**Abstract:** Cytokines interact with their receptors in the extracellular space to control immune responses. How the physicochemical properties of the extracellular space influence cytokine signaling is incompletely elucidated. Here, we show that the activity of interleukin (IL)-2, a cytokine critical to T cell immunity, is profoundly affected by pH, limiting IL-2 signaling within the acidic environment of tumors. Generation of lactic acid by tumors limits STAT5 activation, effector differentiation and anti-tumor immunity by CD8<sup>+</sup> T cells and renders high-dose IL-2 therapy poorly effective. Directed evolution enabled selection of a pH-selective IL-2 mutein (Switch-2). Switch-2 binds the IL-2 receptor subunit IL-2R $\alpha$  with higher affinity, triggers STAT5 activation and drives CD8<sup>+</sup> T cell effector function more potently at acidic pH than at neutral pH. Consequently, high-dose Switch-2 therapy induces potent immune activation and tumor rejection with reduced on-target toxicity in normal tissues. Finally, we show that sensitivity to pH is a generalizable property of a diverse range of cytokines with broad relevance to immunity and immunotherapy in healthy and diseased tissues.

**One Sentence Summary:** Gaggero *et al.*, show that pH-selective IL-2 mutein exert potent responses with limited systemic toxicity.

## INTRODUCTION

Cytokines are small, secreted proteins that control all aspects of the immune response (1, 2). Despite their potential to treat cancer, few cytokines have reached the clinic due to limited efficacy and severe systemic toxicities (3), emphasizing the urgent need for more specific and less toxic cytokine-based therapies. Cytokines activate signaling via receptor dimerization, triggering activation of the JAK (Janus kinase)/STAT (Signal Transducer and activator of transcription) signaling pathway but can also control the activity of diverse serine/threonine kinase signaling networks (4, 5). Interleukin-2 (IL-2) is a powerful regulator of immunity (6). High-dose IL-2 therapy is approved for the treatment of metastatic renal cell carcinoma and metastatic melanoma, but partial efficacy and high levels of systemic on-target toxicity have hindered its wider use (7). IL-2 binds a surface receptor comprised of IL-2R $\alpha$ , IL-2R $\beta$  and  $\gamma$ c chains, triggering the activation of the JAK1/JAK3/STAT5 signaling pathway (8, 9). In addition to STAT5, IL-2 engages non-STAT pathways that contributes to shape its immuno-modulatory properties (8).

Cancers develop mechanisms to evade and scape the immune response, key among them is the establishment of an immunosuppressive microenvironment (10). A hallmark of the tumor microenvironment (TME) is acidosis. Production of lactic acid by tumor cells results in an acidic environment of pH ~6.2-6.5, contrasting with pH ~7.4 found in normal tissues (11–13). The physicochemical environment of tumors profoundly shapes tumor-immune responses. It inhibits the proliferation and cytotoxic activities of CD8 T and NK cells (14, 15) and the differentiation of monocytes into DCs, thus affecting anti-tumor T cell responses (16). However, mechanisms by which it does so are incompletely elucidated. Given that cytokines interact with their receptors in the extracellular space, we asked whether the acidic extracellular environment of tumors compromises the activity of IL-2 within tumors.

## RESULTS

### Acidic extracellular environment disrupts IL-2 signaling

We first asked whether acidic pH, similar to that found within the TME, alters IL-2 signaling and activity. We found that IL-2-driven STAT5 phosphorylation within pre-activated CD8<sup>+</sup> T cells was substantially reduced when cells were cultured in media acidified to pH 6.5 (reflecting the pH found within tumors) from pH 7.5 through addition of HCl (Fig. 1A and Fig. S1A and B). IL-2 appears to be a weak agonist at acidic pH, with the amplitude of STAT5 phosphorylation, rather than the potency ( $EC_{50}$ ) being affected. Similar results were found when media was acidified through addition of lactic acid, but not through addition of NaCl (Fig. 1B). Interestingly, pH sensitivity was not unique to IL-2, with many other cytokines also exhibiting pH dependency (Fig. S1C and D). These preliminary data suggest that activity of several cytokines might be regulated by the pH of the extracellular environment in which they operate.

We observed that IL-2 activated STAT5 to the same extent at pH 6.5 and 7.5 in resting IL-2R $\alpha$ -negative CD8<sup>+</sup> T cells, in contrast to IL-2R $\alpha$ -positive pre-activated CD8<sup>+</sup> T cells, suggesting that acidic pH interferes with the binding of IL-2 to IL-2R $\alpha$  (Fig. S1E). To test this hypothesis, we took advantage of previously characterized IL-2R $\alpha$ <sup>+</sup> and IL-2R $\alpha$ <sup>-</sup> YT cell lines (17). Similar to pre-activated CD8<sup>+</sup> T cells, IL-2-driven signaling in IL-2R $\alpha$ <sup>+</sup> YT cells but not IL-2R $\alpha$ <sup>-</sup> YT cells was diminished under acidic pH (Figure S1F), confirming that binding of IL-2 to IL-2R $\alpha$  is pH-dependent. Moreover, using IL-2 surface-displayed on yeast, and microscale thermophoresis (MST), we confirmed that IL-2:IL-2R $\alpha$  binding is severely reduced at pH 6 or lower (Fig. 1C and Fig. S1G). IL-2 binding to IL-2R $\beta$  was only weakly affected by changes in acidic pH (Fig. S1H), indicating that this is a specific effect affecting the IL-2:IL-2R $\alpha$  interaction.

## **IL-2 anti-tumor activity is blocked by the acidic TME**

We next investigated whether the acidic pH found in the TME negatively impacts IL-2 therapy. We administered bicarbonate *in vivo* to neutralize the acidic pH of the TME (6). Combining bicarbonate treatment with IL-2 (IL-2 conjugated to the Fc portion of human IgG4 (Fc-IL-2) to extend the half-life of IL-2 *in vivo*) improved anti-tumor responses in the B16.SIY melanoma model (Fig 1D and S2A-C). Since lactic acid released by tumors is one of the major contributors to the acidic TME, we used previously described B16.SIY melanoma cells lacking expression of lactate dehydrogenase A and B (LDHA/B) to further assess the effect of intratumoral acidosis on IL-2 therapy (13). Mice were injected with wild type (WT) B16.SIY cells or with LDHA/B double knock-out (LDHA/B DKO) B16.SIY cells and treated with IL-2 (Fig. S2D). Fc-IL-2 therapy minimally reduced tumor growth and increased survival in mice bearing B16.SIY WT tumors (Fig. 1E and S2E). However, in mice bearing LDHA/B DKO B16.SIY tumors, Fc-IL-2 therapy significantly reduced tumor growth and increased survival (Fig. 1D and S2E), again suggesting that tumor acidosis impairs the efficacy of IL-2 therapy.

We evaluated IL-2 activity in CD8<sup>+</sup> T cells from WT and LDH DKO B16.SIY tumor-bearing mice by directly measuring pSTAT5 levels via flow cytometry in blood versus tumor-infiltrating CD8<sup>+</sup> T lymphocytes upon IL-2 administration. While no difference was observed in the levels of IL-2-induced STAT5 phosphorylation in blood CD8<sup>+</sup> T cells (Fig. 1F), STAT5 signaling was significantly reduced in tumor-infiltrating CD8<sup>+</sup> T cells within WT tumors compared with LDH-DKO tumors (Fig. 1G), demonstrating that IL-2 signaling is diminished by the acidotic environment of tumors. Fc-IL-2 treatment did not significantly increase the number of CD8<sup>+</sup> T tumor-infiltrating lymphocytes (TIL) or the ratio of CD8<sup>+</sup> T cells to Treg cells in LDHA/B DKO B16.SIY as compared with B16.SIY tumors (Fig. S2F-I). However, in LDHA/B DKO B16.SIY

tumors, Fc-IL-2 treatment markedly increased the capacity of CD8 TIL to produce IFN- $\gamma$  and TNF (Fig. 1H, I) and reduced the frequency of exhausted CD8<sup>+</sup> T cells (Fig. 1J, K). These findings show that the acidic pH found within tumors inhibits IL-2-driven immunotherapy responses.

### **Engineering of a pH-selective IL-2 mutein**

Given that IL-2 is unable to function at acidic extracellular pH, we used directed evolution to identify IL-2 mutants with improved binding to IL-2R $\alpha$  at low pH. We created mutant libraries of IL-2 by introducing mutations to the 13 amino acid residues at its interface with IL-2R $\alpha$  (Fig. 2A and Fig. S3A, B) using degenerate “NDT” codons encoding for Gly, Val, Leu, Ile, Cys, Ser, Arg, His, Asp, Asn, Phe, and Tyr amino acids. The mutant library was displayed on the surface of yeast by fusion to the yeast protein Aga2p (Fig. 2A). *In vitro* directed evolution was performed by sequential enrichment of yeast binding decreasing concentrations of the IL-2R $\alpha$  ectodomain at pH 5 (Fig. 2A), leading to the identification of an IL-2 variant, hereinafter named Switch-2, characterized by Thr37His, Arg38Leu, Thr41Ser, Phe42Tyr, and Lys43Gly mutations (Fig. S3A, B). We found that Switch-2 not only displayed higher binding to IL-2R $\alpha$  at low pH but that its behavior was pH-selective, reflected in lower binding at neutral pH as compared to WT IL-2 (Fig. 2B and S3C). Mutations in Switch-2 did not alter its affinity towards IL-2R $\beta$  at neutral and acidic pH compared to IL-2 (Fig. S1H and S3D). Next, we assessed the ability of IL-2 and Switch-2 to interact with IL-2R $\alpha$  on the membrane of living cells at neutral versus acidic pH using single-molecule total internal fluorescence (TIRF) microscopy (Fig. 2C). For this purpose, IL-2R $\alpha$  fused to an N-terminal SNAPf-tag was stably expressed in HeLa cells and sub-stoichiometrically labelled with SNAP-Surface 547 to ensure robust quantification by single molecule localization. After adding DY647-labelled IL-2 and Switch-2, respectively, IL-2R $\alpha$  and IL-2 densities were

measured in individual cells by dual-color single molecule localization microscopy to quantify relative binding levels at different pH (Fig. 2C, D and Movie S1-4). These experiments showed substantially reduced IL-2 binding to IL-2R $\alpha$  at pH 6 as compared to neutral pH. By contrast, Switch-2 showed an opposing relationship, exhibiting a strong ligand-receptor interaction at acidic pH and minimal interaction at neutral pH, again confirming its pH-selective binding to IL-2R $\alpha$  (Fig. 2D). Analysis of thermal unfolding profiles revealed that IL-2 and Switch-2 exhibited comparable thermal stability not affected by low pH (Fig. S3E), indicating that low pH specifically inhibits IL-2 signaling by hindering cytokine-receptor interaction and not by reducing protein stability in the cellular context.

