Mechanical Engineering Design Project

MEMS 411, Fall 2022

Racecar Cruise Control

The WashU Racing team is a student group at formula student which annually designs, builds, and tests a 1/3rd scale formula racecar. This project explores the use of an electronically actuated throttle to implement cruise control on the WashU Racing formula student racecar. Through the use of new and existing sensors on the car, in depth engine modeling, and vehicle dynamics, our team was able to make the car accelerate up to and maintain a certain speed. This report centers on the mechanical modeling and implementation of the system. There were three main focus areas: 1. mechanical modeling of the car's acceleration at different engine states and speeds using an acoustics and thermodynamics software called GT-Suite 2. the design of an adapter and control system for an off the shelf electronic throttle body unit from Bosch Motorsport and 3. the design of a system to allow the car's existing mechanical throttle to control the electronic throttle via a rotary potentiometer.

Multiple designs were attempted, but the most minimally intrusive was chosen for the car, as the main customers, the team's aerodynamics and suspension system's valued the ability to change from an electronic throttle to a manual cable throttle in as little time as possible. Further, the system had to be lightweight, waterproof, corrosion resistant, vibration resistant, and able to withstand temperatures up to 140F. Ultimately, the final design allowed the car to get up to speed in a representative test on jack stands. Additional work is needed to be safe to test with an occupant in the vehicle.

1 Introduction

This project began with a cited need from the WashU Racing team for some sort of cruise control for testing their vehicle. The team annually builds an open cockpit formula race car and competes at a collegiate design competition in Michigan. The car is judged on it's design by industry experts, and tested in the harsh conditions of motorsport racing. [SAE].

Figure 1: The WashU Racing WUFR-22 vehicle competing.

The team approach us with an issue they experience regularly during testing: there is no easy way to test the steady state response and handling of the vehicle. Specifically, the team wanted a speed limiter/cruise control that was able to hold the car to a specified speed for aerodynamics and vehicle dynamics testing and validation.

2 Problem Understanding

2.1 Existing Devices

Cruise control has existed on automobiles for over 100 years, however before the 1960's it was largely in a rudimentary form. Early versions of cruise control used mechanical linkages and locks to hold the throttle open a certain amount. More recent versions adopted complete computer control of the throttle and fuel injection, allowing them to maintain speed despite changes in the engine or road conditions, by adjusting throttle as needed. Motorsport is devoid of cruise control for the most part, except for pit lane speed limiters.

Link: https://www.youtube.com/watch?v=bp4Q_tLnayw

Description: Toyota's implementation of cruise control started with the Camry in 1973 during the oil crisis. The standard form of cruise control uses a stalk on the side of the steering column, usually under the turn stalk. As computers have advanced, so has the abilities of cruise control. Beginning in 2000, Toyota brought adaptive cruise control to the US in Lexus products, which

Figure 2: A vacuum tube and speedometer cable used to control the throttle for cruise control (Source: Toyota USA)

Figure 3: A button in the 1967 AMC Ambassador to engage and disengage cruise control (Source: American Cars, 1960-1972: Every Model, Year by Year)

uses and additional suite of radar sensors to distance relative to the car /object in front of the vehicle. This implementation also requires the ability to control the brakes. While these off the shelf systems are well developed, they could not be used in any capacity for this project as they are proprietary and impossible to adapt to the WashU racing's architecture. These system's did inspire the implementation on the racecar, however, as cruise control is actuated via a switch in the cockpit, and uses very similar techniques for sensing the vehicle's speed.

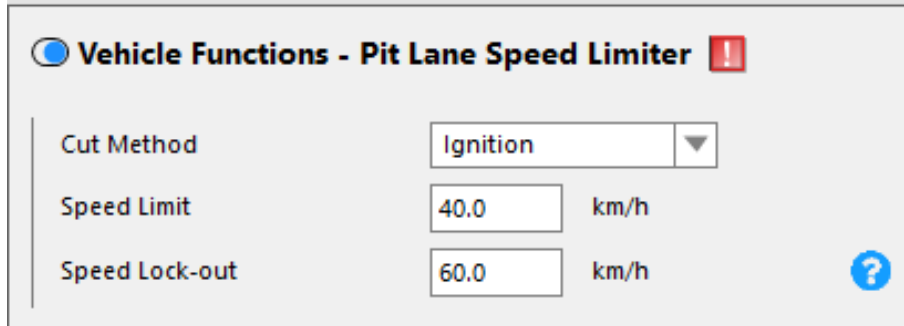

Figure 4: The pit lane speed limiter function in some high end ECU's. this is Haltech's implementation, for reference.

Link: <https://support.haltech.com/portal/en/kb/articles/pit-lane-speed-limiter>

2.1.1 Existing Device #2: Motorsports Pit Lane Limiters

Formula 1 and other motorsports series have required the use of a "pit lane speed limiter" for some time. This requirement was brought about to increase safety in an area where the cars are most likely to collide. These limiters are usually a button on or next to the steering wheel, which, when pushed, keeps the car at a constant speed. These speed limiters are usually implemented in the vehicle's engine control unit, or ECU. Unfortunately the ECU used in the WashU Racing vehicle does not have this feature.

2.2 Patents

2.2.1 Cruise control system (US6081762A)

This patent combines wheel speed sensing, cockpit sensing (brake, throttle, and clutch pedals), and an analysis of road conditions to inform the vehicle's speed through the ECU. This patent also describes the many safety concerns related to cruise control in a street legal vehicle, many of which were issues we were required address in the software involved with this project.

Figure 5: Block diagram of cruise control system

2.3 Codes & Standards

2.3.1 Taxonomy and Definitions for Terms Related to Driving Automation Systems for On-Road Motor Vehicles (J3016_02104)

This international standard defines a range of terminology and common systems relating to autonomous driving, which is paramount for classifying this system and understanding the critical safety considerations when working with both autonomy and humans in and around the vehicle.

2.3.2 Accelerator Pedal Position Sensor for Use with Electronic Controls in Medium- and Heavy-Duty Vehicle Applications—Truck and Bus (J1843_02207)

This standard describes the standards related to throttle position sensing in road going vehicles. It is used as the baseline for the electronic throttle in the race car, and shows multiple methods of detecting throttle position.

