### Abstract

We consider the Laplace–Dirichlet equation in a polygonal domain which is perturbed at the scale  $\varepsilon$  near one of its vertices. We assume that this perturbation is self-similar, that is, derives from the same pattern for all values of  $\varepsilon$ . On the base of this model problem, we compare two different approaches: the method of matched asymptotic expansions and the method of multiscale expansion. We enlighten the specificities of both techniques, and show how to switch from one expansion to the other. **To cite this article:** S. Tordeux et al., *C. R. Acad. Sci. Paris, Ser. I* 343 (2006).

### Résumé

**Développements raccordé et multi-échelle pour un problème de perturbation singulière modèle.** On considère le problème de Laplace–Dirichlet dans un domaine polygonal qui présente une perturbation de taille  $\varepsilon$  en l'un de ses sommets. Cette perturbation est supposée *auto-similaire*, i.e. provient d'un motif fixe dilaté à l'échelle  $\varepsilon$ . Sur ce problème modèle, nous mettons en œuvre deux méthodes : développements asymptotiques raccordés et développement multi-échelle. Nous mettons en évidence les particularités de chaque approche et montrons comment passer d'un développement à l'autre. **Pour citer cet article :** S. Tordeux et al., *C. R. Acad. Sci. Paris, Ser. I* 343 (2006).

### Version française abrégée

On considère un polygone  $\omega$  de  $\mathbb{R}^2$ , qu'on perturbe localement au voisinage d'un de ses sommets,  $O$  placé à l'origine du repère. Le domaine  $\omega$  coïncide au voisinage de  $O$  avec un secteur infini  $K$  dont l'angle associé est noté  $\alpha$ . La perturbation est auto-similaire : elle provient d'un motif  $\Omega$  qui est un domaine infini coïncidant avec le même secteur  $K$  à l'infini ; le domaine perturbé est défini comme :

$$\omega_\varepsilon = \{x \in \omega; |x| > \varepsilon R^*\} \cup \{x \in \varepsilon \Omega; |x| < r^*\}, \quad (1)$$

E-mail addresses: [sebastien.tordeux@insa-toulouse.fr](mailto:sbastien.tordeux@insa-toulouse.fr) (S. Tordeux), [gvial@bretagne.ens-cachan.fr](mailto:gvial@bretagne.ens-cachan.fr) (G. Vial), [monique.dauge@univ-rennes1.fr](mailto:monique.dauge@univ-rennes1.fr) (M. Dauge).

pour des  $r^*$  et  $R^*$  convenables, voir Fig. 1. Nous nous intéressons au problème modèle suivant :

$$\text{Trouver } u_\varepsilon \in H_0^1(\omega_\varepsilon) \text{ tel que } -\Delta u_\varepsilon = f \text{ dans } \omega_\varepsilon, \quad (2)$$

où le second membre  $f \in L^2(\omega_\varepsilon)$  a son support disjoint de la zone de perturbation.

Les singularités du problème de Dirichlet dans le secteur  $K$  jouent un rôle essentiel dans la structure de  $u_\varepsilon$ . Rappeons qu'avec la notation  $\lambda = \pi/\alpha$  et les coordonnées polaires  $(r, \theta)$ , ces singularités sont les  $s^{p\lambda} = r^{p\lambda} \sin(p\lambda\theta)$  pour tout entier relatif  $p$  [3,6].

La technique de *développement asymptotique multi-échelle* [7,1] consiste à construire une approximation globale de  $u_\varepsilon$  dans  $\omega_\varepsilon$ , composée de deux types de termes : les premiers interviennent en la variable standard  $x$  et les seconds en la variable dilatée  $x/\varepsilon$ . Les termes sont superposés à l'aide de fonctions de troncature ( $\chi$  est nulle proche du point  $O$ ,  $\psi$  est nulle à l'infini – voir (11) pour plus de détails) :

$$u_\varepsilon(x) = \chi\left(\frac{x}{\varepsilon}\right) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} v^{\ell\lambda}(x) + \psi(x) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} V^{\ell\lambda}\left(\frac{x}{\varepsilon}\right) + \mathcal{O}(\varepsilon^{(n+1)\lambda}). \quad (3)$$

