Several types of Galactic sources, like magnetars, microquasars, novae or pulsar wind nebulae flares, display transient emission in the X-ray band. Some of these sources have also shown emission at MeV–GeV energies. However, none of these Galactic transients have ever been detected in the very-high-energy (VHE; $E > 100$ GeV) regime by any Imaging Air Cherenkov Telescope (IACT). The Galactic Transient task force is a part of the Transient Working group of the Cherenkov Telescope Array (CTA) Consortium. The task force investigates the prospects of detecting the VHE counterpart of such sources, as well as their study following Target of Opportunity (ToO) observations. In this contribution, we will show some of the results of exploring the capabilities of CTA to detect and observe Galactic transients; we assume different array configurations and observing strategies.

37th International Cosmic Ray Conference (ICRC 2021)

July 12th – 23rd, 2021

Online – Berlin, Germany

*Presenter

1. Introduction

Many different types of sources in the Galaxy exhibit transient signals. Such emission can occur due to accretion/ejection processes, such as jets interacting with the interstellar medium (ISM), strong winds and/or outflows. In these scenarios, particles may be accelerated up to relativistic energies, leading to the production of high-energy (HE, $E > 100$ MeV) and likely very-high-energy (VHE, $E > 100$ GeV) radiation, via leptonic or hadronic processes. While many Galactic sources show variable periodic signals, we are interested in those that display irregular unpredictable emission at different wavelengths.

Several types of Galactic transients exhibiting HE radiation have been detected in the past years by satellites such as *Fermi*-LAT and AGILE. In 2011, AGILE discovered enhanced MeV emission from the Crab Nebula pulsar wind nebula (PWN) [1], confirmed by *Fermi*-LAT [2]. This indicates that this source, considered the VHE standard candle, is actually variable at lower energies. Recently, a Galactic magnetar (SGR 1935 +2157) has been associated with a Fast Radio Burst (FRB) for the first time [3]. This event was not detected in the gamma-ray regime. However, the *Fermi*-LAT has recently discovered GeV emission from an extragalactic magnetar, located in the Sculptor galaxy, which occurred during a giant flare [4]. Microquasars, which are binary systems hosting compact objects -either neutron stars (NS) or black holes (BH)- accreting from a companion star, can lead to the formation of a jet. Some microquasars have also been detected in the HE regime [5–7]. Additionally, novae, which are explosions associated to a white dwarf in a close binary system, have been detected in the MeV regime [8]. Finally, transitional millisecond pulsars (tMSPs) are pulsars in a binary system, which change from an accretion to a radio loud phase; such tMSPs have also been detected in the MeV energy range [9].

The current generation of Imaging Air Cherenkov Telescopes (IACTs) are H.E.S.S. [10], MAGIC [11], and VERITAS [12]. They have successfully discovered more than 200 VHE gamma-ray sources, both of galactic and extragalactic origin. Highlights in the case of Galactic sources include the discovery of gamma-ray binaries with variable emission [13–17], pulsations in the GeV–TeV domain in the emission of pulsars, such as the Crab [18], Vela [19] or Geminga [19] or emission from the Galactic centre, revealing it as the first PeVatron (source of cosmic rays with PeV energies) in the Galaxy [20], among others. IACTs have been aiming at detecting other types of transient emission, such as the aforementioned sources, without success [21–24].

The Cherenkov Telescope Array (CTA) will be the next-generation ground-based gamma-ray observatory [25]. It will be the premier facility for VHE, multi-messenger, and transients astrophysics in the next decade. CTA will comprise two observatories, one in the Northern (Observatorio Roque de los Muchachos, La Palma) and one in the Southern hemisphere (Paranal, Chile). CTA will be able to perform unprecedented observations of VHE transient sources, covering an energy range from 20 GeV to more than 100 TeV. The larger effective area of CTA, compared to the current generation of IACTs, will result in high sensitivity¹ at short timescales (see Fig.1) [26]. This will enable unique studies of the multi-messenger and transient sky [27], which is one of Key Science Projects of the observatory [25]. It is correspondingly necessary to carefully understand the capabilities of CTA to detect such sources (see Carosi, ICRC2021, id.833). In many cases, CTA observations will be based on external triggers from various monitoring instruments (X-ray or HE

¹CTA sensitivity: <https://www.cta-observatory.org/science/cta-performance/>

Figure 1: The differential flux sensitivities of CTA and of *Fermi-LAT* for different energies as a function of observation time.

satellites). Serendipitous discoveries can also take place, i.e., as part of the nominal observation of the Galactic plane survey (GPS). The *Science Alert Generation*, which is a real-time very-short timescale (from 1 to 100 seconds) analysis will play a key role in the follow-up of external triggers and in the serendipitous discovery of transient events (see di Piano, ICRC2021, id.156).

