## **Deterrence Theory in Practice**

According to leading Portuguese criminal justice experts, among the problems that ail the Portuguese criminal justice system is the lack of political involvement and accountability after approving laws that criminalize certain acts as one of the causes of this system's dismay (Carvalho 2002). Legislative politics are said to be disconnected from the criminal justice system. However, this is not a problem that is particular to the Portuguese justice system. The credibility of the justice systems around the world suffers from this problem. This paper deals with this disconnection and how law enforcement, court, and prison criminal subsystems deal with this in maintaining deterrence strategies—central to criminal justice systems.

From previous studies (Mendes 2001), I inferred that statutory sentencing and prison capacity are not aligned policies. Setting the maximal severity of the deterrent threat is independent of the allocation of criminal justice system resources. Once prisons reach and surpass capacity limits and there are no more beds, there is not much judges and parole officers can do but turn to options that in one way or another release prisoners and reduce the intake, and in this way, relieve the pressure on the system. I have elsewhere shown that from the time deterrent policies are adopted, they already lack any connection to reality. The evidence suggests that legislatures, in conformity with the literature on its symbolic role in the fight against crime, do not appear to be concerned with the end result of the threat they adopt. To the extent that legislatures participate in deterrence, they set the “ceilings”—that is, they set the outer limits of

deterrent strategies and little else. One of those limits is the sentencing maxima; another is the allocation of available prison resources. The evidence and the literature point to the idea that legislatures are not concerned with the need for the level of severity, so the crime rate does not appear to be an ingredient in setting the deterrent threat in the legislative arena. They leave it to the administrative and judicial apparatus to give deterrence any real meaning. Thus, the legislative role in deterrence theory in practice is arational; once a legislature adopts a politically correct and electorally safe deterrent threat, it disassociates itself from it.

If there is any rational comprehensiveness to deterrence strategies in practice, that rationality must come from somewhere else—the law enforcement, judicial, and correctional actors of the criminal justice system. The legislative delegation of authority simultaneously allows politicians to claim credit for doing their part to fight crime *and* it also allows them to blame the criminal justice apparatus for any inefficacy in the implementation of the deterrent strategies.

The consequence of delegating deterrent decisions to the police, the prosecutors, the judges, the wardens, and the parole boards is that these actors are really the ones that influence the expected cost of punishment. They design the contours of deterrence theory and set it in motion with the necessary discretion to keep things in balance. The discretion they enjoy allows them to employ, manipulate, and/or ignore legislative directives or intent. Thus, despite the determinate sentencing scheme introduced in the 70s, these actors are to a great extent left to their own devices, free to impose their mark on the expected cost of punishment.

This freedom is not, however, without its limitations. Their hands are likely to be tied by one very real and unavoidable constraint over which they have no power: resource limitation and most especially, the lack of sufficient prison space. This forces the actors to adapt. From a systems-analysis viewpoint, the criminal justice system adjusts the amount of input into the system—criminals—to match to the available

resources they have to work with. The output is the conditional result of the constraints on the system. With so many existing and expected prison beds, judges, wardens, and parole boards must exhaust all outlets to house incoming convicted individuals. But there comes a point where deterrence theory in practice is adjusted to existing circumstances and contexts. Deterrence theory is contingent on the context, as with all other theories. The police, prosecutors, judges, and parole officers, have no choice but to make adjustments in the certainty and imposed severity of punishment to keep the system from collapsing.

If we were to imagine the extreme situation, this would allow us to see what a straightforward application of the deterrent threat adopted by the legislature would demand of the criminal justice system. It would reveal the kinds of decision criminal justice actors potentially face and how they have to deal with the limited resources. Let us imagine that every time someone commits a crime he or she is arrested. Let us also imagine that none of these suspects are released by the police and that all are indicted, charged, and convicted by way of a trial. This is already unrealistic because law enforcement and the courts lack the money and the personnel to accomplish such tasks. But, for the sake of example, let us go on. Suppose that the type of penalty or sanction that all convicted felons receive is a prison sentence—the maximum prison penalty allowable by law. If we were to estimate the expected cost of punishment, this would tell us that it could not be. The cost would be so far out of the bounds of reality that the system would break down. It could not happen simply because there would not be enough prison space to house everyone. Briefly stated, following through with the level of statutory harshness is not an option for criminal justice agencies.