L'approche des *développements asymptotiques raccordés* [4,5] consiste à construire un développement *intérieur*, valide localement autour de la perturbation, et un autre, *extérieur*, valide seulement loin de la perturbation. Ils doivent être *raccordés* dans la région intermédiaire. On utilise une fonction de troncature  $\varphi$  à l'échelle intermédiaire  $r/\sqrt{\varepsilon}$  pour obtenir une approximation globale :

$$u_\varepsilon(x) = \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} u^{\ell\lambda}(r, \theta) + \left(1 - \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right)\right) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} U^{\ell\lambda}\left(\frac{r}{\varepsilon}, \theta\right) + \mathcal{O}(\varepsilon^{(n+1)\lambda/2}). \quad (4)$$

Chaque méthode a ses avantages et ses inconvénients, pour les principaux : la méthode multi-échelle présente l'avantage d'une approximation globale avec estimation optimale du reste, ainsi que le fait que tous les termes du développement sont solutions de problèmes variationnels, alors que la méthode de raccord permet de définir des termes intrinsèques, indépendamment de toute fonction de troncature. Par ailleurs, on peut passer de l'un à l'autre : il suffit de retrancher à  $u^{n\lambda}$  ou à  $U^{n\lambda}$  une combinaison linéaire de fonctions singulières duales  $s^{-p\lambda}$ ,  $p > 0$ , pour retrouver les termes variationnels  $v^{n\lambda}$  ou  $V^{n\lambda}$ .

Les détails des preuves des résultats annoncés sont exposés dans [8].

## 1. Introduction

We consider families of self-similar perturbed domains defined thanks to two domains  $\omega$  and  $\Omega$  of  $\mathbb{R}^2$ , satisfying the following conditions for suitable positive numbers  $r^*$  and  $R^*$ :

- $\omega$  is a bounded polygon with one vertex at the origin  $O$ : inside the ball centered in  $O$  of radius  $r^*$ ,  $\omega$  coincides with an infinite plane sector  $K$  of opening  $\alpha$ ;
- $\Omega$  is an unbounded domain, coinciding with  $K$  outside the ball centered in  $O$  of radius  $R^*$ .

The domains  $\omega_\varepsilon$  are defined as perturbations of  $\omega$  using the pattern  $\Omega$ : For  $\varepsilon$  small enough

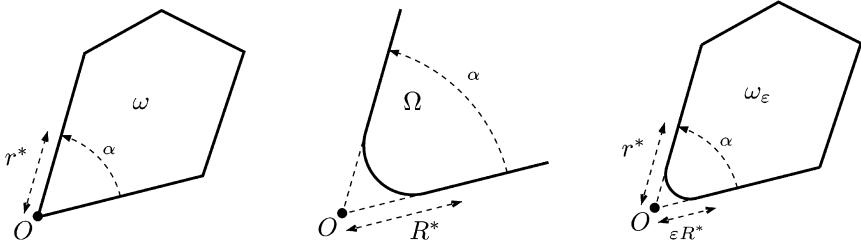

$$\omega_\varepsilon = \{x \in \omega; |x| > \varepsilon R^*\} \cup \{x \in \varepsilon \Omega; |x| < r^*\}. \quad (5)$$

Fig. 1 shows an example of such a situation: the corner is ‘rounded’ at vertex  $O$  to the scale  $\varepsilon$ . Of course, our geometrical setting covers a wider range of cases, and the domain  $\Omega$  may have corners itself, or even cracks. Besides, we do not need any assumption of inclusion of  $\omega_\varepsilon$  into  $\omega$  (or conversely). The domain  $\omega_\varepsilon$  tends to  $\omega$  as  $\varepsilon$  goes to 0, and  $\Omega$  appears to be the limit of the family of domains  $\varepsilon^{-1}\omega_\varepsilon$ .