While certain objects show persistent emission and/or periodically emit variable radiation, in this contribution we will mainly focus on those emitters on those emitters which display irregular and unpredictable transient emission at different wavelengths. We will summarize the work of the Galactic transients task force of the CTA Consortium, which is focused in understanding the capabilities of CTA for detecting transient sources of Galactic origin. The results shown in this contribution will be discussed in more detail in an upcoming CTA Consortium paper.

2. Sensitivity in the Galactic plane

It is important to understand the performance of the CTA Northern and Southern arrays, especially in the Galactic plane, where many TeV sources are located. The sensitivity of the Southern array is illustrated in Fig. 2 for different perspective source locations, and is defined as the minimal flux of a source, such that the source is detectable at 5σ significance within a given energy range. We define the variable S , which stands for the sensitivity multiplied by the energy squared. For the current example, we estimate the performance of CTA for short observation intervals of 60 seconds, within the 100–200 GeV energy range.

As it can be inferred from the figure, upward fluctuations of the sensitivity (worse performance of CTA), are correlated with the simulated Galactic emission. The flux of the expected steady Galactic foreground in the chosen energy range is mostly below the level of a few 10^{-11} erg cm² s⁻¹. This is of the same order as the nominal sensitivity of the observatory in the absence of foregrounds. Correspondingly, the overall degradation in sensitivity for detection of new sources is not significant;

at worst, it amounts to a relative increase of the flux threshold of 5–10%, and only when coinciding with strong Galactic emitters.

As part of our upcoming publication, we will explore the performance along the Galactic plane for different energy ranges and observation times. Given the assumed properties of known Galactic sources, the performance is not expected to significantly diverge from the nominal capabilities of CTA, which are shown in Fig. 1.

Figure 2: Flux sensitivity (S) of CTA-S within 100–200 GeV for 60 s observation intervals, considering different perspective source locations along the Galactic plane. The bottom panel shows a simulation of $F_{\text{gal}}^{>10^{-12}}$, the Galactic emission above a threshold of 10^{-12} erg cm 2 s $^{-1}$. The emission is integrated within 0.25° radial regions around each position, corresponding to different Galactic longitudes, lon , and latitudes, lat . The next panel above shows the corresponding CTA sensitivity. In the third panel we present the median of S for different longitudes within the range, $-4 < lat < 4$ deg, where the shaded uncertainty region represents the 1σ variance of S . Finally, the top panel shows the relative 1σ variance, δS , derived for two ranges in latitude, as indicated. The variance away from the Galactic Plane ($3 < |lat| < 4$ deg) represents the intrinsic statistical uncertainty of the sensitivity calculation. The variance in the inner Galactic region ($|lat| < 1$ deg) includes the intrinsic uncertainty, as well as the additional effect of the steady Galactic foregrounds, which are concentrated in this region.

3. Detecting Galactic transients with CTA

We have tested the capabilities of CTA to detect transient VHE emission for different kinds of Galactic sources. We have assumed different array configurations, namely the full CTA Northern

(CTA-N), and CTA Southern (CTA-S) arrays, as well as different sub-arrays of CTA telescopes, different observing strategies, etc. Below we illustrate our findings with three source examples, microquasars, flaring PWNe and tMSPs, which are sources that are known to show MeV emission.

3.1 Microquasars

Microquasars are binary systems composed of a compact object (BH or NS) which accretes matter from a companion star. Depending on the mass of the companion, they can be divided into high-mass or low-mass systems. Microquasars normally present an accretion disk, and can produce collimated jets of plasma. These jets are normally active during the so-called *hard state*.

We have studied three microquasars located in the Cygnus region: the two high-mass systems Cyg X-1 and Cyg X-3 and low-mass binary V404 Cyg. Both Cyg X-1 and Cyg X-3 are sources of HE gamma rays [5–7], although the nature of their emission mechanisms (hadronic or leptonic) is still uncertain. Correspondingly, the emission may be attributed to a jet interacting with the surrounding interstellar material (ISM), or from the coronal region of the accretion flow. The latter scenario is quite interesting, indicating that microquasars are potential accelerators of cosmic rays via magnetic reconnection [28].

Searches for both transient and persistent VHE emission from microquasars have not resulted in detections, either from the binaries themselves, or from jet–ISM interactions [29, 30]. Only, a hint of transient emission from Cyg X-1 was observed by the MAGIC telescopes in 2006, over an 80-minute observation interval [31]. The low-mass binary V404 Cyg displayed a major flaring episode in X-rays in June 2015, after 26 years in quiescence; unfortunately, only 4σ evidence was observed by *Fermi*-LAT [32], falling short of a correlated detection. No VHE emission was observed either [33].