If collapse is not an option, then what is? What do these agencies do? How do they handle things when the crime rates rise and criminal intake reaches unrealistic levels? The system has not collapsed as of yet and will most likely not collapse because there are built in “oxygen vents”, meaning the system is designed to adjust. Each agent

has the power to adjust. Not all crimes are detected. The police cannot detect all criminal activity and those activities that are detected are not all reported or pursued. So not all suspects are arrested and of those who are arrested, many are released for any number of reasons. They are screened out of the system so that, in principle, only the most serious and most solid cases are sent to the prosecutor. The prosecutors are the middle men. They have a great deal of power to keep the system working. They get to select which cases to prosecute, and only a proportion of those are handed over to the prosecutors' offices proceed. Of those cases that are selected, again only a small number of cases are brought before a court. At least in the U.S. an overwhelming majority of indicted cases are resolved outside the courtroom through plea bargaining. Plea bargains are a good example of adjusting tools the system created to lessen the pressure the system must face. Of those individuals who are convicted by way of a plea or a trial, only some proportion of them is actually sent to prison. And finally of those that do time in prison, a great deal of them only serves a portion of their prison term. Many are released on parole before their sentence is over. Other's sentences are converted to non-incarceration sanctions. And, in some countries, for instance Portugal, the system created what is referred to as an "amnistia" or a pardon; this is a general or partial pardon decree that is issued from time to time and that releases prisoners from serving the remaining portions of their sentences.

This paper is organized as follows. Following the development of the argument and a brief review of the literature on the relationship among the deterrence elements in practice, I lay out the preliminary evidence in Western Europe, and, in particular, Portugal as to whether and how deterrence theory follows through in practice. The findings are discussed in the final section.

### ***The Theory on the Criminal Justice System in Equilibrium***

“Sentencing policy is only as mandatory as police, prosecutors, and judges choose to make it...Legislators, whatever their purpose for supporting mandatory sentencing laws, once the vote is cast move on to other issues. For judges, prosecutors, and defense counsel, it is another story... [they] *must* keep the courts functioning. That they sometime devise ways to avoid application of laws they believe to be uncommonly harsh should come as no surprise.” (Tonry 1992, 267 italics not in the original)

In the late seventies right about the time when determinate sentencing schemes were coming into effect, Daniel Nagin (1978) introduced criminal justice scholars to his theory of a long-run incarceration equilibrium. Just as Michael Tonry’s words suggest, judges, prosecutors, parole officers, as well as the police do not have much of a choice but to use their discretionary powers to keep the system under some sort of feasible control. From the above hypothetical situations, we see that managing the incoming suspects and/convicted individuals with the available resources is a question of survival. Given the fragmentation of the system and the level of discretion that each and every one of the criminal justice actors has, adaptation can get out of balance and this of course takes its toll on the deterrent threat. With the certainty of punishment and the severity of punishment changing constantly due to changes originating from all ends of the criminal justice system so to keep the system’s outputs within the bounds, the expected cost of punishment can get out of control.

The core of the Nagin’s thesis is based on the system-capacity model of the criminal justice system (Phillips and Votey Jr.1972; Shinnar and Shinnar 1975; Green and Allen 1981-2) and the principle of “thermodynamics” (Walker 1985; Benekos 1992). The idea is that resources are scarce. They do not increase proportionately with increases in the crime rates or the level of legislative severity. Because resources are limited, there is a reasonable stability in the level

punishment. "...As pressure is experienced at one point of the system (e.g., getting tougher on crime with more mandatory and longer minimum sentences) it is diffused at some other point in the system (e.g. early release with good time and emergency authority to shorten the length of sentence)." (Benekos 1992, 8).

Nagin argues that in the long run, the criminal justice system adapts to crime rates and the level of harshness of penal sanctions, producing an equilibrium in the incarceration rate. In other words, this means that the actors of the criminal justice system adjust or modify their behavior within the bounds of their power and competency. He uses the following equation to represent his theory of a long-run equilibrium:

$$\text{Incarceration Rate} = \text{Crime Rate} * \text{Probability of Conviction} * \text{Time Served in Prison},$$

where the incarceration rate is the number of individuals imprisoned per some number of population, the probability of conviction represents the certainty with which punishment will be imposed, and time served represents the severity of that punishment.

