NEWS MEDIA COVERAGE AND PUBLIC PERCEPTION OF
ARTIFICIAL INTELLIGENCE: A CORPUS-BASED STUDY OF
TWO BRITISH ONLINE MEDIA SOURCES

BA thesis

2022

ABSTRACT

The United Kingdom is one of the countries highly indexed for artificial intelligence readiness. Artificial intelligence is an ever-growing technology which, due to its broad term, is often not understood too well by the public. Online news media is one source which has the potential power to influence public knowledge and opinion on certain topics. The aim of this thesis is to examine the coverage of AI in two British online newspapers, *The Guardian* and *MailOnline*, during the period 2019-2021, and to compare the findings to the general public's perception of AI.

To achieve the aim, an overview of AI in the UK, as well as of the news media in the UK is provided. Additionally, Chapter One includes an overview of topic-relevant studies in relation to AI in the news media, with particular emphasis on British news media, and public perception of the technology. In Chapter Two, the data collection method, the corpus software Sketch Engine used for the corpus-based analysis, findings as to how AI is presented, what dissimilarities in the different news media occurred during 2019-2021, and whether public perception of AI matches that of the news media coverage are presented. The conclusion summarizes the main findings of the analysis.

RESÜMEE	60

INTRODUCTION

In 1997, reigning world champion Gary Kasparov was beaten by Deep Blue, IBM's chess-playing computer program, which astounded many and was largely the introduction of artificial intelligence (hereafter AI) to the general public due to extensive publicity (IBM n.d.). Today, artificial intelligence systems are being deployed in all areas imaginable with immense potential for change and impact on society. The term, AI, is used quite liberally to describe anything from routine data analysis to complex deep neural networks which do not need constant human intervention (Committee on Standards in Public Life 2020: 12; Gov.uk 2019: para 11). Though a broad term, it has been well explained by Nilsson (2010: 13), a leading AI researcher: "Artificial intelligence is that activity devoted to making machines intelligent, and intelligence is that quality that enables an entity to function appropriately and with foresight in its environment.". Thanks to this data-enabled foresight, AI will be able to perform increasingly complex tasks (Committee on Standards in Public Life 2020: 12). This thesis will focus on AI as a type of technology based on self-learning algorithms that can potentially benefit the development of companies and society. Thereof, AI will be used as an umbrella term, compiling different AI technologies (i.e., machine learning, automation and robotics).

The AI frontier is not fixed but constantly advancing and, thus, countries that do not continuously develop their technologies could fall behind. McKinsey (2019: 4) reports that the United States and China are the leading countries in AI research and employment, whereas in Europe, one of the countries highly indexed for AI readiness is the United Kingdom. Specifically, the UK is in the top quartile globally for research, start-up investment, digital absorption, innovation foundation and ICT (information communication technology) connectedness. It does, however, rank lower on automation potential and human capital

(McKinsey 2019: 4). UK's Committee on Standards in Public Life (2019: 15) also revealed that actual adoption of AI in the public sector remains limited, thus revealing that the British public might not be highly aware of AI and its utilization. However, an area which the UK is already recognised in is technology for healthcare (McKinsey 2019: 1; Committee on Standards in Public Life 2020: 15) and as having the largest software industry in Europe. Additionally, the UK ranked third in the world for private investment into AI companies in 2020, behind only the US and China (Office for Artificial Intelligence 2021: 10) with the US investing 50 times more and China investing eight times more into AI than the UK. Even promising UK start-ups (including DeepMind, SwiftKey and Magic Pony) are being increasingly acquired by large US companies (Google, Microsoft and Twitter – for €410 million, €200 million and €120 million, respectively) before they can mature, limiting the UK's ability to keep and advance its position as a leader (Gerner 2020). As for the future potential, there is high investment into AI, with Grech, CEO of Tech Nation, pointing out that UK firms that were adopting or creating AI-based technologies had received €2.1 billion in funding in 2020, compared to for example €464.7 million raised in Germany, who is also in the top quartile of AI countries and ahead of the UK in some aspects (Gov.uk 2021; McKinsey 2019). Evidently, the UK government has adopted the aim of increasing its involvement in AI. This claim is further supported by the fact that the UK was among the top three countries that passed the highest number of AI-related bills in 2021 (Zhang et al 2022: 12). The reason for this could be that AI could add approximately an incremental 22% (McKinsey 2020: 2) or €279 billion (Committee on Standards in Public Life 2020: 12) to UK's GDP by 2030. This is seen as a paramount growth potential as from 2010 to 2015, productivity grew at only 0.2% a year (McKinsey 2019: 2). The effect that the UK

government estimates AI will have, has increased as recently as from 2019 to 2021: from 5% of GDP (Gov.uk 2019) to a predicted 10% of GDP by 2030 (Gov.uk 2021b).

The UK's substantial involvement in regard to AI largely started in 2017 when the Alan Turing Institute was made the national institute for AI and data science by the government, which examines AI as well as its impact on society. In the same year, the government published its 2017 Industrial Strategy that identified AI and data as one of four 'Grand Challenges' to modernise the UK economy (Gov.uk 2021). The €1.1 billion AI Sector Deal followed in 2018 in which the UK government set a clear goal of becoming a global leader in AI (Gov.uk 2019). This led to the creation of three new bodies: a government Office for AI; an industry-led AI Council; and the Centre for Data Ethics and Innovation (CDEI), which focuses on identifying the measures needed to make sure the development of AI is safe and ethical; currently reviewing public concern on issues such as data bias and online targeting (Committee on Standards in Public Life 2020: 13-14; Gov.uk 2019; Office for Artificial Intelligence 2021: 13). As recently as in September 2021, the government introduced a new ten-year plan called the National AI Strategy in which they outlined how the UK can continue to strengthen its position through "recognising the power of AI to increase resilience, productivity, growth and innovation across the private and public sectors." (Office for Artificial Intelligence 2021: 7). Some of the activities include publishing different frameworks and roadmaps, ensuring that AI programmes are accessible for schools, new visa regimes to attract the world's best AI talent, and monitoring diversity and safety. One of the proposed outcomes was also that public trust in AI would be improved. (Office for Artificial Intelligence 2021: 7-14)

Currently, the AI gap between Europe and the present leaders in AI (the US and China) has increased by 20% from 2017 to 2019 (McKinsey 2019: 3), which is substantial given that

reports agree that AI is going to have a profound effect on societies and economies (Perrault et al 2019; Crawford et al 2016). This is highlighted also by Ouchchy (et al 2020) who observes that the use and application of artificial intelligence has been significantly increasing over the past years. The UK is considered an AI superpower, with particular strengths in research, investment and innovation and, therefore, it is important that public trust is increased. Without it, organizations lack the confidence to invest in data-driven solutions, while citizens are hesitant to participate in data-sharing schemes and adopt data-driven technologies (Spiro et al 2022). Developers and AI companies already fear that the public is mainly met with negative depictions of AI in the media (SCAI 2018) by creating an image of an AI which is still distant (Naughton 2018). One of the main reasons for this is the aim to attract traffic by being sensationalist (Brennen et al 2018; SCAI 2018). Stone (et al 2016: 5) argues that if society approaches AI with fear and suspicion, “missteps that slow AI’s development or drive it underground will result, impeding important work on ensuring the safety and reliability of AI technologies”. Therefore, citizens need to acquire a minimum understanding of this technology to formulate their opinion on its uses. As the public mostly receives information from the news media, their awareness, knowledge, opinions and even behaviours are influenced by the way the news media cover the topic of science and technology (Chuan et al 2019; Dudo et al 2011). Therefore, it is important that the topic is covered extensively, or at least informatively. Siapera (2017: 29) argues that, although there is much debate over the precise nature of the relationship between the media and society, the increasing significance of the news media is still undeniable. Therefore, the articles published in the news media offer an opportunity to examine how a particular topic is presented to the general public.

In relation to the UK, the Select Committee on Artificial Intelligence (SCAI 2018) states that the British public is not fully aware and often has a distorted view of the AI topic. According to research by communications regulator Ofcom (2021: 2), 73% of adults consume news through the Internet. Two of the most widely read digital titles in the UK are *The Guardian* and *MailOnline* (Ofcom 2021; Newman et al 2021: 62). *The Guardian* is a left-leaning British daily quality newspaper, and *MailOnline* is the online version of *The Daily Mail*, a right-leaning British daily middle-market tabloid newspaper. The former has been praised for its investigative journalism, its objective discussion of issues, and criticism (Britannica 2021), whereas *The Daily Mail* has historically been known for its coverage of foreign news (Britannica 2019). The distinction between broadsheets or ‘quality’ newspapers and ‘middle-market’ newspapers can be made in terms of their content and language: the former has a higher news content and generally more in-depth articles with longer sentences and paragraphs; the latter is a mix of entertainment as well as coverage of significant events; thus neither is sensationalist in content (BBC n.d.; Chandler and Munday 2011).