2.4 User Needs

In order to determine what the race team would need this electronic speed control for, two interviews were conducted. The first was with the leads of the aerodynamics system, Alex Nunez and Howard Wu, who talked about their need for data to validate their CFD on the vehicle's outer surfaces and wings. The second interview was with suspension member Taylor Southwick, who talked about the need for constant velocity tuns to test the suspension and get driver feedback on handling.

2.4.1 First Customer Interview

Interviewees: Alex Nunez, Howard Wu

Location: Lopata Gallery, Washington University in St. Louis, Danforth Campus

Date: Sep 12th, 2022

Setting: I asked Alex and Howard to describe the testing scenarios they envisioned with constant speed holding, and asked what they currently do to mimic a constant speed. The entire interview was in Lopata gallery, and too around 60 min. to nail the specifics.

Interview Notes:

What kind of testing do you currently do?

- Constant velocity testing in a straight line. Uses linear potentiometers on suspension to get downforce data from front and rear of the car.
- Coast down testing, where the car must get up to a certain speed and then coast down in neutral to see drag induced from aero kit.
- Constant velocity turns, where the potentiometers are again used to analyze the wing performance.
- We test in all conditions.

What are you doing right now to gather this data?

- Right now we just tell the driver to try to keep the engine at the same speed. They have no way of knowing how fast they are going besides an RPM readout on the dashboard. We have to tell them what gear and RPM to try to hit for each test. It is not accurate at all.

How much time do you have in between different tests?

- Most tests are run back to back, but there can be periods up to 30 min between the different types of tests. Ideally the car is moving as much as possible and there is little downtime.

2.4.2 Second Customer Interview

Interviewees: Taylor Southwick

Location: Zoom

Date: September 13th, 2022

Setting: I asked Taylor to describe how suspension gathers and analyzes data on the car, and how it is used in design. I also asked them how driver feedback is used to tune the car's handling.

Interview Notes:

What kind of data does suspension gather?

- Speed, gear, compression of all four corners, lateral acceleration, position, speed.

How is driver feedback gathered and used? How are they trained?

- Drivers are really bad at giving us feedback, so we really rely on knowing what the car is doing at any particular time. Fortunately we have a system which records all of the sensor data with respect to time and the car's position, so we mainly rely on that. The constant velocity "thing would be sick" because you can look at the vehicle in different conditions which are as close to steady state as you can reasonably get.
- Drivers are trained in a bunch of different obstacles mimicking what they see at the event. It is hard to show them the car can actually push harder sometimes.

2.4.3 Interpreted User Needs

We interpreted the use needs from the above interviews and condensed them into the following list:

Table 1: Interpreted Customer Needs

| Need Number | Need | Importance |
|-------------|---|------------|
| 1 | The system can hold a constant speed at any speed | 5 |
| 2 | The throttle is easy to control when driving, and "feels the same" as the mechanical throttle | 3 |
| 3 | The throttle is easy to mount and dismount | 4 |
| 4 | The throttle is well packaged and able to run in all weather conditions | 5 |
| 5 | The system can be deactivated by the driver at any time | 5 |

2.5 Design Metrics

The race team's requirements lead to a few agreed upon numerical requirements below:

Table 2: Target Specifications

| Metric Number | Associated Needs | Metric | Units | Acceptable | Ideal |
|---------------|------------------|---|-----------|------------|-----------|
| 1 | 4 | Total weight | kg | 2 | 0.5 |
| 2 | 1 | Maximum speed deviation from intended speed | MPH | ± 2.5 | ± 0.5 |
| 3 | 2,5 | Time to throttle deactivation | s | < 1.000 | < 2.000 |
| 4 | 2 | Throttle feel, av. from all drivers | scale 1-5 | 2 | 5 |
| 5 | 3 | Time to change to/from electronic thorttle system from/to mechanical system | min | < 30 | < 5 |

2.6 Project Management

The Gantt chart in Figure 6 gives an overview of the project schedule.