Green and Allen (1981-2) speak of an "adaptive function" of the criminal justice system to mean just what Nagin is getting at. The system "neutralizes overly-severe penalties" and sidesteps laws that were not designed to fit reality in many ways. In the presence of overly harsh penalties, the police are selective of the individuals they feed into the system. Prosecutors are selective of those individuals they charge and/or to whom they offer plea bargains. And finally, to those individuals who are committed to prison, judges impose more lenient sentences and parole offices offer what authors have labelled as "backdoor", "sidedoor", and even "trapdoor" solutions. These are opportunities to cut short prison terms by way of parole or to at least convert the remaining portions into non-prison sentences (Green

and Allen 1981-2; Mullen 1987; Blumstein 1987).

This notion of equilibrium of the incarceration rate or of an adaptive criminal justice system allows us to get at the relationship between the certainty and severity of punishment. I can tentatively say that a stable level of punishment translates into a stable expected cost of punishment despite attempts made to increase severity on the part of legislature. This consequently translates into seemingly ineffective deterrent effects. Why? Because it suggests that the certainty and the severity of punishment are inversely related. If we algebraically manipulate Nagin's equilibrium function, we uncover this inverse relationship:

$$Probability\ of\ Conviction = Incarceration\ Rate * \frac{1}{Crime\ Rate} * \frac{1}{Time\ Served\ in\ Prison}$$

or

$$Time\ Served\ in\ Prison = Incarceration\ Rate * \frac{1}{Crime\ Rate} * \frac{1}{Probability\ of\ Conviction}$$

If the probability of arrest and the severity of punishment are indeed inversely related, then this tradeoff makes effective changes in the deterrent threat, as seen through the expected cost of punishment, difficult to achieve. Increases in statutory penalties are offset by reductions in either imposed penalties or by a lower probability of conviction and arrest. Increases in the probability of arrest are offset by decreases in either the probability of conviction or the severity of the sentences imposed.

***The Role of the Courts, Prosecutors, and Correctional Officers***

Correctional officers are the first to feel the pressure points of the criminal

system. Wardens are those with the least control over the inputs in the system. Yet they are the most burdened by any failures on the part of the other actors, legislatures included, to devise, implement, and adapt deterrent strategies so as to maintain coordination and policies that are feasible and in touch with the available resources. When the seams begin to bulge and prison overcrowding infringes upon the constitutional rights of the prisoners, those actors that do have some adaptive control over the inputs in the system get together to “circumvent” legislative policies (Tonry 1992, 256; Green and Allen 1981-2; Blumstein 1987; Benekos 1992; Cole and Call 1992). Policies designed to be “tough” on crime can end up producing the opposite effect (Walker 1985).

According to Donald Gottfredson and Ralph Taylor, writing for the National Institute of Justice in 1983, there are four things that can be done about the limitation of prison space and avoiding prison overcrowding and prison overcrowding litigation: 1) construction of new prison facilities, 2) reduction of prison intake, 3) acceleration of release, and 4) tolerance of overcrowding. The first option is not up to the police, prisons, and courts. The last option is unconstitutional and has been tested and set right in extensive overcrowding litigation that has obligated courts to order states to reduce prison overcrowding so as to restore constitutional limits on prison capacity (Blumstein 1987; Levitt 1996). That leaves the criminal justice system with options numbers two and three.

Although parole boards are the ones with the power over the convicted individuals once they are sent to a correctional facility, judges are the primary authority when it comes to the level of severity of punishment, for they are the only ones to hand down sentences. Judges also have to deal with prison overcrowding problems. They cannot dismiss capacity problems when sentencing without the problems coming back to them in the form of overcrowding litigation. Not only are judges faced with the dilemma of the overcrowding litigation, where they often have to rule in favor of the

plaintiff, that is, the convicted prisoner (Benekos 1992; Cole and Call 1992; Levitt 1996), they have to impose sentences will lesser future litigation and relieve the pressure placed on the parole officers to release prisoners. In doing so, they have to take into account what resources they have to work with and the incoming flow of prisoners and balance these with the deterrent threat of the sentence. Just sentences for those who have been convicted and effective sentences for those who need to be deterred are sacrificed in the name of efficiency (Waldfogel 1993). When resources are low and/or the rate of conviction is high, judges and juries have no choice but to impose sentences that are a fraction of the maximum sentences that legislatures set. In this way they exercise a “front-door” solution to the problem of overcrowding (Logan 1972; Bullock 1961; Tittle 1969; Green and Allen 1981-2; Andreoni 1991; Louthan 1985; Green and Allen 1981-2; Tonry 1992; Cole and Call 1992; Tullock 1995).

