# Exhaustive motif discovery

Look for the motif that best distinguishes between a positive and negative group of sequences

**Positive**

AAGACCCGAGTAAACCCCTGACCAAGTAGA  
GGTGAGATAAACCCCTAGACCAGTTGACCA  
GTGAGATAAACCCCTATACTCGTAGGGACG  
TTGAGAGTTACCGAAAACCCCTACCCAGTTA

....

**Negative**

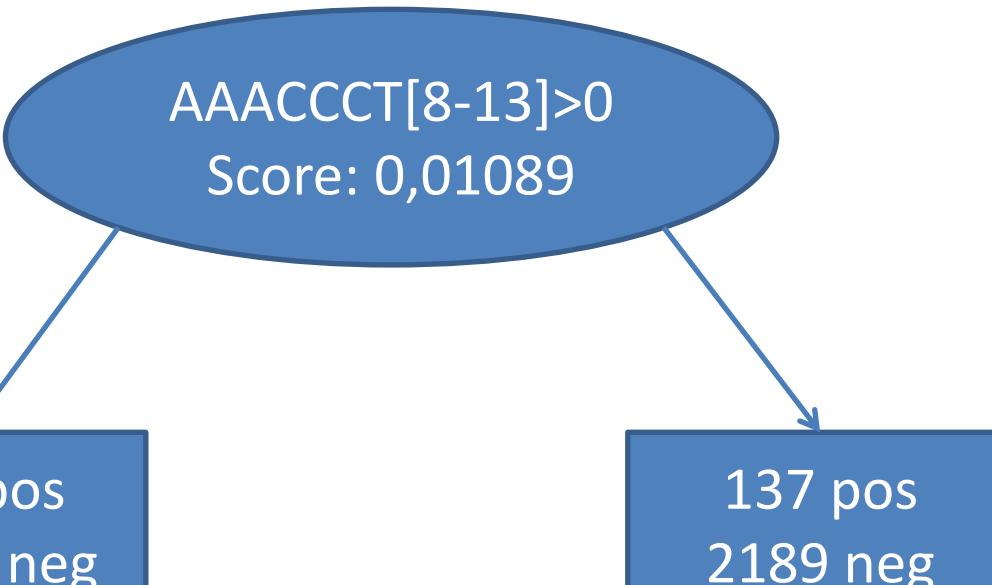

AAGAGCCCAGTAGAGATAGACCAAGTAGA  
GGTGAGATAGACCGTAGACCAGTTGACCA  
GTGAGATATAACCCGGATACCGTAGGGACG  
TGAGAGTTACCAAGATATGAGACCAAGTCTA

- Exhaustively loop over all motifs
  - Calculate a score for each motif selecting the best range and threshold

Motif	Range	Threshold	Score
AAACCCTA	8-13	>0	0,01047
AAACCCT	8-13	>0	0,01089
AACCCTA	9-14	>0	0,01076
...	...	...	...
AC	3-25	>1	0,01044
...	...	...	...

The locations of motifs are saved in a generalized suffix tree to be easy accessible

- Select the motif (combination) that best distinguishes between the positive and negative sequences based on the score
  - Apply this recursively to obtain a decision tree (typical depth of 3)

# Sequences that do not contain motif “AAACCCCT”

# Sequences that contain motif “AAACCCCT”

# OpenMP multithreading

- One thread does suffix tree traversal in parallel openMP region:

```
#pragma omp parallel
#pragma omp single
{
    //recursive traversal in suffix tree
}
```

- Each branch assigned to different OpenMP threads with tasks:

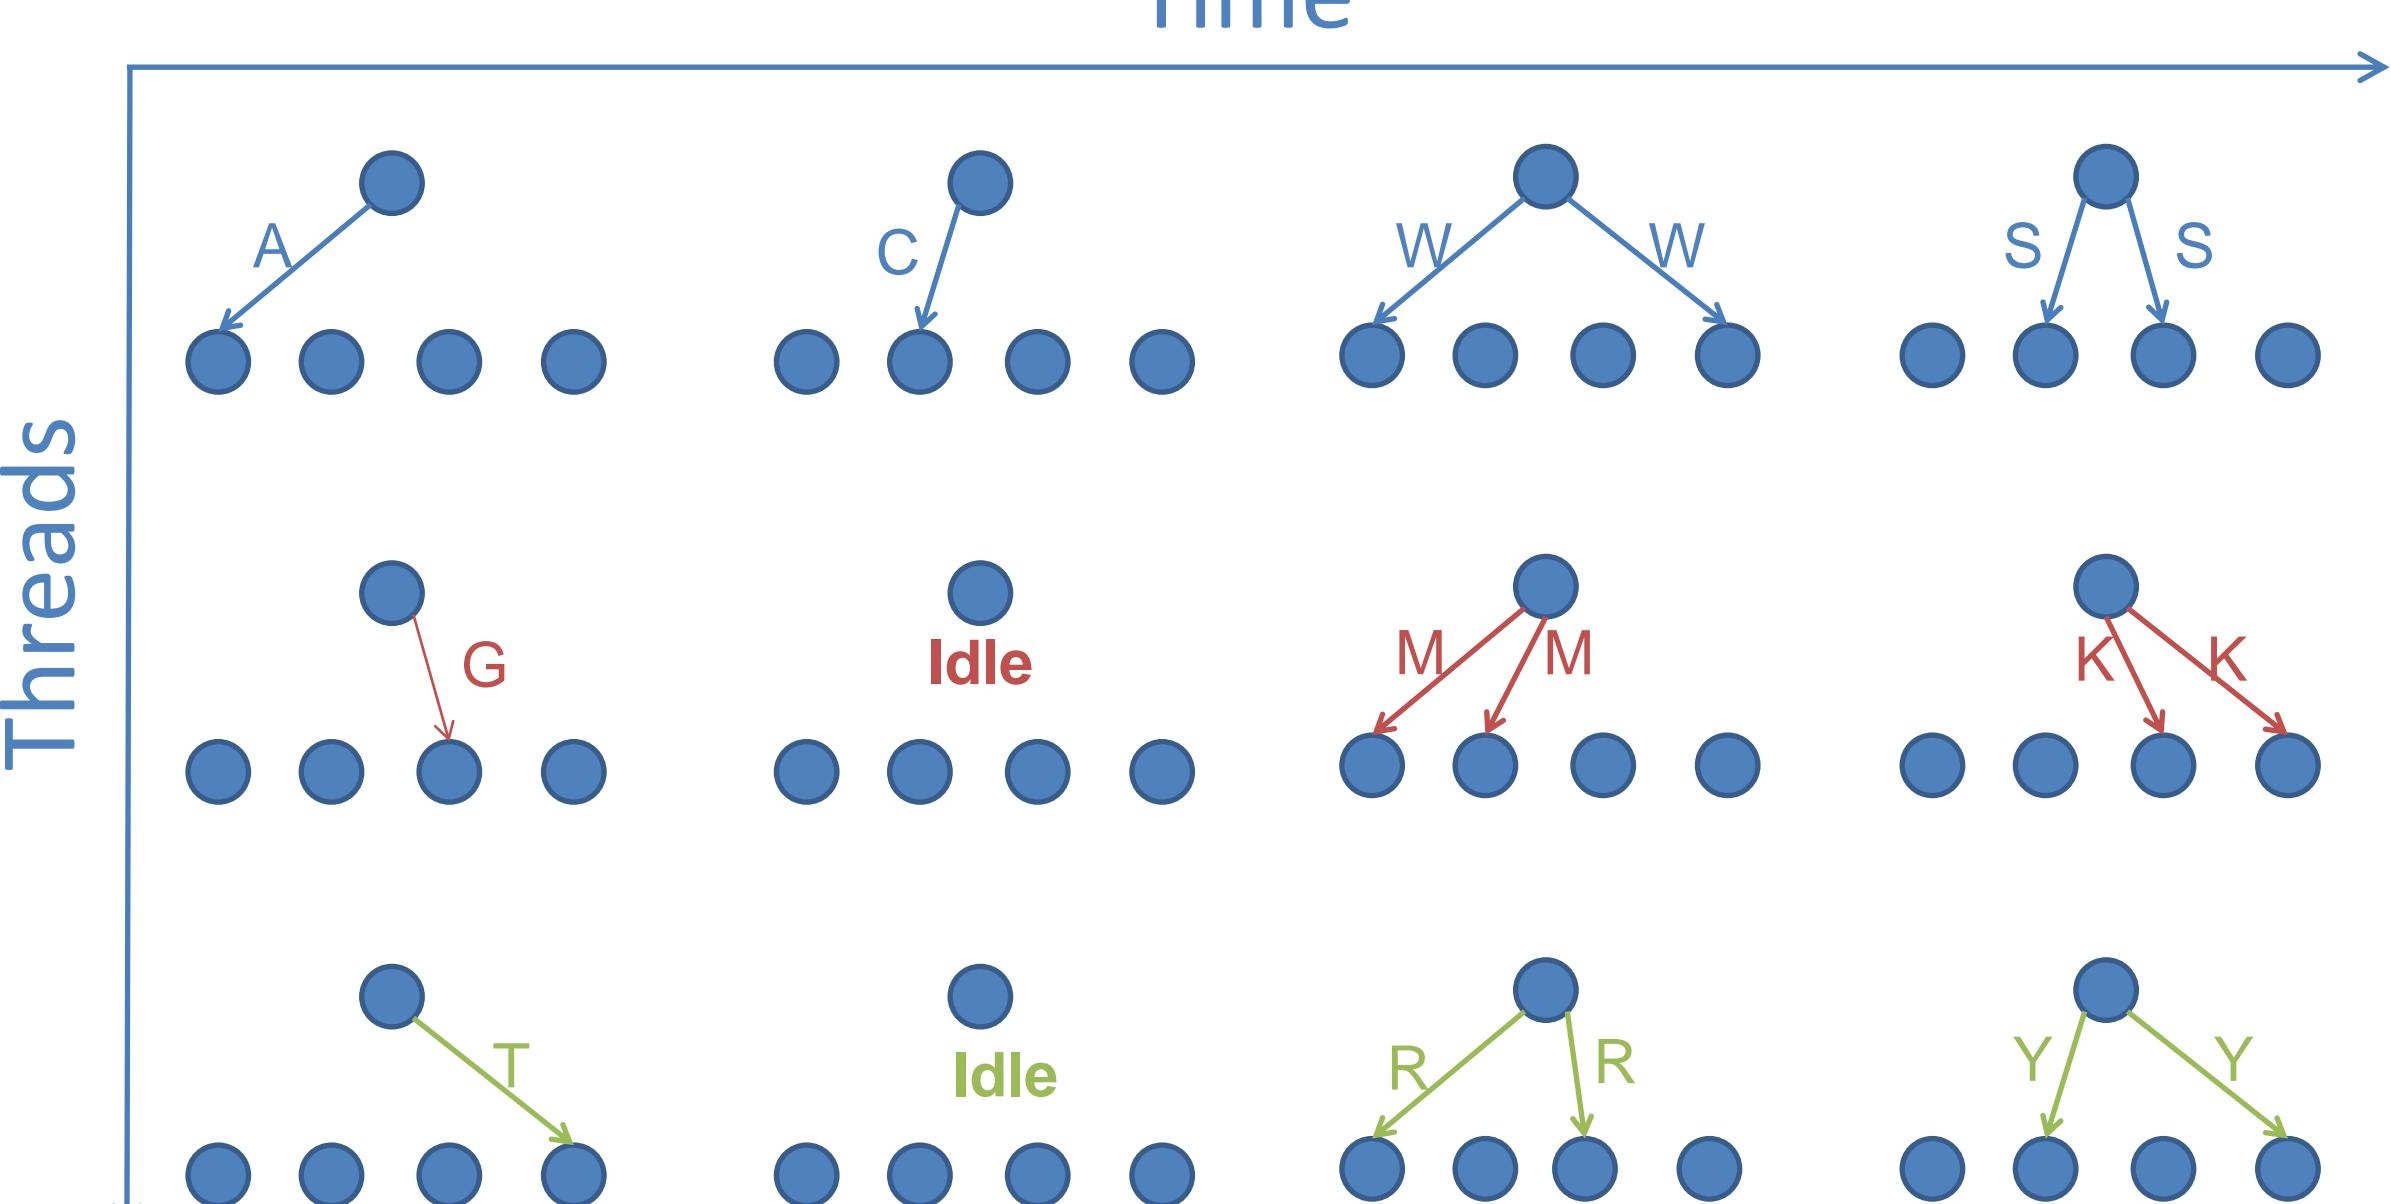

```
#pragma omp task  
{  
    //calculate score for motif  
}
```