We denote by  $u_\varepsilon$  the solution of the Laplace–Dirichlet equation in  $\omega_\varepsilon$ :

$$u_\varepsilon \in H_0^1(\omega_\varepsilon); \quad -\Delta u_\varepsilon = f \quad \text{in } \omega_\varepsilon, \quad (6)$$

where  $f$  is an  $L^2$ -function whose support does not reach the origin  $O$ . The solution  $u_\varepsilon$  clearly converges toward  $u_0 \in H_0^1(\omega)$ , satisfying  $-\Delta u_0 = f$  in  $\omega$ . We aim at describing precisely the asymptotic behavior of  $u_\varepsilon$  by means of (i) a multi-scale expansion, and (ii) matched asymptotic expansions. We give in §2 the first terms of these expansions,

Fig. 1. Example of domains  $\omega$ ,  $\Omega$  and  $\omega_\varepsilon$ .

the complete expansions being described in §3 and §4, and compared with each other in §5. Details and proofs for the stated results can be found in [8].

The multi-scale approach of this problem has already been studied within a very general framework in [7]. Our purpose is to give for this model problem a simple explicit presentation for the two distinct, and even competing, techniques of multi-scale and matched expansions. Besides, this allows to prove formulas for transforming each expansion into the other one.

**Notation.** We need some notation used throughout the Note.

- *Singular exponents and functions* associated with the Laplace–Dirichlet problem in the sector  $K$  are denoted by  $p\lambda$  and  $s^{p\lambda}$ , respectively, with:

$$\lambda = \frac{\pi}{\alpha}, \quad p \in \mathbb{Z}, \quad p \neq 0 \quad \text{and} \quad s^{p\lambda}(r, \theta) = r^{p\lambda} \sin(\lambda\theta), \quad \text{with } (r, \theta) \text{ polar coordinates in } K.$$

- *Remainders* will be measured in the energy norm: we will write  $\mathcal{O}_{H^1}(\varepsilon^\kappa)$ , which means that the norm in  $H^1(\omega_\varepsilon)$  is uniformly bounded by  $C\varepsilon^\kappa$  as  $\varepsilon \rightarrow 0$ .

## 2. The first terms of the expansions

We present here the principles of the two methods, and provide the first terms of each expansion.

### 2.1. Multi-Scale Expansion (MSE)

The MSE method consists in looking for an expansion of  $u_\varepsilon$  in powers of  $\varepsilon$  with ‘coefficients’ combining the two scales  $x$  and  $\frac{x}{\varepsilon}$ . Let  $\chi$  be a smooth cut-off function vanishing at point  $O$  and  $\psi$  a smooth cut-off function localized near  $O$ . As a result of the MSE method we find for the first terms, see Theorem 1

$$u_\varepsilon = \chi\left(\frac{x}{\varepsilon}\right)v^0(x) + \psi(x)\varepsilon^\lambda V^\lambda\left(\frac{x}{\varepsilon}\right) + \mathcal{O}_{H^1}(\varepsilon^{2\lambda}), \quad (7)$$

and, next

$$u_\varepsilon = \chi\left(\frac{x}{\varepsilon}\right)(v^0(x) + \varepsilon^{2\lambda} v^{2\lambda}(x)) + \psi(x)\left(\varepsilon^\lambda V^\lambda\left(\frac{x}{\varepsilon}\right) + \varepsilon^{2\lambda} V^{2\lambda}\left(\frac{x}{\varepsilon}\right)\right) + \mathcal{O}_{H^1}(\varepsilon^{3\lambda}). \quad (8)$$

Here, the first term  $v^0$  coincides with the limit  $u_0$ . The *profiles*  $V^\lambda$  and  $V^{2\lambda}$  are defined in the infinite pattern domain  $\Omega$ . Thus information concerning the perturbing pattern is contained in the profiles (whose contribution is localized near  $O$ ), and  $v^0, v^{2\lambda}$  carry information corresponding to the bounded domain  $\omega$  (whose influence does not reach the corner).

In our MSE analysis, all the terms  $v(x)$  and all the profiles  $V(X)$  are solution of variational problems in  $\omega$  and  $\Omega$ , respectively.

## 2.2. Matched Asymptotic Expansions (MAEs)

The MAEs method consists in constructing two full different expansions (outer and inner expansions, cf [4]) of  $u_\varepsilon$  in powers of  $\varepsilon$ . The coefficients of the outer expansion are functions of the slow variable  $x$ , and those of the inner one are functions of the rapid variable  $x/\varepsilon$ . The outer expansion is valid far from  $O$  and the inner one in a layer close to  $O$ . But neither of these two expansions is valid everywhere. They have to be *matched* and glued inside an intermediate region.