To determine the structural basis by which Switch-2 exhibits pH-dependent receptor binding, we solved the structure of the Switch-2:IL-2R $\alpha$  complex to 3.2-Å resolution (Fig. 2E). Superposition of the complexes formed by Switch-2 and wild-type IL-2 showed no major perturbations in their receptor binding architecture, with a root mean square deviation (RMSD) of 1.56 Å. At the Switch-2:IL-2R $\alpha$  binding interface, side-chain densities were clear for the amino acid mutations found in Switch-2 (Fig. S4A). Despite overall similarity in the topology of binding between the IL-2 and Switch-2 complexes, the electrostatic interaction networks of the two structures differed significantly in the mutated region (Fig. 2E, F). In the IL-2:IL-2R $\alpha$  structure an extensive network is observed. Inter-chain salt bridges are located at either end of this region, formed by Glu29:Lys43 and Asp6:Arg38 of IL-2R $\alpha$  and IL-2 respectively (Fig. 2F). The side chain of Arg38 is positioned such that it may form a further hydrogen bond to His120 of IL-2R $\alpha$ , which itself can also form a second hydrogen bond to Asn27 of IL-2R $\alpha$  (Fig. 2F). Much of this network is lost in Switch-2, replaced with just a single inter-chain hydrogen bond between Tyr42 of Switch 2 and Asn27 of IL-2R $\alpha$  (Fig. 2F).

A close examination of the IL-2-IL-2R $\alpha$  binding interface reveals a putative "pH Switch" consisting of the interaction between Arg38 in IL-2 and His120 in IL-2R $\alpha$  (Fig. 2F). We hypothesized that at the low pH in the TME, His120 would become protonated, resulting in release of IL-2 from IL-2R $\alpha$ , and therefore lack of signaling. To test this hypothesis, we ran molecular dynamics (MD) simulations of the IL-2-IL-2R $\alpha$  complex and Switch-2-IL-2R $\alpha$  complex with histidine side chains protonated (corresponding to pH 6) or neutral (mimicking pH 7) and examined the structural stability of the complexes (Fig. S4B). For IL-2-IL-2R $\alpha$  at pH 6, the complex fully dissociated within 4  $\mu$ s in two out of five replica simulations, while the complex did not dissociate within 4  $\mu$ s in any of the five replicas at pH 7, suggesting that the lowered stability of IL-2-IL-2R $\alpha$  at acidic pH is due to protonation of histidines. In line with this, in the simulations that show dissociation, Arg38 and His120 are separated before the interaction interface is fully disrupted (Fig. S4C and Movie S5). For Switch-2-IL-2R $\alpha$ , the complex did not dissociate within 4  $\mu$ s in any of the five replicas at pH 6 or pH 7, suggesting that the decreased pH sensitivity of Switch-2 is due to loss of the Arg38-His120 interaction. To ensure that dissociation was not the result of protein unfolding caused by high temperature in the simulations, we calculated the backbone RMSD over time for IL-2 and the IL-2 binding domain of IL-2R $\alpha$  and we observed in both cases that there is no substantial unfolding (Fig. S5). Interestingly, Switch-2 has a histidine substitution at position 37, which is near Asp4 and Asp5 in IL-2R $\alpha$  (Fig. 2F). It is thus tempting to speculate that Switch-2 presents a distinct "pH Switch" centered around His37, which reinforces the stability of the Switch-2:IL-2R $\alpha$  interface under acidic conditions.

Next, we investigated Switch-2 functionality at acidic pH. First, we characterized the levels of STAT5 phosphorylation induced by IL-2 and Switch-2 in non-preactivated and pre-activated CD8<sup>+</sup> T cells at pH 7.5 and 6.5. In resting IL-2R $\alpha$ -negative CD8<sup>+</sup> T cells, both IL-2 and Switch-

2 induced comparable STAT5 activation at pH 6.5 and 7.5 (Fig. 2G). In pre-activated CD8<sup>+</sup> T cells however, IL-2 triggered stronger STAT5 activation at pH 7.5 than at pH 6.5 (Fig. 2H). Switch-2, on the other hand, exhibited opposing behavior, triggering more potent STAT5 activation at pH 6.5 than at pH 7.5 (Fig. 2H). Similar results were obtained comparing IL-2R $\alpha$ <sup>-</sup> and IL-2R $\alpha$ <sup>+</sup> YT cells (Fig. S6A, B). We further confirmed that the pH-selective behavior of Switch-2 is dependent upon IL-2R $\alpha$ , observing its loss when the *Il2ra* gene was disrupted using CRISPR in pre-activated cells (Fig. S6C). Similar results were obtained in lactic acid-containing low pH media (Fig. S6D). STAT5 signaling appeared to be more sensitive to acidic pH than other IL-2-driven signaling pathways, including ERK1/2, Akt, S6R, which displayed distinct levels of pH sensitivity (Fig. S6E-H). Stimulation of Treg cells with IL-2 and Switch-2 at pH 6.5 and 7.5 yielded comparable results to those obtained with pre-activated CD8<sup>+</sup> T cells (Fig. S6I).

### **Switch-2 triggers more potent CD8<sup>+</sup> T cell effector function at acidic pH**

IL-2 drives T cell expansion and acquisition of effector functions, including the production of IFN- $\gamma$  (18). Consistent with prior studies, we observed that acidic pH inhibits T cell expansion during the activation phase (Fig. S7A) (14) and T cell effector functions (19). We therefore investigated the ability of CD8<sup>+</sup> T cells stimulated with either IL-2 or Switch-2 to expand and produce effector cytokines in neutral and acidic pH conditions. CD8<sup>+</sup> T cells were initially activated with anti-CD3 and anti-CD28 antibodies at pH 7.5, and then switched to either pH 7.5 or 6.5 media in the presence of IL-2 or Switch-2. Whereas IL-2 induced CD8<sup>+</sup> T cell proliferation at pH 7.5, its effect was reduced at pH 6.5 (Fig. S7B, C). Switch-2, on the other hand, induced CD8<sup>+</sup> T cell proliferation both at pH 7.5 and 6.5 (Fig. S7B, C). Considering that cytokine secretion is pH-sensitive (20–23), we next studied cytokine secretion profiles by activated CD8<sup>+</sup> T cells stimulated with IL-2 or Switch-2 at pH 7.5 or 6.5. Expansion in IL-2 elicited strong cytokine

secretion by CD8<sup>+</sup> T cells at pH 7.5, but almost fully lost its activity when cells were cultured at pH 6.5 (Fig. 3A). Switch-2 on the other hand, elicited almost a mirror image in terms of pH-selectivity, triggering stronger cytokine release by CD8<sup>+</sup> T cells at pH 6.5 than at pH 7.5 (Fig. 3A). Moreover, at acidic pH, cytokines associated with effector function, such as IFN- $\gamma$ , GM-CSF, and TNF were upregulated to a greater extent in cells expanded with Switch-2 than with IL-2 (Fig. 3A) (24). These results were confirmed using intracellular staining and flow cytometry (Fig. 3B and Fig. S7D, E).

To further define the effects of extracellular acidic pH on IL-2 activity at the molecular level, we performed RNA-seq analysis on CD8<sup>+</sup> T cells after 4 hours of stimulation with IL-2 variants in neutral or acidic pH conditions. Remarkably, principal component analysis of global gene expression profiles showed that cells treated with Switch-2 at pH 7.5 and 6.5 grouped together with cells treated with IL-2 at pH 6.5 and 7.5, respectively (Fig. 3C). In keeping with these results, gene set enrichment analysis (GSEA) showed that differentially expressed genes between Switch-2 and IL-2-stimulated cells at pH 6.5 were significantly enriched for IL-2-signature genes (25) generally induced by IL-2 at pH 7.5 (Fig. S8A). This data further supports the preferential activity of Switch-2 in acidic versus neutral pH. To identify IL-2-driven genes most sensitive to the effects of pH, we compared IL-2- and Switch-2-driven genes in CD8<sup>+</sup> T cells cultured at pH 7.5 and pH 6.5. While the number of IL-2-induced genes at neutral pH was severely attenuated at acidic pH, the number of genes induced by Switch-2 at neutral and acidic pH was comparable (Fig. S8B). Differentially-expressed genes were grouped into nine unique clusters (Fig. 3D and Data S1), with clusters 1 and 2 enriched in immune-related gene sets, including those involved in IL-2-STAT5 signaling (Fig. S8C). Cluster 2 comprised IL-2-driven genes whose expression levels were significantly reduced at acidic pH (Fig. 3D). Switch-2, on the other hand, induced upregulation of

these genes at acidic pH while exhibiting weak activity at neutral pH (Fig. 3D). Cluster 2 included genes associated with T cell activation and effector function (*Hk2*, *Ifng*, *Il2ra*, *Il18r1*, *Ccl17*, *Cxcl10*, *Gzma* and *Gzmb*) (18, 26, 27) (Fig. 3E and Fig. S8D-F). Some IL-2-induced genes, such as *Bcl2* and *Cish*, show less sensitivity to changes in pH, agreeing with our data showing that pH differentially affect IL-2 signaling (Fig. 3E).

Taken together, these data support the notion that acidic pH limits IL-2-induced gene expression programs within CD8<sup>+</sup> T cells, and that the pH-selective activity of Switch-2 is reflected in the global gene expression changes it induces at acidic and neutral pH.