Another option that judges have employed to sidestep increased certainty of punishment and limited prison capacity is the “sidedoor” solution (Gottfredson 1987; Blumstein 1987; 1988). This consists in judges converting already imposed sentences into non-prison sentences, so as to create new space. Prisoners can serve the remaining portion of their sentence under house arrest, performing community service, paying a fine, etc. And finally, there is the “trapdoor” solution, a term that Donald Gottfredson (1987) coined. This consists of the adoption of “emergency release laws” that act as “safety valves” and come into effect in extreme situations.

Resources and the probability of conviction aside, judges are said to employ a psychological discounting function where they account for the declining marginal disutility of the prisoners’ imprisonment experience (Fitzmaurice and Pease 1986; Ostrom and Ostrom 1999). Each additional year in prison has less deterrent effect because the prisoner’s value in terms of legal income earning capacity decreases, which only contributes to the probability of recidivism, and because prisoners themselves do some adapting. They become accustomed to prison life to the extent that one more year

will not make much of a difference when discounted to the present. Since resources constraints and the probability of conviction cannot be ignored, the consequence of the judges' balancing act is an even higher judicial discount rate, which results in a lower level of severity of punishment than that announced by the legislatures.

Then there is the figure of the prosecutor. Prosecutors have the "single most unreviewed exercise of power in the criminal justice system" (Gottfredson and Gottfredson 1980, 146). They decide which cases filed by the police. When the legislature tightens its control over the courts, prosecutorial power increases. The discretion judges lose is shifted to the prosecutors so that the game is still on this side of the court. Even juries tend to deliver fewer guilty verdicts when the severity is very high and the hands of the judges are tied as to the minimum mandatory required sentence in the face of a guilty verdict (Andreoni 1991). Penalties and the probability of conviction are interdependent.

### ***A Look at the Evidence***

If we take a given criminal justice system at any given moment and examine the deterrence components what do you find? What can a static observation of the world tell us about how criminal justice agencies and subsystems carry out the deterrent threat once the legislatures set the initial deterrent threat in the statutes they adopt? They can tell us plenty. Above Nagin (1978), Green and Allen (1981-82), and Tsebelis (1989; 1990; 1991; 1993; 1995), and others tell us implicitly assume that the criminal justice is about being equilibrium. Equilibrium, in turn, implies that some thing or phenomenon that is in equilibrium might not always be in equilibrium. In other words, and for the purpose of my study here, the criminal justice system stretches, contracts, etc.. Its subsystems act and react to the shocks to the systems, shocks constituting changes brought about by the legislatures on the one hand, and by all the other bureaucratic and judicial agencies on the other. This gives us a notion that these agencies are responsive

to one another. They have to be to secure some sort of balance in the criminal justice system and keep it from collapsing.

An ideal criminal justice system would have the capacity to house all arrested individuals convicted to the maximum penalty allowable by law. But in reality nothing is ideal, nor is “ideal” ever the objective, as any economist would tell us. Not as long as there are resource constraints. And governments are never without them. This means public policies are not meant to solve all public problems and the goal is never zero pollution, zero health problems, etc. or, in this case, zero crime and total justice, meaning every one who commits a crime is arrested for it, convicted and sent to prison for as long as the law permits.

So this being the case, I can examine how the elements under the control of the agencies that implement and effectively set the deterrent threat vary across jurisdictions, namely:

- 1) Given that we know tradeoffs must and do occur to keep the system in balance?

How can we detect them?

- 2) How do different jurisdictions “trade things off” as they are faced with their resource constraints? What balancing acts are done, and on whose part?