For the reason that the UK is considered to be one of the best countries for AI growth, it is important that the British news media cover the topic informatively. Public perception can fuel what direction development takes; therefore, the future of AI in the UK also depends on how the media covers it and, thus, what the public will read out of it. The topic of public understanding of and opinion towards AI has been more prominent in academic writing, whereas less has been written about how the news media covers AI. Of the few, Brennen et al (2018) looks at an eight-month period in the UK news media, Duberry and Hamidi (2021) concentrates on AI in relation to the coronavirus pandemic, and Sun et al (2020) conducts an analysis of 40 years of American newspapers.

The aim of this thesis is to examine the coverage of AI in two newspapers representing the British news media during 2019-2021 and to compare these to the general public's perception of AI. Specific research questions include:

RQ1: What keywords are most relevant in British news media about AI?

RQ2: How do *MailOnline* and *The Guardian* differ in their coverage of AI?

RQ3: How have AI keywords changed between 2019-2021?

RQ4: Do different survey results of British public perception of AI match the ideas portrayed by the news media?

To achieve the aim, an overview of AI, its application and everyday examples is provided. Additionally, the first chapter includes an overview of topic-relevant studies in relation to AI in the news media and public perception of the technology. In the second chapter, the data collection method, the corpus software Sketch Engine used for the corpus-based analysis, findings and a discussion are presented. The conclusion summarizes the main findings of the analysis.

1. NEWS MEDIA COVERAGE AND PUBLIC PERCEPTION OF ARTIFICIAL INTELLIGENCE

This chapter serves as the background to the study with an overview of AI, its applications, risks and benefits, as well as everyday examples of its use in order to introduce the technology. This is followed by an outline of previous research done in regard to AI in the news media, with a particular emphasis on the British news media. After that, the topic of public perception of AI is discussed, as the analysis in Chapter Two will include a discussion of how public perception matches news media coverage of AI.

1.1 Artificial intelligence application and recent developments

AI is handled as a branch of computer science which is based on self-learning algorithms. It has the capability to mimic and potentially extend human intelligence by automatically extracting data, understanding its patterns and correlations, learning from said patterns, making data-driven decisions, and solving problems (Deloitte 2017: 2-4; Deng 2018: 180; Committee on Standards in Public Life 2020: 12). Other cognitive capabilities include, for example, motion (robotics), creativity and dialogue. The latter is made possible by natural language processing (NLP), which enables AI to read, comprehend and generate human languages (Deng 2018: 180). It is important to note that “fully functioning AI systems do not exist yet, and it has been estimated that they will be with us anywhere between 2029 and the end of the century” (Everitt et al 2018; Makridakis 2017: 52). It means that the AI of 2022 is still considered ‘weak AI’ or ‘narrow AI’. The theoretical form of AI which has advanced to human-like intelligence levels, is referred to as Artificial General Intelligence (AGI) or, as it is commonly called, ‘strong AI’ or ‘true AI’ (Insider 2020; IBM Cloud Education 2020). While weak AI focuses on performing a specific task, such as answering questions based on user input or playing chess, and relies on human interference (data input, parameter defining), strong AI

can perform a variety of functions, eventually teaching itself to solve problems (IBM Cloud Education 2020), thus replicating the full depth and breadth of human skills and cognition.

The main purpose of AI is to execute tasks that are complicated for humans or, if continuously performed by humans, lead to a decrease in effectiveness. Yet, although AI offers massive gains in efficiency and performance to practically all industry sectors, not only has its application increased but also concerns regarding its uses. Figure 1 presents the lists of the risks and benefits of AI as highlighted by industry experts and researchers compiled by the author. The lists do not include long-term risks and opportunities (i.e. existential risks) that are foreseen by some (Ord 2020: 37) as these are associated with a super-intelligent AI, which is still considered distant (Naughton 2018; Makridakis 2018: 52) and such views are even met with criticism (Dafoe 2020: para 9).

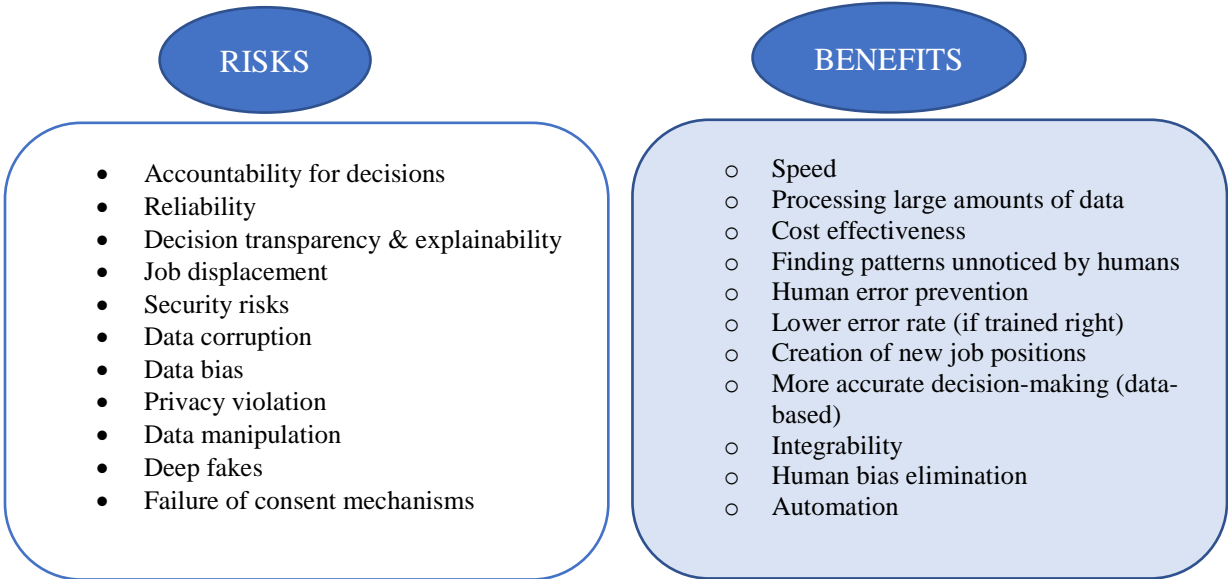

Figure 1. Overview of the risks and benefits of modern AI.
 Source: compiled by the author, based on: Brundage et al 2018; CDEI 2020; CDEI 2021; Committee on Standards in Public Life 2020; Dafoe 2018; Deng 2018; Everitt et al 2018; Gov.uk 2019; Hall et al 2017; Informatics Europe & EUACM 2018; Nadimpalli 2017.

The risk of bias is one of the more prevalent discussion points although the Committee on Standards in Public Life (2020: 27) argues that AI systems will be no more biased than the

human processes they are replacing; there is also the potential benefit of *human* bias elimination. Additionally, some existing systems are designed in a way that makes it impossible to measure bias but AI can, in some cases, successfully identify and reduce said bias, or at least help measure it more statistically. Nevertheless, data scientists are sceptical when it comes to the idea that any AI system could be completely free of bias. Due to this, research on AI fairness and transparency has exploded since 2014 (Zhang et al 2022: 11). Other risks include transparency (i.e., whether it is explained exactly what and how will be done with the collected data) and security risks.

On the benefits side, AI can help find patterns unnoticed by humans, reduce human error, create more precise analytics, and turn data collecting devices into powerful diagnostic tools. One example of this is wearable devices such as smartwatches and fitness trackers.

In 1950, British mathematician Alan Turing was the first to envision AI (computers, in his case) as algorithms that are able to emulate human intelligence. Five years later, AI was formally initiated after it was coined by computer scientist John McCarthy for a workshop at Dartmouth University (Deloitte 2017: 2; Nilsson 2010: 42). From there on, the field has experienced exponential growth of data and connected devices, algorithms, and faster processing through the use of cloud computing (Deloitte 2017: 2; Deng 2018: 180). An important advance in AI has been machine learning, which is present in technologies from machine translation to self-driving cars and is the most widely-used form of AI (Gov.uk 2019; Hutson 2017).