A pH-selective effect of Switch-2 versus IL-2 on STAT5 signaling within murine CD8<sup>+</sup> T cells could be observed *in vitro* (Fig. S9A). We next characterized binding and signaling activity of Switch-2 *versus* IL-2 *in vivo*. IL-2 binding is followed by rapid internalization of the IL-2-IL-2R complex (28). To trace IL-2 binding and/or uptake *in vivo*, we administered AF647-labelled Fc-IL-2 and Switch-2 to B16.SIY tumor-bearing mice and analyzed its binding/uptake by CD8<sup>+</sup> T cells 30 min after the injection of the labeled IL-2 on day 11 when there was no difference in tumor size between IL-2- and Switch-2-treated mice. We found that IL-2 was preferentially taken up by IL-2R $\alpha$ <sup>+</sup> CD8<sup>+</sup> T cells in peripheral blood and lung compared with those found within the tumor or tumor-draining lymph-nodes (tdLNs), which are considered acidic niches (Fig 3F and Fig. S9B-F) (29). By contrast, Switch-2 was preferentially taken up by IL-2R $\alpha$ <sup>+</sup> CD8<sup>+</sup> T cells within the tumor and tdLNs compared with those in peripheral blood and lung (Fig. 3F and Fig. S9B-F). Moreover, by selecting for each condition CD8<sup>+</sup> TILs expressing comparable levels of IL-2R $\alpha$ , it is possible to observe that Switch-2 uptake by CD8<sup>+</sup> TILs is stronger than IL-2 uptake, opposite to what we observed in the lung (Fig. 3F). IL-2R $\alpha$  is a direct target of IL-2 induced pSTAT5. Correspondingly, in contrast to IL-2, Switch-2 treatment led to higher IL-2R $\alpha$  expression on CD8<sup>+</sup>

T cells within tumor and tdLNs compared to blood and lung CD8<sup>+</sup>T cells. Furthermore, in line with these data, Fc-IL-2 induced STAT5 phosphorylation preferentially in CD8<sup>+</sup> T cells in the blood, while Fc-Switch-2 triggered STAT5 phosphorylation at a greater extent in the tumor and tdLN (Fig. S9G-L). Overall, these observations confirm the preferential *in vivo* activity of Switch-2 within acidic pH tissue environments.

### **Switch-2 elicits potent anti-tumor immune responses**

High-dose IL-2 treatment can activate cytotoxic T and Natural Killer (NK) cell-mediated tumor killing, resulting in complete responses in 7% of metastatic melanoma patients treated (30). Yet its therapeutic efficacy is limited by poor activation of TILs within the TME. Our data demonstrated that intra-tumoral acidosis profoundly limits IL-2 activity within the TME (Fig. 1C-K and Fig. S2). Indeed, a large number of TILs within the tumor are dysfunctional (31). Importantly, TILs isolated from tumors can be reactivated and expanded *in vitro* in the presence of IL-2. These data suggest that improper targeting and function of IL-2 within the TME might limit its *in vivo* efficacy. Given its enhanced activity at acidic pH, we tested the therapeutic efficacy of Switch-2 in four different tumor models. Switch-2 therapy led to stronger anti-tumor responses compared to IL-2 in the immunogenic MC38 colon carcinoma model, with more than one third of animals achieving full remission (Fig. 4A and Fig. S10A, B). The cured animals rejected a subsequent rechallenge with MC38, demonstrating the induction of durable anti-tumor immunity by Switch-2 (Fig. 4B). In the 4T1 mammary cancer model, Fc-Switch-2 treatment significantly reduced the rate of tumor growth while Fc-IL-2 had a minimal effect (Fig. 4C and Fig. S10C-F). Similar results were observed in the B16.SIY tumor model, where Fc-Switch-2 therapy significantly delayed tumor growth and increased survival (Fig. 4D and Fig. S10G, H). Notably, when Fc-Switch-2 therapy was combined with sodium bicarbonate treatment, the beneficial anti-

tumor effect of Switch-2 was completely abrogated, further supporting pH-switchable nature of Switch-2 *in vivo* (Fig. S10I-K). Moreover, the combination of anti-PD-L1 and Switch-2 treatment controlled established B16.SIY tumors more effectively than anti-PD-L1 and IL-2 treatment alone (Fig. S11). Overall, these data demonstrate potent anti-tumor efficacy of Switch-2 in a variety of solid tumor models.

Previous studies have shown that lactic acidosis in tumors is less prevalent in small tumors such as early metastatic lesions (32). Thus, we investigated the effect of Switch-2 on anti-tumor immunity to lung metastases. Mice were intravenously injected with B16-F10-mCherry-OVA tumor cells and treated with IL-2 or Switch-2 therapy for five days. Both Fc-IL-2 and Fc-Switch-2 induced robust anti-tumor responses (Fig. S12A-C) with concomitant increase in the frequency of lung SIINFEKL peptide:MHC tetramer-binding CD8<sup>+</sup> T cell populations compared to the untreated group, although the relative frequency of CD8<sup>+</sup> and Treg cells remained unchanged (Fig. S12D-G). Furthermore, the number of NK cells in tumor-bearing lungs was significantly increased by Fc-IL-2 and Switch-2 treatment, although Switch-2 had a stronger effect (Fig. S12H). Overall, these data reveal potent anti-tumor efficacy of both IL-2 and Switch-2 in driving immunity to early metastatic lesions.

To gain mechanistic insight into how Switch-2 leads to more potent anti-tumor responses, we characterized tumor infiltrating lymphocytes and draining lymph node cells using the B16.SIY model using flow cytometry (Fig. 4E-H and Fig. S13). Switch-2 and IL-2 triggered a small but not significant increase in the CD8/Treg ratio as compared to PBS-treated controls (Fig. S13A-D). Switch-2, on the other hand, induced greater CD8<sup>+</sup> T cell proliferation with concomitant increase in the frequency of SIY antigen-specific CD8<sup>+</sup> TIL and an increase in the frequency of infiltrating NK cells (Fig. 4E, F and S13E, F), a feature of effective IL-2 anti-tumor responses. This was

accompanied by greater IFN- $\gamma$  and TNF production by CD8<sup>+</sup> T cells in Switch-2 treated animals (Fig. 4G, H and S13G, H). Notably, a higher fraction of CD8<sup>+</sup> TILs in Switch-2-treated animals had a CD44<sup>+</sup> effector phenotype, yet no major changes was observed in the levels of the exhaustion markers PD-1 and TIM3 compared to IL-2-treated animals (Fig. S13I-M). Similar results were obtained in tdLN, including increased frequencies of tumor-specific CD8<sup>+</sup> T cells upon Switch-2 treatment versus IL-2 (Fig. S14), consistent with our previous data demonstrating superior activity of Switch-2 in LNs (Fig. S9D, E). In agreement with these observations, FTY720 treatment, which inhibits immune cell egress from lymph nodes, resulted in reduced anti-tumor responses by both IL-2 and Switch-2 (Fig. S14H-K). However, Switch-2 treatment retained higher activity than IL-2 treatment in combination with FTY720 administration, supporting the idea that Switch-2 is more active than IL-2 within the TME. Overall, these data indicate that the superior anti-tumor activities of Switch-2 are mediated via induction of effector CD8<sup>+</sup> T cells responses.

To gain a deeper insight into how Switch-2 regulates CD8<sup>+</sup> TILs, we performed single-cell RNA-seq analysis of TILs from B16.SIY tumors treated with Fc-IL-2 or Fc-Switch-2. Clusters 5 and 6 contained cytotoxic CD8<sup>+</sup> T cells with a higher frequency of *Klrd1* (CD94) and *Gzma*, expression, respectively, while both clusters expressed *Itgb1*, which encodes CD29 (Fig. 5A, B and S15A, B and Data S2) (33–35). We observed that the distribution of the CD8<sup>+</sup> TILs from the IL-2 and Switch-2-treated mice was mostly overlapping and distinct from the PBS group (Fig. S15C), and characterized by higher proportion of proliferating cells (Fig. S15D). Importantly, however, Switch-2 treatment caused an increase in the frequency of cytotoxic CD8<sup>+</sup> T cells forming clusters 5 and 6 (Fig. 5C). Analysis of differentially expressed genes between Switch-2 versus IL-2 groups confirmed Switch-2 treatment increased expression of genes associated with cytotoxic T cell function (Fig. 5D and Data S3).

### **Reduced systemic toxicity upon Switch-2 therapy**

A major limitation of current IL-2 therapies is their high systemic toxicity, characterized by vascular leak syndrome (36). We hypothesized that Switch-2 therapies would be less toxic, due to its low activity at neutral pH found in peripheral tissues. To test this, we subjected mice to high-dose therapy with the two IL-2 variants. We found that high IL-2 doses induced pulmonary oedema as indicated by increased wet weight of lungs following treatment, whereas high dose Switch-2 therapy caused substantially less pulmonary oedema and vascular permeability (Fig. 6A-C). This was paralleled by reduced activity of Switch-2 in the periphery and lungs in mice injected with Switch-2 compared to IL-2 (Fig. S9D-I) (29) as well as lower percentages of NK cells in the periphery in mice injected with Switch-2 (Fig. 6D, E). On the other hand, we found that Switch-2 increased the numbers of NK and cells in the LNs at higher extent than IL-2 (Fig. 6F). These data further demonstrate Switch-2 displayed biased activity towards acidic pH tissue environments *in vivo*, thus leading to strong anti-tumour activities with minimal peripheral toxicity.

### **DISCUSSION**

Collectively, these data demonstrate that cytokines are exquisitely sensitive to the pH of the tissue in which they operate. The practical implications of these findings are significant. By exploiting directed evolution, we improved the tissue-specific activity, efficacy and systemic toxicity profile of IL-2, defining Switch-2 as a potential new immunotherapy for cancer, alone or in combination with checkpoint blockade or adoptive cell therapy.

Currently, the majority of new IL-2 therapeutics are focused on biasing the activity of IL-2 towards its dimeric receptor, which consists of IL-2R $\beta$  and IL-2R $\gamma$ , and away from its high affinity trimeric receptor, which includes IL-2R $\alpha$ . These new IL-2 therapies stimulate NK cells

and certain subsets of T cell expressing the dimeric, and not the trimeric, form of the receptor. However, this approach fails to exploit expression by highly-activated tumor-specific T cells of both IL-2R $\alpha$  and IL-2R $\beta$ . In addition, this approach expands peripheral NK cells, which have been shown in mice to cause vascular leak syndrome (37). Switch-2 represents a highly differentiated therapy in which the balance of signaling has been adjusted to favor the trimeric form of the IL-2 receptor only in the acidic tumor environment while significantly reducing its activity in peripheral blood. Switch-2 challenges the dogma that selective binding to dimeric IL-2 receptor is the optimal approach for tumor therapy, and improves IL-2 bioactivity within the tumor microenvironment while avoiding IL-2 mediated toxicity. While here we focus on IL-2, our data show that pH sensitivity might be a generalizable phenomenon relevant to a broad spectrum of cytokines; however, more in depth studies are necessary to confirm this observation. Our findings therefore provide a basis for exploring the effect of pH and other physicochemical characteristics of the extracellular environment on cytokine activity and function in healthy and diseased tissues.

