16 **Abstract**

17 Lithosiini (Lepidoptera: Erebidae: Arctiinae) is characteristic in having some species that  
18 feed on lichens, whereas the majority of moths, feeds on vascular plants. However, larval  
19 diet of most Lithosiini species is poorly known. This study examines if Lithosiini species,  
20 collected in a tropical rainforest of Borneo (nine species) and a temperate forest of Japan  
21 (eight species), feed on lichens as larvae, based on stable isotope analyses. As a result,  
22 the  $\delta^{15}\text{N}$  values for eight of nine Lithosiini species collected from Borneo were notably  
23 lower than those of nine co-occurring herbivorous non-Lithosiini species, and were  
24 similar to those of sympatric, lichen-feeding termites; however,  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of  
25 one Lithosiini species (*Adites* sp.) were significantly higher than those of the other moth  
26 species and similar to those of humus-feeding termites and predatory insects occurring at  
27 the same site. These results have suggested that the Lithosiini in the Southeast Asian  
28 tropical rainforests contain some species that feed on lichens as their larval main diet and  
29 at least one species whose larvae feed on humus or animal-derived materials. In contrast,  
30 the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of all examined Lithosiini species (eight species) in the  
31 temperate forest have suggested that their larvae fed on plants and not on lichens. Our  
32 stable isotope ratio analysis presented quantitative evidence suggesting lichen-feeding by  
33 Lithosiini moths in a tropical rainforest without observation of feeding behavior during  
34 the larval stages.

35 **Key words:** larval diet, Lepidoptera, Lithosiini, Sarawak, stable C and N isotopes.

36 **INTRODUCTION**

37 The Lithosiini (Lepidoptera: Erebidae: Arctiinae) contain ca. 3,150 known species and  
38 are estimated to contain approximately twice as many unknown species (Conner 2009).  
39 This tribe is distinctive in having some lichen-feeding species as larvae (Hampson 1900;  
40 Holloway 2001; Pöykkö & Hyvärinen 2003; Wagner *et al.* 2008; Conner 2009), although  
41 most lepidopteran species feed on vascular plants at the larval stages (Powell *et al.* 1998;  
42 Richardson *et al.* 2010; Table S1). In addition, there are known to be some Lithosiini  
43 species in each of which both lichen-feeding larvae and larvae that exclusively feed on  
44 non-lichen food resources, such as vascular plants and mosses, coexist within a  
45 population (Holloway 2001; Conner 2009).

46 Presently, however, the diversity and phylogenetic distribution of the lichen-feeders  
47 in Lithosiini are poorly known (Anderson *et al.* 2017). The scarcity of the information is  
48 partly because a tremendous amount of time, effort and labor power is required to find,  
49 collect, rear and observe a sufficient number of larvae (Novotny *et al.* 2002; Bodner *et al.*  
50 2010), taking into account of intraspecific and within-population variations in diets  
51 (Novotny *et al.* 2002).

52 Stable isotope ratio analysis is useful for reconstructing the larval diet of Lithosiini  
53 using the trophic relationship between the moths and their food resources. This method is  
54 based on the empirical relationship of nitrogen and carbon isotope ratios between animal  
55 and their food resources: the nitrogen isotope ratio ( $\delta^{15}\text{N}$ ) values of the animals are

56 approximately 3.4‰ higher than those of the food resources, and the carbon isotope ratio  
57 ( $\delta^{13}\text{C}$ ) values of the animals are approximately the same as those of the food resources  
58 (DeNiro & Epstein 1978; Minagawa & Wada 1984). The nitrogen that composes the  
59 tissue of lichens is mainly derived from inorganic nitrogen in rainwater (Hietz *et al.* 2002;  
60 Ellis *et al.* 2003; Fogel *et al.* 2008), while plants obtain nitrogen mainly by absorbing  
61 soluble nitrogen from the soil (Högberg 1997). The  $\delta^{15}\text{N}$  in those lichens thus tends to be  
62 lower than the  $\delta^{15}\text{N}$  in plants (Högberg 1997). Assuming that this empirical rule is the  
63 case, moths that feed mainly on lichens can be distinguished from those that feed mainly  
64 on plants by measuring the  $\delta^{15}\text{N}$  of the body tissue of the moths (Adams *et al.* 2016; Shin  
65 *et al.* 2018). A fraction of lichens are known to obtain nitrogen through nitrogen fixation  
66 by symbiotic cyanobacteria (Lücking *et al.* 2009). Because nitrogen in such nitrogen-  
67 fixing lichens tends to be close to the  $\delta^{15}\text{N}$  value of atmospheric nitrogen (0‰) (Hietz *et*  
68 *al.* 2002), the  $\delta^{15}\text{N}$  values in Lithosiini moths feeding on nitrogen-fixing lichens should  
69 be different from those in plant-feeding moths. However, the difference is not always  
70 distinct, because the  $\delta^{15}\text{N}$  values of plants are empirically known to be sometimes close  
71 to 0‰ as those of nitrogen-fixing lichens in tropical areas (Hietz *et al.* 2002).

