17 **Abstract:** Neuroprotective, anti-inflammatory and remyelinating properties of androgens are
18 well-characterized in demyelinated male mice and men suffering from multiple sclerosis.
19 However, androgen effects mediated by the androgen receptor (AR), have been only poorly
20 studied in females who make low androgen levels. Here, we show a predominant microglial
21 AR expression in demyelinated lesions from female mice and women with multiple sclerosis,
22 but virtually undetectable AR expression in lesions from male animals and men with multiple
23 sclerosis. In female mice, androgens and estrogens act in a synergistic way while androgens
24 drive microglia response towards regeneration. Transcriptomic comparisons of demyelinated
25 mouse spinal cords indicate that, regardless of the sex, androgens up-regulate genes related to
26 neuronal function integrity and myelin production. Depending on the sex, androgens down-
27 regulate genes related to the immune system in females and lipid catabolism in males. Thus,
28 androgens are required for proper myelin regeneration in females and therapeutic approaches
29 of demyelinating diseases need to consider male-female differences.

30

31 **Introduction**

32 Multiple sclerosis (MS), known as the most common cause of non-traumatic disability in young
33 adults, is characterized as an autoimmune, demyelinating and neurodegenerative pathology of
34 the central nervous system (CNS). If the early relapsing-remitting form leads to spontaneous
35 regeneration of lost myelin (or remyelination), the latter fails in progressive MS resulting in
36 irreversible neurological disabilities¹. The disease is sexually dimorphic, namely with a three-
37 fold higher prevalence in women and more severe forms occurring at a later age in men^{2,3}. Any
38 dysregulation of the female or male sexual hormones were correlated with worsening of the
39 disease⁴⁻⁶.

40 The experimental autoimmune encephalomyelitis (EAE), used as an immune model for
41 MS, led to show the neuroprotective / anti-inflammatory and remyelinating effects of estrogens
42 in females through the astroglial estrogen receptors (ER) α and the oligodendroglial ER β ^{7,8}.
43 Similarly, neuroprotective and anti-inflammatory properties of androgens - mediated through
44 the androgen receptor (AR) – were characterized in males upon their preventive⁹⁻¹² or curative¹³
45 administration in EAE animals and namely attributed to the negative selection of T cells
46 depending on AR-mediated up-regulation of the autoimmune regulator Aire in the thymus¹³.
47 Androgen remyelinating properties demonstrated in the cuprizone model of chronic CNS
48 demyelination¹⁴ and the model of focal demyelination induced by stereotactic injection of
49 lysolecithin (LPC) demonstrated AR-mediated recruitment of oligodendrocyte progenitor cells
50 (OPCs) and their differentiation into oligodendrocytes, the CNS myelinating cells^{14,15}. The
51 apparent critical role of sexual hormones in MS also led to clinical trials in relapsing-remitting
52 MS using the pregnancy hormone estriol in women and testosterone in men, which led to
53 improved subclinical markers of disease activity¹⁶ and reduced brain atrophy, respectively^{17,18}.

54 Although the hormonal environment of males and females is obviously different, it
55 should however not be restricted to the existence of high androgen levels in males, and
56 fluctuating estrogen and progesterone levels in females since males also make estrogens,
57 particularly in the brain that has high levels of aromatase enzyme converting testosterone into
58 estradiol, and females also make low levels of androgens¹⁹. In male mice, prophylactic
59 administration of estrogens reduces EAE incidence and severity¹⁰ while testosterone-induced
60 remyelination upon LPC injection requires aromatase activity for recruiting OPCs to the
61 lesion²⁰. In female mice, preventive administration of androgens beneficially controlled T cell-
62 mediated spleen secretion of the pro- and anti-inflammatory cytokines IFN- γ and IL-10,

63 respectively^{9, 21} whereas androgens prevented the contact between EAE female T cells and
64 astrocytes responsible for the production of pro-inflammatory molecules *in vitro*²².

65 However, it is not known if androgens are required for spontaneous remyelination in
66 females or how androgens may act in the female demyelinated CNS. Here, we addressed these
67 questions by using pharmacological and genetic approaches in immune and non-immune
68 models of CNS demyelination. We show strong AR up-regulation in the demyelinated lesions
69 from female mice and MS female patients mostly in microglia/macrophages, but not from male
70 animals and patients. In females, we demonstrate the synergism of androgens and estrogens for
71 increasing OPC recruitment and the unique involvement of androgens in the response of
72 microglia/macrophages to demyelination. Finally, we uncover sexual dimorphism
73 characterizing dihydrotestosterone (DHT) effects in the demyelinated CNS at the molecular
74 level.