AI is used in virtually all businesses, across a range of industries from banking and finance, to healthcare and transportation; in fact, most humans interact with it in some capacity on a daily basis. This brief section will showcase some everyday examples of AI: media

suggestions (e.g. the audio-streaming service Spotify’s “Discover Weekly” playlists for each individual user), product recommendations, spam filters and navigation apps, self-driving cars, chatbots (customer service 24 hours a day), web search, robot vacuum-cleaners, noise-cancelling headphones, search engines, face-recognition services (face ID), payment transaction validation and verification, and IoT devices (wearables, i.e. smartwatches) (Deloitte 2017: 2, 5, 16; Deng 2018: 174; Nilsson 2010: 616; Bar Standards Board 2019: 3; Brundage et al 2018: 9; Insider 2020; Office for Artificial Intelligence 2021: 16). It can be observed that AI technologies are becoming embedded in people’s everyday lives.

1.2 Media Coverage of AI

The year 2016 was described by Microsoft CEO Satya Nadella as “the year of the bots” (Bruner 2016). There were advances in speech interfaces using NLP algorithms, as well as growth in investments in AI start-ups. This, combined with warnings about the dangers of AI from well-known scientists and innovators such as Stephen Hawking, Bill Gates and Elon Musk, as well as unrealistic predictions from the news media, led to an increased hype around the topic (Deloitte 2017: 5).

Yet, there have been few studies conducted analysing the reporting of AI in the news media. In fact, the author was able to find only one solely UK-based research. Brennen et al (2018) examined at an eight-month period across six mainstream news outlets using a mixed-method analysis approach. Their key findings include: about 60% of news articles are indexed to industry products, initiatives, or announcements; right-leaning outlets highlight issues of economics and geopolitics (automation, national security, investment), whereas left-leaning outlets highlight issues of ethics of AI (discrimination, data bias, privacy).

Sun et al (2020) focused only on American newspapers, reasoning that the US is the leader in AI development with the methods of content analysis and media framing theory. This led to them coding fourteen topics. The topic with the most articles was robot/humanoid, followed by brain/life science and regulation/policy. Some examples of the keywords manually selected to represent each theme, respectively, include: *robot, movie, android; brain, scientist, science;* and *government, regulate, military*. Additionally, they looked at potential argumentation patterns. The most prevalent were labelled as pragmatic patterns (a variety of applications; everyday utility - robots), relativizing patterns (AI utility is overestimated) and economically optimistic patterns (AI boosts the economy).

Duberry and Hamidi (2021) examined the portrayal of AI specifically in the context of the COVID-19 pandemic during the month of April 2021 in French and English-speaking mainstream media. They found that no news article provided a definition of AI (thus relying on the readers' knowledge) and that most articles highlighted the technology in the context of information processing and adaptability. Additionally, that American newspaper coverage is more optimistic than pessimistic, whereas European newspapers (Switzerland, France, the UK) present a more balanced perspective of the risks and benefits associated with AI.

Similarly, Bunz and Braghieri (2022) conducted an analysis of AI applications in the healthcare sector with an emphasis on AI systems replacing or outperforming medical experts and/or being personified (i.e. discussed more as 'having intentions' and being a 'boss' than as a system). Here, Bunz and Braghieri took both the US and the UK into consideration (The Wall Street Journal, The Daily Telegraph and The Guardian). The results indicate that instead of replacing humans, AI systems are mostly linked to outperforming them. Bunz highlights this as an issue: that outperforming human expertise places AI above critique. The most frequent word

in the titles between 2015 and 2019 is ‘technology’ or its variant ‘tech’, followed by ‘AI’, ‘intelligence’ and ‘health’. Notably, words ‘robot’, ‘doctor’, ‘future’ and ‘medicine’ are less frequent. They observed that the framing of AI systems in the healthcare sector is technology-related, not healthcare-related.

In regard to stakeholders, Brennen et al (2018) concludes that 33% of unique sources are from the industry sector (i.e., from company executives, researchers, employees), 17% from academia (including researcher employed by a university), and about 5% from government sources. This is supported by Bunz and Braghieri (2022) who found that Google is by far the most cited stakeholder, even in the healthcare sector, almost double the times of Facebook. Overall, by far the most cited entities or people are from the tech industry or business-related (Google Facebook, Microsoft, IBM) (Sun et al 2020; Bunz and Braghieri 2022), followed by public institutions (e.g., the American Food and Drug Administration, the European Union and the World Health Organization) and universities (e.g., MIT, Oxford University and University of Pennsylvania) (Bunz and Braghieri 2022). The most referenced individual is Elon Musk (Brennen et al 2018). Sun et al (2020) explored the topic further and expanded it to include nations and found that China, the US and Japan are the three nations mentioned most frequently.

To sum up, Bunz and Braghieri (2022) and Duberry and Hamidi (2021) focused on AI in relation to the healthcare industry, with the latter specifically on the coronavirus pandemic. Regarding the time period examined, Brennen et al (2018) concentrated on eight months in 2018, Bunz and Braghieri (2022) on one month in 2021; Sun et al (2020) included articles from 1977 to 2018, Duberry and Hamidi (2021) from 1980 to 2019. Sun et al (2020) is US-based, Duberry and Hamidi (2021) Europe-based with one British news media source, and Bunz and Braghieri (2022) is both US- and UK-based. Taking the limitation in previous research into

consideration, this study will examine the representation of AI across industries; secondly, include articles beginning from the end date of the last related study¹, thus starting from 2019 to 2021; and lastly, considering the UK is now recognized as one of the leading countries in AI development, this study will follow the example of Brennen et al (2018) and be UK-based in its scope.

1.3 Public understanding of AI

Public perception of a subject as vague and varied as AI can be difficult to pinpoint, in addition to being likely to change quickly with every new innovation, scandal or statement by a famous individual. It is only recently that people have started to distance AI from the creations of Hollywood (SCAI 2018: 23). It is pertinent to understand how the public perceives AI, which can then be linked to what aspects should the public be educated on, for example, by the news media; and if the news media has succeeded in this task.

As previously mentioned, AI is a broad term but not only is the term broad but also the public's understanding of it. Although media coverage on the topic of AI is frequent, people from the UK are confused by what it actually is and how it works - leading to a distorted view of the topic (Gallup 2019; Holder et al 2018; SCAI 2018; Kantar Public 2019; CDEI 2022). In 2019, 63% of people reportedly knew something about AI (PAS 2020: 6), whereas in 2021, CDEI (2022: 9) found that 90% have heard of the term "AI", potentially indicating an increase in knowledge or at least in exposure to the topic. Yet, only 13% of the respondents felt they could explain the term 'artificial intelligence' (CDEI 2022: 48). Holder et al (2018: 7) also conducted a survey and found that the a large proportion of the British public (39.5%) consider

¹ Bunz and Braghieri (2022) analysed news media coverage in 2021, but it was only for the duration of one month and regarding the healthcare sector

their knowledge of AI 'limited', whereas only 8.4% claim to know 'a lot' about it or consider themselves experts; 16.4% have heard the term but are unsure of its meaning; and 9.1% claimed to have never heard of it. Another survey reported that those who 'knew a lot' about AI was 12% in 2019 (Kantar Public 2019: 1), thus having grown. Holder et al (2018: 8) expanded on their findings and tested respondents' knowledge. The findings link with previous and future findings (SCAI 2018; Gallup 2019) that people tend to have a false perception of AI, even those who claim to understand it. For example, their survey concluded that 1 in 5 respondents think AI is currently capable of modifying itself, and 1 in 6 that predicting human actions was in its capacity. These responses were high amongst those who had said they 'knew a lot about AI', which indicates that even those claiming to be knowledgeable of AI, still do not understand the exact capabilities of the technology. Additionally, 62% of respondents claimed they had had no contact with or had not used an application which utilizes AI, whereas only 15% said they had used or had had contact with AI. This is explained by Zhang and Dafoe (2019) who state that most do not associate, for example, Google Translate, tagging people on Facebook, Google Search, and Netflix recommendations with AI. Thus, public understanding on this topic is mostly surface-level. Furthermore, Nader et al (2022: 6) enquired after what technologies Americans specifically use and found that most often, either regularly or not, they use digital assistants, predictive texts, wireless networks, and digital recommendation systems. On the other hand, the technologies that most admitted to never using included self-driving cars, virtual reality gaming, smart home devices, and big data. Of these technologies, respondents did not associate AI with the following: wireless networks, big data and digital recommendation systems. Another survey found that British people are uncomfortable with AI being used to power Internet search engines which is a common practice (CDEI 2022: 48).