One gains confidence in arriving at an answer for these major questions by looking at what the worldly evidence across jurisdictions for any given year has to offer. In this section, I attempt to do just that by providing a series of tables, graphs, and scatterplots of Western European criminal justice systems, with particular focus on the Portuguese system. In the case of Western Europe, I have two sets of data: 1995 data from the *European Sourcebook of Crime and Criminal Justice Statistics of the Council of Europe*; and 1994 data from the *United Nations World Surveys on Crime Trends and Criminal Justice Systems*. In the Appendix to this chapter, I provide 1994 UN data on specific major crimes for those interested.

Finally in Portugal, I have a time dimension with data reaching back to 1960 and as recent as 1997. These data are from the Portuguese Research and Planning Office of the Ministry of Justice—the *Gabinete de Estudos e Planeamento do Ministério e Justiça* (GEPMJ).

### ***Western Europe***

Table 1 includes data on total offense rate (offenses/100,000 persons), the number of arrests, the number of convictions, statutory and imposed sentence lengths in years, prison population, and prison capacity. Figure 1 is the graphic depiction of much of what we see listed in Table 1: the total offense rate, the number of arrests, the number of convictions, prison capacity, and the prison population in 17 Western European nations. Several Appendix Tables 1-6 covering 19 UN nations for specific major crime types in 1994) are provided for those interested in specific crime types. The purpose of Figure 1 is to illustrate the discrepancies between the offense rate, deterrent elements of arrests and convictions, and prison data and to pinpoint some indications of “balancing acts” or tradeoffs within nations. As is plain to visualize, the number of arrests constitutes a small proportion of total reported offenses; the number of convictions is, in turn, a smaller fraction of the number of arrests. Even so, the number of convictions is overwhelming compared to the space available to put these convicted individuals, provided they are convicted to some type of prison confinement. Most obvious to reader is the lack of or very near capacity of the prison systems in these countries. Switzerland, for instance, a nation with an offense rate in the same ballpark as that of, say, Finland, arrests and convicts fewer times than Finland. But compare the prison population and capacity figures. Finland has more room to house incoming convicted felons. Compare a Southern European nation, such as Portugal with, say, Ireland. Portugal has a somewhat similar arrest figure to that of Ireland; but notice that since Portugal, contrary

to Ireland, was already operating above capacity in 1995, it is plausible to expect that Portugal convicted a lot fewer than Ireland, less than half the number of times.

It is evident from Figure 2 shows that the prison population tracks and many times exceeds the capacity for that population in every nation under observation for which I have inmate and capacity data. The few exceptions, Austria, Denmark Finland, Germany, Sweden, Switzerland, and Ireland, are a small ways away from reaching the limit, after which tradeoffs are most likely to occur with greater consequences.

[Table 1 about here]

[Figures 1-2 about here]

Table 2 compares statutory and imposed severity for six Western European nations and for four different offenses (those Western European nations for which imposed sentence data is available). This table shows that, again, judicially-imposed sentences are a very small fraction of the statutory maxima. England Wales are among the harshest Western European nations when it comes to statutory severity and that Sweden is among the most lenient. Table 2 tells us, in the case of murder, for instance, these two nations are on opposite ends of the statutory severity scale, but they have very similar levels of imposed severity. In the case of theft, England and Wales impose a mere .02% of the statutory maxima, 40 years, for an average imposed sentence length of almost 10 months. In Sweden, the actual average imposed sentence length is not much different from that of the English and Welsh imposed sentence despite the statutory maximum penalty of six years in penalty.

[Table 2 about here]

[Appendix Tables 1-6 about here]

### ***Portugal***

In Portugal, the evidence is indicative that criminal justice agencies, just as in Western Europe, respond to the pressures of resource constriction that is evident on

Figures 3 and 4. Figure 3 displays, the number of individuals charged with a crime, the number of persons convicted, the number of persons serving time in prison, the number of persons incarcerated, and finally, the prison capacity from 1960 to 1994.<sup>i</sup> To note is companion table, Table 3, which provides the numbers that serve as the basis of this graph. This number of persons charged with a crime and convicted and well as those sentenced to prison began to decrease. This downward trend is also apparent when we look at the evolution of the Portuguese prison system. From 1960 to 1972/74, prison occupation was well below capacity. The number of prisons decreased dramatically as Portugal made its transition to a democratic regime in 1974. This number went from 207 in 1960 to 112 in 1972 and dropped even further to 79 by 1974 and stabilized around 36 by 1978.