72 To date, five Lithosiini species in the European temperate zone and two Lithosiini  
73 species in the Southeast Asia have been examined by the stable isotope ratio analysis,  
74 suggesting that only one of the five examined species (*Lithosia quadra*) fed on lichens  
75 (Adams *et al.* 2016; Shin *et al.* 2018). Although the previous studies supported a view

76 that there are some Lithosiini species which do not use lichens as the primary food, the  
77 number of investigated species and study sites are not enough for concluding so. It is  
78 therefore necessary to examine whether larvae feed on lichens, for sufficient number of  
79 Lithosiini species, in various climate regions, particularly in tropical regions, where the  
80 species richness of Lithosiini is considered to be notably high (Holloway 2001).

81 In this study, we assess the larval diet of several Lithosiini species in a tropical  
82 rainforest and in a temperate forest, with special reference to the lichen-feeding. We thus  
83 measure and analyze the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  of their tissues and those of co-occurring moth  
84 species. This study adds new information on the phylogenetic distribution of lichen-  
85 feeding species in Lithosiini.

## 86 MATERIALS AND METHODS

### 87 Study site

88 We conducted our study in the following two sites: Lambir Hills National Park (hereafter,  
89 ‘Lambir’), located at 4°12’ N and 114°02’ E (100–250 m a.s.l.) in tropical rainforest  
90 climate areas in Sarawak, Malaysia on Borneo; and Kamigamo Experimental Station,  
91 Kyoto University (hereafter, ‘Kamigamo’), located at 35°04’04” N and 135°45’38” E (224  
92 m a.s.l.) in temperate and humid climate areas on the main island of Japan.

93 The main type of vegetation at Lambir is a primary lowland mixed dipterocarp forest  
94 (Ashton & Hall 1992). The mean annual temperature and rainfall are 27°C and 2,600 mm,

95 respectively, with no clear dry season (see Kumagai *et al.* 2009 for the details of  
96 meteorological conditions in Lambir). Construction facilities at this study site include two  
97 observation towers, ladders attached to trunks of several emergent trees, and aerial  
98 walkways suspended between emergent trees at approximately 20 m above the ground,  
99 which allow access to the branches and leaves in the forest canopy ranging from the  
100 ground to approximately 60 m above the ground (Inoue *et al.* 1994; Yumoto &  
101 Nakashizuka 2005).

102 The vegetation at Kamigamo is mainly composed of secondary evergreen coniferous  
103 forests dominated by *Pinus densiflora* and *Chamaecyparis obtusa*, and secondary broad-  
104 leaved forests dominated by *Quercus serrata* (Osada *et al.* 2003). The mean annual  
105 temperature and rainfall are 14.7°C and 1,578 mm, respectively (Field Science Education  
106 and Research Center, Kyoto University 2016).

### 107 **Moth sampling**

108 In Lambir, adult moths were sampled with a light trap set at the forest floor in a plot  
109 located in the primary mixed dipterocarp forest at approximately 250 m above sea level,  
110 three times on August 27, 2017, March 19, 2019, and November 22, 2019. On each  
111 sampling, light trapping was started immediately after dusk. The light trap was equipped  
112 with six 4-W ultraviolet tubes (2-way black light, MBL-LB, MAXER DENKI Co.) and a  
113 200 cm wide and 180 cm high white cloth, which was suspended from a height of 170 cm

114 above the ground. All moths attracted and approached to the light trap were collected with  
115 insect nets for three hours after sunset, and they were then killed in a bottle containing  
116 ethyl acetate.

117 In addition, we conducted another type of light-trapping from the sunsets on the 28th  
118 of June and the 30th of August to the following mornings in 2019. At each of the dates,  
119 we set up light traps that were different from the above-mentioned light-trapping, at five  
120 locations. The light trap was designed to collect moths without human operations and  
121 each trap was equipped with an ultraviolet LED light (375 THREE, Association of  
122 Wildlife Research (<http://www.npo-wildlife.com/>)), a board for intercepting light-  
123 attracted flying moths, a funnel, and a vessel to collect the fallen moths. Flying moths  
124 were attracted to the trap by ultraviolet light, hit the board, and fell into a vessel filled  
125 with volatilized ethyl acetate. All moths trapped in the vessel were collected the following  
126 morning.

127 In Kamigamo, light-trapping was conducted at a plot near the summit of the highest  
128 hill at an elevation of approximately 224 m on May 25, June 22, July 16, August 20, and  
129 September 17, 2020, in the same way as conducted three times (the former method) in  
130 Lambir. Similar to the Lambir survey, we captured all individual moths that flew onto the  
131 white cloth for approximately three hours after sunset.

132 The moths were pinned and then dried in an oven at 60°C for 48 h. Among the  
133 collected moths, only the species of Lithosiini, as well as the species whose larvae have

134 been confirmed to feed on plants by previous studies using more than three individuals,  
135 were analyzed. In Lambir, nine species (27 individuals) of Lithosiini, and nine species  
136 (27 individuals) of non-Lithosiini moths that had been confirmed to feed on plants based  
137 on the rearing or observation by Holloway (1983, 1987, 1993, 1998, 2001, 2005) were  
138 analyzed for their isotopic compositions (Table S2). In Kamigamo, the isotopic signatures  
139 were measured for eight species (24 individuals) of Lithosiini, and 37 species (111  
140 individuals) of non-Lithosiini moths that had been confirmed to be herbivores by Kishida  
141 (2011a; 2011b, 2020), Hirowatari *et al.* (2013), and Nasu *et al.* (2013) on the basis of  
142 rearing and observations (Table S3).