75 **Results**

76 **AR is up-regulated in demyelinated female but not male patients**

77 We delineated *AR* transcript expression in the corpus callosum from female and male
78 mice demyelinated by LPC stereotactic injection (Fig. 1a). At 7 days post-lesion (dpl), we
79 observed a strong *AR* up-regulation in female lesions (Fig. 1b, d) while *AR* transcripts could be
80 detected at much lower level in male lesions (Fig. 1c, d). In contrast, the cerebral cortex from
81 both sexes displayed high *AR* transcription. In female lesions, *AR* and the microglial Iba1
82 staining were substantially colocalized suggesting that *AR* was mostly up-regulated in microglia
83 (and possibly infiltrated macrophages^{23, 24}) and at a much lower level in GFAP-expressing
84 astrocytes and Olig2⁺ oligodendrocytes (Fig. 1e). Antibodies directed to AR and the main
85 conversion product of testosterone, DHT, led to confirm AR expression in microglia and a clear
86 DHT staining in both nuclear and perinuclear areas (Fig. 1f-h). In males, the cortex mostly
87 displayed *AR*⁺ Iba1⁻ and *AR*⁺ GFAP⁻ cells (Fig. 1i) in agreement with the previously reported
88 neuronal expression of AR²⁵. The faint *AR* expression in the lesion incited us to visualize the
89 transcription of the estrogen receptors ER α and ER β . Both transcripts (*Esr1* and *Esr2*,
90 respectively) were observed in female and male lesions (Fig. 1j, k). However, *Esr1* expression
91 was significantly higher in male lesions compared to *Esr2* and to both *Esr1* and *Esr2* in female
92 lesions (Fig. 1l, m). Thus, the female demyelinated areas display a high level of AR protein and
93 transcripts whereas the demyelinated male lesions display quite undetectable *AR* but substantial
94 *Esr1* expression.

95 To evaluate the relevance of AR expression in MS lesions, we performed *AR in situ*
96 hybridization (ISH) and immunostaining experiments in brain sections from non-neurological
97 control and MS female and male donors (Supplementary Tables 1 and 2). White matter samples
98 were used to detect *AR* mRNA expression in immunofluorescently labelled Iba1⁺
99 microglia/macrophages. Quantification showed a significantly greater proportion of Iba1⁺ cells
100 expressing *AR* mRNA in MS samples compared to controls with a significant effect of sex, as
101 significantly more Iba1⁺ cells expressed *AR* in females (Fig. 2a, b). Within MS donors, female
102 samples showed a significantly greater proportion of *AR*⁺Iba1⁺ cells compared to males without
103 significant differences among different demyelinated lesion types (Fig. 2c). Additional female
104 and male grey matter were immunostained and showed AR protein expression in many cells
105 with the morphology of neurons, while the white matter had some but not much AR expression
106 in both sexes (Supplementary Fig. 1a,b,h,i). However, in females with MS, cells expressing AR
107 protein appeared to be increased in active lesions and perilesional areas of chronic active
108 lesions, where there is potential to remyelinate, and fewer in the centre of chronic active lesions
109 and normal appearing white matter (Supplementary Fig. 1c-f). In males, there was little AR
110 expression in active or chronic active lesions (Supplementary Fig. 1j, k). In females, some
111 lesional AR⁺ cells were CD68⁺ corresponding to activated microglia/macrophages
112 (Supplementary Fig. 1g). Also in support of these data, *AR* mRNA expression in microglia from
113 MS and control donors from a publicly available single-nuclei RNA sequencing database²⁶
114 appeared higher in MS female samples compared to males (Supplementary Fig. 1l). Altogether
115 these data confirmed that the sexual discrepancy observed in mice may be relevant in human
116 and microglia/macrophages may be a target for AR signaling during remyelination in females.

117 **Androgens induce remyelination in LPC-demyelinated females**

118 *AR* up-regulation in the demyelinated female mice and patients led us to delineate the
119 effects of testosterone and DHT, which both are AR ligands, even though testosterone may also
120 act via ERs. We induced LPC-demyelination of ovariectomized female animals that received a
121 daily intranasal administration of testosterone, DHT or vehicle starting 15 hrs after LPC
122 injection (Fig. 3a). At 7 dpl, only testosterone significantly increased the density of PDGFRα⁺
123 OPCs (p=0.001) without significant modification of the number of PDGFRα⁺ Ki67⁺
124 proliferating OPCs (Fig. 3b, c). In contrast, both molecules increased the percentage of CC1⁺
125 differentiated oligodendrocytes (p=0.0004 and p=0.0084, respectively). As expected from the
126 increased number of OPCs, the total number of Olig2⁺ oligodendroglial cells was significantly
127 increased under testosterone (Fig. 3d, e, p=0.0016). Testosterone and DHT promoted the