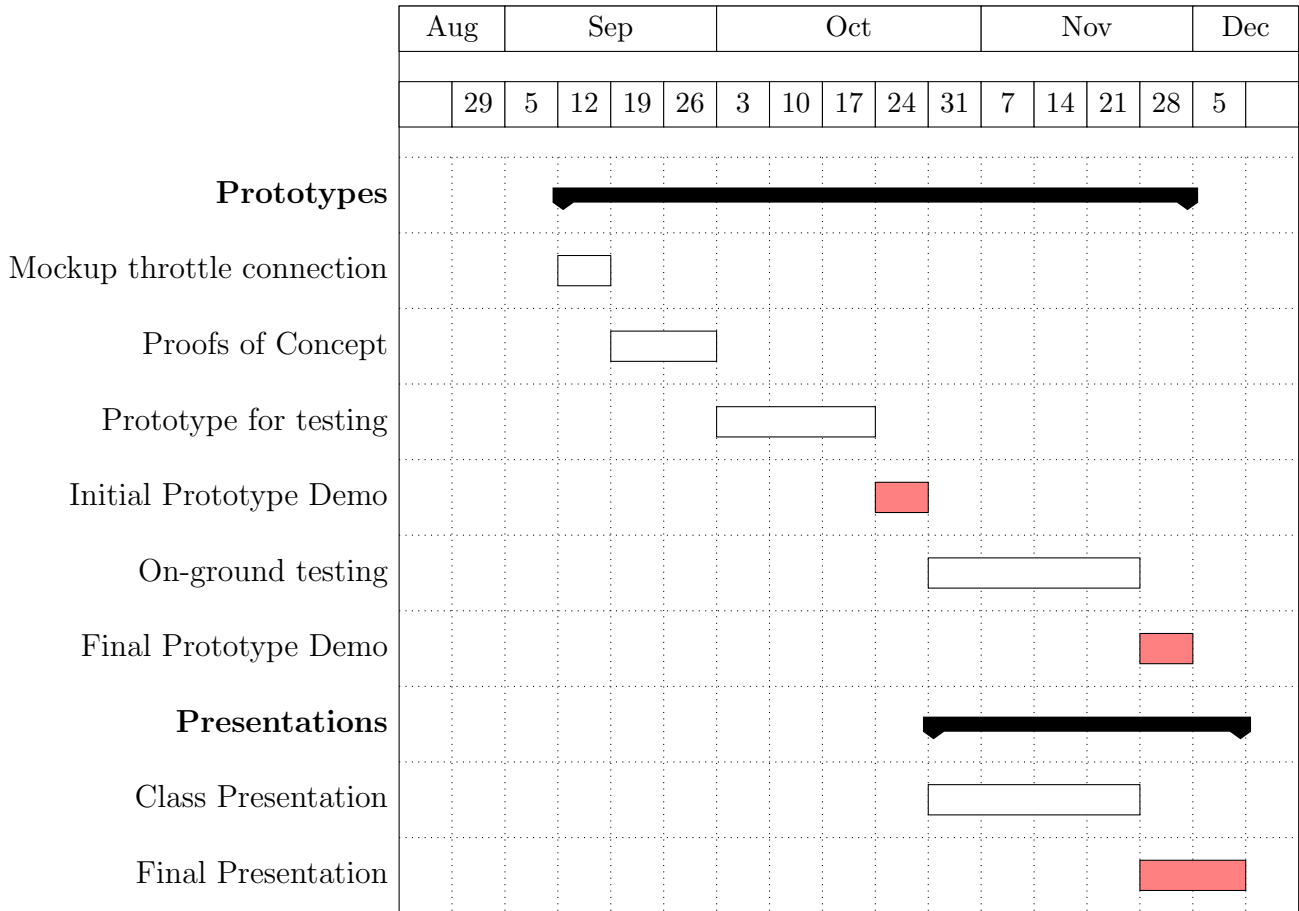

Figure 6: Gantt chart for design project

3 Concept Generation

3.1 Mockup Prototype

Our mock-up prototype consisted of placing a linear potentiometer around the vehicle cockpit in different locations, CAD modeling, and testing different options for electronic throttle bodies. Electronics were prototyped at first on a bread board, then a proto-board. Prototyping on the software side was done in GT-suite, an advanced gas dynamics and acoustics modeling software which can simulate engine response under different conditions.