Furthermore, when examining the different terms associated with AI (e.g., machine learning, robotics, automation), Zhang and Dafoe (2019) demonstrate that most Americans tend to have some knowledge of the terms but they are not aware how widespread AI is. Whereas only 9% of the British public said they had heard the term ‘machine learning’, it turned out that they are in fact familiar with machine learning’s different applications, as the majority recognized at least one of the eight examples given (Ipsos MORI 2018: 22).

Data, which AI technologies use, is another topic that warrants exploration. CDEI (2022: 24) reports that British people do not know how their personal data is being collected and used, in addition to uncertainties whether organisations are transparent in this regard. Data security was indeed seen as the biggest risk for data use in society (could be hacked, stolen or even sold). Interestingly, risks of bias and job loss were at the bottom of risks perceived with new technologies (CDEI 2022: 27). According to another survey, willingness in the UK to share personal data is highest in relation to improving medical research and care, which, in fact, is higher in the UK than in the rest of the European Union by 7% (Eurobarometer 2020: 2). In fact, AI in healthcare is one of the aspects people feel most positive about and could see the greatest potential for benefits, for example, by faster and more accurate diagnosis of diseases (Ipsos MORI 2017; Kantar Public 2019; PAS 2020; Nader et al 2022; CDEI 2022). However, it was felt that human involvement was pertinent to ensure that personal contact continues where it is needed (Ipsos MORI 2017: 32)

As to AI's impact, Pew Research Center (Smith et al 2017) revealed in 2017 that Americans tend to observe AI as a topic of apprehension, not enthusiasm. On the other hand, Gallup (2018) points out that, when it comes to AI in general, public discussion in the US and the UK has remained optimistic rather than negative, but some topics (e.g., job and economic

impact) are generally regarded as potentially having a growing negative correlation. To support this, Deloitte (2017: 11) found that most people believe AI will empower work instead of replacing humans. This was similar to the findings of Holder et al (2018) regarding specifically the perceptions of the British public. When asked when their current skills will become obsolete, the US is more optimistic than the UK. Of those who think their skills will become obsolete, a large proportion in the US (22.4%) answered that it will happen in 10 years or more, whereas people from the UK thought it would happen in 1 to 4 years (20.9%). People in both countries though, think that AI will eliminate more jobs than it will create (64.3%) (Gallup 2018). Experts, on the other hand, say that AI and automation will generate more jobs than they will displace (World Economic Forum 2020). However, people rarely fear to lose their *own* job and is therefore perceived as a problem which will affect others (Gallup 2018; Archer et al 2018: 9).

In regard to trust, the National Health Service (NHS) is highly trusted (89%) (CDEI 2022: 64), whereas social media companies and the government are the least trusted entities to act in people's best interest (36% and 39% trust, respectively). Notably, big technology companies (24%) are more trusted (60%) than social media companies. The academics (academic researchers at universities), police and banks are trusted by most (76%, 72% and 71%, respectively) (CDEI 2022: 64). Respondents with the lowest digital familiarity expressed high trust in the police and banks, but were less likely to trust academics (CDEI 2022: 63).

Some surveys even enquired about specific emotions and words respondents would associate with AI (Kantar Public 2019; CDEI 2022; Nader et al 2022). Kantar Public (2019: 2) found that most respondents (64%) were excited to see what AI can do, but still felt that more research is required (82%) on how AI will be used in everyday life. More recently (Figure 2), AI was predominantly associated with being 'scary' and 'futuristic', as well as feeling

favourable outlooks, further asserting that people have a false understanding of AI. Where these research findings lack, however, is that they have not been linked with how people consume information about artificial intelligence. More importantly, as the public mostly receives information from and is influenced by the news media, it is important that the public is educated on the aspects that they are least familiar with by the news media.

An overview of the terms associated with AI, what the public does not understand, what has negative and what positive connotations regarding AI can be found in Appendix 1.

2. CORPUS-BASED STUDY OF THE COVERAGE OF ARTIFICIAL INTELLIGENCE IN *THE GUARDIAN* AND *MAILONLINE* DURING 2019-2021

This chapter analyses the coverage of artificial intelligence in the British online news media on the example of *The Guardian* and *MailOnline* and compares it to the public perception of AI in the UK as determined by previous studies. The chapter describes the methods and procedure of the study discusses its findings as to how AI is presented, what differences in the different news media occurred during 2019-2021 and whether public perception of AI matches that of the news media coverage.

2.1 Method

The aim of the study was to examine the coverage of AI in two British news media sources and to compare these to the general public's perception of AI. To this purpose, an electronic text corpus ('AI corpus', hereafter referred to as AIC) was compiled from two online UK news sources, by searching for 'artificial intelligence' during the period of 01 January 2019 until 31 December 2021. The set of pragmatic decisions that presided over the corpus building phase will be discussed in detail below.

The outlets were strategically selected on the basis of the following criteria: that they were national and UK-oriented in their scope; that they publish articles based on news reporting on a daily basis; that they have a large number of digital readers; that they represent different types of news media (quality paper and middle-market tabloid); and lastly, that they represent different political leanings (liberal and conservative), providing the means for comparison of two different types of news media. Two of the most widely read digital titles in the UK are *The Guardian* and *MailOnline*, which are also of different political views and formats with the

former being a more liberal quality paper and the latter a more conservative middle-market tabloid. The features of the two chosen outlets are outlined in Table 1.

Table 1. Overview of chosen news media sources.

Newspaper	Established	Digital Delivery (Monthly)	Type	
<i>The Guardian</i>	1821	18,422,000	Liberal	Quality paper
<i>MailOnline</i>	1896	22,430,000	Conservative	Middle-market tabloid

Source: Newsworks n.d.; Britannica 2019; Britannica 2021.

Taking the limitations in previous research into consideration and for the analysis to be as up-to-date as possible, this study will include articles from the end date of the last related study conducted by Brennen et al (2018) thus starting from 2019 and ending in 2021. Additionally, the time period allows for comparison to be drawn between the three years.

The articles were collected from the LexisNexis archive (following the example of Duberry and Hamidi 2021, and Sun et al 2020) through targeted search of the phrase ‘artificial intelligence’. The author decided to focus only on ‘artificial intelligence’ and not its related phrases, such as ‘machine learning’ and ‘robotics’ (as opposed to Sun et al 2020), because as mentioned in 1.2, people do not necessarily associate the terms with ‘artificial intelligence’.

The primary search produced 276 articles for *The Guardian* and 417 articles for *MailOnline*. The exclusion criteria included: if (a) ‘artificial intelligence’ was not mentioned in the headline or lead section, and (b) article had less than 100 words, as such articles do not provide sufficient information on the dominant AI keywords promoted by the British media outlets (Sun et al 2020). After reading 50 sampled pieces, the author found that some of the articles only mentioned AI in passing, without presenting any substantial discussion of the topic. Although past studies (Sun et al 2020; Burcher et al 2016) have utilized the approach of having the keyword appear at least twice in the full text in addition to at least once in the title or lead

paragraph, in this case this prompted articles which may have mentioned AI but were still irrelevant to the topic². LexisNexis enables a relevancy score “based on the term’s frequency, location in document, and how much discussion of the topic occurs” (LexisNexis n.d.: 3). Thus, to focus on the news substantially relevant to AI, the following rule was applied: the relevance score had to be 80% or more (major or strong passing reference) to be included. The author then screened articles by manually removing the following: book, stage, videogame, film and TV reviews; obituaries; letters and other genres not classified as news (Sun et al 2020). This yielded 171 news articles for *The Guardian* and 315 for *MailOnline*. The full-text articles were downloaded from the newest to the oldest to form an overall news corpus (AIC) of 486 published items. Altogether the corpus amounts to 417,523 words, with a 5.9% type-token ratio (TTR = unique words / tokens x 100) as a raw measure of lexical diversity (Paganoni 2019). AIC consists of two sub-corpora which are *The Guardian* (TG) sub-corpus, consisting of about 154,040 words, and the *MailOnline* (MO) sub-corpus, consisting of about 263,482 words.