Things start gradually to pick up as the democratic regime progresses. By this, the number of persons charged with a crime, as well as the number of persons convicted to a given sanction, gradually increases, particularly in the mid 1980s. Notice, however, that the correctional subsystem never quite accompanies the growth in law enforcement, prosecution, and court loads. This indicates that resources capped at a given point and the prison system did not and could not grow to match the growth in crime. This is when the pressure on a criminal justice system with 40-some prisons begins to build and by the mid 1980s prison capacity is very near the limit. In fact in 1985 prison capacity was already at 114%. By the early to mid 1990s, the prison constraints reached an all-time high. Interesting to note in Portugal is the role of the “amnistia” or a governmental pardon. When the pressure did begin to mount by the middle of the 1980s, the Portuguese legislative bodies<sup>ii</sup> created a legislative act designed to relieve pressure on the prison system. Eight pardons were approved from 1981 to 1994.

Figure 3 vividly depicts the mounting stress on the Portuguese criminal justice system beginning especially in the mid 80s and growing dimmer with each passing year thereafter. Figure 4 concentrates on the latter portion of Figure 3. Comparing Figure 4

with last two columns of Table 4, as well as the last two columns of Table 3, we can more easily visualize the physical bound that the Portugal legislative bodies imposed on Portuguese law enforcement and the wider judicial apparatus.

[Tables 3 and 4 about here]

[Figures 3 and 4 about here]

Even though the Portuguese criminal justice system experienced this pressure, it did not collapse. The number of convictions kept growing and so did the number of individuals sentenced to prison at least until 1993. So what happened? Tradeoffs. From 1993 to 1997, the number of convicted individuals began to drop, despite an increase in offenses, and in the number of persons charged (for those interested in more detailed and disaggregated data for each districts in Continental Portugal, refer to Appendix Tables 7 and 8). To be exact, convictions dropped 9% and the number of person serving time 11% from 1993 to 94 alone.

[Appendix Tables 7-8]

Figure 5 shows that in 1997, the number of arrests represented a mere 7% of total offenses recorded by the three major police forces (the *Polícia Judiciária*, the *Polícia de Segurança Pública*, and the *Guarda Nacional*); and the number of convictions represented only 1% of total offenses and 16% of all arrests. Figure 6 merely breaks these aggregate numbers among the Continental Portuguese districts. As shown in Figure 7, with the exception of one district, Bragança, the prison population exceeded the prison capacity in every district in Continental Portugal, the most severe of these districts being Évora, Faro, Lisboa, Porto, and Setúbal. These are indications of the system operating within its bounds, conforming and adjusting to them.

[Figures 5-7 about here]

With all of these legislative and resource restrictions, there must occur tradeoffs among the agencies. Figure 8 (for total offenses) shows three scatterplots with the respective regressional equations: 1) relationship between the probability of arrest and

the probability of conviction; 2) average maximum imposed sentence and the probability of arrest, and 3) the average maximum imposed sentence and the probability of conviction. These plots appear to indicate tradeoffs between deterrence elements. The relationship appears to be negative between the probability of arrest and the probability of conviction—a clear indication of these deterrent elements responding to one another. It also appears to be negative between the average imposed sentence severity and each of the certainty deterrent elements, however the latter two relationships are not statistically significant as the regression coefficients below the plots indicate.

[Figure 8 about here]

### ***Conclusion***

Having examined and discussed the tradeoffs that occur among criminal justice agencies within Western European criminal justice systems, we can see in this paper that, as Nagin and others argue, these systems manage to survive under the conditions that the level of statutory harshness and the level of prison resources available to them impose on them. How? By the agencies making use of the built-in flexibility that allows for interactive maneuvering and adjustments on the part of the administrative and judicial apparatus. Criminal justice systems do not collapse. They do not continuously expand as the level statutory penal harshness does and would require. Critics are quick to point out that the system has grown out of control. The legislatures do not allow for that; and really an economic outlook on the subject of crime would never claim that the objective of criminal justice systems is a zero crime rate because of something called budget restrictions. Justice systems do not grow indefinitely, but as I have observed and compared elements of deterrence across jurisdictions above, they do bend and stretch a good deal as a result of the adjustments made on the part of those

whom the legislatures intended: the police who control the probability of arrest and detection; the prosecutors who greatly influence the probability of conviction; the judges who decide the actual punishment within very broad limits; and the parole boards who have the last say about the time served in prison for those individuals who were convicted and sentenced to incarceration.