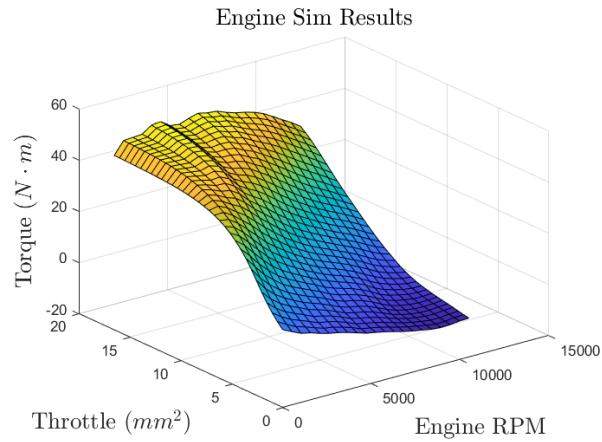

Figure 7: Throttle opening vs. torque response

Figure 8: Breadboard prototyping

3.2 Functional Decomposition

Below are a few functions that we identified as critical

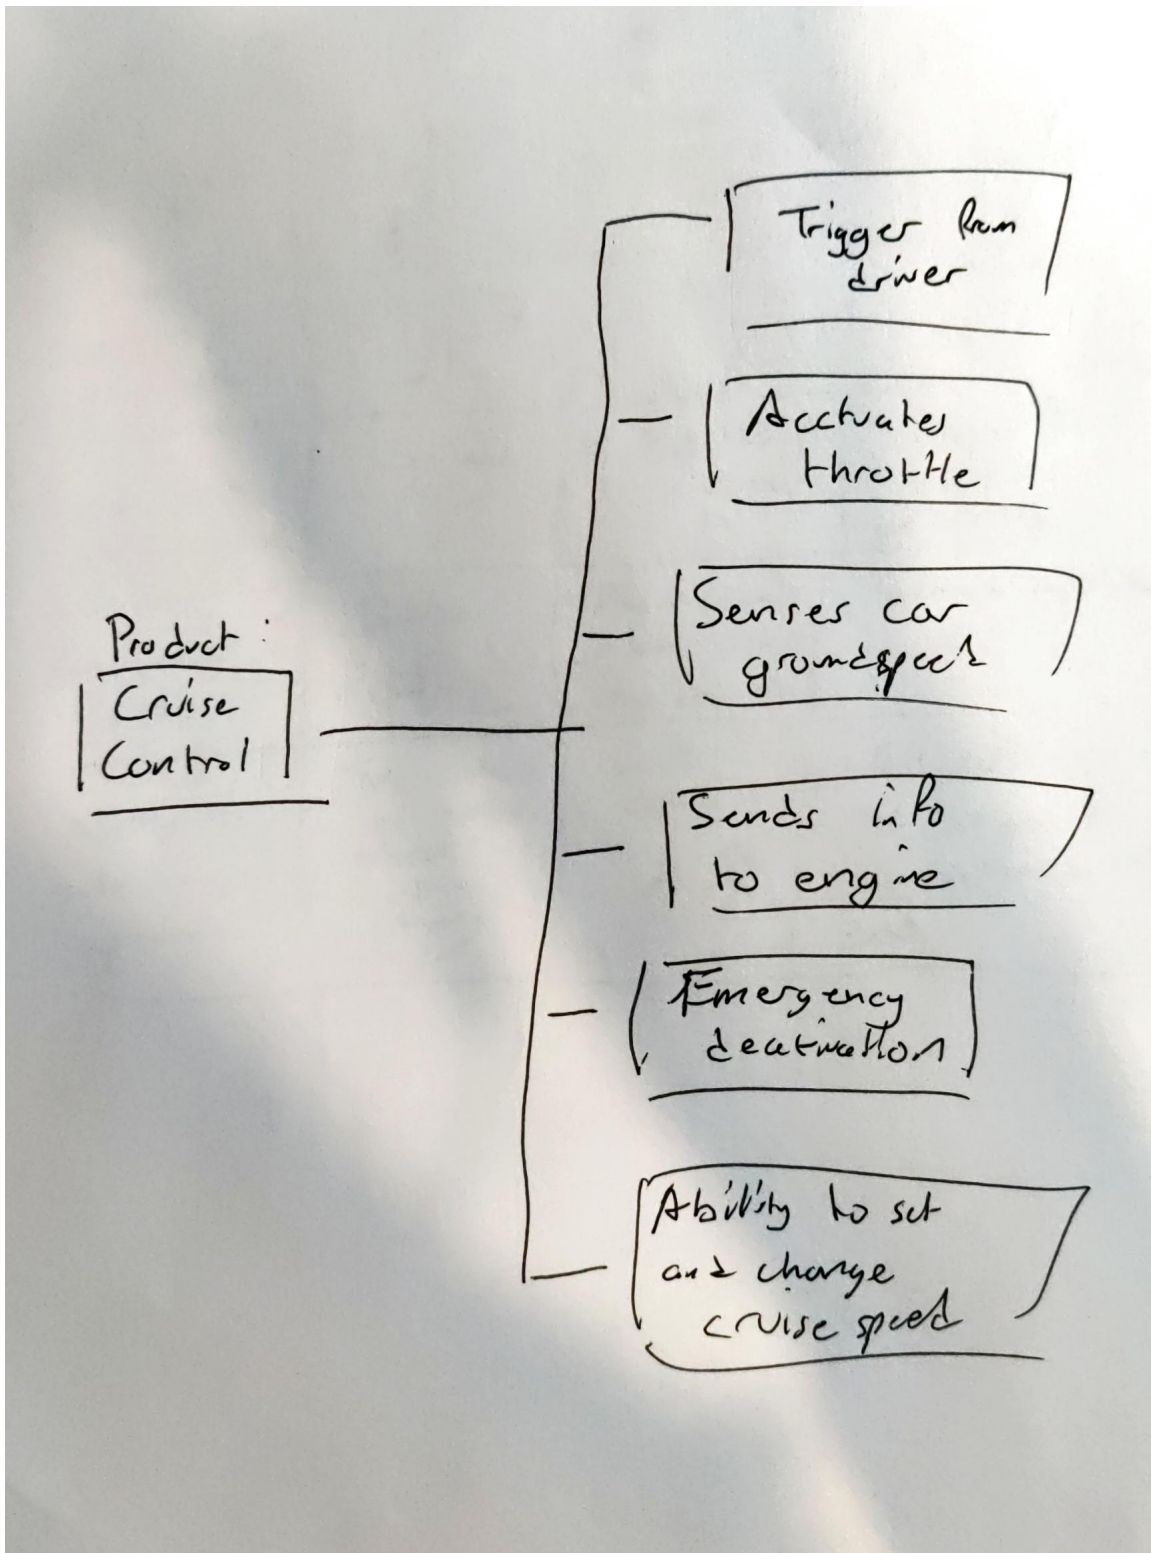

Figure 9: Function tree for the cruise control system

3.3 Morphological Chart

The below chart lays out the device requirements and potential solutions we brainstormed.

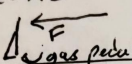

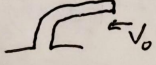

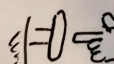

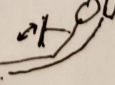

| Trigger from driver | Button  | Switch  | Automatic  |
|-------------------------------|--|--|--|
| Activates throttle | Pulls throttle cable  | stepper motor operates butterfly valve  | OPR the shaft  |
| Senses ground speed | Pilot tube  | Rotary pot  in axle | Hall effect  gear for speed |
| Sends throttle info to engine | Splice  | Pass through in code  | Use different sensors or multiple |
| Emergency stop | Button  | Pots in pedals (if brake pressed stop e-throttle) | Software verification  |
| Ability to set/change speed | Two buttons on steering wheel  | Lever in cockpit  | All software If (at speed) keep speed until — end |