The Corpus Linguistics software used for the analysis is the March 2022 version of the Sketch Engine software. Sketch Engine’s features for analysing different aspects of corpora include word sketch, word sketch difference, wordlist, concordance, thesaurus, n-grams and keywords (Kilgariff et al 2014). Keyword and term extraction showcases units which are typical of a focus corpus or which “define its content or topic” (Sketch Engine n.d.-a). Keywords and term extraction n.d.). Keywords are individual words and terms are “multi-word expressions” which appear more frequently in the focus corpus than in the reference corpus, and are displayed as lemmas. Mainly nouns and adjectives will be included in the result since the frequencies of

² For example, this 2021 *MailOnline* article titled: “‘Armed and dangerous’ MIT grad, 29, is sought in shooting death of newly engaged Yale student - as it's revealed cops quizzed him over killing before he went on the lam”; ‘artificial intelligence’ is mentioned five times but only in relation to the person’s occupation.

other parts of speech tend to be similar in all texts. This corpus-assisted study employs the keyword, concordance and word sketch features. This approach enables much larger amounts of material to be analysed than in conventional content or qualitative thematic analysis (Seale 2012: 476). While a simple word list provides frequency, a keyword list compares the frequencies of one corpus against another in order to determine which words occur statistically more often in one or the other and thus, the keywords produced indicate that the given words have high saliency and that they are worth exploring (Baker 2006: 124-125). The limitation of keyword lists is that they lack context. Fortunately, it is not difficult in keyword analysis to discover the context in which words are being used in order to further assess predominant meanings. Concordance enables to explore the “company that words keep” (Firth 1957).

The corpus software Sketch Engine was subsequently implemented to extract keywords and multi-word terms by keyness, a score computed by a statistical formula that shows what words are typical of the focus corpus because of their higher (or unusual) frequency against a reference corpus (Scott 1997: 236), here the English Web Corpus (hereafter enTenTen20). As the name suggests, the enTenTen20 is an English corpus made up of texts collected in 2020 from the Internet and, as of April 2022, consists of 36.5 billion words (Sketch Engine n.d.-b). The corpus has been built using a web crawler, which can effectively avoid data not suitable for text corpora (e.g., forms, advertisement) (Suchomel and Pomikálek 2020). The N variable, “a variable which allows the user to focus on higher or lower frequency words” (Kilgariff 2009: 1), was set for mid-frequency words (i.e. from rank 500 upwards), thus excluding rare words. The procedure of extracting key keywords and multi-word terms was performed to guide the analysis towards the most prominent concepts in the study corpus.

By comparing the AIC to the enTenTen20 reference corpus, Sketch Engine's keyword tool produced 100 keywords and multi-word terms, ordered by keyness, was created in Sketch Engine to be used as a starting point in the analysis of AI coverage. Arguably, the full keyword list of nouns and adjectives (which includes verb forms in the case of verbal nouns) sums up the basic vocabulary of AI coverage and highlights recurrent subtopics. The same amount of multiword terms (nominal lexical collocations in this case) were extracted as well which have been proven to be very useful to better circumscribe the semantics of keywords, whose social and cultural implications could not just be captured by automatic extraction (Paganoni 2019: 29), showing meaning relationships between them and thus preparing the ground for the analysis.

In order to find out how *The Guardian* and *MailOnline* differ in their coverage, a list of 100 keywords was extracted from the TG and MO sub-corpora as the focus corpora against the enTenTen20 reference corpus. Furthermore, the author looked at concordances for some keywords to better understand their context. Lastly, two word sketches were created with the term 'artificial intelligence' to understand which collocates were the most strongly related to the specific term.

In order to discover what topics were most prevalent in each year (2019, 2020, 2021), three additional sub-corpora were created (AI 2019, AI 2020, AI 2021) and the top 50 multiword terms were extracted from each sub-corpus. Here, the reference corpus was chosen to be the rest of the AIC (i.e., AI 2019 against AI 2020 and AI 2021) because the enTenTen20 does not include the year 2021 and one of the limitations of the enTenTen20 corpus is that it contains minimal metadata, i.e., date of production (Jakubiček, n.d.: 2). The keywords were then categorised into five thematic groups: technology, healthcare, implications, products and arms.

The fourth and final research question regarding public perception of AI and whether this is connected to news media coverage is presented as a discussion using previous studies and a figure created on the basis of the table of terms connecting AI and public perception.

2.2 Findings and Discussion

The full keywords and multi-word terms list of 100 lemmas for the AIC in general, TG and MO, as well as the AI 2019, AI 2020 and AI 2021 sub-corpora can be found in Appendix

2. Table 2 includes the first 30 multi-word terms for AIC with frequencies and keyness scores, as well as, keywords for *The Guardian* and *MailOnline*.

Table 2. 30 keywords for AIC compared with enTenTen20, with parameter N=500, using Sketch Engine.

No.	AI multi-word terms	Frequency	Score	The Guardian	MailOnline
1	artificial intelligence	1057	5,294	human	Facebook
2	social media	150	1,522	machine	human
3	machine learning	128	1,516	Google	researcher
4	facial recognition	98	1,401	tech	image
5	neural network	85	1,342	UK	Google
6	ai system	78	1,321	company	machine
7	deep learning	68	1,277	bias	patient
8	using artificial intelligence	67	1,276	researcher	predict
9	chief executive	57	1,234	digital	use
10	new technology	54	1,222	cancer	scientist
11	use of ai	58	1,221	scientist	video
12	science fiction	56	1,205	tool	detect
13	breast cancer	47	1,193	science	app
14	tech company	43	1,159	develop	brain
15	fake video	42	1,151	deepfake	firm
16	human brain	36	1,145	Facebook	science
17	killer robot	34	1,14	expert	user
18	tech giant	34	1,136	use	drone
19	facial expression	32	1,132	research	train
20	tech firm	32	1,13	future	camera
21	recognition technology	32	1,128	train	develop
22	mental health	31	1,127	learn	company
23	computer program	31	1,127	potential	identify
24	clinical trial	31	1,127	app	cancer
25	dark matter	42	1,122	firm	expert
26	computer science	31	1,122	faculty	scan
27	prime minister	35	1,122	predict	UK
28	learning algorithm	30	1,119	US	tech
29	self-driving car	32	1,114	drug	create
30	home office	36	1,112	automation	able

With *artificial intelligence* at the top as expected, the selection of content words can be read as a snapshot of the technologies, actors and crucial issues in AI. In between are a number of terms related to the technological domain and references to Silicon Valley *chief executives* (57 hits) and *tech giants* (34 hits), and other *tech companies* (43 hits) and *firms* (32 hits) occupying the middle ground. The actors with a lower keyness score are government-related (*prime minister* is identified 35 times and the *home office* 36 times). Interestingly, the first academia-related actor *computer scientist* comes in at rank 37 with 24 occurrences in the whole corpus. That means that *chief executives* from the industry sector (such as Deepmind's, Benevolent AI's and Youtube's) are two times more prevalent in AI news than academics. This could be tied to the fact that news introducing novel products or (advances in) industry initiatives are far more frequent than those reporting on academic studies or reports. This corresponds with the findings of Brennen et al (2018). On the other hand, they found that government sources were behind academia which is not the case in this study. Concordances reveal that *prime minister* is mostly modified by *former* (David Cameron) and his dealings with becoming chair of a US firm; as well as *home office* having collocates of *according to* (mostly in MO) - using the Home Office as a credible source -, and *racial bias* and *legal challenge* (mostly in TG) regarding a visa application system. Thus, even though mentions have grown since 2018, the context is mostly neutral or negative and not reflective of UK government's pursuit of AI supremacy.

Moreover, the results highlight the continuous digital duopoly of Facebook (443 occurrences) and Google (463), against the 107 occurrences of Microsoft. In actual fact, the topicality of the three platforms seems to correspond to their respective positioning in the digital market. According to the 2021 report released by the Reuters Institute for the Study of

Journalism, Google and Facebook are the Big Two of online advertising (Newman et al 2021: 13). The most referenced individual continues to be Elon Musk (Brennen et al 2018) with 110 hits; of these more than 75% are in MO which could also be related to the higher number of articles in the MO sub-corpus.