## **MATERIALS AND METHODS**

### **Cell culture and media**

B16.SIY WT and B16.SIY LDHA/B DKO (kindly provided by Marina Kreutz, University of Regensburg) (13), IL-2R $\alpha$ - YT (kindly provided by Jamie Spangler, John Hopkins University) and IL-2R $\alpha$ + YT (38), and 4T1 (ATCC, CRL-2539) cells were cultured in RPMI 1640 with GlutaMAX supplemented with 10% fetal bovine serum (FBS) and penicillin/streptomycin. IL-2R $\alpha$ - and IL-2R $\alpha$ + YT cells were validated by Eurofins. MC38 (Kerafast, ENH204-FP) were cultured in Dulbecco's modified MEM (DMEM) with GlutaMAX supplemented with 10% FBS, penicillin/streptomycin, 0.1 mM minimum non-essential amino acids, 1 mM sodium pyruvate, and

10 mM HEPES. B16-F10-mCherry-OVA (kindly provided by Max Krummel, University of California San Francisco) were passaged in DMEM supplemented with 10% FBS and penicillin/streptomycin. HeLa cells (ATCC, CCL-2) stably transfected with SNAPf-IL-2R $\alpha$  were cultured in MEM medium supplemented with Earle's balanced salts, glutamine, 10% FBS, non-essential amino acids, and HEPES buffer without addition of antibiotics. For baculovirus preparation and protein production, *Spodoptera frugiperda* (Sf9; ThermoFisher, 12659017) and *Trichoplusia ni* (High Five; ThermoFisher, B85502) cells were cultured in SF900 III SFM media (Invitrogen; 12658027) and in Insect Xpress media (Lonza; BELN12-730Q), respectively. Human T cells were cultured in RPMI 1640 with GlutaMAX (Gibco, 61870036) supplemented with 10% FBS, minimum non-essential amino acids, 1 mM sodium pyruvate, and penicillin/streptomycin. When the pH of the media was adjusted to conduct short or long-term experiments, HCl was used to acidify the media and 20 mM HEPES pH 6.5 was added to maintain stable the pH at 6.5 in the presence of 5% CO<sub>2</sub>. An equivalent amount of HEPES pH 7.5 was added to the media at pH 7.5. In the case of murine T cells, the media was further supplemented with 50 mM  $\beta$ -mercaptoethanol.

### **Protein production**

Human IL-2 (residues 1-133) and Switch-2 were cloned into the pFB-CT10HF vector in frame with the N-terminal gp67 and the C-terminal histidine tag; human IL-2R $\alpha$  ectodomain (residues 1-217) was cloned in the same vector with a C-terminal biotin acceptor peptide (BAP)-LNDIFEAQKIEWHW followed by a histidine tag; for *in vivo* experiments, the Fc portion of human IgG4 was cloned at the N-terminal of IL-2 and Switch-2. Proteins were produced using the baculovirus expression system. Briefly, vectors were recombined in DH10Bac bacteria (Gibco) and the generated bacmid were used to generate the baculovirus. Baculovirus was produced and amplified in Sf9 cells and used to infect High Five cells for protein expression. Two days after

infection, His-Pur Ni-NTA resin (Invitrogen; 88222) was used to capture the proteins released in the cell culture supernatant. Proteins were purified by size exclusion chromatography on a Superdex 75 Increase column (GE Healthcare; 29-1487-21). Proteins were conserved in 10 mM HEPES (pH 7.2) and 150 mM NaCl (HBS buffer). In the case of IL-2R $\alpha$ , the protein was reduced with 10 mM cysteine, alkylated with 20 mM iodoacetamide (39), and biotinylated with BirA ligase in the presence of 100  $\mu$ M biotin. For analysis of *in vivo* IL-2 uptake, Fc-IL-2 and Fc-Switch-2 were labelled with 4-fold excess of Ester NHS 647 Alexa Fluor (ThermoFisher, A20006). Proteins used for *in vivo* experiments were confirmed endotoxin-free by Pierce LAL Chromogenic Endotoxin Quantification Kit (ThermoFisher; 88282).

For microscopy experiments, IL-2 and Switch-2 were cloned into the pMAL vector in frame with N-terminal Maltose Binding Protein (MBP) and YbbR tag (DSLEFIASKLA peptide) (40), and a C-terminal histidine tag. BL21 *Escherichia coli* cells were used to express the protein upon O/N induction with 1mM IPTG at 20 °C. The periplasmic fraction was isolated by osmotic shock and recombinant proteins were captured by His-Pur Ni-NTA resin. Proteins were purified by size exclusion chromatography on a Superdex 75 Increase column. Site-specific enzymatic labelling via the ybbR-tag was performed using coenzyme A conjugated with DY647P1 maleimide (DY647, Dyomics) and the phosphopantetheinyl transferase Sfp as described previously (41).

### **Human T cell isolation and culture**

Peripheral Blood Mononuclear Cells (PBMCs) of healthy donors were isolated from buffy coats (Etablissement Français du Sang) by density gradient centrifugation using Pancoll human (Pan Biotech, P04-60500).  $200 \times 10^6$  PBMCs were stained with 15  $\mu$ l of anti-human CD8 FITC antibody (Clone HIT8a; Biolegend; 300906) for 15 min at 4 °C, washed and incubated with 70  $\mu$ l anti-FITC microbeads (Miltenyi; 130-048-701). CD8<sup>+</sup> T cells were isolated by magnetic separation using LS

columns (Miltenyi; 130-042-401) and activated for 3 days in complete media using coated anti-human CD3 antibody (Clone OKT3; Biolegend; 317326) and 2 µg/ml soluble anti-human CD28 antibody (Clone CD28.2; Biolegend; 302934). Activation was always carried on at neutral pH 7.5, except when specifically indicated. For proliferation assay, CD8<sup>+</sup> T cells were labelled with CellTrace Violet (Thermo Scientific; C34557) prior to T cell activation following the manufacturer protocol. For mRNA purification, activated CD8<sup>+</sup> T cells were rested O/N, transferred in complete media pH 7.5 or 6.5 and stimulated for 4 h with 10 nM IL-2 or Switch-2. Activated CD8<sup>+</sup> T cell used for analyzing cytokine expression and for secretome analysis were cultured for 3 days in media at pH 7.5 or 6.5 in the presence of 10 nM IL-2 or Switch-2 and subsequently stimulated for 4 h. Cell stimulation cocktail containing transport inhibitors (eBioscience; 00-4975-93) was used for cytokine expression analysis by flow cytometry. Supernatant for Luminex analysis were collected upon stimulation with cell stimulation cocktail (eBioscience; 00-4970-93).

CD4<sup>+</sup> cells were isolated using 40 µl of anti-human CD4 FITC antibody (Clone A161A1; Biolegend; 357406) following the same protocol of CD8<sup>+</sup> T cell isolation.

### **Signaling experiments**

IL-2 signaling was evaluated on YT cells, freshly isolated CD8<sup>+</sup>, pre-activated CD8<sup>+</sup> T cells after resting O/N, and on Treg cells from freshly isolated CD4<sup>+</sup> T cells. Cells were stimulated for 15 min with the indicated amount of IL-2 or Switch-2 in media at pH 7.5 or 6.5. In the case of time-course experiments cells were stimulated for 6 h, 3h, 2 h, 1 h, 30 min, 15 min with 10 nM or 10 pM IL-2. IL-2 signaling in Treg cells was evaluated after 15 min stimulation of freshly isolated total CD4 cells.

### **Sample processing and staining for flow cytometry analysis**

Cells were incubated with Zombie aqua Fixable viability kit (Biolegend; 423101) for 20 min at 4 °C and then stained for surface markers 30 min at 4 °C in MACS buffer (Miltenyi; 130-091-221) using anti-human CD8 FITC, anti-human CD3 BV711 (clone UCHT1; Biolegend; 300463), or anti-human CD25 APC (clone M-A251; Biolegend; 356110). For the analysis of cytokine expression, cells stained for surface markers were subsequently fixed and permeabilised using BD Cytotfix/Cytoperm kit (BD Biosciences; 554714). Anti-human IL-2 BV421 (clone MQ1-17H12; Biolegend, 500328), anti-human TNF $\alpha$  PE/Dazzle 594 (clone Mab11; Biolegend, 502946), and anti-human IFN $\gamma$  APC (clone B27; Biolegend, 506510) were used. All the antibodies were used at 1:100.

For dose-response and kinetic experiments, stimulated cells were immediately fixed with 2% PFA for 15 min at RT. Cells were subsequently washed with PBS and permeabilised with ice-cold methanol for 30 min on ice and fluorescently barcoded as previously described (42). In brief, individual wells were stained with a combination of different concentrations of PacificBlue (Thermo Scientific; 10163) and DyLight800 NHS-dyes (Thermo Scientific; 46421). 16 barcoded samples were pooled together and stained for surface markers with anti-human CD3 BV711, anti-human CD4 FITC or anti-human CD8 FITC and for phosphoproteins with 1:100 anti-STAT5 PE (clone 47/Stat5; BD Biosciences; 612567), 1:100 anti-ERK1/2 AF647 (clone 4B11B69; Biolegend, 677504), 1:50 anti-Akt AF647 (clone 193H2; Cell Signaling Technologies, 2337S), and 1:100 anti-S6R PE (clone D57.2.2E; Cell Signaling Technologies; 5316S) in MACS buffer for 1h at RT. In the case of signaling experiments on Treg cells, samples were washed and stained with 1:10 anti-human FoxP3 AF647 (clone 259D/C7; BD Biosciences; 560045) using the FoxP3/transcription factor staining buffer set (eBioscience; 00-5523-00).