Every one of these actors holds the power over one or more components that comprise deterrence theory. If statutory severity rises with no adequate or rationally associated increase in the prison capacity, the expected cost of punishment will not necessarily increase. What does this mean in practice? It means that we would see the probability of arrest, the probability of conviction, the length of court-imposed sentences, as well as the effective length of time served in prison fluctuate with the intention of keeping the system in balance. Campaign slogans promising tougher penalties and consequently the adoption of stiffer statutory penalties does not mean a greater deterrent effect. The initial deterrent threat may rise, but as I have discussed, that threat is altered as the criminal justice subsystems find ways to counteract the pressures that the increases in deterrent harshness places on them.

I investigated how the police, the courts (in particular) and correctional subsystem, as a fragmented system, operationalize deterrent theory. The evidence shows that prison capacity is extremely limited compared to the input that the criminal justice systems receive. The police, prosecutors, judges, and parole officers, due to unavoidable resource constraints especially prison capacity, make adjustments in the certainty of punishment and the imposed severity of punishment to keep the system from becoming extinct. The survival of the criminal justice system implies that the certainty and severity of punishment play off one another. In other words, the certainty of punishment responds to the severity of punishment and vice-versa, and both respond to the availability of prison space.

*Source:* GEPMJ

*Notes:* Convictions refers to individuals sentenced to unsuspended prison incarceration. Prison population includes individuals awaiting trial. Prison capacity refers to beds in central and regional prison facilities but excludes beds in three special prison facilities.

\*1993 prison data refers to 1992 prison data.

**Figure 1: Offenses, Arrests, Convictions, and Prison Population for Western Europe, 1995**

Source: European Sourcebook of Crime and Criminal Justice Statistics of the Council of Europe 1999-2000.

\* There are no prison population figures for Greece and The Netherlands.

**Figure 3: Offenses, Persons Charged, Convicted, and Serving Time, and Prison Data, Portugal, 1960-94**

Source: See Table 7.4 for data; Barreto 1995

Note: The time units on the X-axis are biannual year numbered sequentially from 1960-80; they correspond to a single year thereafter so that year 1 is 1960, year 2 is 1962, year 12 is 1981, etc.

**Figure 4: Offenses, Persons Charged, Convicted, and Serving Time in Portugal,**

**1990-94**

Year	N° Offenses	N° Charged	N° Convicted	N° Serving Time
1990	216999	56192	21833	6367
1991	244901	71687	22863	4884
1992	265819	82972	30351	5986
1993	283860	74274	37442	7212
1994	317882	95107	34484	6488

Source: Barreto 1995

Notes: Individuals charged are those brought before a criminal court. Convictions include sanctions other than unsuspended prison sentences. Individuals serving time include only those sentenced to prison incarceration.

\* These are pardon or "amnistia" years.

*Notes:* Prison data pertain to central and regional prison facilities; Lisboa and Porto are excluded from the figure for greater resolution on the Y-axis, but the data for these two districts appear in the companion table.

**Figure 8: Scatterplots of the Probability of Arrest, Probability of Conviction, and Average Imposed Sentence Length for Total Crimes in Portugal, 1997**

$$ProbArrest = .214 + .774 ProbConviction \quad R^2 = .461 \quad S_e = .053 \quad N=18$$

(.031) (.209)

$$AverSentLength = 39.614 + 11.729 ProbArrest \quad R^2 = .005 \quad S_e = 11.550 \quad N=18$$

(5.117) (39.667)

$$AverSentLength = 32.877 + 40.304 ProbConviction \quad R^2 = .049 \quad S_e = 11.292 \quad N=18$$

(6.550) (44.206)

---

<sup>i</sup> The time units on the X-axis are biannual years numbered sequentially from 1960-1980 and annually thereafter so that year 1 is 1960, year 2 is 1962, year 12 is 1981, ... and year 25 is 1994.

<sup>ii</sup> In Portugal, both the national and regional legislative assemblies and the executive body (the Government) have the authority to legislate.