Undoubtedly, the AI topic is reported first and foremost as a technological system (*machine learning, neural network, AI system, deep learning, computer program, computer science, learning algorithm*), followed by technological innovation (*facial recognition, new technology, self-driving car*) and societal change. Notably, the preferred meaning of *science* appears to be *science fiction* (frequency 43) and not *computer science* (frequency 32). Moreover, the noun *video* is modified by *fake*, and *robot* by *killer*. Killer robots refer to ‘Lethal Autonomous Weapon Systems’ (LAWS) which are essentially ‘combat robots’. Killer robots are mostly a thing of the future still but there already numerous movements trying to stop the development of these systems (WILPF 2020: 2). Notably, the higher appearance of the term in the MO sub-corpus could indicate that MO might still occasionally lean towards being sensationalist, even though it is a middle-market newspaper. The high frequency of keyword *use* (both as a verb and a noun: *using artificial intelligence, use of AI*) is a significant clue that alludes to the human intentionalities on which AI ultimately relies, despite more radical claims that see it as being independent of human reason.

Finally, words related to the healthcare sector (*breast cancer, human brain, mental health, clinical trial*) are present at the top of the list. Analytics firm GlobalData (2021) found that AI is expected to have the greatest impact on the sector. An example of this is a 2019 *MailOnline* (9 Aug 2019) news article which explains that AI “...could diagnose breast cancer better than doctors after being trained to read MRI scans.”. One strong theme is indeed AI

systems that can diagnose *patients*, or *detect* diseases. The use of AI in healthcare has been sped up due to the COVID-19 outbreak in 2020. In the same year, 90% of large pharmaceutical firms initiated AI projects (Waltham 2021). Britain's two biggest biopharmaceutical companies, AstraZeneca and GSK, entered into a five-year partnership with the University of Cambridge to fund the Cambridge Centre for AI in Medicine (CCAIME) with the aim to *develop* AI technologies which will advance *clinical trials*, personalised medicine and drug discovery (O'Neill 2020). An example, this time from *The Guardian* (31 Mar 2020), demonstrates how AI is being used to screen 15,000 drugs in search for a coronavirus cure.

When comparing the two sub-corpora (Appendix 2) in order to answer the research question "How do *MailOnline* and *The Guardian* vary in their coverage of AI?", it appeared that some keywords (e.g., *ai*, *intelligence*, *technology*, *computer*, *robot*) are common to both news media and were thus removed from comparison (Table 2).

In regard to stakeholders, *MailOnline* mentioned Facebook far more often than Google, whereas in *The Guardian* it was the other way around. This could allude to the fact of *MailOnline* as a middle-market tabloid and that Facebook The nations most frequently mentioned in TG are the UK, followed by the US; similarly in MO, the UK is mentioned the most, but is followed by China. This is explained by the fact that these newspapers are UK-based in scope and thus report on the happenings in this country. American newspapers, on the other hand, mostly mentioned China, America and Japan (Sun et al 2020), which is understandable considering that these were (and still are) the leaders in AI during the time period chosen for the study (1977-2018). Looking at the concordances of the countries, *MailOnline*'s references to China are mostly in relation to the AI arms race, including its constant developments in the military industry, e.g.,

China is developing underwater AI robots that can hide in the sea and attack enemy vessels with torpedoes WITHOUT human guidance. (8 July 2021)

Another context is China using the technology to ‘spy’ on their people. *The Guardian* mentions the US mostly in connection with its tech companies.

Furthermore, when discussing the adjectivity of *humans*, *The Guardian* mostly pairs it with *human right*, *human being*, and *human player* (i.e. poker, videogames). MO has a higher tendency to use *human* in context with the *human brain*, *human pilot* (in regard to autonomous fighter *drones*). MO’s tendency to highlight the militaristic uses of AI is further illustrated by the keyword *machine* modifying the noun *gun*, in addition to *learning* (the latter is the only noun modified by *machine* in the TG sub-corpus’s first 100 multiword terms, and the former only appears as a noun compound once in entirety of the TG sub-corpus).

In 1.2., it was revealed that left-leaning outlets usually focus on issues of ethics of AI (discrimination, data bias, privacy). This is supported by the findings of this study in that *The Guardian*, a more liberal outlet, has a high keyness score for keywords such as *bias*, *human right*, *gender* and *diversity* (especially the *lack of diversity*). Moreover, the articles highlight ethical concerns surrounding topics such as *deepfakes* and *autonomous weapons*. It can be said then that *The Guardian* places greater emphasis on the various limits and dangers of AI, not just ethical concerns. Even the use of the word *potential* in *The Guardian* is related not to potential benefits but to *potential harm* instead. *MailOnline*, a more conservative outlet, mainly discusses two industry-related topics: the arms industry and healthcare. The different newspaper types play a role here, as *The Guardian*, a quality paper goes more in-depth on the topic of AI, whereas *MailOnline*, a middle-market tabloid focuses coverage of significant events in different industries, as well as foreign news (China-US arms race). Brennen (et al 2018) found that

although the discussion of automation and job loss is common across coverage, left-leaning outlets frequently discuss jobs lost through automation, whereas right-leaning outlets claim AI will lead to the creation of new jobs. In the time range 2019-2021, it is apparent that these stances/ have prevailed with *The Guardian* discussing jobs in the context of verbs such as *take*, *lose* and *displace* more than *generate* and MailOnline in the context of *create* more than *lose* or *replace*.

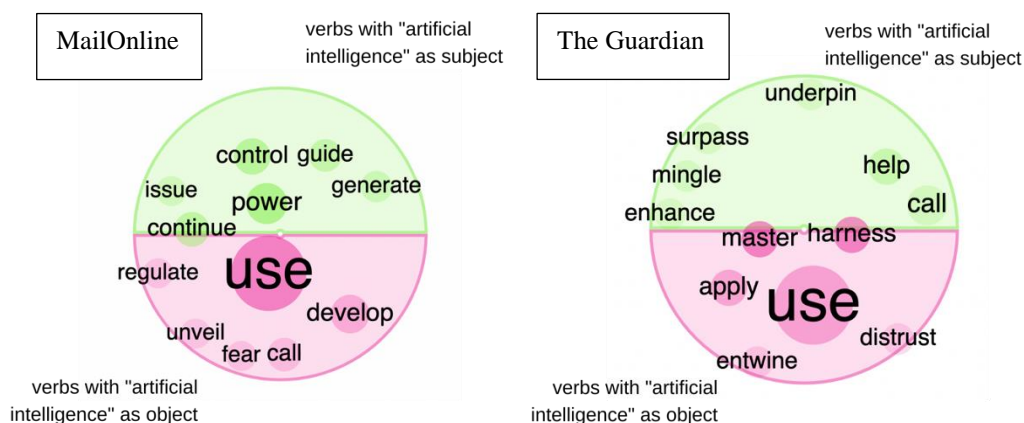

Figure 3. Word sketch of ‘artificial intelligence’ in the *MailOnline* and *Guardian* sub-corpora.

When examining the term ‘artificial intelligence’s’ grammatical and collocational behaviour (Fig. 1), it should be noted that the typicality score (LogDice) indicates how strong the collocation is. The higher the score, the stronger the collocation, meaning the words in the collocation do not frequently combine with many other words (Kilgariff et al 2014). The word sketch identified that the following verbs with ‘AI’ as the object have the strongest collocations in the *MailOnline* sub-corpus: many still *fear* (score = 8.1) and are thus calling for a need to *regulate* (8.1) AI. Similarly in *The Guardian*, the verb *distrust* is connected to AI, as well as how different sectors should *harness* (9.8) AI to improve outcomes and that other countries/companies are already *mastering* (9.8) its technologies ahead of the UK. Verbs with ‘AI’ as a subject in MO include: *powered* (11.3), *controlled* (10.5) and *guided* (9.6) by AI,

demonstrating AI's prevalence and potential uses; that it *continues* (10.0) to advance and be a priority, although some still *issue* (8.6) warnings. AI has the ability to *generate* (8.9) (photos, cancer treatment plans) and *create* (8.4) (music, images). In TG: AI can *help* (9.4), e.g., spot fake videos. Similarly to MO, verbs that illustrate how AI is already among us were also highly scored: AI and humans *mingle* (9.1), and that AI *underpins* (9.0) many aspects of everyday life. There are also discussions whether AI will truly *enhance* (9.0) rather than replace us.

Brennen (et al 2018) found that right-leaning outlets emphasise that there should be no regulating AI as this would limit companies and lead to their slower development compared to, for example, China. Coverage regarding AI regulation has thus changed in conservative outlets from against regulation:

the government must resist the temptation to slow down its [AI's] advance through inappropriate red tape and burdensome taxation (Telegraph, 23 Jan. 2018)

to in favour of it:

We have to prevent the avoidable tragedy that is coming if we do not regulate our killer robots (MailOnline, 17 Jan. 2020).