# IUPAC support:

- Characters that represent two or more nucleotides
  - Multiple branches for one thread
  - Top-down approach
  - Range omitted

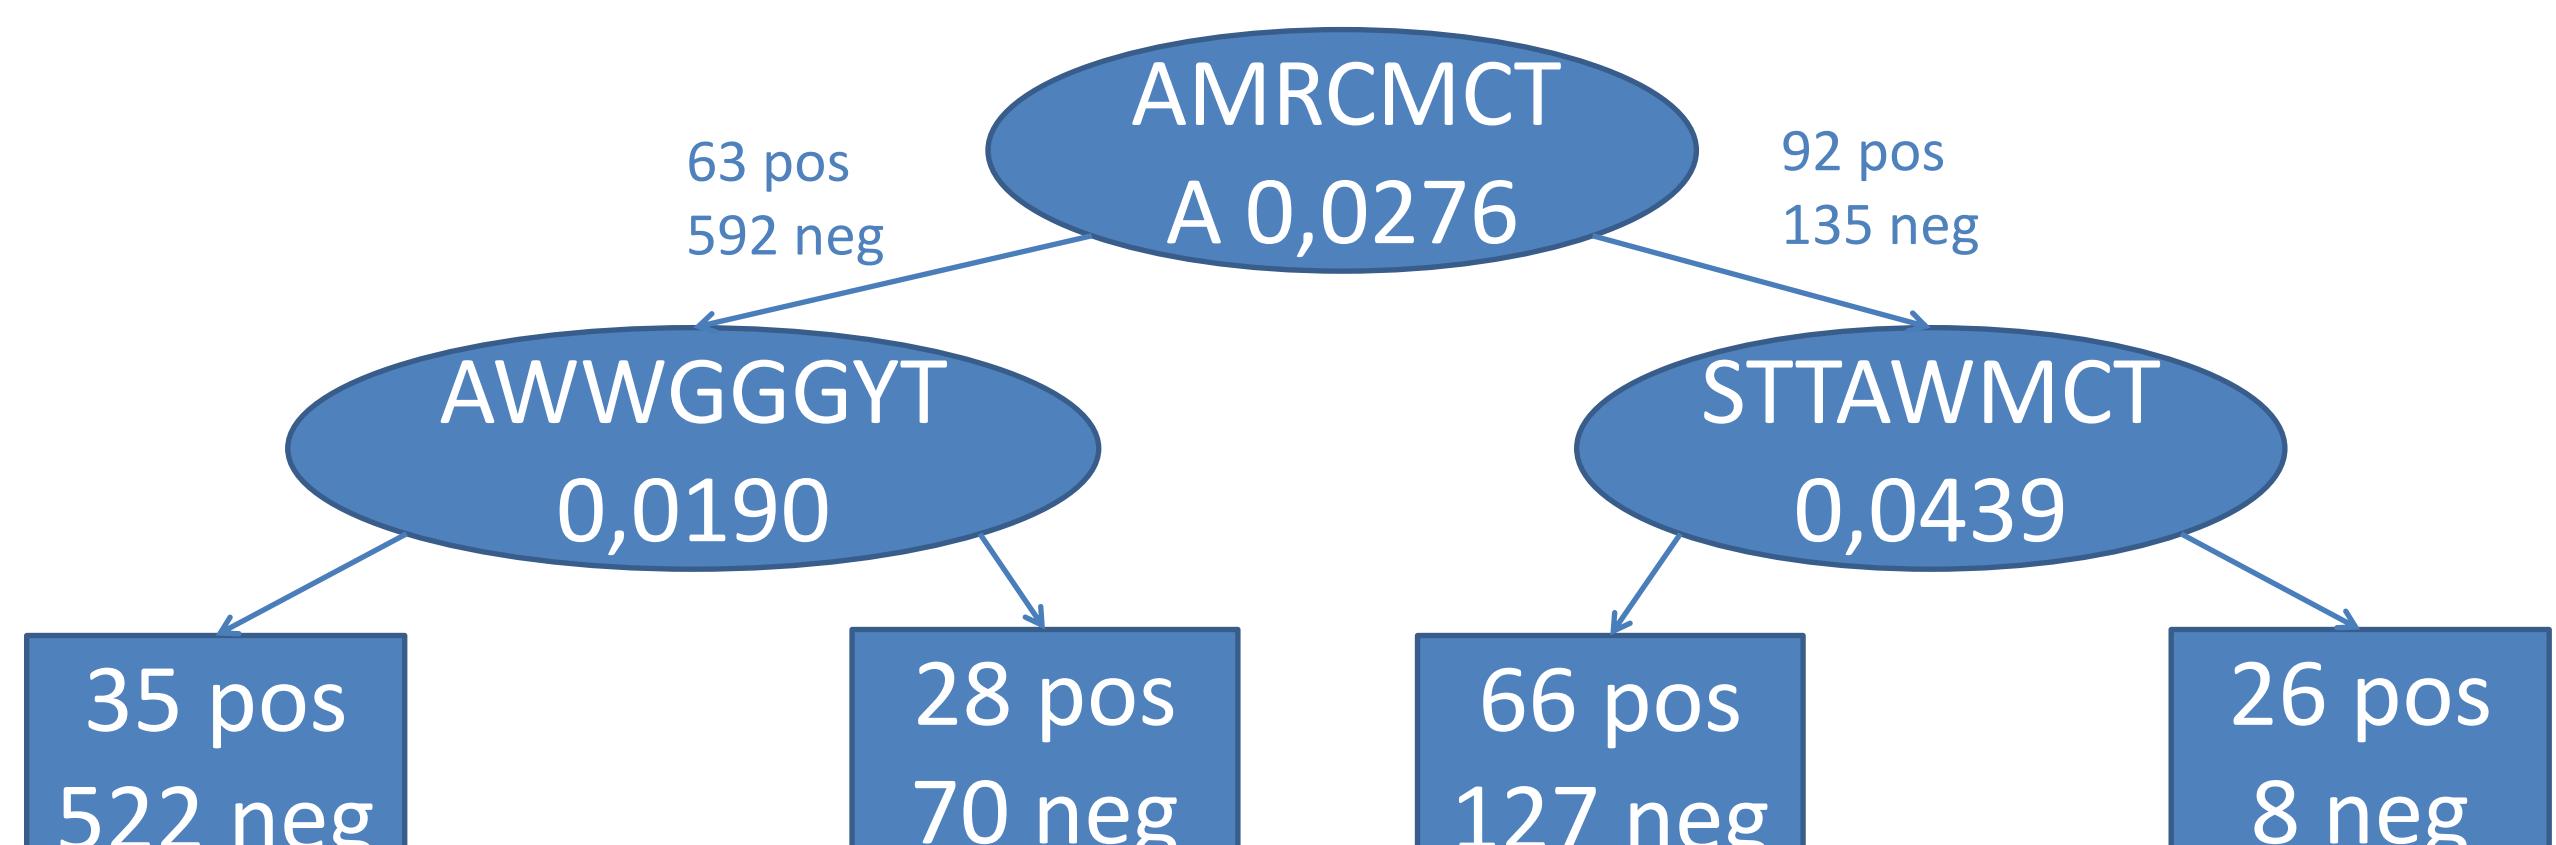

W	A or T	S	C or G
M	A or C	K	G or T
R	A or G	Y	C or T

# Parallelization of suffix tree traversal:

# Results

- Benchmark “ribo” dataset with known motifs:
    - “AAAACCCTA”
    - “GGCCCAW”
  - Limit IUPAC characters to degeneracy 2
  - Maximum motif length 8

- 1,3MB sequences takes 40 min (1 thread)
  - Idle threads cause suboptimal speedup
  - Speedup on personal computer:
