In [2] we used results on the size of the smallest minimal blocking sets of $\mathrm{Q}(4, q)$, $q$ even (from [1]) and projection arguments the find the following characterization of the smallest minimal blocking sets of $\mathrm{Q}(6, q)$, $q$ even, $q \geqslant 32$:

**Theorem 1** *Let $\mathcal{K}$ be a minimal blocking set of $\mathrm{Q}(6, q)$, different from an ovoid of $\mathrm{Q}(6, q)$, $|\mathcal{K}| \leqslant q^3 + q$. Then there is a point $p \in \mathrm{Q}(6, q) \setminus \mathcal{K}$ with the following property: $T_p(\mathrm{Q}(6, q)) \cap \mathrm{Q}(6, q) = p\mathrm{Q}(4, q)$and $\mathcal{K}$ consists of all the points of the lines $L$ on $p$ meeting $\mathrm{Q}(4, q)$ in an ovoid $\mathcal{O}$, minus the point $p$ itself, and $|\mathcal{K}| = q^3 + q$.*

The results of [1] could be proven for $q = 3$ and replaced by computer results for $q = 5, 7$. Using then the same projection arguments we found the above characterization for $q = 3, 5, 7$.

Using inductive arguments we can find results for $\mathrm{Q}(2n, q), q = 3, 5, 7$. The situation is now very dependent of $q$, since for example $\mathrm{Q}(6, 3)$ has an ovoid, but $\mathrm{Q}(6, q)$, $q = 5, 7$, not. For $q = 5, 7$, we found the following characterization.

**Theorem 2** *Let $\mathcal{K}$ be a minimal blocking set of $\mathrm{Q}(2n + 2, q)$, $n \geqslant 2$, $|\mathcal{K}| \leqslant q^{n+1} + q^{n-1}$. Then there is an $(n - 2)$-dimensional space $\pi$, $\pi \subset \mathrm{Q}(2n + 2, q)$, $\pi \cap \mathcal{K} = \emptyset$, with the following property: $T_\pi(\mathrm{Q}(2n+2, q)) \cap \mathrm{Q}(2n+2, q) = \pi\mathrm{Q}(4, q)$ and $\mathcal{K}$ consists of all the points of the lines $M$ on $p_i$, $p_i \in \pi$, meeting $\mathrm{Q}(4, q)$ in an ovoid $\mathcal{O}$, minus the points $p_i$ themselves, and $|\mathcal{K}| = q^{n+1} + q^{n-1}$.*

For $q = 3$ we found a characterization using ovoids of $\mathrm{Q}(6, 3)$.

**Theorem 3** *Let $\mathcal{K}$ be a minimal blocking set of $\mathrm{Q}(2n + 2, q)$, $n \geqslant 3$, $|\mathcal{K}| \leqslant q^{n+1} + q^{n-2}$. Then there is an $(n - 3)$-dimensional space $\pi$, $\pi \subset \mathrm{Q}(2n + 2, 3)$, $\pi \cap \mathcal{K} = \emptyset$, with the following property: $T_\pi(\mathrm{Q}(2n+2, 3)) \cap \mathrm{Q}(2n+2, 3) = \pi\mathrm{Q}(6, 3)$ and $\mathcal{K}$ consists of all the points of the lines $M$ on $p_i$, $p_i \in \pi$, meeting $\mathrm{Q}(6, 3)$ in an ovoid $\mathcal{O}$, minus the points $p_i$ themselves, and $|\mathcal{K}| = q^{n+1} + q^{n-2}$.*