### 143 **Leaf litter sampling**

144 Leaf litter was collected from 20 plots near the site where moths were sampled in  
145 Kamigamo on June 22, 2020. Ten fallen leaves were collected from the ground litter in a  
146 plot of approximately 30 cm<sup>2</sup>; each plot was set at least 10 m away from each other. Each  
147 sample of the collected leaf litter was gathered in a paper bag, dried up in an oven at 60°C  
148 for 48 h, and grinded using a ball mill.

### 149 **Stable isotopic measurements**

150 The moth legs and powdered samples of leaf litter materials were weighed on a micro-  
151 balance and placed in Sn capsules. The  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values were measured using a mass  
152 spectrometer (Delta V Advantage; Thermo Fisher Scientific, Waltham, MA, USA)

153 coupled with an elemental analyzer. These isotope ratios are expressed in standard  $\delta$ -unit  
154 notation, defined as  $\delta^{15}\text{N}$  or  $\delta^{13}\text{C} = (\text{R}_{\text{sample}}/\text{R}_{\text{standard}} - 1) \times 1,000$ , where, R is either the  
155  $^{15}\text{N}/^{14}\text{N}$  ratio for nitrogen or the  $^{13}\text{C}/^{12}\text{C}$  ratio for carbon. The standards were atmospheric  
156 nitrogen and Vienna Pee Dee belemnite for nitrogen and carbon, respectively. The  
157 analytical precision was better than 0.2‰ for  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values.

### 158 **Data analysis**

159 We performed a one-way analysis of variance (ANOVA) to compare the values of  $\delta^{15}\text{N}$   
160 and  $\delta^{13}\text{C}$  of Lithosiini moths with those of non-Lithosiini moths collected from the two  
161 sites. Tukey-Kramer HSD post hoc tests were performed for multiple comparisons of the  
162 ANOVA results. All analyses were conducted using RStudio Desktop version 3.5.2 (R  
163 Development Core Team 2018).

164 Hyodo *et al.* (2011) measured the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of leaf litter at the same  
165 tropical study site as ours in Lambir. By incorporating these values into the empirical  
166 rules for the increment of the values at higher trophic levels (DeNiro & Epstein 1978;  
167 Minagawa & Wada 1984, see Appendix S1), the ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of  
168 herbivores at the locality were estimated (Fig. 1). The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of each target  
169 moth species were assessed by comparing with the estimated ranges of herbivores.  
170 Similarly, based on the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of the litter sampled at Kamigamo, we  
171 estimated the ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values that most herbivores present there were

172 expected to show (Fig. 2).

## 173 RESULTS

### 174 Stable isotope ratios of moths in the tropical rainforest

175 The  $\delta^{15}\text{N}$  values significantly varied among the moth species (ANOVA,  $F_{17, 36} = 18.85$ ,  $P$   
 176  $< 0.0001$ , Fig. 3). Eight Lithosiini species had significantly lower  $\delta^{15}\text{N}$  values than four  
 177 non-Lithosiini species (*Eupterote* sp., *Hyposidra talaca*, *Phalera javana*, and *Biston*  
 178 *insularis*). Four Lithosiini species (Lithosiini sp. 2, sp. 3, *Barsine crustata*, and *Teulisna*  
 179 sp.) had significantly lower  $\delta^{15}\text{N}$  values than all nine non-Lithosiini species. One  
 180 Lithosiini species (*Schistophleps* sp.) had significantly lower  $\delta^{15}\text{N}$  values than all the non-  
 181 Lithosiini species (Tukey-Kramer HSD post-hoc test,  $P < 0.05$ , Fig. 3). Among eight  
 182 Lithosiini species, there was no significant difference in the  $\delta^{15}\text{N}$  values (Tukey-Kramer  
 183 HSD post-hoc test,  $P > 0.05$ , Fig. 3).

184 The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of nine non-Lithosiini moths were within, or were  
 185 considerably close to, the estimated ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values for herbivores at the  
 186 study site, whereas the  $\delta^{15}\text{N}$  values of eight (other than *Adites* sp.) of nine Lithosiini  
 187 species were markedly out of the ranges (Fig. 1).

188 The remaining one Lithosiini species, *Adites* sp., was considerably different from  
 189 the other above-mentioned Lithosiini species in the  $\delta^{15}\text{N}$  value, which was significantly  
 190 higher than in the other Lithosiini species and higher among four of non-Lithosiini species

191 (*Hypochrosis binexata*, *Daphnusa ocellaris*, *Petelia medardaria*, and *Hamodes propitia*).  
 192 There were no significant differences in  $\delta^{15}\text{N}$  values between *Adites* sp. and the other five  
 193 non-Lithosiini species (*Lyssa zampa*, *Eupterote* sp., *Hyposidra talaca*, *Phalera javana*,  
 194 and *Biston insularis*) (Tukey-Kramer HSD post-hoc test,  $P > 0.05$ , Fig. 3).