Following along the topic of change in yearly reporting, the years 2019-2021 are looked at. Presented in Table 3 are the five topics retained for final interpretation. Additionally, five representative keyword examples are presented depicting the meaning of each topic.

Table 3. Keyword topics in AI 2019, AI 2020 and AI 2021 sub-corpora.

Topics	technology	healthcare	implications	product	arms
Keyword examples	facial recognition, virtual reality, computer science, intelligence algorithm, big tech	breast cancer, MRI scan, protein structure, clinical trial, mental health	AI ethic, new job, porn scam, trans people, black people, human right	pie recipe, electronic toothbrush, sex doll, pressure sensor, chat service	autonomous weapon, human pilot, air force, drone swarm, robot submarine
Keywords in AI 2019, AI 2020 and AI 2021	2019 (6)	2019 (6)	2019 (14)	2019 (9)	2019 (3)
	2020 (2) ↓	2020 (22) ↑	2020 (4) ↓	2020 (8)	2020 (4)
	2021 (6) ↑	2021 (12)	2021 (6)	2021 (19) ↑	2021 (2)

The topic ‘product’ has two sub-categories: AI goods and programs (e.g., pressure sensor), and results/achievements (Henry VIII in the context of “Scientists use artificial intelligence to work out how much of Shakespeare's collaborative history play he actually wrote” (*MailOnline*, 25 Jan 2019)). Throughout 2019-2021, keywords representative of the topic the ‘arms’ industry remained somewhat similar in frequency/relevance with the number rising by one keyword in 2020 and dropping by two the following year.

The topic by which 2019 differs from 2020 and 2021 the most is implications with 14 representative keywords out of 50. Implications keywords include *ai ethic*, *new job*, *porn scam*, *black patient*, *public service* and *vulnerable people*, thus showcasing that AI ethics was a major discussion point in 2019. Of the entities mentioned, 80% are from the US and 20% are related to the arms industry. Notably, none are from the UK.

Healthcare (22 keywords) and the arms industry (4 keywords) are the two keyword topics that appeared most frequently in the 2020 news articles. The increase in keywords related to healthcare was to be expected, again, because of Covid-19. However, advances were not made just in regard to the pandemic, but also cancer detection (*breast cancer*, *cancer screening*, *cancer patient*) and the *protein folding problem*. In regard to the entities mentioned, about 60%

are from the UK and only one is distinctly American. Thus, a complete shift occurred as the happenings in the UK pulled almost complete focus.

In the year 2021, healthcare is not as relevant as in 2020 but is still being reported on in regard to, for example, *mental health*, *brain scans*, and *brain wave*. The highest number of keywords related to products are also from that year (19 keywords). Furthermore, while in previous years, keywords illustrating AI goods and programs appear the most (66.7% in 2019, 87.5% in 2020), in 2021, results/achievements by AI are higher with 58%. Some examples of these include: AI decodes *sperm whale* clicking sounds, AI able to reveal climate change *tipping point*, and AI ends debate whether *Jaffa Cake* is a cake or biscuit.

The Select Committee on Artificial Intelligence (SCAI) stated in 2018 that people have just started distancing AI from the creations of Hollywood. This is supported by this study in that the term *science fiction* appears predominantly in 2019 in reference to it potentially being a thing of the past: “AI has evolved rapidly from the realm of science fiction to something that permeates our everyday lives.” (*The Guardian* 2019). Lastly, this study will analyse where else public perception (Fig. 3) and news media presentation of AI coincide and where they do not.

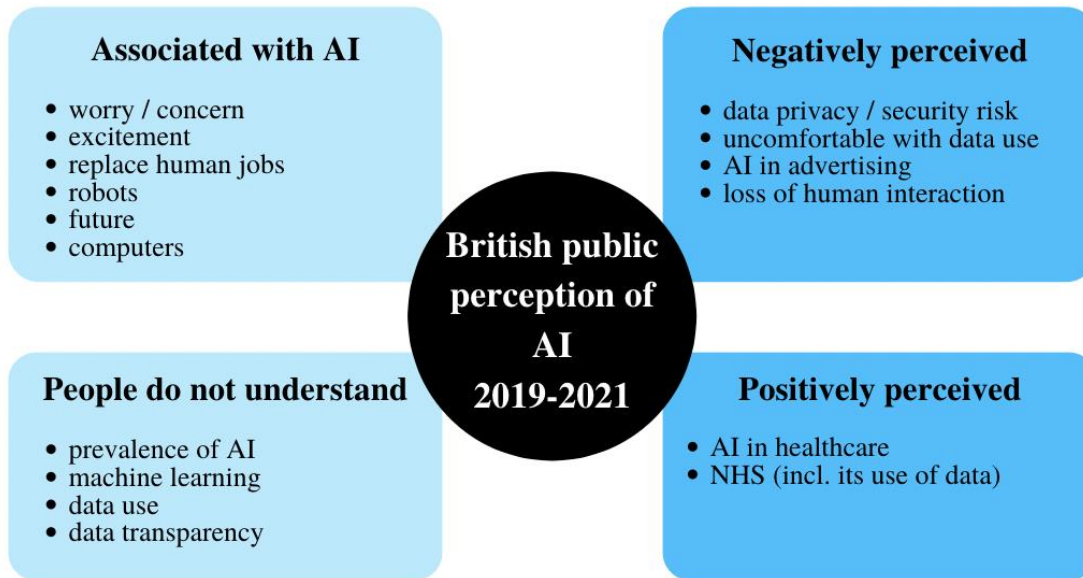

Figure 3. British public perception of AI during 2019-2021 according to research surveys (Gallup 2019; Kantar Public 2019; PAS 2020; Nader et al 2022; CDEI 2022)

As explored in 1.3 people ‘worry’ or have ‘concerns’ regarding ‘scary’ AI. The noun *concern* even appears in the AIC, though at the bottom of the keyword list with a keyness ranking of 98 and with 206 occurrences. Specifically, as mentioned above, MO includes the word *fear* and TG the word *distrust* regarding AI. However, even though ‘concern’ regarding AI has mostly prevailed throughout the years, the British public have started to feel *excitement* as of late regarding the potential benefits of AI, which cannot be related to any AIC top 100 keywords or multi-words. Another quality associated with AI is *replacing human jobs*. Although previous studies (Brennen et al 2018) indicate that job loss is connected to automation, in this corpus ‘job loss’ is most strongly connected to *robots* (verbs with ‘robot’ as subject: *replace, take over*, both appear four times). Similarly, nouns modified by ‘robot’ include nouns related to war or force: *takeover, revolution, and overlord*. The surveys revealed that people indeed most associate AI with *robots* as well as *computers*, which are two AI technologies with high keyness scores in the AIC (7th with 447 occurrences, 12th with 472 occurrences,

respectively). Collocates surrounding *robots* in the AIC reveal that in the category ‘robot’ and/or..., *artificial intelligence* has the highest frequency with five hits. This reveals a direct correlation between public association and news media coverage of certain topics. Additionally, people perceive AI as something which will affect the *future* (48th with 321 occurrences) rather than the present; but that the future is coming sooner rather than later. In AIC as well, *future* is used as a noun 197 times and is modified by adjectives implicating nearness (*near* (4 times), *not-too-distant* (once)), instead of distance (*dystopic* and *distant* (both once)).

‘Machine learning’, on the other hand, is a technology which most people do not understand or have not even heard of. In the AIC, *machine learning* is the top third multi-word term, ahead of *robots* and *computers*, showcasing its high relevancy to AI news articles. However, it has only 128 hits in the AIC, thus it appears about 70% or four times less than *robot* or *computer*, again demonstrating that what the news media portrays more frequently, the public understands or has heard of. There is also the probability that people remember topics that are more specific, like *robots* and *computers*, and emotion-evoking (*killer robots*) than more general and hard to understand. ‘Data use’ and ‘transparency’ are two other topics which people are confused by; in the top 100 multi-word terms list *data* only modifies *science* (22 occurrences). When investigating concrete collocations of *data* in the AIC, it is revealed that *data privacy* and *data protection* appear once throughout the corpus, and of the verbs with ‘data’ as object: *data* is *collected* (3 times), *used to* (2 times) and *gathered* (1 time) which are verbs that with more frequent use, could have alluded to *data* collection and its use. Data privacy is one aspect that people perceive as negative and the previously mentioned noun-form of *concern* is indeed most frequently modified by *privacy* with 9 occurrences.

