnership agreements, nor did he consider embedded gains, though he indicated they were a factor. The Court accepted the 40 percent discount, without explicit reasoning about whether it accepted the discount for capital gains taxes or if they were just rejecting the IRS's expert due to his testimony. This is a classic case of what not to do as an expert.

## Nonvoting Stock Discount

Lots of analysts make the mistake of thinking that there is a big difference between the value of voting and nonvoting stock. At a control level, I can understand there being a difference in value. However, at the minority level, the difference is really small. Studies have been done comparing different classes of stock in public companies, and the discounts were low. Exhibit 14.2 includes a section of a report that we issued a while ago. This just does not come up that often.

### EXHIBIT 14.2 Voting vs. Nonvoting Section From Report

The Class B common shares have no voting rights. However, based on the certificate of incorporation, if less than 1,875 shares of the Class A common shares are not held by the original shareholders, the Class B shares obtain voting rights.

However, due to its current lack of voting rights, an additional discount must be considered because an asset with voting rights is more valuable than one without voting rights, thus, providing a theoretical basis for such a discount. However, the various studies measure the premium for voting rights over nonvoting rights, so that is how the data is applied.

A study performed by Vijay M. Joy and Allan L. Riding shows that nonvoting shares in public companies tend to trade at approximately a 7 percent discount to voting shares in the same company.<sup>1</sup>

<sup>10</sup> *Estate of Jones v. Commissioner*, 116 T.C. No. 11 (March 6, 2001).

<sup>11</sup> *Estate of Dailey v. Commissioner*, TCM 2001-263 (October 3, 2001).

**EXHIBIT 14.2 Voting vs. Nonvoting Section From Report**

According to Shannon Pratt,

Where differentials in favor of voting stock exist, they generally have been under 5 percent, and no study has indicated a differential of over 10 percent. Again, the distribution of the stock can have a bearing. If one stockholder has total control anyway and there is no cumulative voting, the question of whether the minority shares are voting or nonvoting is academic unless a split of the control block is foreseeable.<sup>2</sup>

A more recent study has been conducted annually by The Financial Valuation Group in Tampa, Florida.<sup>3</sup> According to James Hitchner:

Yearly research by The Financial Valuation Group in Tampa identified nonfinancial and nonutility companies whose stock trades in two classes on listed exchanges. The research focused on operational companies and, thus, excluded the highly regulated financial and utility companies, except where financial or utility data was required as a proxy to fill certain gaps in data. In each case, both the voting and nonvoting stock were offered, side by side, in their various markets. This list was ultimately reduced to the stock of companies where the only difference between the shares was the voting rights. The dividends were the same, and the shares were equal in all respects, with the exception of voting rights, where the Class A shares generally were granted four to ten times as much voting power per share. This research seems to indicate that where the shares traded represented only a minority interest, a small added value was placed on the voting shares by the marketplace.<sup>4</sup>

A summary of the results reveals the following:<sup>5</sup>

Voting Premiums				
	Year End		Average Hi-Low	
	Median	Mean	Median	Mean
1992	3.54%	6.65%	4.51%	7.68%
1993	1.48%	2.17%	4.14%	4.81%
1994	0.82%	5.50%	2.29%	5.35%
1996	2.86%	3.50%	1.57%	3.29%
1998	0.00%	0.57%	1.42%	2.19%
1999	2.14%	5.91%	7.77%	5.91%
2000	2.01%	9.08%	1.02%	8.67%
2001	1.56%	9.05%	2.22%	1.63%
2002	1.89%	6.52%	1.68%	7.22%
2003	0.39%	6.43%	1.29%	6.51%
2004	0.00%	5.35%	0.47%	6.52%
2005	0.00%	0.44%	0.24%	1.82%

(continued)

### EXHIBIT 14.2 Voting vs. Nonvoting Section From Report

Statistically, the median is a better indicator of the central point of the data because one outlier can skew a mean. The data in the preceding table indicates that the nonvoting premiums have declined to less than 1 percent in the most recent years. In this case, the Class B shares will obtain voting rights at some point, which also points to a lower differential. Therefore, a premium of 1 percent for the voting shares over the value of the nonvoting shares has been deemed appropriate for the subject company stock.

Although the illustration appears to be old, the data that has been published from various studies has not been updated in the recent past. It seems that there is such a small difference between the voting and nonvoting shares that it is hardly worth the time and cost to perform an updated study. Although the facts and circumstances of a particular valuation assignment may justify performing such an analysis, we find that it cannot be cost-justified most of the time.