For *in vivo* analysis of STAT5 phosphorylation, tumor-draining lymph node (tdLN) and tumor samples were mechanically disrupted on a cell strainer directly in Lyse/Fix buffer (BD Biosciences, 558049). Blood was immediately diluted in the Lyse/Fix buffer. Samples were fixed for 7 min, washed, permeabilized with Perm buffer III (BD Biosciences, 558050) for 30 min. Cells were subsequently stained for 1h at RT with 1:100 anti-mouse CD3 PerCP-Cy5.5 (clone 17A2; Biolegend, 100218), anti-mouse CD8 PE-Cy7 (clone 53-6.7; Biolegend, 10722), 1:200 anti-mouse-CD45 BV711 (clone 30-F11; Biolegend, 103147), 1:30 anti-STAT5 PE. For the other analysis, single cell suspension of murine lungs and lymph nodes were obtained by mechanical disruption on a cell strainer. Red blood cells were lysed using RBC lysis buffer for mouse (Alfa Aesar; J62150). For phenotypical analysis, B16.SIY subcutaneous tumor and lungs from B16-F10-mCherry-OVA metastatic model were cut in small pieces and digested with 1 mg/ml collagenase (Sigma, C6885) and 0.1 mg/ml DNase I (StemCell, 07470) in RPMI/25 mM HEPES for 50 min at 37 °C under shaking. The cell suspension was passed through a cell strainer and subsequently resuspended in PBS at 10<sup>6</sup> cells/ml. An equal volume of Lympholyte-M (Cedarlane; CL5031) was underlaid and the samples were centrifuged at 1,200 g for 20 min. The lymphocyte layer was collected, washed with PBS, resuspended in 4 ml of 37% isotonic solution of Percoll (Cytiva; 17089101), and centrifuged 10 min at 600 g. In the case of the lungs from the metastatic melanoma model the samples were subsequently incubated for 3 min with the RBC lysis buffer. For the *in vivo* IL-2 tracking experiments, samples were mechanically disrupted on a cell strainer. For analysis of cytokine expression, the samples from two mice were pooled together and cells were stimulated for 4 h at 37 °C with Cell Stimulation Cocktail (Thermo Fisher; 00-4675-93) After treatment with TruStain FcX (anti-mouse CD16/32) Antibody (Biolegend; 101320), samples were incubated for 10 min at RT with R-PE labelled Pro5 MHC Pentamer (ProImmune) specific for H-

2Kb SIYRYYGL or with BV421-H-2K(b)/SIINFEKL (OVA<sub>257-268</sub>) MHC Tetramer (kindly provided by NIH Tetramer Core Facility), washed and then stained for surface and intracellular markers following the same procedure described before. The following antibodies were used: 1:200 anti-mouse CD3 PerCP-Cy5.5 (clone 17A2; Biolegend; 100218), 1:200 anti-mouse CD4 BV605 (clone RM4-5; Biolegend; 100548), 1:200 anti-mouse CD4 AF700 (clone GK1.5; Biolegend; 100430), 1:200 anti-mouse CD8 AF488 (clone 53-6.7; Biolegend 100723), 1:200 anti-mouse-CD45 BV711 (clone 30-F11; Biolegend; 103147), 1:200 anti-mouse CD122 PE/Dazzle 594 (clone TM-b1; Biolegend; 123217), 1:100 anti-mouse PD-1 BV785 (clone 29F-1A12; Biolegend; 135225), 1:50 anti-mouse TIM3 BV421 (clone RMT3-23; Biolegend; 119723), anti-mouse NK1.1 BV605 (clone PK136; Biolegend; 108739) anti-mouse FoxP3 PE (clone FJK-16s; eBioscience; 12-5773-82), 1:100 anti-mouse Ki67 PE-Cy5 (clone SolA15; eBioscience; 15-5698-82), 1:200 anti-mouse NK1.1 BV605 (clone PK136; Biolegend; 108739), 1:50 anti-mouse CD44 APC-Cy7 (clone IM7; Biolegend, 103027), 1:20 CD62L APC (clone MEL-14; Biolegend, 104412), 1:100 anti-mouse CD25 BUV395 (clone PC61; BD Biosciences, 564022), 1:200 anti-mouse TNF $\alpha$  BV605 (clone MP6-XT22; Biolegend; 506329), 1:200 anti-mouse IFN $\gamma$  APC (clone XMG1.2; Biolegend; 505809).

Flow cytometry was performed using LSR Fortessa X20 (BD) instrument and data were analyzed with FlowJo software (TreeStar Inc, version 10) or with FCS express 7 (DeNovo Software).

### **Animal models**

6-weeks old female C57Bl/6JRj mice (Janvier) were subcutaneously injected in the right flank with  $3 \times 10^4$  B16.SIY WT or B16.SIY LDHA/B DKO or with  $3.5 \times 10^5$  MC38 cells in PBS and Matrigel (1:1) (Corning; 356232). For the metastatic melanoma model  $6 \times 10^5$  cells in 150  $\mu$ l PBS were intravenously injected. 20  $\mu$ g of Fc-IL-2 or Switch-2 were administered intraperitoneally

(i.p). from day 7, when the size of the subcutaneous tumor reached 100 mm<sup>3</sup>, until day 11. When indicated, mice were treated with 200mmol/l NaHCO<sub>3</sub> in the drinking water starting 3 days prior tumor injection and until the end of the experiment (23). 100 µg of *InVivo*MAB anti-mouse PD-L1 (clone 10F.2H11; BioXCell, BE0361) or *InVivo*MAB rat IgG2b isotype control (BioXCell, BE0090) were administered i.p. at 7, 10 and 13. Treatment with 50 µg FTY720 (Sigma, SML0700) was performed every 4 days by i.p. injections starting from day 5 until the end of the experiment. In the case of the MC38 model, surviving mice were rechallenged at day 88 with subcutaneous injection of 3.5x10<sup>5</sup> in the left flank in parallel with control age-matched mice. 10<sup>5</sup> 4T1 cells were injected in 6-weeks old female Balb/cByJRJ mice (Janvier) and treated with i.p. injections of 20 µg of Fc-IL-2 or Fc-Switch-2 from day 7 to day 13. Tumor was measured using a calliper and tumor volume was calculated using the formula length x width<sup>2</sup>/2. For *in vivo* analysis of STAT5 phosphorylation and IL-2 uptake, mice were sacrificed 30 min after the last injection of IL-2. In the case of IL-2 uptake studies, the last injection was performed using AF647-labelled Fc-IL-2 or Fc-Switch-2 or an equimolar amount of AF647 in the PBS-treated group. For the analysis of TILs, mice were sacrificed at day 15 after tumor injection, for B16.SIY subcutaneous model, or at day 16, for B16-F10-mCherry-OVA metastatic model. For toxicity test 20 or 50 µg of Fc-IL-2 or Switch-2 were given for 5 consecutive days by i.p. injections and mice were sacrificed the day after the last injection. The blood vessel permeability in the lung was assessed by retro-orbital injection of 50 µl of 50 mg/ml Evens blue 30 min before sacrificing the mice. Lungs were perfused with PBS, dried O/N at 80°C, weighted, and incubated O/N in 1.5 ml of formamide at 55°C. The amount of extracted dye was evaluated by measuring the OD at 260 nm and the ng of Evans blue per mg of dry lung tissue was calculated. Pulmonary oedema (pulmonary wet weight) was evaluated by measuring the wet weight after lung collection and subtracting the dry weight after

the lungs were exsiccated O/N at 80 °C. Animals experiments were conducted in accordance with the “Ministère de l'enseignement supérieur, de la recherche et de l'innovation” (protocol #19862-2019022809122912).

### **Generation and selection of IL-2 library**

Adapting a previously described protocol for yeast display (43), we cloned IL-2 cDNA in pCT302 vector for the expression in yeast. The IL-2 library was generated assembling 8 overlapping primers, among which two of them containing the homology regions necessary for the combination with the pCT302 vector (Table S1). Three of the primers had NDT codons (encoding for Gly, Val, Leu, Ile, Cys, Ser, Arg, His, Asp, Asn, Phe, Tyr amino acids) used to randomly mutate Thr37, Arg38, Thr41, Phe42, Lys43, Glu60, Glu61, Glu63, Leu66, Glu68, Val69, Asp109, and Glu110 residues. The PCR product was further amplified using Lib Fw and Lib Rv primers (Table S1), at a final concentration of 10 µM, to obtain at least 25 µg of DNA.

*S. cerevisiae* strain EBY100 was transformed by electroporation with 25 µg of insert DNA and 5 µg of the linearized and purified plasmid. Transfected yeasts were grown in SDCAA media for 1 day at 30°C and in SGCAA for 2 days at 20°C at each round of selection. The library, with a size of  $5 \times 10^7$ , was screened by magnetic-activated cell sorting (MACS) using LS column (Miltenyi; 130-042-401): the first round of selection was carried on with  $10^{10}$  cells and the subsequent ones with  $10^8$  cells to ensure at least 10-fold coverage for each round. Biotinylated IL-2R $\alpha$  ectodomain was used at different concentrations to select pH-resistant IL-2 variants: more in detail, the first two rounds were performed using IL-2R $\alpha$  tetramer at 100 nM in pH 5, the third and fourth round with 1 µM and 100 nM IL-2R $\alpha$  monomer, respectively. IL-2R $\alpha$  tetramers were generated by incubating IL-2R $\alpha$  and Streptavidin (SA)-Alexa 647 at a ratio of 4:1.

### **Crystallography**

Proteins were expressed and purified as described above. The CD25:Switch2 complex was formed by mixing CD25 at 32  $\mu$ M with Switch-2 protein at a 20% excess based on molarity followed by dialysis overnight against 20mM BisTris pH 6.0, 150 mM NaCl. The complex was purified using a pre-equilibrated Superdex 75 (10/300 GL, Cytiva) gel filtration column. The final purified complex was concentrated to 7 mg/ml using a 30 kDa cut-off Amicon Ultracel device (Millipore). The sample was prepared for crystallization by filtration through a 0.2  $\mu$ m centrifugal filtration device (Neo Biotech).

Crystallization was performed by hanging drop vapor diffusion in 24 well Linbro plates (Hampton research) by mixing drops containing 0.75  $\mu$ l each of reservoir and protein solution which was then equilibrated against 500 ml of reservoir solution. The reservoir solution consisted of 19% PEG 3350, 0.2 M sodium tartrate dibasic dihydrate and 10% glycerol, yielding a final pH of 6.9 in the crystallization drop. The plates were incubated at 18  $^{\circ}$ C, and crystals formed over the course of a week. The crystals were harvested with additional cryoprotection provided by passage through a smear of Paratone-N (Hampton research) on a glass slide and subsequent plunge cooling in LN<sub>2</sub>. Data were collected at Beamline I03 Diamond Light Source (U.K.) using an Eiger2 XE 16M detector (Dectris). The data were processed using Xia2/Dials (44) and scaled using aimless (45) from the CCP4 suite (46). Molecular replacement was performed using Phaser (47) with the IL-2 and CD25 coordinates from PDB entry 2b5i (39) used as the search model. One strong solution was found in space group  $P322_1$ , with a single complex present in the asymmetric unit. Refinement was performed using Phenix Refine (48), between cycles of manual analysis and rebuilding performed using Coot (49). Molprobit (50) was used for structure evaluation and validation. Full processing and refinement statistics are presented in Table S2.