Although ‘the need for regulation’ has apparently dropped in 2019-2021 public’s association with AI, maintaining the ‘human’ (loss of human interaction, loss of human skills, human experts involvement required) aspect of AI has remained; this is also present in the news media with emphasis put on *human expert* (AI 2019) and *human being*. Moreover, the public is favourably inclined towards the use of AI in healthcare and by the NHS. As seen from the findings of this study, the healthcare industry is indeed covered extensively and the NHS appears 64th with 121 mentions, mostly in relation to *huge potential* and *exploring* how AI can help.

Interestingly, *autonomous weapons*, *risks of bias* and *cyber-attacks* are three topics that purportedly only Americans associate with AI. Only *cyber-attacks* does not appear in the AIC top 100 but the other two do (*autonomous weapons* with 24 occurrences; *racial bias* with 17 occurrences). There is no apparent reasoning for this other than the fact that the frequencies of these terms are simply lower than other terminology which is more prevalent. Another concept that only came out of American surveys is people’s understanding of *smart home devices* as related to AI. In the AIC, there is no mention of any smart home device (such as virtual assistant or robot vacuum cleaner), implicating that the news media usually portrays AI in the context of harder-to-grasp technology, which leaves people confused as to the prevalence of AI and its uses in daily life.

CONCLUSION

AI technologies are making remarkable progress and are having real-world impact on people, institutions and culture. Although the United States and China continue to fight over the AI frontier, one of the leading European countries in AI readiness is, in fact, the United Kingdom. Currently, the UK is already recognised for its technology for healthcare.

Previous research about AI in the news media shows that news is mostly technology-related, even in specific industries, such as healthcare. Differences occur in newspapers with different political views, with left-leaning outlets focusing on issues of ethics of AI, and right-leaning on issues of economics and geopolitics. Overall, discourse remains pragmatic and even optimistic.

On the other hand, people show a general understanding of what AI is, but no real comprehension of how AI is used or how it works. The present study analysed *The Guardian* and *MailOnline* from January 2019 to December 2021 to find out how AI is presented in the British news media, in addition to whether the representation corresponds with public perception of the topic. Moreover, each year in the study was examined to find how they differed from one another, i.e., what topics were relevant to them the most and also how did the different online newspapers vary in their coverage of AI. Articles were collected from the LexisNexis database with the combined study corpora having a word count of 417,523. The analysis was conducted with the Sketch Engine corpus analysis tool.

The findings of the specific research questions presented in the Introduction are as follows: firstly, the keywords most relevant in British news media about AI are precise technical terms representing systems what/which the general public mostly does not understand. Overall, industry-related entities remain the most cited but there has been a growth in the mentioning of

the UK government during 2019-2021. The context, however, is not in trajectory with their/its own development plans but rather related to facts released by them or, more frequently, of their controversies. Healthcare is the most prominent topic during the analysed time period, partially in relation to Covid-19 but also just general advances. Secondly, *MailOnline* and *The Guardian* differ in their coverage of AI in both format and political leaning with *The Guardian* emphasising the potential limitations and pitfalls of AI, thus going more in-depth, and *MailOnline* focusing on the coverage of significant events in the healthcare and arms industry. Yet, keywords occurring in both newspapers mostly highlighted how AI is already present in our everyday lives. Thirdly, AI keywords have changed between 2019-2021 from emphasis on AI ethics in 2019 to healthcare and the UK in 2020 to innovative achievements by AI in 2021 highlighting the ever-evolving nature of AI. Lastly, this study highlighted that public perception has a direct correlation with news media coverage of certain topics, since the examined news media did indeed more frequently cover topics which the public associated with AI, as opposed to those which the public was confused about.

Maria Johanna Milder

News media coverage of artificial intelligence: a corpus-based study of two British online media sources

Tehisintellekti meediakajastus: kahe briti võrguväljaande korpusanalüüs

Bakalaureusetöö

2022

Lehekülgede arv: 59

Annotatsioon:

Tehisintellekt on tehnoloogia, mis järjest areneb ning mis seeläbi on ka meedias ülemaailmselt tähelepanu pälvinud. Üks tehisintellekti juhtivaid riike Euroopas on Ühendkuningriigid, kuid kelle elanikud ei mõista kui palju nad juba praegu tehisintellektiga kasvõi igapäevaselt kokku puutuvad. Bakalaureusetöö eesmärk on uurida tehisintellekti kajastumist kahes briti võrguväljaandes, The Guardian'is ja MailOnline'is. Uurimistöö korpus koosneb 486 artiklist, mis koguti LexisNexis andmebaasist. Artiklid sisestati Sketch Engine tarkvarasse, mille abil viidi läbi korpuse analüüs, rõhuga võtmesõna ja konkordantsi tööriistadel. Sissejuhatuses tutvustatakse Suurbritannia positsiooni tehisintellekti maastikul, meedia rolli arvamuse kujundamisel ning kahte erinevat briti võrguväljaannet. Esimene peatükk annab täpsema ülevaate tehisintellektist ja selle kasutustest, kuidas meedia on kajastanud tehisintellekti ning milline on avalik arusaam tehisintellektist. Teine peatükk kirjeldab korpuse kompileerimist ning tutvustab analüüsimeetodit. Seejärel viiakse läbi korpuse analüüs ning tuuakse välja tulemused, millele järgneb diskussioon. Kokkuvõttes kommenteeritakse tulemusi ning antakse soovitus võimalikuks edaspidiseks uuringuks. Korpuse analüüsist selgus, et briti meedias esinevad tehisintellektiga seoses enim tehnilised võtmesõnad, mis esindavad tehnoloogiad, millest üldsus enamasti aru ei saa. Tervishoid on analüüsitud ajavahemikul kõige silmapaistvam teema, osaliselt seoses Covid-19ga, aga ka üldiste tehisintellekti arendustega seoses. Teiseks, MailOnline ja The Guardian erinevad tehisintellekti kajastamisel nii formaadi kui ka poliitilise suunitluse poolest: The Guardian rõhutab tehisintellekti võimalikke piiranguid ja ohte, minnes rohkem süvitsi ning MailOnline keskendub tervishoiu- ja relvatööstuse oluliste sündmuste kajastamisele. Mõlemas ajalehes esinevad märksõnad rõhutasid siiski enamasti seda, kuidas tehisintellekt juba eksisteerib inimeste igapäevaelus. Kolmandaks on tehisintellektiga seotud võtmesõnad muutunud analüüsitud ajaperioodil: 2019. aastal rõhutati tehisintellekti eetikat, 2020. aastal tervishoidu ja Ühendkuningriiki ning 2021. aastal tehisintellekti uuduslikke saavutusi. Lisaks, tuli uuringust välja, et üldsuse arusaam on otseses seoses uudismeedia kajastusega teatud teemadel.

Märksõnad: tehisintellekt, Ühendkuningriik, meedia, korpusanalüüs

Lihtlitsents lõputöö reprodutseerimiseks ja lõputöö üldsusele kättesaadavaks tegemiseks

Mina, Maria Johanna Milder,

1. annan Tartu Ülikoolile tasuta loa (lihtlitsentsi) minu loodud teose

News media coverage of artificial intelligence: a corpus-based study of two British online media sources,

mille juhendaja on Ülke Türk,

1.1.reprodutseerimiseks säilitamise ja üldsusele kättesaadavaks tegemise eesmärgil, sealhulgas digitaalarhiivi DSpace-is lisamise eesmärgil kuni autoriõiguse kehtivuse tähtaja lõppemiseni;
1.2.üldsusele kättesaadavaks tegemiseks Tartu Ülikooli veebikeskkonna kaudu, sealhulgas digitaalarhiivi DSpace'i kaudu kuni autoriõiguse kehtivuse tähtaja lõppemiseni.

2. olen teadlik, et punktis 1 nimetatud õigused jäävad alles ka autorile.

3. kinnitan, et lihtlitsentsi andmisega ei rikuta teiste isikute intellektuaalomandi ega isikuandmete kaitse seadusest tulenevaid õigusi.

Maria Johanna Milder

Tartus, 24.05.2022

Autorsuse kinnitus

Kinnitan, et olen koostanud käesoleva bakalaureusetöö ise ning toonud korrekselt välja teiste autorite panuse. Töö on koostatud lähtudes Tartu Ülikooli maailma keelte ja kultuuride kolledži anglistika osakonna bakalaureusetöö nõuetest ning on kooskõlas heade akadeemiliste tavadega.

Maria Johanna Milder

Tartus, 24.05.2022

Lõputöö on lubatud kaitsmisele.
