Silicon photonics holds the promise of converging electronics and photonics. The key component, a low-cost high-performance laser, is still missing however within this platform. Although novel solutions have been proposed to increase the light emission directly from silicon (or Ge), compared with their III-V counterparts [1-2], these solutions are still in their infancy. Recently, the epitaxial growth of III-Vs on silicon regained a wide interest. III-V nanowire growth has been widely investigated. However, most of the III-V nanowire lasers on silicon require a complex cleaving and transfer process, which make these devices not suitable for dense integration [3]. In addition, the large cavity dimensions along the nanowire axis (several microns) hinder dense integration. Here, we present the first room-temperature operation of an ultra-short InP nanowire laser that is epitaxially grown on an exactly [001] oriented silicon substrate. The sub-micron sized laser cavity largely enhances the interaction of the lasing mode with the gain medium, and a large spontaneous emission factor has been obtained.

Insert: 45 °titled SEM view of the InP/Si nanowire cavity

To obtain these results, we developed a unique epitaxial process which enlarges the lateral dimensions of a defect-free InP/Si nanowire such that it can sustain high quality optical modes. As shown in Fig.1, as the first step, holes of 100 nm diameter are defined in a SiO<sub>2</sub> mask to expose the silicon surface. After depositing and annealing a layer of Ge, epitaxial growth of InP was carried out in a metal organic chemical vapor deposition (MOCVD) reactor. The defect necking effect [4] of the narrow holes blocks propagation of the dislocations from the lattice-mismatched interface and defect-free InP is obtained at the mask surface. On this virtual lattice matched substrate, InP nanowires are grown along the [111] direction. Lateral overgrowth of InP on the SiO<sub>2</sub> mask took place right after the beginning of the nanowire growth, therefore the dimension of the formed nanowire cavity is much larger than the SiO<sub>2</sub> hole. The insert of Fig. 1 shows a 45 °titled scanning electron microscope (SEM) picture of a typical InP nanowire on silicon. The length of the nanowire cavity is only 700 nm.

Thanks to the limited dimensions of the SiO<sub>2</sub> hole that connects the cavity and the substrate, the downwards leakage loss is low enough to permit room-temperature laser oscillation. A Nd:YAG laser with 7 nanoseconds pulsed output is used as the optical pump source. Fig.2(a) shows the light in-light out (L-L) curve measured in a photoluminescence (PL) setup. The PL spectrum recorded above threshold is also shown in the insert. The clear slope transition in the L-L curve is a strong signature of threshold behavior. By applying a classic rate equation fitting process, a large spontaneous factor of 0.1 is obtained, which indicates very compact optical confinement. In order to identify the optical mode that oscillates in the short nanowire cavity, a finite-difference time-domain (FDTD) based numerical tool (Lumerical) was used, and the simulated optical mode distributions are plotted in Fig.2(b) and (c). As one can expect, regular Fabry-Perot modes, which are found in most of the demonstrated nanowire lasers, cannot oscillate in this cavity due to the irregular bottom contact with the substrate. Instead, a helically propagating cavity mode with hexagonal whispering gallery-like mode pattern in the transverse plane is found by simulations [5]. Its insensitivity to the bottom contact helps to maintain a relative high-Q factor for the lasing mode (~400 in this case). The asymmetrical mode profile shown in Fig.2(c) is mainly caused by the presence of the InP-filled SiO<sub>2</sub> trench at the bottom.

In conclusion, an ultra-short InP nanowire laser with compact mode size was epitaxially grown on a (001) silicon substrate. Optically pumped room-temperature lasing was achieved. This monolithic integrated micro-laser is very promising for applications that require high integration density.