195 The  $\delta^{13}\text{C}$  value was significantly different among all moth species (ANOVA,  $F_{17, 36}$   
 196 = 8.43,  $P < 0.0001$ , Fig. 4). *Adites* sp. had the highest and significantly higher  $\delta^{13}\text{C}$  values  
 197 than most of the other moth species studied, except for the three non-Lithosiini species  
 198 (*Hypochrosis binexata*, *Hamodes propitia*, and *Hyposidra talaca*). The non-Lithosiini  
 199 species, *Phalera javana*, had the lowest and significantly lower  $\delta^{13}\text{C}$  values than the three  
 200 Lithosiini species (*Trischalis stomata*, *Asura* sp., and *Adites* sp.) and five non-Lithosiini  
 201 species (*Lyssa zampa*, *Petelia medardaria*, *Hypochrosis binexata*, *Hamodes propitia*, and  
 202 *Hyposidra talaca*) (Tukey-Kramer HSD post-hoc test,  $P < 0.05$ , Fig. 4). There were no  
 203 significant differences in  $\delta^{13}\text{C}$  values among the six Lithosiini species (*Teulisna* sp.,  
 204 Lithosiini spp. 1–3, *Barsine crustata*, and *Schistophleps* sp.) and three non-Lithosiini  
 205 species (*Biston insularis*, *Daphnusa ocellaris*, and *Eupterote* sp.) (Tukey-Kramer HSD  
 206 post-hoc test,  $P > 0.05$ , Fig. 4). Thus, based on the  $\delta^{13}\text{C}$  values, the eight Lithosiini species  
 207 that showed lower  $\delta^{15}\text{N}$  values than those of the non-Lithosiini species (Fig. 3), were not  
 208 discriminated as a group from the non-Lithosiini species (Fig. 4).

209 **Stable isotope ratios of moths in the temperate forest**

210 The  $\delta^{15}\text{N}$  value was significantly different among the moth species ( $F_{53, 105} = 6.45$ ,  $P <$   
 211  $0.0001$ , multiple comparisons by Tukey-Kramer HSD post-hoc test,  $P < 0.05$ , Fig. 5). A  
 212 non-Lithosiini species, *Comostola subtiliaria nympha*, showed the lowest  $\delta^{15}\text{N}$  value,  
 213 which was significantly lower than those of 17 species, including one Lithosiini species,  
 214 *Cyana hamata hamata* (Tukey-Kramer HSD post-hoc test,  $P < 0.05$ , Fig. 5). Another non-  
 215 Lithosiini species, *Athetis stellata*, showed the highest  $\delta^{15}\text{N}$  value, which was not  
 216 significantly different from those of 29 species, including all Lithosiini species (Tukey-  
 217 Kramer HSD post-hoc tests,  $P < 0.05$ , Fig. 5). Thus, the distribution of the  $\delta^{15}\text{N}$  values  
 218 for all Lithosiini species overlapped with that of all non-Lithosiini species (Fig. 5).

219 The  $\delta^{13}\text{C}$  value was significantly different among the moth species ( $F_{53, 105} = 5.34$ ,  $P$   
 220  $< 0.0001$ , Fig. 6). A non-Lithosiini species, *Herpetogramma luctuosale zelleri*, showed  
 221 the lowest  $\delta^{13}\text{C}$  value, which was significantly lower than those of 13 species, including  
 222 the two Lithosiini species, *Eilema japonica japonica* and *Miltochrista miniata* (Tukey-  
 223 Kramer HSD post-hoc test,  $P < 0.05$ , Fig. 6). Another non-Lithosiini species, *Paragona*  
 224 *cleorides*, showed the highest  $\delta^{13}\text{C}$  value, which was significantly higher than those of 23  
 225 species, including the three Lithosiini species, *Cyana hamata hamata*, *Eilema aegrota*,  
 226 and *Eilema deplana pavescens* (Tukey-Kramer HSD post-hoc test,  $P < 0.05$ , Fig. 6). Thus,  
 227 similar to the distribution of the  $\delta^{15}\text{N}$  values, the distribution of the  $\delta^{13}\text{C}$  values in all  
 228 Lithosiini species overlapped with that of all non-Lithosiini species (Fig. 6).

229           The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of the eight Lithosiini species overlapped considerably  
230   with the range of 37 non-Lithosiini species, and with the range of expected values that  
231   was estimated based on the values of litter, for herbivores in the study site (Fig. 2).

## 232   **DISCUSSION**

233   The remarkable overlap between the ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values expected for  
234   herbivores in the tropical rainforest (Lambir) and those of the nine non-Lithosiini moth  
235   species targeted the expected ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values for herbivores can be  
236   inferred from the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values measured for leaf litters in the same habitat, as  
237   mentioned above (DeNiro & Epstein 1978; Minagawa & Wada 1984). The overlap  
238   between the expected ranges and the ranges of the values measured for moths in a habitat  
239   suggests that the moths are herbivores. The remarkable overlap between them in the  
240   tropical rainforest (Lambir) in this study (Fig. 1) strengthens the suggestions of Holloway  
241   (1983, 1987, 1993, 1998, 2001, 2005) with quantitative evidence that these nine moth  
242   species are plant-feeders. On the other hand, there was a difference in  $\delta^{15}\text{N}$  values  
243   between eight (other than *Adites* sp.) of the nine Lithosiini species collected from Lambir  
244   and the above-mentioned plant-feeding moth species (Fig. 3). Furthermore, the ranges of  
245    $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of the eight Lithosiini species deviated remarkably from those  
246   estimated for herbivores at the study site (Fig. 1). These results suggest that the eight  
247   Lithosiini species feed mainly on lichens during their larval stages at the study site. The

248 similarity between the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of these eight Lithosiini species and the  
249 values measured by Hyodo *et al.* (2011) for a lichen-feeding termite species,  
250 *Hospitalitermes hospitalis* (Fig. 7), at the same study site also strongly supports this  
251 suggestion.