We have tested different scenarios in which we would expect transient and persistent emission from any of these binary systems. CTA will not be able to detect a flare from V404 Cyg. However, our simulations indicate that CTA will detect transient emission in both Cyg X-1 and Cyg X-3, where we wish to highlight the expected detection of Cyg X-1 in only 0.5 h, as shown in Fig.3.

For a small number of microquasars, the jets are persistent, such as for SS433. This microquasar has been detected in the MeV range by *Fermi*-LAT [34]; it is the only one also detected in the TeV range, as reported by HAWC [35]. The observed extended TeV emission is due to the interaction between the jet and the surrounding nebula (the so-called *lobes*), while the central binary remains undetected. To date, this source has not been detected by an IACT [36], which would have helped to fill in the as-yet unexplored GeV–TeV energy range between *Fermi*-LAT and HAWC. Our simulations indicate that both the CTA-N and CTA-S arrays will be able to detect the central binary SS433 and its lobes with high significance. CTA will thus provide crucial insight into the emission models of microquasars, and advance our understanding of jet formation.

3.2 Flares from PWNe

The discovery of MeV flares from the Crab Nebula [1, 2] revealed that PWNe can also display transient variable emission, even if most of these systems are detected as steady sources. These flares, however, have never been detected in the GeV–TeV regime. The CTA observatory will advance our understanding of the origin of the Crab Nebula flares. The low-energy threshold of

CTA will allow sampling of the *Fermi*-LAT spectral shape. Complementary observations in the TeV regime will be used to explore a possible inverse Compton (IC) component of the emission, which might arise via the off-scattering of the MeV flares.

We have tested how the Northern CTA array will detect such flaring episodes, using two array configurations. The first is the full CTA array (CTA-N), including four Large Size Telescopes (LSTs) and 15 Medium Size Telescopes (MSTs). The second configuration is a partial sub-array of telescopes, composed exclusively of four LSTs (CTA-N LSTs), which dominate the low-energy sensitivity range of the observatory. Our conclusion is that CTA will be able to detect these flares in less than 5 h, even if only the reduced 4-LST sub-array is available. The results for detecting flaring episodes with different flux levels is show in Fig.3.

Figure 3: *Left:* Spectral energy distribution of Cyg X-1 during a flaring episode similar to that reported in [31] (magenta points). CTA will detect this binary in 30 minutes of observation (black points; model in cyan). *Right:* simulation of different flaring models (black lines), result of the synchrotron (green) and IC (purple) contributions. The red lines correspond to the sensitivities of CTA-North and the 4 Large Size Telescopes (LSTs) of CTA-North (for 5 h). The steady Crab spectrum is plotted for comparison (gray shaded area). Figures extracted from the CTA Consortium paper on Galactic transients (in prep.)

3.3 Transitional millisecond pulsars (tMSPs)

tMPS are binaries composed of a low-mass star and a pulsar with a millisecond-duration period. These systems change from an accretion-powered phase to a radio loud phase. Three tMSPs have been detected at HE by *Fermi*-LAT during the accretion-powered phase [9]. Transitions between the two states can occur on timescales from days to weeks, producing variability in the whole electromagnetic spectrum. We have tested whether CTA could detect emission from two systems, PSR J1023+0038 and XSS J1227-48538, which are detected with *Fermi*-LAT in the 0.1–10 GeV energy range during the accretion phase. We show that the full CTA array will be able to detect persistent emission from these sources by performing long integration-time observations (>50h).

4. Summary

CTA will perform real-time TeV studies of the variable Galactic sky. Its unique sensitivity to short-timescale events and its low energy threshold make this observatory a powerful and efficient

instrument to detect and discover new transient sources. The observational strategy of CTA includes both follow-up of externally triggered events, and serendipitous discoveries, taking place e.g., while conducting a Galactic plane Survey. CTA will be able to detect microquasars such as Cyg X-1, Cyg X-3 and SS433 in the GeV-TeV domain for the first time. It will also be able to probe the flaring episodes of PWNe (namely the Crab Nebula) at VHE. CTA will detect for the first time the VHE component of tMSPs, by performing dedicated long-time observations (>50h) during the accretion state.

The unique capabilities of CTA will also likely result in the detection of other large variety of Galactic transients, such as novae, flares from known gamma-ray/X-ray binaries and magnetars. Serendipitous discoveries are also possible. CTA will play a key role in identifying the nature of new transients by performing follow-up observations of wide field-of-view instruments. CTA will help to reveal their most energetic counterpart, and to unveil the acceleration mechanisms at work. The real-time analysis *Science Alert Generation* will play a key role in the follow-up and observation strategies of externally triggered events and also in the serendipitous discovery of transient events.