### Conclusion

By now the valuation analyst should realize that supporting valuation adjustments relating to control and minority issues is not a piece of cake. In fact, it does not even rise to the level of being a good cookie. The empirical studies have their share of problems, and it seems that so much judgment has to enter into the process of supporting these adjustments that a valuation analyst is probably better off making the necessary changes to the cash flows to allow the benefit stream to be on a control or minority basis. This way, the analyst can value the company or the interest and not rely on these studies. If the analyst does rely on the studies, he or she needs to be able to support what is done with sanity checks to prove that the answer makes sense. If the analyst blindly relies on these studies, he or she will probably be wrong most of the time.

Let's move on to the continuation of valuation adjustments in the next chapter.

## Chapter 15

# Premiums and Discounts (Valuation Adjustments)— Part II

### Learning Objectives

In this chapter, I will attempt to explain the following stuff that never made it into the last chapter, including the following:

- Discounts for lack of marketability
- Private company discounts
- Key person discounts
- Blockage discounts
- Other discounts and premiums
- Application of discounts and premiums

### Introduction

In the last chapter, I discussed valuation adjustments that addressed control or minority issues. In this chapter, I am going to cover everything else that I can think of relating to other types of valuation adjustments.

This could be a good time to take another look at table 14.1 because it shows the type of value derived from the various methods discussed throughout this book. The valuation analyst really does need to understand the type of value estimate that each of these methods yields in order to know what type of discounts and premiums may be appropriate in any given situation.

### Discount for Lack of Marketability (Illiquidity)

A discount for lack of marketability (DLOM) is used to compensate for the difficulty of selling shares of stock that are not traded on a stock exchange compared with those that can be traded publicly. If an investor owns shares in a public company, he or she can pick up the telephone, call a broker, and generally convert the investment into cash within three days. That is not the case with an investment in a closely held business. Therefore, publicly traded stocks frequently have an element of liquidity that closely held shares do not. This is the reason that a DLOM may be applied. It is intended to reflect the market's perceived reduction in value for not providing liquidity to the shareholder. Also, it is important to understand that liquidity is not an on-off switch where you either have it or you do not. Rather, liquidity is a continuum where there are varying degrees of liquidity in both the public market and for private companies.

A DLOM may also be appropriate when the shares have either legal or contractual restrictions placed upon them. These may be in the form of restricted stock, restrictions resulting from buy-sell agreements, bank loan restrictions, or other types of contracts that restrict the sale of the shares. Even when the valuation subject is a 100 percent interest, a DLOM may be appropriate if the owner cannot change the restrictions on the stock. However, most valuation analysts agree that a DLOM for a controlling interest will be lower than a DLOM for a minority interest.

In order to make this section easier to follow, I am going to divide the discussion about the DLOM between *qualitative* and *quantitative* methods used to support this adjustment. There is a growing belief in the U.S. Tax

Court, the SEC, and many state courts that valuation analysts are not doing a good enough job in quantifying the DLOM. Using all the qualitative techniques and then seeing the valuation analyst pull a number from a hat has not provided users of our reports with a warm, fuzzy feeling. However, we still need the qualitative stuff because the quantitative data can be dangerous if not used properly, or in some cases, by itself. In fact, even if it is used properly, the result does not always make sense.

So, let's make sure we understand where we are going with this discussion. The picture that follows tells the story.

We want to get from the level of value that is freely traded to the level of being a closely held interest. Although the picture only addresses minority values, a DLOM may apply to a control value, as well. So, let's get this out of the way right now.

## DLOM for Control

There is debate that has been going on for a very long time among valuation professionals about whether a DLOM should be deducted for a controlling interest. Those that favor a DLOM for a controlling interest support this notion with the fact that there is an uncertain time horizon to complete a sale. Many business brokers have stated that it is typical for a closely held business to sell in a six- to nine-month time period. Therefore, if a business takes longer to sell, a DLOM may be justified. Economic conditions, the financial status of the subject company, the industry, and other such factors could cause a delay in the time it takes to sell the business. We are assuming that the business is priced correctly and the delay is not being caused by an owner who has visions of grandeur about the value of the company. Those who argue against the DLOM for a controlling interest take the position that although the controlling owner is trying to sell the business, that owner is continuing to receive the cash flow from the business in the form of dividends or distributions, which mitigates the illiquidity of waiting for a sale. But what if the company is not making distributions?

Another justification for a DLOM at the control level is that there is a significant cost to prepare and execute an offering for sale. However, be careful not to confuse this with transaction costs that might be considered a cost of liquidation. Some valuation analysts will use a brokerage cost to support the level of the DLOM. However, this is frequently incorrect. Securities are valued at their market price and not net of brokerage commissions. This is the same manner in which a parcel of real estate is valued. Therefore, the cost to sell an asset is irrelevant.

There are also other risks, such as the eventual sale falling through, and many of the transactions include some form of deferred proceeds. Things like notes and earnouts can reduce liquidity. Another justification for applying a DLOM is that there is an inability to hypothecate (for instance, the inability to borrow against the estimated value of the stock).