In order to have a representation of  $u_\varepsilon$  everywhere and to optimize remainders, we use a cut-off function at the intermediate scale  $r/\sqrt{\varepsilon}$ . Let  $\varphi$  be a smooth cut-off function with  $\varphi(\rho) = 0$  for  $\rho \leq 1$  and  $\varphi(\rho) = 1$  for  $\rho \geq 2$ . As a result of the MAEs method we find for the first terms, see Theorem 2,

$$u_\varepsilon = \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right)u^0(x) + \left(1 - \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right)\right)\varepsilon^\lambda U^\lambda\left(\frac{x}{\varepsilon}\right) + \mathcal{O}_{H^1}(\varepsilon^\lambda), \quad (9)$$

and, next

$$u_\varepsilon = \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right)(u^0(x) + \varepsilon^{2\lambda} u^{2\lambda}(x)) + \left(1 - \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right)\right)\left(\varepsilon^\lambda U^\lambda\left(\frac{x}{\varepsilon}\right) + \varepsilon^{2\lambda} U^{2\lambda}\left(\frac{x}{\varepsilon}\right)\right) + \mathcal{O}_{H^1}(\varepsilon^{3\lambda/2}). \quad (10)$$

Here, again, the first term  $u^0$  coincides with the limit  $u_0$ . The term  $u^{2\lambda}$  is defined on  $\omega$  whereas the *profiles*  $U^\lambda$  and  $U^{2\lambda}$  are defined in the infinite domain  $\Omega$ . The terms  $u^\lambda(x)$ ,  $U^\lambda(X)$  and  $U^{2\lambda}(X)$  are solution of ‘super-variational problems’, i.e. problems set in spaces larger than the variational spaces, and where standard formulations have non-unique solutions. Moreover, the terms  $u^{p\lambda}$  and  $U^{p\lambda}$  are, in general, distinct from the  $v^{p\lambda}$  and  $V^{p\lambda}$  and differ by a combination of dual singular functions, see Theorem 3.

## 3. Multiscale expansion

In the MSE approach, the global expansion is valid everywhere and consists of terms involving the two scales  $x$  and  $x/\varepsilon$ , superposed via cut-off functions:  $\chi$  and  $\psi$  are smooth and radial, satisfying:

$$\begin{cases} \chi(X) = 1 & \text{for } |X| > 2R^* \quad \text{and} \quad \chi(X) = 0 & \text{for } |X| < R^*, \\ \psi(x) = 1 & \text{for } |x| < \frac{r^*}{2} \quad \text{and} \quad \psi(x) = 0 & \text{for } |x| > r^*. \end{cases} \quad (11)$$

**Theorem 1.** *The solution  $u_\varepsilon$  of problem (6) admits the following multiscale expansion into powers of  $\varepsilon$*

$$u_\varepsilon(x) = \chi\left(\frac{x}{\varepsilon}\right) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} v^{\ell\lambda}(x) + \psi(x) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} V^{\ell\lambda}\left(\frac{x}{\varepsilon}\right) + \mathcal{O}_{H^1}(\varepsilon^{(n+1)\lambda}), \quad (12)$$

where the terms  $v^{\ell\lambda}$  and  $V^{\ell\lambda}$  do not depend on  $\varepsilon$ , and are defined in  $\omega$  and  $\Omega$  by Eqs. (13) and (14).

### 3.1. Short description of the terms

Generically,  $v^{\ell\lambda}$  and  $V^{\ell\lambda}$  solve the variational problems

$$v^{\ell\lambda} \in H_0^1(\omega) \quad \text{such that } \forall v' \in H_0^1(\omega), \quad \int_{\omega} \nabla v^{\ell\lambda} \cdot \nabla v' = \int_{\omega} f^{\ell\lambda} v', \quad (13)$$

$$V^{\ell\lambda} \in W_0^1(\Omega) \quad \text{such that } \forall V' \in W_0^1(\Omega), \quad \int_{\Omega} \nabla V^{\ell\lambda} \cdot \nabla V' = \int_{\Omega} F^{\ell\lambda} V', \quad (14)$$

where  $W_0^1(\Omega)$  is the space  $\{V \in W^1(\Omega); V = 0 \text{ on } \partial\Omega\}$ , with the weighted space  $W^1(\Omega)$  defined as:

$$W^1(\Omega) = \{V \in \mathcal{D}'(\Omega); (1+R)^{-1}V \in L^2(\Omega), \nabla V \in L^2(\Omega)\} \quad \text{with } R = |X|. \quad (15)$$

The right-hand sides  $f^{\ell\lambda}$  and  $F^{\ell\lambda}$  are defined recursively.