Figure 10: Morphological chart for cruise control

3.4 Alternative Design Concepts

3.4.1 Concept #1: The Huge Stepper Motor

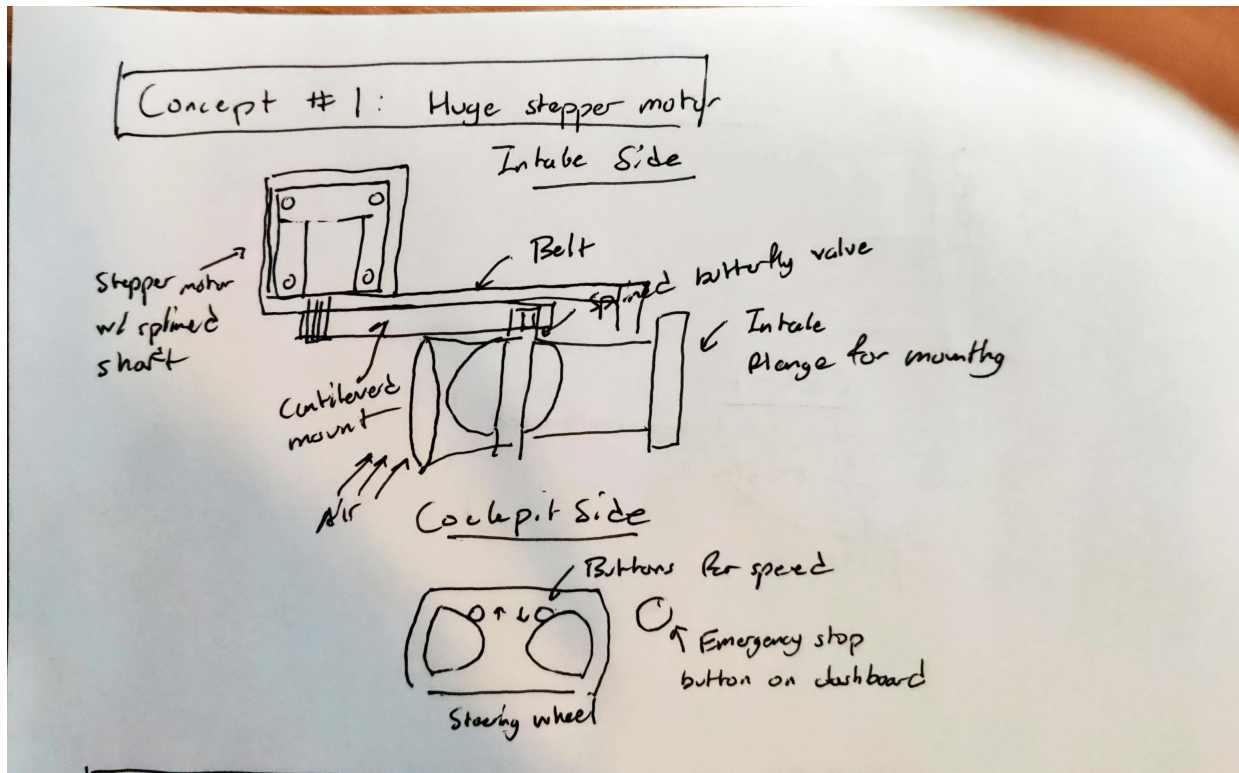

Figure 11: Sketches of Huge Stepper Motor Concept

Description: A giant stepper motor we had laying around in the garage is connected to the existing butterfly valve on the mechanical setup via a belt. The butterfly valve would need a splined portion affixed to it somehow, possibly aluminum welding. On the control and cockpit side of the device, cruise control would be activated and deactivated by pushing two buttons down on the steering wheel at the same time. These buttons would then increase and decrease speed. An emergency stop button would also be added to the vehicle

The advantages of this setup are excellent accuracy and speedy control (the large stepper motor in the garage moves very quickly and can be geared to have a very fine adjustment of throttle position. It is also able to run off the 12V architecture already on the racecar.

Disadvantages of this setup are that it is extremely heavy and cantilevered far outside the racecar, which could be dangerous if the car were to be in a side impact. Additionally, it is best to avoid cantilevering heavy objects off of the side of the intake, as it could induce additional stresses while the vehicle is vibrating from normal engine operation.

3.4.2 Concept #2: Bosch Throttle w/ Pedal Based Control

Figure 12: Sketches of the OTS concept

Description: This solution sees an off the shelf Bosch electronic throttle body mounted via an adapter plate of some sort to the intake plenum. This system includes a butterfly valve, nice mating surface, and a datasheet. The cockpit and control scheme for this solution depends on a switch in the cockpit which simply toggles on/off cruise control whenever it is flipped up. If cruise control is deactivated by any other method then the switch has to be flipped down and back up again, so down is always off. Potentiometers are also mounted in the pedalbox in this design, allowing any changes in pedal position outside a certain dead zone to deactivate cruise control.

Advantages of this system are the reliability and quality of an off the shelf motor, speed, and most importantly safety. Using a tested system for the actual butterfly valve is a huge plus when it comes to drive confidence since it has a robust return spring, meaning it will always default to the closed position.

Disadvantages of this design are that this unit needs both 12V and 6V rails to run properly, which makes it difficult to interface with the car's electrical system. Further, the potentiometers will require significant modifications to the pedalbox. This would make quickly changing from the e-throttle system to the legacy mechanical cable difficult and slow.

3.4.3 Concept #3: Sliding Plate with Linear Potentiometer

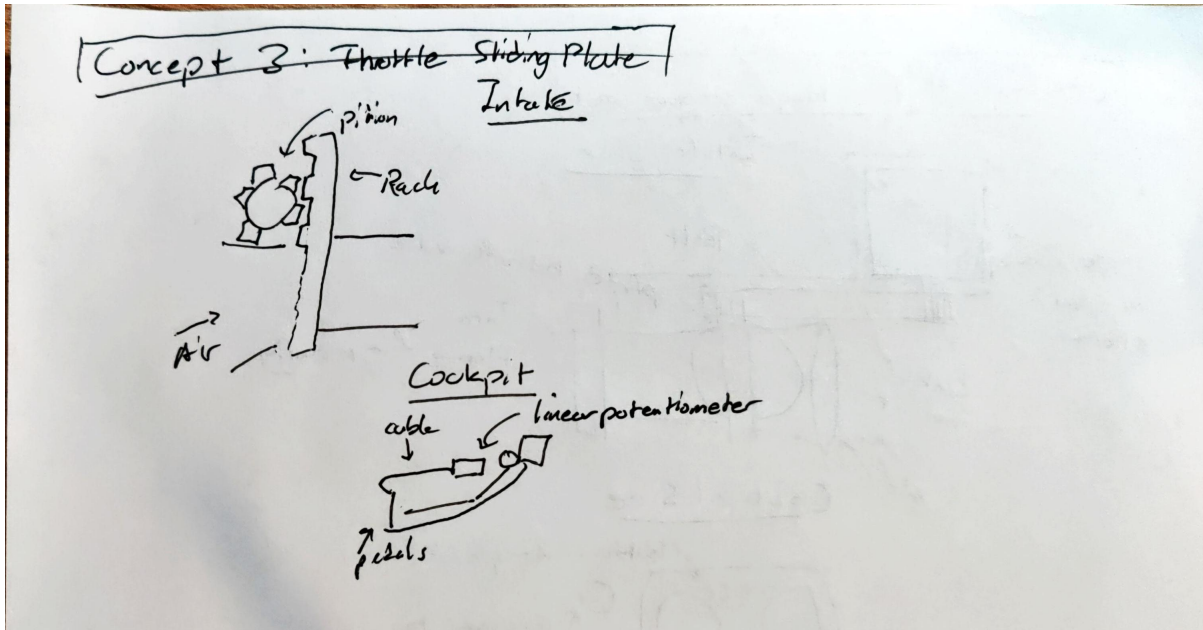

Figure 13: Sketches of the Sliding Plate Concept

Description: This solution implements the throttle control using a plate that moves vertically on the end of the intake plenum via a rack and pinion. In the cockpit this system uses a linear potentiometer mounted to one of the frame tubes. This potentiometer mounting would require a shorter throttle cable, but otherwise wouldn't require adapting the intake besides a 3D printed gear and slider with the rack on one side.

Advantages of this system are the price, disadvantages are pretty much everything else: slow to put on, poor accuracy, heavy, etc. We also foresaw issues with the rack falling off of the pinion gear, which would be unsafe.