128 expression of one of the main myelin proteins, MBP ($p < 0.0001$) with however a significantly
129 stronger effect of testosterone (Fig. 3f, g; $p = 0.005$) suggesting that the latter may induce
130 additional effects. Then, we evaluated the local inflammatory cells, microglia and astrocytes.
131 Both androgens significantly decreased the amount of microglia in the lesion (Fig. 3h, i;
132 $p < 0.0001$). Only DHT was able to promote the expression of the anti-inflammatory microglial
133 marker Arg-1 ($p = 0.0003$). Moreover, unlike previous data from LPC-demyelinated males^{15, 20},
134 testosterone and DHT (Fig. 3j, k) significantly decreased GFAP ($p < 0.0001$) and STAT3
135 ($p < 0.0001$) labeling suggesting a decreased astrocyte reactivity in testosterone- and DHT-
136 treated females. To quantify remyelination under DHT treatment, we evaluated myelin sheath
137 thickness by determining the g-ratio (axon diameter / total outer diameter of the myelinated
138 fiber) at 14 dpl (Fig. 3l, m). Electron microscopy visualized a higher number of myelinated
139 axons in DHT-treated females consistent with the significant decrease of the g-ratio values
140 plotted according to axon diameters and mean g-ratio value (Fig. 3n, o; $p < 0.0001$). Thus,
141 androgens promote remyelination in female mice as previously described in male mice with
142 nevertheless differences between testosterone and DHT-induced control of local inflammatory
143 cells and oligodendrocytes.

144 **Synergistic androgen and estrogen effects in myelin repair in females**

145 The differential effects observed above for testosterone compared to DHT suggested
146 that testosterone could induce its effects via both AR and ER after its aromatase-mediated
147 conversion to estradiol (E2). In a consistent way, aromatase was up-regulated in the female
148 mouse demyelinated area, independently of the mechanical injury induced by the injection
149 (Supplementary Fig. 2). We analyzed the LPC lesions from female mice treated with intranasal
150 administration of vehicle, DHT, E2 or DHT+E2 at 7 dpl (Fig. 4a). Neither DHT nor E2
151 administered alone modified the number of OPCs unlike DHT+E2, which significantly
152 increased them (Fig. 4b, c; $p = 0.034$) without increasing their proliferation. Similarly, only
153 DHT+E2 increased the total number of Olig2⁺ cells (Fig. 4d, e; $p < 0.0001$). In contrast, the
154 percentage of CC1⁺ oligodendrocytes ($p < 0.0001$; $p = 0.0002$; $p < 0.0001$, for DHT, E2 and
155 DHT+E2, respectively) and MBP ($p < 0.0001$) immunolabeling were increased regardless of the
156 treatment with nevertheless a significantly stronger effect of DHT+E2 compared to E2 alone
157 ($p = 0.004$; Fig. 4d-g). Iba1⁺ microglial area was also significantly decreased by each treatment
158 compared to the vehicle (Fig. 4h, i; $p < 0.0001$) whereas only DHT alone or combined with E2
159 promoted the expression of Arg-1 (Fig. 4h, i; $p < 0.0001$). Thus, the effects of estrogens and
160 androgens appeared synergistic for increasing the density of differentiated oligodendrocytes,

161 while DHT induces a specific additional effect on microglia phenotype. We further validated
162 that endogenous testosterone may induce effects via both AR and ER by using the aromatase
163 inhibitor fadrozole²⁰. In the presence of fadrozole, testosterone still increased MBP staining
164 ($p < 0.0001$) even though the increase was significantly lower ($p = 0.04$) than the one induced by
165 testosterone alone (Fig. 4j-l) corroborating the additive effects of DHT and E2 on MBP
166 expression. Moreover, testosterone+fadrozole decreased Iba1 ($p = 0.0014$ and $p = 0.0021$,
167 respectively) and increased Arg-1 ($p < 0.0001$) (Fig. 4m, n) in agreement with the unique ability
168 of DHT to induce this marker.