- For  $\ell = 0$ , we have  $f^0 = f$ , defined in problem (6) ( $v^0$  is equal to the limit solution  $u_0$ ), and  $F^0 = 0$ ;
- For  $\ell = 1$ , the function  $f^\lambda$  is 0 and  $F^\lambda = \mathbf{b}_\lambda^0([\Delta_X, \chi]\mathfrak{s}^\lambda) = \mathbf{b}_\lambda^0(\Delta_X(\chi\mathfrak{s}^\lambda) - \chi\Delta_X(\mathfrak{s}^\lambda))$ , with the scalar coefficient  $\mathbf{b}_{p\lambda}^0$  arising from the decomposition into singular functions of  $v^0$ , cf. [6,3]:

$$v^0(x) = \sum_{p=1}^q \mathbf{b}_{p\lambda}^0 \mathfrak{s}^{p\lambda}(r, \theta) + \mathcal{O}_{r \rightarrow 0}(r^{q\lambda}), \quad \forall x \in \omega, \forall q \in \mathbb{N}; \quad (16)$$

- The next terms are generically nonzero:  $f^{\ell\lambda}$  comes from the expansion at infinity of the previous profiles  $V^{p\lambda}$  ( $p < \ell$ ), namely for the first one

$$V^\lambda(X) = \sum_{p=1}^q \mathbf{B}_{p\lambda}^\lambda \mathfrak{s}^{-p\lambda}(R, \theta) + \mathcal{O}_{R \rightarrow \infty}(R^{-q\lambda}), \quad \forall X \in \Omega, \forall q \in \mathbb{N}, \quad (17)$$

and  $F^{\ell\lambda}$  from the decomposition into singular functions of the previous terms  $v^{p\lambda}$  ( $p < \ell$ ).

#### 4. Matched asymptotic expansions

Let  $\varphi$  be a smooth cut-off with  $\varphi(\rho) = 0$  for  $\rho \leq 1$  and  $\varphi(\rho) = 1$  for  $\rho \geq 2$ . The outer and inner expansions of  $u_\varepsilon$  are glued together with the cut-off function  $x \mapsto \varphi(r/\sqrt{\varepsilon})$ :

**Theorem 2.** *The solution  $u_\varepsilon$  of problem (6) admits the following expansion into powers of  $\varepsilon$*

$$u_\varepsilon(x) = \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} u^{\ell\lambda}(r, \theta) + \left(1 - \varphi\left(\frac{r}{\sqrt{\varepsilon}}\right)\right) \sum_{\ell=0}^n \varepsilon^{\ell\lambda} U^{\ell\lambda}\left(\frac{r}{\varepsilon}, \theta\right) + \mathcal{O}_{H^1}(\varepsilon^{(n+1)\lambda/2}), \quad (18)$$

where the terms  $u^{\ell\lambda}$  and  $U^{\ell\lambda}$  do not depend on  $\varepsilon$ , and are defined in  $\omega$  and  $\Omega$  by Eqs. (19) and (20).