4 Concept Selection

4.1 Selection Criteria

From the concept generation stage and background research, we generated five critical criteria to judge all of the mechanical, electrical, and software options off of. The three options below are ideas I came up with, mainly for the hardware side of the project, although they inevitable also involve some electrical and programming considerations.

| | Price | Safety | Accuracy/Actuation Speed | Ease of installation | Weight | Row Total | Weight Value | Weight (%) |
|--------------------------|-------|--------|--------------------------|----------------------|--------|--------------|--------------|---------------|
| Price | 1.00 | 0.14 | 1.00 | 0.33 | 0.33 | 2.81 | 0.05 | 4.85 |
| Safety | 7.00 | 1.00 | 9.00 | 7.00 | 7.00 | 31.00 | 0.54 | 53.50 |
| Accuracy/Actuation Speed | 1.00 | 0.11 | 1.00 | 0.33 | 0.20 | 2.64 | 0.05 | 4.56 |
| Ease of installation | 3.00 | 0.14 | 3.00 | 1.00 | 5.00 | 12.14 | 0.21 | 20.96 |
| Weight | 3.00 | 0.14 | 5.00 | 0.20 | 1.00 | 9.34 | 0.16 | 16.13 |
| Column Total: | | | | | | 57.94 | 1.00 | 100.00 |

Figure 14: Analytic Hierarchy Process (AHP) to determine scoring matrix weights

4.2 Concept Evaluation

These five criteria were judged for each concept in a weighted scoring matrix, which then presented which options were most viable.

| Alternative Design Concepts | | Concept #1 | | Concept #2 | | Concept #3 | |
|-----------------------------|------------|--------------|----------|--------------|----------|--------------|----------|
| | | Rating | Weighted | Rating | Weighted | Rating | Weighted |
| Selection Criterion | Weight (%) | Rating | Weighted | Rating | Weighted | Rating | Weighted |
| Price | 4.85 | 2 | 0.10 | 5 | 0.24 | 4 | 0.19 |
| Safety | 53.50 | 3 | 1.61 | 5 | 2.68 | 1 | 0.54 |
| Accuracy/Actuation Speed | 4.56 | 3 | 0.14 | 4 | 0.18 | 1 | 0.05 |
| Ease of installation | 20.96 | 3 | 0.63 | 4 | 0.84 | 3 | 0.63 |
| Weight | 16.13 | 3 | 0.48 | 4 | 0.65 | 5 | 0.81 |
| Total score | | 2.952 | | 4.584 | | 2.210 | |
| Rank | | 2 | | 1 | | 3 | |

Figure 15: Weighted Scoring Matrix (WSM) for choosing between alternative concepts

4.3 Evaluation Results

There were multiple parts to each concept, mostly the choice of a sensing mechanism for the e-throttle positioning based on pedal input, a method for actuating the throttle, and a method for setting/changing speed. Each of these were considered in the selection process, and we eventually decided that no single concept had all of the features we wanted, although concept#2 came the closest. We valued safety most, by far. Considering we plan to use this system for testing with a driver in the vehicle, using the Bosch system on the end of the intake made the most sense, as it is certified to run on other motorsport vehicles and comes with proper documentation. The throttle also has multiple mechanisms to ensure it is never open when the driver intends it to be closed.

On the cockpit side, we chose to implement the toggle switch, as it was intuitive, simple to mount and make for prototyping, and offered the basic functionality the suspension and aerodynamics team's requested. This setup also meant we could avoid making changes to the pedalbox entirely. Unfortunately, that meant in order to change the speed of cruise control the software had to be flashed.

4.4 Engineering Models/Relationships

The most important mechanical model for our project was the throttle sweep in GT-Suite. GT-Suite is a gas dynamics, combustion, and general thermodynamics tool designed originally for engine simulation. As a part of the competition Jonah developed a model for the engine in the previous year, which was modified and updated to resemble the engine with the e-throttle on it. GT-suite essentially models the system as a series of pipes, orifices, etc. and ensures conservation of mass and energy at all of the system boundaries to determine parameters such as the air pressure, velocity, engine speed, etc. GT-suite was used here to determine the torque the engine could output at a given throttle, measured in mm^2 of open area (although this value was later translated into deg of throttle opening to make programming the controller easier), and engine RPM. Below is the results of this sweep.

| Torque [Nm] | | RPM | | | | | | | | | | | | | | | | | | |
|---------------------------------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|
| | | 2000 | 2525 | 3050 | 3575 | 4100 | 4625 | 5150 | 5675 | 6200 | 6725 | 7250 | 7775 | 8300 | 8825 | 9350 | 9875 | 10400 | 10925 | 11450 |

Figure 16: Torque outputs at different engine states used to program the controller

From this sweep we are able to determine the tractive force of the vehicle in any reasonable operating state, which, when compared to the drag, allows us to balance out the forces and reach a steady speed.

Another model that was considered for the control of the vehicle was the drag and rolling resistance. The drag can be modeled from the following equation:

$$F_{drag} = \frac{1}{2} \rho C_D A v^2$$

Where F_{drag} is the force resisting forward motion due to air resistance, ρ is the density of air, C_D is the drag coefficient of the vehicle, which was kindly provided by the aero team on WashU Racing, and A is the frontal area, which was also provided by the aero team.

To determine if we needed to account for it in the model, we also tried to calculate the rolling resistance of the vehicle. The force due to rolling resistance can be calculated from the following formulas:

$$F_r = c m g$$

Where F_r is the force due to rolling resistance, m is the mass, and c is the coefficient of rolling resistance, which can be found by:

$$c = 0.005 + (1/p)(0.01 + 0.0095(v/100)^2)$$

Where p is the tire pressure in bar, and v is the velocity in KM/H. The WashU Racing car can be assumed to travel at a maximum of 100kph on cruise control (60 MPH) with a minimum tire pressure of 0.6bar, which yields a maximum coefficient of 0.005, which is negligible. Therefore we did not include rolling resistance in the PID controller for cruise control.