169 **AR blockade alters spontaneous remyelination in females**

170 To determine if androgen effects are required for the full regeneration of myelin upon
171 demyelination, we blocked AR by using the specific AR antagonist flutamide (Fig. 5a). At 7
172 dpl, flutamide significantly decreased the number of OPCs ($p = 0.0014$) and Olig2⁺ ($p = 0.03$)
173 cells. Moreover, the percentage of Olig2⁺ CC1⁺ differentiated oligodendrocytes was decreased
174 in flutamide-treated animals ($p = 0.002$; Fig. 5b-e). As expected, flutamide also decreased MBP
175 staining in the lesion (Fig. 5f, g; $p = 0.002$), increased the level of Iba1⁺ microglia ($p = 0.0022$)
176 and decreased the proportion of microglia expressing Arg-1 (Fig. 5h, i; $p = 0.0016$). At 10 dpl,
177 the blocking effect of flutamide could still be detected on MBP (Fig. 5j, k, $p < 0.0001$ and
178 Supplementary Fig. 3) and microglia (Fig. 5l, m; $p < 0.0001$). As a whole, these results support
179 the idea that androgen signaling via AR plays a role during remyelination in female mice both
180 in oligodendroglia and microglia.

181 **AR is required for microglial response to demyelination in females**

182 The specific response of microglia to DHT and the predominant expression of AR in
183 this cell type incited us to conditionally remove AR from CX3CR1⁺ microglia/macrophages.
184 LPC-demyelinated females displaying or not the floxed AR alleles were treated with DHT or
185 the vehicle and analyzed at 7 dpl (Fig. 6a). In mutant animals, DHT treatment failed to decrease
186 Iba1 staining and to increase the proportion of these cells co-expressing Arg-1 unlike in the
187 wild-type animals (Fig. 6b, c). Moreover, conditional AR removal prevented OPC
188 differentiation into Olig2⁺CC1⁺ oligodendrocytes under DHT treatment indicating that
189 microglial AR controls OPC differentiation upon CNS demyelination in female mice (Fig. 6d,
190 e). Similarly, the removal of AR from microglia prevented the ability of DHT to decrease
191 astrogliosis (Fig. 6f, g).

192 **DHT efficiently mitigates the course of EAE disease in females**

193 Given the important role of AR-mediated signal in myelin regeneration in females and
194 because remyelination cannot be considered independently of the peripheral immune process
195 characterizing MS, we further investigated the role of testosterone and DHT in the EAE model.
196 Androgens were administered according to a curative protocol at onset of neurological
197 symptoms²⁰ in ovariectomized EAE female mice assigned to intranasal administration of the
198 vehicle, testosterone or DHT for 30 days (Fig. 7a). Vehicle-treated females displayed the typical
199 profile of disease progression with hindlimb paralysis with a 3.0-3.5 clinical score reached by
200 day 8 and persisting until the end of the experiment. Testosterone or DHT-treated females
201 displayed significantly lower scores throughout the whole experiment. However, DHT tended
202 to be less efficient (Fig. 7a) suggesting that testosterone may act via different mechanisms
203 compared with DHT.

204 MBP immunostaining visualized higher myelin levels in the spinal cord from androgen-
205 treated females compared to the vehicle (Fig. 7b, c; $p=0.0004$ and $p=0.007$ for T and DHT,
206 respectively). The detection of the non-phosphorylated neurofilament, Smi-32, an established
207 marker for axonal damage revealed a much lower expression in androgen-treated animals
208 suggesting androgen-mediated neuroprotection in agreement with electron microscopy images.
209 Indeed, a lower number of axons surrounded by thin layers of myelin or devoid of myelin
210 sheaths was observed in the drug-treated mice (Fig. 7d, e). Assessment of myelin sheath
211 thickness revealed that androgens significantly reduced the mean g-ratio compared with the
212 vehicle ($p<0.0001$). In addition, testosterone treatment resulted in a mean g-ratio value
213 significantly lower ($p=0.029$) than the value from the DHT-treated animals.

214 In order to investigate androgen effects on local inflammatory cells, we labelled spinal
215 cord slices with the pan-microglia/macrophage and the anti-inflammatory markers, Iba1 and
216 Arg-1, respectively. Iba1⁺ staining was significantly decreased by testosterone ($p=0.0018$) and
217 DHT ($p=0.0023$) compared to the control, whereas Arg-1 staining was fully collapsed in the
218 presence of androgens (Fig. 7f, g; $p=0.0002$). GFAP⁺ astrogliosis also decreased under
219 androgen treatment ($p<0.0001$) in correlation with the higher MBP level ($p<0.0001$) observed
220 in those conditions (Fig. 7h, i). The expression of Claudin-5, one of the tight junctional proteins
221 expressed by endothelial cells comprising the blood-brain barrier (BBB), was also increased in
222 the drug-treated animals (Fig. 7j, k; $p<0.0001$ and $p=0.0126$ for T and DHT, respectively)
223 suggesting that androgens are involved in the preservation of BBB integrity. In female mice,

224 androgens thus appeared to mitigate the severity of EAE disease including the neurological
225 scores, demyelination, the inflammatory cell density, as well as the expression of the junctional
226 protein Claudin-5.