252 Adams *et al.* (2016) and Shin *et al.* (2018) used methods similar to those used in this  
253 study and examined whether Lithosiini were lichen feeders by measuring the  $\delta^{13}\text{C}$  and  
254  $\delta^{15}\text{N}$  values of the moths and lichens in the European temperate zone and the Southeast  
255 Asian subtropical zone, respectively. Their results demonstrated that the majority of their  
256 target Lithosiini species were not lichen feeders. In addition, these results seem to be  
257 consistent with our results of stable isotope ratio analysis of Lithosiini moths collected  
258 from Kamigamo, suggesting that the majority of Lithosiini moths do not feed on lichens  
259 in the temperate region (Figs. 5, 6). Thus, the results of stable isotope analysis of  
260 Lithosiini moths inhabiting non-tropical forests are inconsistent with those of Lithosiini  
261 moths inhabiting tropical rainforests.

262 The great difference in  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values between Lithosiini moths in the tropical  
263 rainforest and those in temperate forests could be explained by the following hypothetical  
264 scenario. The food habits of the majority of Lithosiini moth species differ between  
265 tropical and non-tropical zones; a majority of Lithosiini species do not feed on lichens in  
266 the temperate zone, or in sub-tropical and temperate zones, whereas a majority feed on

267 lichens in tropical rainforests. Some differences in environmental conditions between  
268 tropical and non-tropical zones may affect the differences in food habits. However, there  
269 is another explanation. The difference could be a randomly derived result due to  
270 unintended selection biases: the sample size (the number of target species) and the number  
271 of study sites were limited. Although the food resources during larval stages have been  
272 clarified for most Lithosiini species in a particular region (*e.g.*, European temperate zone,  
273 Table S1), they have not been sufficiently investigated for the majority of described  
274 Lithosiini species. For example, this has been investigated at most for 38% and 6% of  
275 Lithosiini species recorded from Japan (East Asian temperate zone) and Borneo (the  
276 Southeast Asian tropics), respectively (Table S1). To explore these possibilities, or to  
277 determine whether there are any significant differences in the percentage of lichen-  
278 feeding species in Lithosiini species between non-tropical and tropical zones, the stable  
279 isotope ratios of nitrogen and carbon should be analyzed for a larger number of Lithosiini  
280 species in both climatic zones at much broader spatial scales.

281 In Lambir, the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of *Adites* sp. were remarkably different not only  
282 from those of the other eight Lithosiini species, which are suggested to be lichen feeders  
283 as mentioned above, but also from those of the plant-feeding non-Lithosiini moth species  
284 (Fig. 1), as well as those measured by Hyodo *et al.* (2010) for eight species of herbivorous  
285 insects at the same study site (Fig. 7). On the other hand, the values were similar to those  
286 of animals that feed on matter derived from animal bodies, such as predatory and

287 detritivorous insects (e.g., Carabidae spp. inhabiting the same site, Hyodo *et al.* 2010),  
288 and those of animals that feed on soil organic matter, including humus or litter of dead  
289 plant tissues, such as soil-feeding termites (e.g., *Prohamitermes mirabilis* inhabiting the  
290 same site, Hyodo *et al.* 2011) (Fig. 7). These similarities suggest that *Adites* sp. possibly  
291 feeds on animal-derived matter or soil organic matter during the larval stages. Although  
292 no Lithosiini species has been found to feed on animal-derived matter or humus during  
293 larval stages, several species of the tribe Arctiini and Syntomini, which belong to the  
294 subfamily Arctiinae together with the tribe Lithosiini, have been found to feed on animal-  
295 derived matter or humus (Krasnoff & Roelofs 1989; Pierce 1995; Conner 2009). This fact  
296 supports the possibility of animal-derived matter or humus feeding in *Adites* sp.

297 Larvae of three Lithosiini species have been suggested to feed on lichens in the  
298 tropical rainforest zone of Southeast Asia (Holloway 2001). However, to the best of our  
299 knowledge, food habits remain to be clarified with robust evidence, such as records of  
300 larval rearing, for almost all of the 300 described Lithosiini species in this zone (Holloway  
301 2001), except for the eight Lithosiini species that have been suggested to feed on lichens  
302 in this study. To understand the diversity, evolution, and ecology of Lithosiini, it is  
303 necessary to identify food resources for many Lithosiini species whose larval food  
304 preferences are not yet known. This may require finding or collecting a sufficient number  
305 of larvae for observation to determine their dietary habits under a wide range of  
306 environmental conditions or under well-controlled laboratory conditions in captivity.

307 Under the conditions in which larval food resources vary plastically in response to  
308 changes in environmental conditions, it is extremely difficult to identify the larval food  
309 resources of Lithosiini only by direct observation of the feeding behavior of larvae.  
310 Therefore, the stable isotope ratio analysis performed in this study, which can provide  
311 evidence supporting food resources during larval stages without observation of feeding  
312 behavior, would be useful for future studies attempting to determine phylogenetic  
313 distribution of lichen-feeding in and around the lineage of Lithosiini for better inference  
314 of the origin(s) of lichen feeding in moths.