### **RNA-seq analysis**

RNA of human CD8<sup>+</sup> T cells was purified using Quick-RNA Microprep kit (Zymo Research; R1051). Clean sequence reads were obtained by removing bad quality reads from raw data using fastp. Reads were removed when containing adapter, when containing more than 10% of uncertain nucleotides (N) in either R1 or R2 or when containing more than 50 percent low quality nucleotides (Base Quality less than 5). Read mapping and quantification were performed by Novogene using STAR v2.6.1d with mismatch=2 and FeatureCounts v1.5.0-p3 software with the GRCh38 human genome. Differential expression analysis was performed using DESeq2 (51), and heatmaps were realized with pheatmap R packages. GSEA analysis was performed using GSEA 4.1.0 and compare to the IL-2 gene signature described in Mitra S. et al. 2015 (25). Within the top 500 variable genes, 476 significantly differentially expressed genes ( $p_{adj} < 0.05$ ,  $\text{Log}_2(\text{fold change}) > 0.6$ ) were clustered by hierarchical clustering. Functional enrichment analysis was performed on clusters using enricher function from clusterProfiler R packages (52) and hallmark gene sets v7.4 from MsigDB.

### **scRNA-seq sample preparation**

Mice were sacrificed the day after the end of the therapy and tumors were excised and tumor infiltrating lymphocytes were enriched using lymphocyte M density gradient protocol. Then MagniSort mouse CD8 T cell enrichment kit (ThermoFisher, 8804-6822-74) was used to enrich for CD8<sup>+</sup> TILs from the cell suspension. An equal amount of cell from each biological replicates (n=3) was pooled together and stained using Zombie aqua Fixable viability kit, anti-mouse CD3 PerCP-Cy5.5, and anti-mouse CD8 PE (Biolegend, 100708). Live CD3<sup>+</sup>CD8<sup>+</sup> cells were sorted and used for scRNA-seq. 13,000 cells were loaded on 10x Genomics Chromium system and libraries were prepared with Chromium Next GEM Single Cell 3' Reagent Kit v3.1 (dual index) following manufacturer's instructions.

## scRNA-seq analysis

Raw sequencing data were processed and aligned to mouse genome (GRCm38) with 10x Genomic Cell Ranger pipeline (53) (version 6.1.2). Single cell data were then analyzed using Seurat (54) R package (version 4.1.0). Low quality cells with number of detected genes < 300 and mitochondrial genes RNA content > 7% and putative cell multiplets with number of detected genes > 6000 were excluded from the analysis. Single cell count data were normalized and genes with highly variable expression were identified using SCTransform methods. Using CellCycleScoring function, each cell was associated with either G1, S or G2/M cell cycle phase. Cell cycle association was done depending on expression score of genes related to each cell cycle phase in each cell. All used cell cycle genes were mouse version of human genes provided in Seurat package. The 3000 most variable genes were used to compute 30 principal components with principal component analysis (PCA). Shared nearest neighbor graphs were built using all principal components. Cells were then clustered according to shared nearest neighbor graphs using Louvain algorithm with resolution parameter set to 0.5. Embedding of cells in a 2D space was computed with Unique Manifold Approximation and Projection (UMAP) on all principal components. Small clusters of cells with high expression of genes specific to myeloid, melanoma or NK cells were removed from the dataset. Myeloid cells clusters were identified by high expression of *Cd74*, *Cd68*, *Tyrobp*. A melanoma cancer cells cluster was identified by high expression of *Mlana*. An NK cells cluster was identified by high expression of *Ncr1*, *Klrk1c*, *Tyrobp*. Remaining cells were reanalyzed using the exact same pipeline from normalization to 2D space embedding and setting resolution parameter to 0.4 for clustering. In total 12044 cells passed all filtering steps, 4045 from PBS sample, 1701 from Fc-IL-2 sample and 6298 from Fc-Switch-2 sample.

Differentially expressed genes between group of cells were determined using Wilcoxon test. Only genes expressed in at least 10% of cells in either group and with at least an average absolute log<sub>2</sub> fold change of 0.2 were tested. Multiple testing correction for p-values was done using Bonferroni correction based on the total number of genes in the dataset. Genes with adjusted pvalue < 0.05 were considered differentially expressed.

### **Statistical analysis**

Data are presented as mean ± s.e.m. of at least three independent experiments and multiple groups comparisons were performed using one-way ANOVA with Tukey's correction unless otherwise stated. Survival curves are represented as Kaplan-Meier curves and statistical significance was determined by Log-rank test with Bonferroni's correction. ns = not significant, \*p<0.05, \*\*p<0.01, \*\*\*p<0.001, \*\*\*\*p<0.0001. All the analysis were performed using Prism 9 software (GraphPad).

**Author contributions:** Conceptualization: SG, RR, IM, SM. Methodology: SG, JMF, SW, EP, FS, MGB. Investigation: SG, AC, ML, HW, JP, JY, AGC, RM, XT, PF, FET, KLL.

Visualization: SG, ML, HW, JY, AGC, RM, PF, FET. Funding acquisition: JP, RR, IM, SM.

Project administration: RR, IM, SM. Supervision: RR, IM, SM. Writing – original draft: SG, RR, IM and SM. Writing – review & editing: SG, JP, KLL, RR, IM, SM.

**Competing interests:** SG, IM, and SM are inventors on patent application (UK patent application No. 2110547.3) submitted jointly by the University of Dundee and Inserm that covers Switch-2. SM and IM holds patent royalties from Medicana Therapeutics. RR holds paid consultancies with Lyell Immunopharma and Achilles Therapeutics. RR has industrially funded collaborations with F-Star Therapeutics and AstraZeneca.

**Data and materials availability:** RNA-seq data are deposited and available in the Gene Expression Omnibus (GEO) under the accession number GSE213441. Structure of Switch-2/IL-2R $\alpha$  complex is available on PDB database under the code 7ZMZ. All relevant data are available from the corresponding author upon request.

## **Figures:**

**Fig. 1. Low pH impairs IL-2 activity.** (A) Dose-response of STAT5 phosphorylation in pre-activated CD8<sup>+</sup> T cells stimulated with IL-2 in pH 7.5 or 6.5 media. (B) Dose-response of STAT5 phosphorylation in pre-activated CD8<sup>+</sup> T cells stimulated with IL-2 in media at pH 7.5 +/-12 mM

NaCl, or in media at pH 6.5 generated by addition of 12 mM HCl or 15 mM Lactic Acid (LA). Data are the pooled results of 3 independent experiments with technical duplicates. (C) Schema showing staining of IL-2-expressing yeast with biotinylated IL-2R $\alpha$  and AF647-conjugated streptavidin (left panel). Dose-dependent binding at different pH of IL-2R $\alpha$  serial dilutions to the surface of IL-2-expressing yeast (right panel). (D) Effects of IL-2 treatment on tumor growth of B16.SIY tumors with or without NaHCO<sub>3</sub> treatment (n=12 for each group). (E) Growth and survival curves of B16 WT or LDH KO tumors (n=12 for each group). (F, G) STAT5 phosphorylation in CD8<sup>+</sup> T cells from blood (F) and tumor (G). Representative histogram plots (left panel) of STAT5 phosphorylation and scatter plots (right panels) of the mean (n=6 for each group). (H-K) Dot plots of representative samples (H, J) and percentages (I, K) showing the expression of IFN- $\gamma$  and TNF (H, I) and PD-1 and TIM3 (J, K) in CD8<sup>+</sup> T cells. Each symbol represents a single mouse (F, G, K) (n=18) or two mice pooled together (I) (n=9). Data are the pooled results of two (D-G) or three independent experiments (C, I, K). Statistical significance was determined by one-way ANOVA with Tukey's correction (D, E left panel, F, G, I, K) or by Log-rank test with Bonferroni's correction (E right panel).

**Fig. 2. Selection of a pH-resistant IL-2 variant.** (A) Schematic representation of the IL-2 mutant library expressed at the yeast surface and interacting with the biotinylated IL-2R $\alpha$  tetramer (left panel). Amino acids that were mutated during the generation of the IL-2 library are displayed in red. Histogram overlays assessing IL-2R $\alpha$  staining of the library at each round (Rd) of selection at pH 5 is shown (right panel). (B) Dose-dependent binding at different pH of IL-2R $\alpha$  serial dilutions to IL-2 or Switch-2 displaying yeasts. (C) Quantification of the IL-2/IL-2R $\alpha$  interaction at the plasma membrane of live cell by dual color TIRF microscopy with labelled IL-2R $\alpha$  and IL-2 (left panel) and representative images showing trajectories from 100 consecutive frames of

simultaneous dual color imaging of IL-2 and Switch-2 binding to IL-2R $\alpha$ -expressing HeLa at different pH. **(D)** Graph showing the IL-2 binding normalized to the IL-2R $\alpha$  cell surface expression. Each data point representing the result from a single cell. Significance was calculated by Kolmogorov-Smirnov test. **(E)** Overlay of the IL-2:IL-2R $\alpha$  and Switch-2:IL-2R $\alpha$  complex crystal structures. IL-2 and Switch-2 engage IL-2R $\alpha$  with identical geometry (RMSD=1.56Å). The RMSD represents alignment of all atoms. Superposition of the C-alpha positions of the complexes formed by Switch-2 or wild-type IL-2 (pdb entry 1Z92) along with their partner CD25, with a root mean square deviation (RMSD) of 1.53 Å<sup>2</sup> over 235 residues. IL-2 is colored in cyan and Switch-2 in slate blue. IL-2R $\alpha$  is colored in yellow for the IL-2 and Switch-2 complexes. **(F)** Close-up views of the IL-2:IL-2R $\alpha$  (left panel) and Switch-2:IL-2R $\alpha$  (right panel) binding interfaces. Hydrogen bonds and salt bridges are shown as purple dashed lines. Hydrogen bonds were defined using standard accepted values of ~2.5 to 3.5 Å, with salt bridge lengths extending to 4.5 Å. Under each inset box a two-dimensional interaction map of the IL-2:IL-2R $\alpha$  or Switch-2:IL-2R $\alpha$  interface is shown. Amino acids are depicted as nodes in the interaction maps. Interactions between amino acids are shown as solid blue lines. **(G, H)** Dose-response curve of phospho-STAT5 induced by IL-2 and Switch-2 at pH 7.5 and 6.5 in not pre-activated **(G)** and pre-activated CD8 T cells **(H)**. Data are the pooled results of two **(B)** or three independent experiments **(G, H)**.