##### 4.1. Short description of the terms

Generically,  $u^{\ell\lambda}$  and  $U^{\ell\lambda}$  solve ‘super-variational’ problems:

$$\text{Find } u^{\ell\lambda} \in V_{loc,0}(\omega) \quad \text{such that} \quad \Delta u^{\ell\lambda} = -\delta_0^\ell f \quad \text{in } \omega \quad \text{and} \quad u^{\ell\lambda} - \sum_{p=1}^{\ell-1} a_{p\lambda}^{\ell\lambda} \mathfrak{s}^{-p\lambda} \in H^1(\omega), \quad (19)$$

$$\text{Find } U^{\ell\lambda} \in V_{loc,\infty}(\Omega) \quad \text{such that} \quad \Delta U^{\ell\lambda} = 0 \quad \text{in } \Omega \quad \text{and} \quad U^{\ell\lambda} - \sum_{p=1}^{\ell} A_{p\lambda}^{\ell\lambda} \mathfrak{s}^{p\lambda} \in W^1(\Omega), \quad (20)$$

where the spaces  $V_{loc,0}(\omega)$  and  $V_{loc,\infty}(\Omega)$  are defined as

$$V_{loc,0}(\omega) = \{u \in \mathcal{D}'(\omega); \Phi u \in H_0^1(\omega), \forall \Phi \in \mathcal{C}^\infty(\bar{\omega}) \text{ with } O \notin \text{supp}(\Phi)\}, \quad (21)$$

$$V_{loc,\infty}(\Omega) = \{U \in \mathcal{D}'(\Omega); \Phi U \in H_0^1(\Omega), \forall \Phi \in \mathcal{C}^\infty(\bar{\Omega}) \text{ with compact support}\}. \quad (22)$$

In (19)  $\delta_0^\ell$  is the Kronecker symbol. The coefficients  $a_{p\lambda}^{\ell\lambda}$  and  $A_{p\lambda}^{\ell\lambda}$  are constructed by induction, and play also the role of right-hand sides: In these super-variational problems, uniqueness is enforced by prescribing an asymptotics in terms of dual singular functions. The coefficients  $a_{p\lambda}^{\ell\lambda}$  and  $A_{p\lambda}^{\ell\lambda}$  come from the decomposition into singular and dual-singular functions of the terms  $U^{p\lambda}$  and  $u^{p\lambda}$  for  $p < \ell$ , respectively.

**Remark 1.** The scale  $r/\sqrt{\varepsilon}$  used in expansion (18) is, in a certain sense, arbitrary. If, instead, we choose the scale  $x/\varepsilon^\gamma$  with  $\gamma \in (0, 1)$ , we find for the remainder  $\mathcal{O}_{H^1}(\varepsilon^{(n+1)\lambda \min\{\gamma, 1-\gamma\}})$ . Thus the scale  $r/\sqrt{\varepsilon}$  optimizes the remainder.

## 5. Comparison between the two expansions

**Theorem 3.** *The expansions (12) and (18) can be compared as follows: the terms  $u^{n\lambda}$  and  $v^{n\lambda}$  coincide away from the corner point i.e. for  $r \geq r^*$ ; the profiles  $U^{n\lambda}$  and  $V^{n\lambda}$  coincide in the corner region i.e. for  $R \leq R^*/2$ .*

*More precisely, we have the identities (for the definition of the coefficients  $a_{p\lambda}^{n\lambda}$  and  $A_{p\lambda}^{n\lambda}$ , see Section 4)*

$$\begin{cases} v^{n\lambda}(x) = u^{n\lambda}(x) - \psi(x) \sum_{p=1}^{n-1} a_{p\lambda}^{n\lambda} \mathfrak{s}^{-p\lambda}(x), & x \in \omega, \\ V^{n\lambda}(X) = U^{n\lambda}(X) - \chi(X) \sum_{p=1}^n A_{p\lambda}^{n\lambda} \mathfrak{s}^{p\lambda}(X), & X \in \Omega. \end{cases} \quad (23)$$

## 6. Extensions

Several extensions of the previous results are possible, requiring more or less effort. First, we can consider a smooth right-hand side  $f$  whose support does reach the perturbation region. In this case, the so-called logarithmic-polynomial singularities have to be considered to take the Taylor expansion of  $f$  near the corner point  $O$  into account. Other boundary conditions may be treated as well. The Neumann case, for instance, is slightly more involved due to the logarithmic singularity and the absence of Poincaré inequality. Lastly, we mention the three-dimensional case: if the domain  $\omega$  has only a conical point at  $O$ , the analysis is very similar to the two-dimensional case. However, in presence of edges, these techniques might still be used, but with non straightforward adaptations (see [2] for edge and corner-edge asymptotics without small parameters).