#### 315 **ACKNOWLEDGEMENTS**

316 Our study was conducted in accordance with the Memorandum of Understanding signed  
317 by the Forest Department Sarawak (FDS) and the Japan Research Consortium for  
318 Tropical Forests in Sarawak (JRCTS) in December 2012. We thank Mohd Shahbudin  
319 Sabki, Engkamat Anak Lading, and Mohamad bin Kohdi of FDS for help in obtaining  
320 permission to conduct this study. We also thank the staff of the Research, Development  
321 and Innovation, Division of FDS, the staff of the Lambir Hills National Park, Yuki  
322 Nakano, Natsuki Komada, and Sally Kanamori for supporting our field surveys in the  
323 park. We are grateful to the staff of the Field Science Education and Research Center of  
324 Kyoto University for permission to undertake our research at Kamigamo Experimental  
325 Station. This study was financially supported by Grants-in-Aid for Scientific Research

326 (17H01912) and JST/JICA, SATREPS (JPMJSA1902).

433 **SUPPORTING INFORMATION**

434 Additional Supporting Information may be found online in the Supporting Information  
435 section at the end of the article.

436 Appendix S1. A method for estimating the range of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values that herbivores  
437 in a site are expected to exhibit, based on the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of litter in that site.

438 Table S1. The numbers of Lithosiini species whose larval food resources have been  
439 confirmed to be lichens, both lichens and non-lichens, and non-lichens in the European  
440 temperate zone, Japan, and Borneo. The percentages among all of the recorded Lithosiini  
441 species from each region are provided in the parentheses.

442 Table S2. The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of moths in Lambir Hills National Park. The sample  
443 size (the number of individuals examined in this study) was three for each species.

444 Table S3. The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of moths in Kamigamo Experimental Station, Kyoto  
445 University. The sample size (the number of individuals examined in this study) was three  
446 for each species.

447

448 **Figure legends**

449 Fig. 1 Scatter plot of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of Lithosiini, non-Lithosiini, and litter in a  
450 tropical rainforest (Lambir). The plots and bars indicate their mean values and  
451 standard deviations. The rectangle area enclosed by the red broken line  
452 indicates the predicted ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values estimated for plant-  
453 feeding insects based on the empirical rules for the increase of their values  
454 through an elevation of trophic level from the values of litter, which were  
455 obtained from Hyodo *et al.* (2011).

456 Fig. 2 Scatter plot of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of Lithosiini, non-Lithosiini, and litter in a  
457 temperate forest (Kamigamo). The plots and bars indicate their mean values  
458 and standard deviations. The rectangle area enclosed by the red broken line  
459 indicates the predicted ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values estimated for plant-  
460 feeding insects based on the empirical rules for the increase of their values  
461 through an elevation of trophic level from the values of litter.

462 Fig. 3  $\delta^{15}\text{N}$  values of Lithosiini (solid circles) and non-Lithosiini (open circles) moths  
463 in a tropical rainforest (Lambir). A plot and horizontal bar indicate the mean  
464 and standard deviation, respectively, for each moth species. The sample size  
465 was three for each moth species and 15 for litter. The same letters indicate no  
466 significant difference in the value between the compared species (Tukey-  
467 Kramer post hoc test,  $P > 0.05$ ).

468 Fig. 4  $\delta^{13}\text{C}$  values of Lithosiini (solid circles) and non-Lithosiini (open circles) moths  
469 in a tropical rainforest (Lambir). A plot and horizontal bar indicate the mean  
470 and standard deviation, respectively, for each moth species. The sample size  
471 was three for each moth species and 15 for litter. The same letters indicate no

472 significant difference in the value between the compared species (Tukey-  
473 Kramer post hoc test,  $P > 0.05$ ).

474 Fig. 5  $\delta^{15}\text{N}$  values of Lithosiini (solid circles) and non-Lithosiini (open circles) moths  
475 in a temperate forest (Kamigamo). A plot and horizontal bar indicate the mean  
476 and standard deviation, respectively, for each moth species. The sample size  
477 was three for each moth species and 20 for litter. The same letters indicate no  
478 significant difference in the value between the compared species (Tukey-  
479 Kramer post hoc test,  $P > 0.05$ ).

480 Fig. 6  $\delta^{13}\text{C}$  values of Lithosiini (solid circles) and non-Lithosiini (open circles) moths  
481 in a temperate forest (Kamigamo). A plot and horizontal bar indicate the mean  
482 and standard deviation, respectively, for each moth species. The sample size  
483 was three for each moth species and 20 for litter. The same letters indicate no  
484 significant difference in the value between the compared species (Tukey-  
485 Kramer post hoc test,  $P > 0.05$ ).

486 Fig. 7 Scatter plot of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of Lithosiini, lichen-feeding termite, soil-  
487 feeding termites, herbivorous insects, predatory insects, and litter in a tropical  
488 rainforest (Lambir). The plots and bars indicate their mean values and standard  
489 deviations. The rectangle area enclosed by the red broken line indicates the  
490 predicted ranges of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values estimated for plant-feeding insects  
491 based on the empirical rules for the increase of their values through an elevation  
492 of trophic level from the values of litter, which was obtained by Hyodo *et al.*  
493 (2011). The values for lichen-feeding termite, soil-feeding termites,  
494 herbivorous insects, and predatory insects were obtained from Hyodo *et al.*  
495 (2010, 2011).