**Fig. 3. The IL-2 mutein Switch-2 is preferentially active at acidic pH.** **(A, B)** Analysis of cytokine expressed by pre-activated CD8<sup>+</sup> T cells after 3 days of culture at pH 7.5 or 6.5 in the presence of 10 nM IL-2 or Switch-2. Cells were stimulated with PMA/ionomycin and supernatant of stimulated cells was analyzed by Luminex assay **(A)**. The bubbles represent the amount of the released cytokines that has been normalized to control condition (IL-2 pH 7.5 = 100). **(B)** Dot plot showing the expression of IFN- $\gamma$  and TNF in one representative donor out of five. **(C)** Principal

component analysis (PCA) of RNA-seq data. Pre-activated CD8<sup>+</sup> T cells from three different donors were stimulated for 4 h after resting O/N. **(D, E)** Heatmap of the 476 top variable and significant genes **(D)** and of a set of T cell-specific genes **(E)**. Gene expression is represented as z-score. **(F)** IL-2R $\alpha$ -dependent uptake of labelled Fc-IL-2 and Fc-Switch-2 in CD8<sup>+</sup> T cells from mouse tumor and lung (left panels). In the right panel the AF647 uptake within cells expressing similar levels of IL-2R $\alpha$  (red gate in the left panel) is shown.

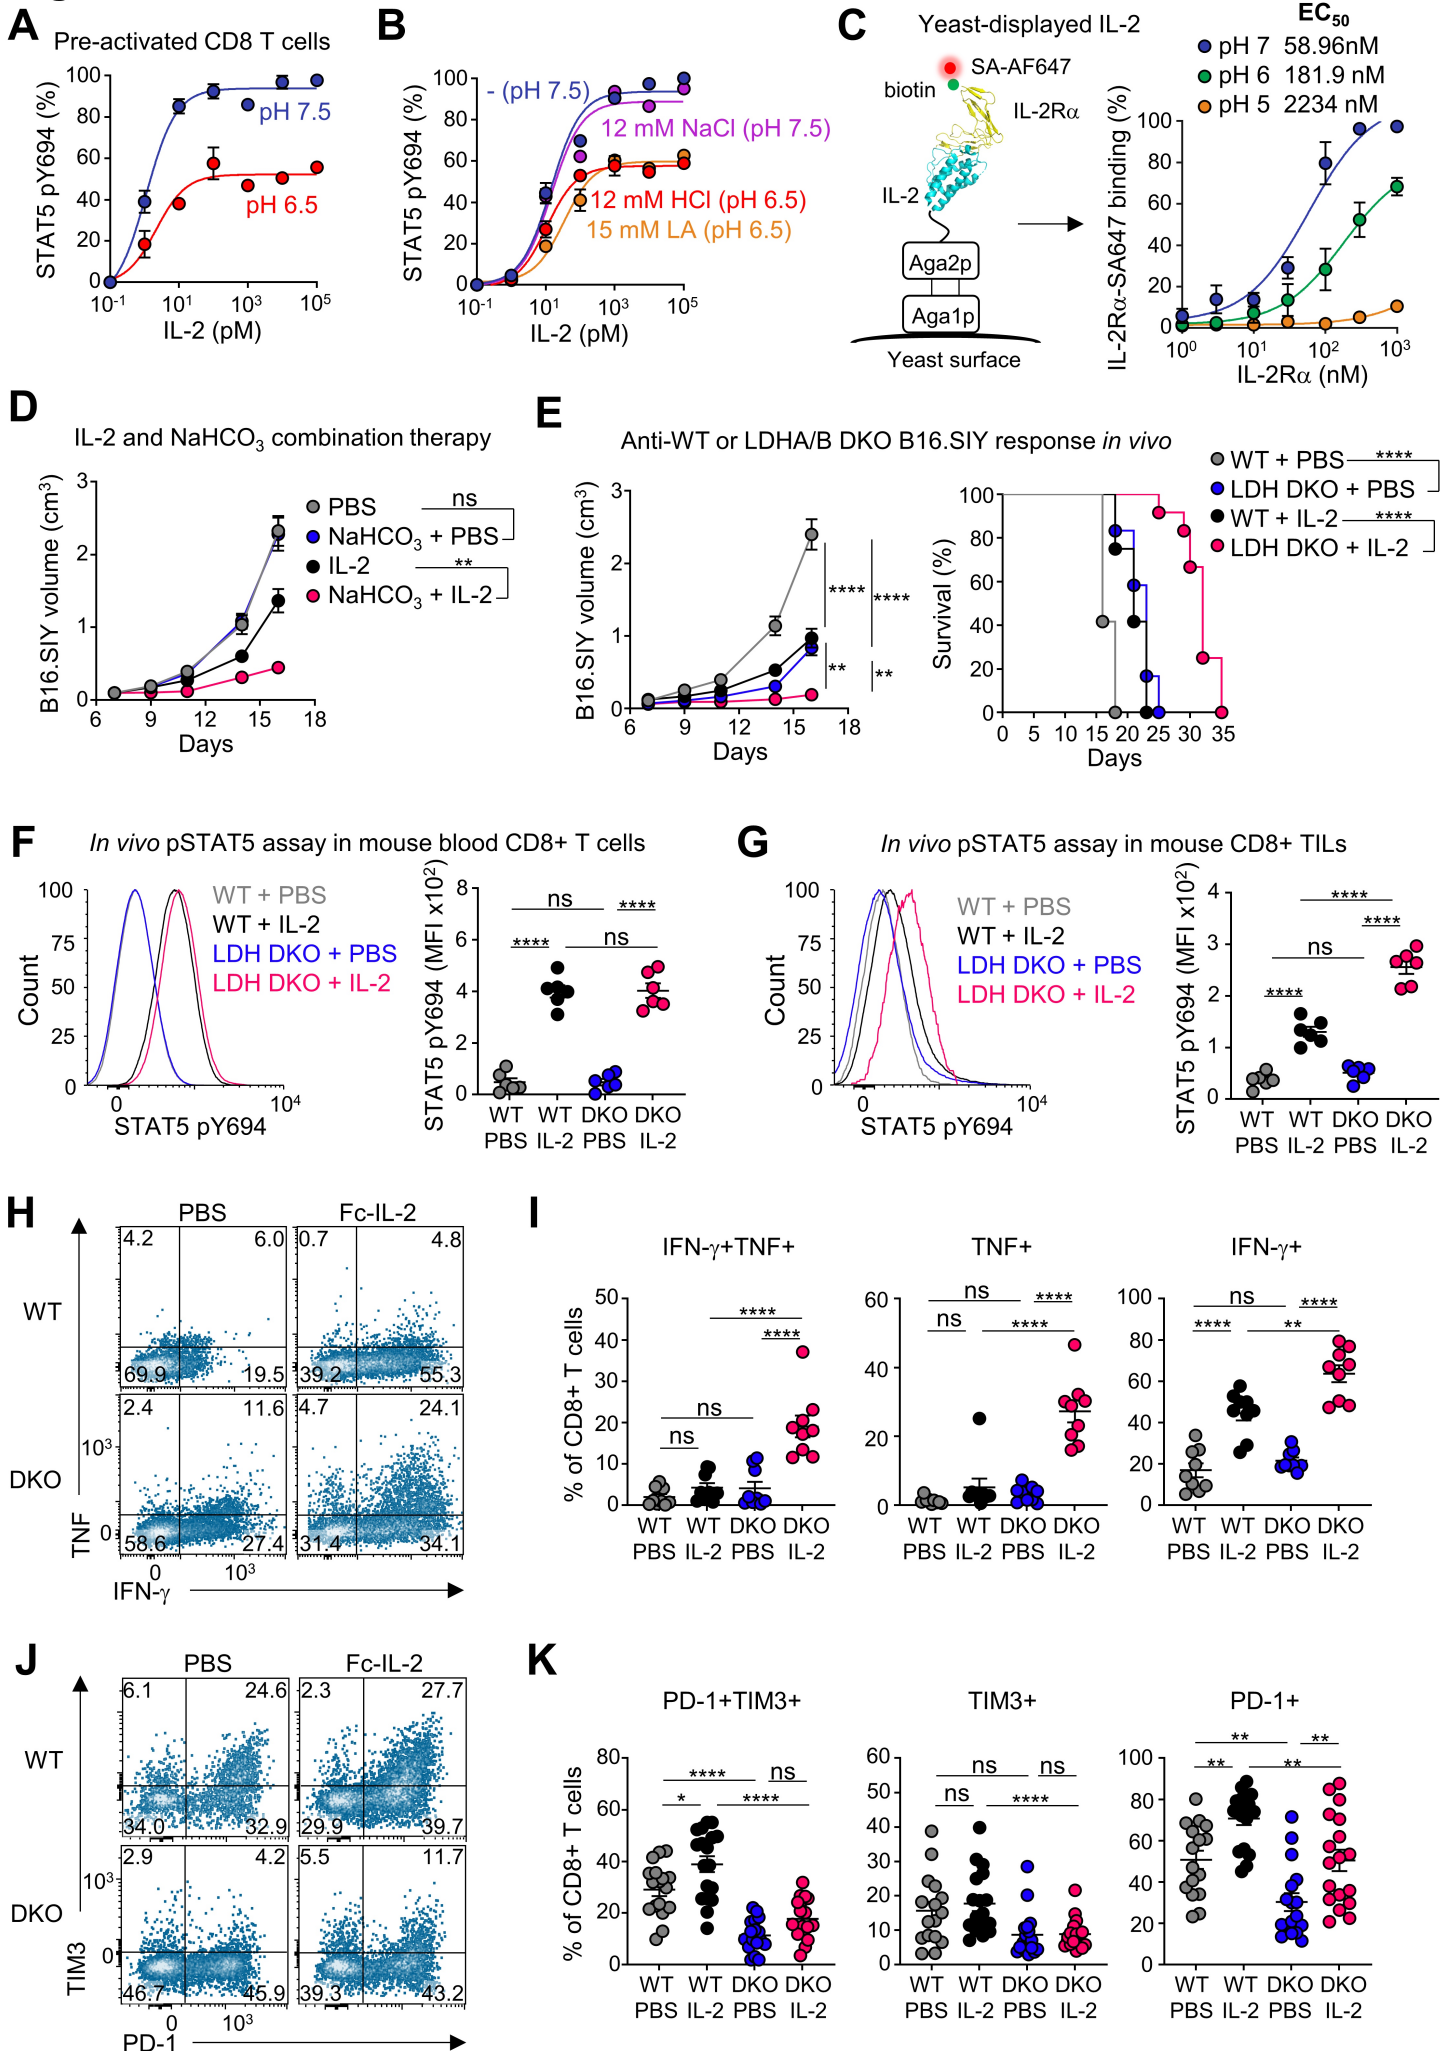

**Fig. 4. Switch-2 therapy stimulates potent anti-tumor immunity and tumor control.** **(A)** Tumor growth and survival curve of MC38-bearing mice (n=12). **(B)** Tumor volume in MC38-rechallenged and age-matched control mice (n=5). **(C)** Weight of 4T1 tumor. **(D)** Tumor growth and survival curve of B16.SIY WT-bearing mice (n=10 for PBS, n=12 for Fc-IL-2 and Fc-Switch-2). **(E, F)** Representative dot plot **(E)** and percentages **(F)** of antigen-specific CD8<sup>+</sup> T cells in B16.SIY WT-bearing mice (n=12). **(G, H)** Representative dot plot **(G)** and percentages **(H)** of TNF and IFN- $\gamma$  expression in CD8<sup>+</sup> T cell infiltrating B16.SIY WT tumor (n=9). Each symbol represents a single mouse **(C, F)** or two mice pooled together **(H)** and data are the pooled results of two **(A-F)** or three independent experiments **(H)**. Significance was determined by one-way ANOVA with Tukey's correction **(A and D left panel, C, F, H,)** or by Log-rank test with Bonferroni's correction **(A and D right panel)**.