5 Concept Embodiment

It was very obvious at first that the actual initial prototype would not work. The below pictures describe where we were trying to place the potentiometer to register the throttle cable inputs and the original throttle adapter plate design. Both had issues with mounting, stability, and just plainly didn't work.

Figure 17: First prototype of the adapter plate

Figure 18: Initial placement of the potentiometer

5.1 Initial Embodiment

The real initial prototype is the V2 described below. We immediately jumped to an outsourced SLS 3D printed component because none of the materials at WashU were strong enough and had UV/chemical resistance, which would not work for any actual testing. In the first prototype that would be tested on a running car there were a few critical performance requirements:

- The prototype must be able to seal fully
- The E-throttle plate must not yield at all under full engine load, causing the engine runaway effect
- The engine model and tune must be accurate enough for the PID controller to hold a constant speed
- The whole assembly must be rigid enough to inspire confidence in the drivers

This second prototype was able to accomplish all of the above goals, but the model was a bit shaky and required a lot of tuning. Part of the reason could be that I had to re-tune the engine on the fly using my laptop while actuating the throttle with my other hand (not recommended).

Figure 19: The E-throttle adapter plate component

Figure 20: Assembly and context drawing with BOM

5.2 Proofs-of-Concept

After testing with the initial prototype and connecting the throttle to a linear potentiometer mounted in the cockpit, our group realized that in order to meet our goal of quickly switching from the nominal throttle cable system to our system, we needed an entirely different mounting solution for the potentiometer.

It was also realized that PLA was not sufficient for the final prototype, as under the high vacuum induced by high engine loads it was not air tight, and would cause a runaway effect in the throttle, where the engine RPMs climb, causing more vacuum, which in turn raises the engine RPM even higher, and so on.

Finally, as with most first designs on the WashU Racing vehicle, there were numerous issues accessing certain bolts with commonly available tools in the garage, and many bolts had to be re-positioned to allow for better tool fitment. Unthreaded inserts with a chamfer on one side were also added to avoid any direct contact between the 3-D printed portions of the part and threaded components, which had a habit of digging into the part and destroying it over time.

5.3 Design Changes

To reduce the time to mount the e-throttle to the vehicle, we used the same butterfly valve and throttle actuation system as the normal mechanical throttle cable, which included a rotary potentiometer so the ECU had information on the throttle inputs, to control the electronic throttle. This meant the throttle cable could remain exactly the same length, with largely the same routing, and neatly provide information to both the ECU e-throttle about the user's intended throttle position. The material was also changed from PLA to nylon 12, which was much stronger, easier to seal, and had a much better surface roughness since it used SLS 3D printing, which has a much higher resolution than the FDM printing used for the first prototype.

6 Design Refinement

6.1 Model-Based Design Decisions

Multiple models were developed, and existing models changed to account for the addition of this component to the vehicle. This paper will cover the mechanical models, although the paper by Kejriwal and Wheelock [FSAEpaper] gives a more in-depth description of the PID controller used to regulate the vehicle's speed based on the engine model explained here, and the wheel-speed collected from the car in real time.

1. Heat

The effects of heat on this part were considered by estimating the possible heat transfer under the worst case scenario of the car motionless with engine at high RPMs and after the engine block has reached its maximum operating temperature. All modes of heat transfer were considered. Convection was determined to be negligible by measuring the air temperature to the side of the engine where the adapter plate is located. Even stagnant air in the garage did not reach higher than 120F at this point, not nearly hot enough to be a concern for the adapter plate. Similarly, conduction was determined negligible because the plenum and runners which connect the adapter plate to the engine block are made of Ultem 1010, which has a very low thermal conductivity of $0.24 \frac{W}{mK}$

Radiation was analyzed by assuming the engine head to be a gray body with the thermal properties of black enamel paint (which coats the outside of the engine) [**emissivity**]. Half of the head area was used for area, the temperature of the head was 140F, and the temperature of the surrounding air was 70F. Of course in a real scenario, not even 10% of this power will be turned into heat in the adapter plate, but without complicated thermal FEA determining an imperial value is very difficult. This rough conservative estimate should suffice.

$$P = \sigma \epsilon A (T - T_c)^4$$

$$P = 5.67E - 8 * 0.80 * 0.0322 * (60 - 21)^4$$

$$P = 0.0034W$$

0.0034W is a negligible amount of heating power.

2. Structural

A structural analysis was performed using solidworks FEA using known material properties from Formlabs for SLS nylon 12 printed components. [**formlabs**]

Figure 21: Static FEA analysis of the component

The base of the throttle was fixed at the bolted connection to the plenum. A load was applied at the mounting bolts for the e-throttle which was 3x its weight under static conditions, meant to represent the team's widely agreed upon worst case loading scenario of a 3-g bump (since the e-throttle is a sprung component - which are isolated from bump loads by the suspension - it is unlikely to even see this high of a load). Another pressure was added to the internal surface for the vacuum load from the GT-suite values. A maximum stress of 1400 psi occurred, while the yield strength of the material was 7000 PSI

3. Vibrations

Another simulation was used to determine the natural frequencies of this component when fixed at one end and loaded at the other using the weight of the e-throttle. The two main resonant frequencies to avoid are the idle frequency of the component, which is around 2,500 RPM and the red-line of the car which is around 13,000 RPM. The engine passes through all other values rather quickly.

| Mode No. | Frequency(Rad/sec) | Frequency(Hertz) | Period(Seconds) |
|----------|--------------------|------------------|-----------------|
| 1 | 1,557.3 | 247.85 | 0.0040347 |
| 2 | 3,717.8 | 591.7 | 0.00169 |
| 3 | 7,078.2 | 1,126.5 | 0.00088768 |
| 4 | 10,261 | 1,633 | 0.00061236 |
| 5 | 15,087 | 2,401.1 | 0.00041647 |

Figure 22: Vibration study results showing natural frequencies

Fortunately none of the natural frequencies with significant displacements (1 & 3) were anywhere near idle or red-line.

6.2 Design for Safety

Design for safety, beyond simply ensuring the part wouldn't fail under vacuum loading, or in any possible running conditions, was mostly on the software side. In summary, if the driver places their foot on the throttle, presses the cockpit killswitch, or steers too hard/quickly, the e-throttle will disengage itself automatically. Further, if the wheelspeed varies too quickly or far from the target wheelspeed (which would be indicative of the car accelerating much too quickly for nominal cruise control) the system will deactivate. Drivers were all instructed in the functionality of the system in some depth as well to make sure they aren't going in to testing blind.