1 **Appendix S1. A method for estimating the range of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values that**  
2 **herbivores in a site are expected to exhibit, based on the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$**   
3 **values of litter in that site.**

4 Many previous studies have shown that the  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values of herbivores in a  
5 site can be estimated from the  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values of leaf litter in that site, respectively,  
6 from the empirical rule expressed by the following equations (DeNiro & Epstein 1978;  
7 Minagawa & Wada 1984):

$$8 \quad \delta^{15}\text{N}_{\text{herb}} = \delta^{15}\text{N}_{\text{litt}} + \Delta^{15}\text{N},$$

$$9 \quad \delta^{13}\text{C}_{\text{herb}} = \delta^{13}\text{C}_{\text{litt}} + \Delta^{13}\text{C},$$

10 where,  $\delta^{15}\text{N}_{\text{herb}}$ ,  $\delta^{15}\text{N}_{\text{litt}}$ , and  $\Delta^{15}\text{N}$  are the  $\delta^{15}\text{N}$  values for herbivores, leaf litter, and the  
11 trophic enrichment, respectively, and  $\delta^{13}\text{C}_{\text{herb}}$ ,  $\delta^{13}\text{C}_{\text{litt}}$ , and  $\Delta^{13}\text{C}$  are the  $\delta^{13}\text{C}$  values for  
12 herbivores, leaf litter, and the trophic enrichment, respectively. In general, the  $\Delta^{15}\text{N}$  is  
13 estimated to be  $3.4 \pm 1.1\text{‰}$  (mean  $\pm$  SD) (Minagawa & Wada 1984), and the  $\Delta^{13}\text{C}$  is  
14 estimated to be  $0.8 \pm 1.1\text{‰}$  (DeNiro & Epstein 1978).

	Both lichen and non-lichen	0 (0.0)	
	Non-lichen	13 (4.4)	
	(Food resources detected)	16 (5.4)	
	(Unknown)	281 (94.6)	
	(Total: All recorded species)	297 (100)	

**Table S2** The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of moths in Lambir Hills National Park.

The sample size (the number of individuals examined) was three for each species.

Taxa	$\delta^{13}\text{C}$ (‰) (mean $\pm$ SE)	$\delta^{15}\text{N}$ (‰) (mean $\pm$ SE)
Eupterotidae		
Eupterotinae		
<i>Eupterote</i> sp.	-30.7 $\pm$ 0.1	3.8 $\pm$ 1.1
Sphingidae		
Smerinthinae		
<i>Daphnusa ocellaris</i>	-31.7 $\pm$ 0.9	1.1 $\pm$ 1.7
Uraniidae		
Uraniinae		
<i>Lyssa zampa</i>	-29.3 $\pm$ 1.6	2.7 $\pm$ 0.8
Geometridae		
Ennominae		
<i>Biston insularis</i>	-32.0 $\pm$ 2.3	5.3 $\pm$ 1.9
<i>Hypochrosis binexata</i>	-27.7 $\pm$ 1.1	-0.4 $\pm$ 0.4
<i>Hyposidra talaca</i>	-26.4 $\pm$ 0.7	4.1 $\pm$ 0.4
<i>Petelia medardaria</i>	-28.0 $\pm$ 0.6	1.2 $\pm$ 0.9
Notodontidae		
<i>Phalera javana</i>	-35.2 $\pm$ 1.5	4.2 $\pm$ 1.8
Erebidae		
Arctiinae		
Lithosiini		
<i>Adites</i> sp.	-23.1 $\pm$ 0.9	6.4 $\pm$ 1.1
<i>Asura</i> sp.	-27.9 $\pm$ 1.1	-3.8 $\pm$ 1.3
<i>Barsine crustata</i>	-30.9 $\pm$ 0.3	-2.3 $\pm$ 1.9
<i>Schistophleps</i> sp.	-29.7 $\pm$ 0.3	-5.5 $\pm$ 1.6
<i>Teulisna</i> sp.	-32.7 $\pm$ 1.1	-1.0 $\pm$ 0.6
<i>Trischalis stomata</i>	-28.8 $\pm$ 1.1	-4.2 $\pm$ 1.1
Lithosiini sp.1	-29.8 $\pm$ 2.2	-5.0 $\pm$ 0.2
Lithosiini sp.2	-30.7 $\pm$ 0.4	-1.5 $\pm$ 2.0
Lithosiini sp.3	-31.4 $\pm$ 0.6	-3.5 $\pm$ 1.6
Calpinae		
<i>Hamodes propitia</i>	-27.4 $\pm$ 0.9	1.7 $\pm$ 0.5

**Table S3** The  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of moths in Kamigamo Experimental Station, Kyoto University.

The sample size (the number of individuals examined) was three for each species.