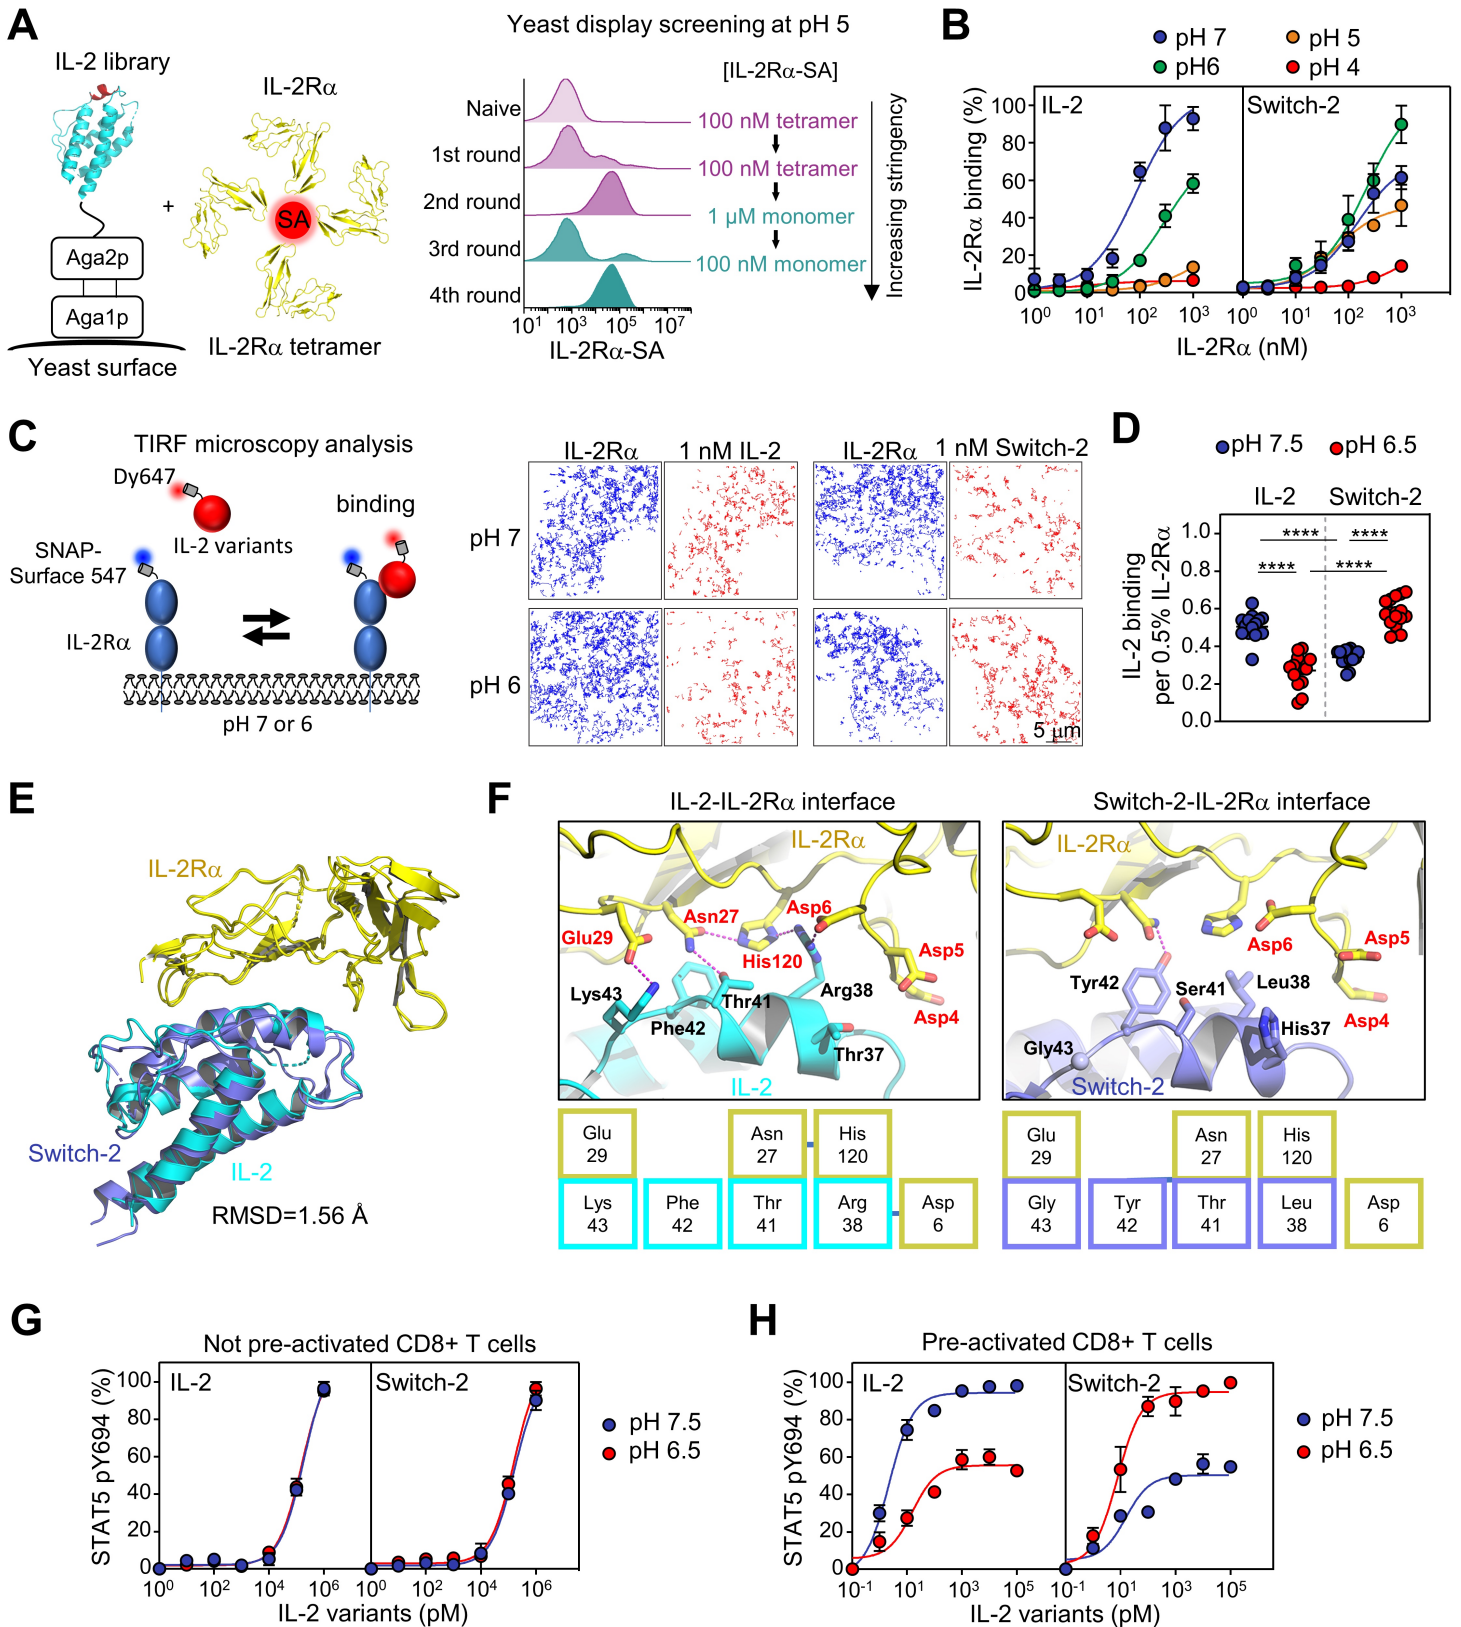

**Fig. 5. scRNA sequencing reveals induction of potent cytotoxic CD8<sup>+</sup> cell responses within tumors after Switch-2 therapy.** **(A)** UMAP from scRNA-seq colored by cluster. **(B)** Heatmap of CD8<sup>+</sup> T cell clusters depicting the top 20 differentially expressed genes of each 8 clusters. **(C)** Bar plot of the proportion of each sample in the different clusters normalized by the total number of cells of each sample. **(D)** Volcano plot of the differentially expressed genes in Fc-Switch-2 versus Fc-IL-2 sample in cluster 5 and 6.

**Fig. 6. Switch-2 drives reduced toxicity in systemic tissues.** (A) Mice were treated for 5 days with i.p. injections of 100  $\mu$ l PBS or 20 or 50  $\mu$ g of Fc-IL-2 or Switch-2 for 5 days. (B) Representative images of lung tissue stained with hematoxylin and eosin after treatment with Fc-IL-2 and Fc-Switch-2. (C, D) Pulmonary edema evaluated by lung wet weight (C) and amount of Evans blue per mg of lung tissue (D) after treatment with Fc-IL-2 and Fc-Switch-2 (n=6). (E, F) Percentage of NK cells in blood (E) and LN (F) of mice treated with either PBS, 20  $\mu$ g of Fc-IL-2 or Fc-Switch-2. (B-F) Each symbol represents a single mouse and data are the pooled results of two independent experiments. Significance was determined by one-way ANOVA with Tukey's correction.