6.2.1 Risk #1: Engine runaway

Description: Engine runaway is when an improperly sealed intake leads the engine to rev above where the user intends, uncontrolled.

Severity: Critical

Probability: Occasional

Mitigating Steps: Seal adapter plate as well as possible, ensure surface is sanded or finished by manufacturer, use a gasket, perform structural and vibrational analysis

6.2.2 Risk #2: Unintended throttle variation

Description: Throttle variation from the intended user input can make the car uncontrollable, and lead to a crash. We need multiple mechanisms to make sure that the throttle does not deviate from the directions of the user at any time.

Severity: Catastrophic

Probability: Likely

Mitigating Steps: To ensure the throttle matches what the user directs, we implement hardware based throttle verification through multiple sensors on the throttle cable. We also added multiple driver shutdown options, so if the throttle does vary, the user can shut the car down quickly. Finally, we bench tested the throttle for a few hours before using it on the car, to validate our setup.

6.2.3 Risk #3: Throttle Flutter

Description: The e-throttle will occasionally flutter when powered. This will degrade engine performance slightly.

Severity: Marginal

Probability: Frequent

Mitigating Steps: We have tried to mitigate throttle flutter as much as possible by switching away from PWM control. At this point it seems mostly harmless, if not a bit annoying to listen to.

6.2.4 Risk #4: Structural Failure

Description: The e-throttle adapter plate could fall off of the car if it is not strong enough under the full vacuum load.

Severity: Catastrophic

Probability: Seldom

Mitigating Steps: The e-throttle adapter has been designed from a strong material, using FEA to estimate our safety margin. The part was also designed with a high safety factor of 4 to ensure it never approaches yielding, or displaces too much and fails to seal with the intake or the e-throttle.

6.2.5 Risk #5: Melting

Description: The e-throttle adapter plate could melt.

Severity: Catastrophic

Probability: Unlikely

Mitigating Steps: Nylon 12 is used for the e-throttle, which has a rather high heat deflection temperature of 340F. The top of the engine was measured, and the highest the head ever sees is around 200F, so melting should not be an issue.

| | | Probability that something will go wrong | | | |
|------------------|--------------|--|---|---------------------------------|--|
| Category | | Frequent Likely to occur immediately or in a short period of time; expected to occur frequently | Likely Quite likely to occur in time | Occasional May occur in time | Seldom Not likely to occur but possible |
| Severity of risk | Catastrophic | Unintended throttle variation | | | Structural Failure |
| | Critical | | | Engine Runaway | |
| | Marginal | Throttle Flutter | | | |

6.3 Design for Manufacturing

Number of components (excluding fasteners): 5

Number of threaded fasteners: 10

Number of NTC parts: 5

We do not believe there are any unnecessary components in our current design, and would actually add a sealed ball bearing to decrease the friction of the device to rotation if we had another prototype.

Most of the DFM for this component was ensuring approach and departure angles were shallow enough to be printed properly on the SLS printer. Xometry has extremely capable SLS printers so this turned out not to be a significant issue. Some other major considerations for manufacturing included: -Using threaded inserts wherever possible to avoid threading into 3D printed plastic (SLS printed threads are bad, FDM ones are completely non-viable).

- Calling out a surface roughness on the flanges for better sealing

- Leaving a bit of extra material on the inside of the adapter plate so it could be sanded down while still maintaining the minimum 20mm restriction required by the competition.

6.4 Design for Usability

The e-throttle was designed to be as intuitive as possible. To reduce the learning curve and keep muscle memory from the mechanical system, the actuation of the e-throttle was mapped to match the pedal actuation required for the same opening amount for the original mechanical system, and the engine tune was kept as similar as possible. This ensured that the driver would get the expected amount of power from the engine at a certain throttle position. The throttle was also

tuned to respond as quickly as possible to changes on the throttle pedal side - being able to go from fully open to fully closed in less than 50ms.

Unfortunately, impairments were not considered when making this design, as the current driver pool is only able bodied, with no visual, motor control, or hearing impairments. Regardless, there is no sound or sight related to the e-throttle, only feeling through the right foot and motions with the right arm, which should not pose any difficulty to the hearing or visually impaired.

7 Final Prototype

7.1 Overview

Our final prototype is the culmination of my efforts in the mechanical space refining the adapter plate, throttle cable mounting, and sensor mounting, my work in the mechanical modeling, and my groupmates work in designing a PID controller and circuit board which is used to control the E-throttle [FSAEpaper].

This prototype uses an Arduino connected to hall effect sensors mounted around the rear wheel hubs to gather wheel-speed data. The data from these sensors is compared to the target wheel speed on board the Arduino, and the throttle is opened or closed to adjust the engine torque.

We tested the final prototype by placing the car on jackstands at all four corners, mounting the e-throttle and controller near the firewall, and setting the cruise control to activate once the wheel speed sensors on the car read 20 miles per hour. We then turned the car on shifted the car into second gear, and manually actuated the throttle up to 5000 RPM, which correlated to 20 mph. We saw variations of no more than ± 150 RPM, which would suggest the system could keep the car steady within ± 0.5 MPH.

7.2 Documentation

Fig. 24 demonstrates the top view of the e-throttle mounted on the car. Note the cable orientation allows the same length throttle cable to be used with this system, as with the stock mechanical system. In this configuration the e-throttle is also minimally cantilevered, and was able to support at least a 10 lb load (which we tested by hanging a weight from the e-throttle).

Fig. 25 demonstrates the rear view of the e-throttle. The throttle cable had to be zip-tied in places to the intake and frame to work in this configuration. To further refine the device I would suggest 3D printing and gluing guides along the path of the cable to ensure as smooth of actuation as possible.

Finally, Fig. 26 shows the configuration the e-throttle was in while we were actually running the vehicle. This configuration would not be suitable for actual driving, as it requires a second power source and has many exposed wires, however with a PCB and waterproof enclosure it could very well see a testing day.