Taxa	$\delta^{13}\text{C}$ (‰) (mean $\pm$ SE)	$\delta^{15}\text{N}$ (‰) (mean $\pm$ SE)
Limacodidae		
Limacodinae		
<i>Phrixolepia sericea</i>	-31.6 $\pm$ 1.2	2.8 $\pm$ 1.2
Zygaenidae		
Chalcosiinae		
<i>Pidorus atratus</i>	-32.7 $\pm$ 0.6	-1.3 $\pm$ 1.3
Tortricidae		
Tortricinae		
<i>Archips audax</i>	-32.1 $\pm$ 2.2	-4.3 $\pm$ 1.6
Olethreutinae		
<i>Hystrichoscelus spathanum</i>	-28.5 $\pm$ 2.1	1.9 $\pm$ 3.0
<i>Rhopobota ilexi</i>	-31.5 $\pm$ 0.8	-6.7 $\pm$ 1.4
Pyralidae		
Pyralinae		
<i>Hypsopygia regina</i>	-27.3 $\pm$ 0.5	0.8 $\pm$ 1.5
Phycitinae		
<i>Addyeme confusalis</i>	-28.6 $\pm$ 1.5	1.9 $\pm$ 0.8
Crambidae		
Crambinae		
<i>Chrysoteuchia distinctella</i>	-32.0 $\pm$ 0.1	0.4 $\pm$ 0.5
Pyraustinae		
<i>Herpetogramma luctuosale zelleri</i>	-33.1 $\pm$ 0.8	4.5 $\pm$ 3.0
<i>Palpita nigropunctalis</i>	-27.7 $\pm$ 1.4	4.1 $\pm$ 1.8
Drepanidae		
Drepaninae		
<i>Macrocilix mysticata watsoni</i>	-30.3 $\pm$ 0.2	-0.5 $\pm$ 0.2
Geometridae		
Ennominae		
<i>Alcis angulifera</i>	-28.4 $\pm$ 1.4	0.6 $\pm$ 2.3
<i>Euchristophia cumulata cumulata</i>	-29.5 $\pm$ 0.9	-2.0 $\pm$ 0.3
<i>Garaeus specularis mactans</i>	-29.8 $\pm$ 1.9	-2.6 $\pm$ 2.0
<i>Nothomiza formosa</i>	-28.8 $\pm$ 1.8	-2.7 $\pm$ 3.0
<i>Ourapteryx nivea</i>	-30.1 $\pm$ 1.7	-3.2 $\pm$ 1.4
<i>Ourapteryx obtusicauda</i>	-28.6 $\pm$ 1.1	-2.1 $\pm$ 0.7
<i>Paradarisa chloauges kurosawai</i>	-27.7 $\pm$ 0.8	-1.1 $\pm$ 4.0
<i>Plagodis pulveraria japonica</i>	-32.3 $\pm$ 1.0	-2.7 $\pm$ 2.0
<i>Platycerota incertaria</i>	-27.5 $\pm$ 0.7	-5.3 $\pm$ 2.5
<i>Plesiomorpha flaviceps</i>	-26.3 $\pm$ 0.2	-5.5 $\pm$ 2.5
<i>Rhynchobapta cervinaria</i>	-30.4 $\pm$ 0.9	-0.3 $\pm$ 1.2
<i>Synegia hadassa</i>	-26.2 $\pm$ 0.3	-5.3 $\pm$ 2.3
Geometrinae		
<i>Comostola subtiliaria nympa</i>	-27.5 $\pm$ 0.3	-8.5 $\pm$ 0.3

<i>Idaea remissa</i>	-28.4 ± 0.5	-2.0 ± 1.6
<i>Idaea denudaria</i>	-28.0 ± 0.7	3.6 ± 0.6
<i>Scopula epiorrhoe</i>	-26.9 ± 1.8	-0.9 ± 1.8
Larentiinae		
<i>Chloroclystis excisa</i>	-27.6 ± 1.9	-4.2 ± 2.4
<i>Chloroclystis v-ata lucinda</i>	-27.3 ± 1.6	-5.5 ± 1.1
Notodontidae		
Notodontinae		
<i>Cnethodonta grisescens grisescens</i>	-31.1 ± 1.8	2.2 ± 0.2
Noctuidae		
Eriopinae		
<i>Callopietria japonibia</i>	-29.2 ± 1.7	0.9 ± 0.5
Noctuinae		
<i>Sineugraphe oceanica</i>	-28.8 ± 0.7	1.3 ± 3.0
Hadeninae		
<i>Athetis stellata</i>	-29.6 ± 0.5	7.2 ± 1.7
Erebidae		
Lymantriinae		
<i>Kidokuga piperita</i>	-29.4 ± 2.4	2.7 ± 0.1
Herminiinae		
<i>Zanclognatha helva</i>	-28.7 ± 0.8	-3.4 ± 0.2
Arctiinae		
Lithosiini		
<i>Cyana hamata hamata</i>	-31.0 ± 0.1	-0.3 ± 0.9
<i>Eilema aegrota</i>	-30.0 ± 0.9	-2.4 ± 1.8
<i>Eilema deplana pavescens</i>	-29.8 ± 0.9	-1.8 ± 2.2
<i>Eilema japonica japonica</i>	-27.3 ± 0.2	-4.1 ± 1.8
<i>Eilema nankingica</i>	-28.2 ± 0.4	-6.4 ± 0.6
<i>Macrobrochis staudingeri staudingeri</i>	-28.1 ± 0.5	-1.7 ± 0.5
<i>Miltochrista miniata</i>	-26.9 ± 0.8	-0.5 ± 0.8
<i>Philenora latifasciata</i>	-28.4 ± 0.2	-1.7 ± 1.3
Calpinae		
<i>Oraesia excavata</i>	-27.7 ± 0.6	2.1 ± 0.5
Erebinae		
<i>Paragona cleorides</i>	-23.3 ± 1.2	0.1 ± 2.6