- 182 : Institute of Particle and Nuclear Studies, KEK (High Energy Accelerator Research Organization), 1-1 Oho, Tsukuba, 305-0801, Japan
- 183 : Department of Physics and Astronomy, University of Sheffield, Hounsfield Road, Sheffield S3 7RH, United Kingdom
- 184 : Centro de Ciências Naturais e Humanas, Universidade Federal do ABC, Av. dos Estados, 5001, CEP: 09.210-580, Santo André - SP, Brazil
- 185 : Dipartimento di Fisica e Astronomia, Sezione Astrofisica, Università di Catania, Via S. Sofia 78, I-95123 Catania, Italy
- 186 : Department of Physics, Humboldt University Berlin, Newtonstr. 15, 12489 Berlin, Germany
- 187 : Texas Tech University, 2500 Broadway, Lubbock, Texas 79409-1035, USA
- 188 : University of Zielona Góra, ul. Licealna 9, 65-417 Zielona Góra, Poland
- 189 : Institute for Nuclear Research and Nuclear Energy, Bulgarian Academy of Sciences, 72 boul. Tsarigradsko chaussee, 1784 Sofia, Bulgaria
- 190 : University of Białystok, Faculty of Physics, ul. K. Ciołkowskiego 1L, 15-254 Białystok, Poland
- 191 : Faculty of Physics, National and Kapodestrian University of Athens, Panepistimiopolis, 15771 Ilissia, Athens, Greece
- 192 : Universidad de Chile, Av. Libertador Bernardo O'Higgins 1058, Santiago, Chile
- 193 : Hiroshima Astrophysical Science Center, Hiroshima University, Higashi-Hiroshima, Hiroshima 739-8526, Japan
- 194 : Department of Applied Physics, University of Miyazaki, 1-1 Gakuen Kibana-dai Nishi, Miyazaki, 889-2192, Japan
- 195 : School of Allied Health Sciences, Kitasato University, Sagami-hara, Kanagawa 228-8555, Japan
- 196 : Departamento de Astronomía, Universidad de Concepción, Barrio Universitario S/N, Concepción, Chile
- 197 : Charles University, Institute of Particle & Nuclear Physics, V Holešovičkách 2, 180 00 Prague 8, Czech Republic

- 198 : Astronomical Observatory of Ivan Franko National University of Lviv, 8 Kyryla i Mephodia Street, Lviv, 79005, Ukraine
- 199 : Kobayashi-Maskawa Institute (KMI) for the Origin of Particles and the Universe, Nagoya University, Chikusa-ku, Nagoya 464-8602, Japan
- 200 : Graduate School of Technology, Industrial and Social Sciences, Tokushima University, Tokushima 770-8506, Japan
- 201 : Space Research Centre, Polish Academy of Sciences, ul. Bartycka 18A, 00-716 Warsaw, Poland
- 202 : Instituto de Física - Universidade de São Paulo, Rua do Matão Travessa R Nr.187 CEP 05508-090 Cidade Universitária, São Paulo, Brazil
- 203 : International Institute of Physics at the Federal University of Rio Grande do Norte, Campus Universitário, Lagoa Nova CEP 59078-970 Rio Grande do Norte, Brazil
- 204 : University College Dublin, Belfield, Dublin 4, Ireland
- 205 : Centre for Astro-Particle Physics (CAPP) and Department of Physics, University of Johannesburg, PO Box 524, Auckland Park 2006, South Africa
- 206 : Departamento de Física, Facultad de Ciencias Básicas, Universidad Metropolitana de Ciencias de la Educación, Santiago, Chile
- 207 : Núcleo de Formação de Professores - Universidade Federal de São Carlos, Rodovia Washington Luís, km 235 CEP 13565-905 - SP-310 São Carlos - São Paulo, Brazil
- 208 : Physik-Institut, Universität Zürich, Winterthurerstrasse 190, 8057 Zürich, Switzerland
- 209 : Department of Physical Sciences, Aoyama Gakuin University, Fuchinobe, Sagamihara, Kanagawa, 252-5258, Japan
- 210 : University of the Free State, Nelson Mandela Avenue, Bloemfontein, 9300, South Africa
- 211 : Faculty of Electronics and Information, Warsaw University of Technology, ul. Nowowiejska 15/19, 00-665 Warsaw, Poland
- 212 : Rudjer Boskovic Institute, Bijenicka 54, 10 000 Zagreb, Croatia
- 213 : Department of Physics, Konan University, Kobe, Hyogo, 658-8501, Japan
- 214 : Kumamoto University, 2-39-1 Kurokami, Kumamoto, 860-8555, Japan
- 215 : University School for Advanced Studies IUSS Pavia, Palazzo del Broletto, Piazza della Vittoria 15, 27100 Pavia, Italy
- 216 : Aalto University, Otakaari 1, 00076 Aalto, Finland
- 217 : Agenzia Spaziale Italiana (ASI), 00133 Roma, Italy
- 218 : Observatoire de la Cote d'Azur, Boulevard de l'Observatoire CS34229, 06304 Nice Cedex 4, France