227 **DHT decreases deleterious T cells and cytokines only in EAE females**

228 The lower severity of EAE disease observed in females upon androgen treatment could
229 be due in part to the remyelinating effects of the hormones (shown in the LPC model) and/or
230 reflect a lower level of demyelination related to a reduced immune response. We addressed the
231 question by investigating both peripheral immunity and immune cell infiltration into the CNS.
232 Our analysis was restricted to DHT in order to focus specifically on AR-mediated effects. We
233 wondered also if a sex-dependent discrepancy might exist in the control of immune cells by
234 AR-mediated androgen signaling. Ovariectomized EAE female and castrated EAE male mice
235 received DHT or the vehicle for 8 days from onset of the first neurological symptoms and were
236 analyzed at this early time point when neurological scores become significantly different
237 between the vehicle- and the hormone-treated group before occurrence of any potential
238 compensatory mechanism (Fig. 8a-c).

239 Immune cells were analyzed by flow cytometry in both the secondary lymphoid organs
240 and the spinal cord by using the gating strategies presented in Supplementary Fig. 4-7. In the
241 spleen from female mice (Fig. 8d), the percentage of CD90⁺ T cells ($p=0.0003$), namely CD4⁺
242 cells ($p=0.047$), was significantly decreased. In the draining lymph nodes (Fig. 8e), known to
243 be essential for the balancing of tolerogenic versus detrimental responses in the CNS via the
244 dendritic cells²⁷, we detected a lower proportion of CD11c⁺ dendritic cells (likely deleterious
245 ones; $p=0.0157$) as well as a strong decrease in the percentage of CD44^{hi} CD45RB^{hi}
246 effector/memory CD4⁺ T cells expressing high membrane level of the prominent activation
247 markers CD44 and CD45RB ($p=0.0044$). T cell effectors including Tbet⁺/Th1 ($p=0.03$) and
248 RoR γ ⁺/Th17 ($p=0.04$) cells, known to be deleterious in EAE, were also decreased as well as
249 the levels of the two pro-inflammatory cytokines IFN- γ ($p=0.005$) and TNF- α ($p=0.031$). In the
250 spinal cord (Fig. 8f), the decrease of the percentage of leukocytes labelled by the pan-leukocyte
251 marker CD45 was consistent with the decrease of CD90⁺ T cells ($p=0.005$), the lower number
252 of cellular foci visualized at periphery of spinal cord and the lower density of infiltrated CD3-
253 expressing T cells (Supplementary Fig. 8). Gating of the spinal cord myeloid cells indicated
254 that percentages of the whole population of phagocytes, with as much CD45⁺ CD11b⁺ CD44-
255 microglia as CD45⁺ CD11b⁺ CD44⁺ macrophages, remained unmodified. In addition, the non-

256 activated (resting, rMG) microglia remained the most abundant phenotype compared to the
257 activated one (aMG). However, DHT accentuated this distribution by significantly increasing
258 the proportion of resting cells ($p=0.041$). As observed above in the lymph nodes, pro-
259 inflammatory cytokine levels were also decreased, namely IL-1 β ($p=0.017$) and IFN- γ
260 ($p=0.0094$). As a whole, in EAE females, DHT decreases the proportion of CD4⁺ T cells, more
261 specifically the deleterious effectors Th1 and Th17 in the lymph nodes. It reduces also the
262 proportion of activated microglia to the advantage of resting cells consistent with the significant
263 reduction of several pro-inflammatory cytokines in the CNS.

264 In male mice, DHT failed to regulate any of the immune cells or cytokine levels
265 regulated in females suggesting an almost exclusive effect in the thymus where testosterone
266 induces negative selection of CD4⁺ T cells¹³. Nevertheless, one exception was the increase of
267 CD11c⁺ dendritic cells in the lymph nodes ($p=0.047$) suggesting that unlike females, male
268 dendritic cells may be tolerogenic (Fig. 8e). Our data also indicated notable differences in the
269 percentages of immune cells between females and males (Supplementary Fig. 9a-c). Indeed, in
270 the secondary lymphoid organs, CD4⁺ T cells, effector/memory CD4⁺ CD44^{hi} CD45^{hi} cells
271 ($p=0.0022$) and the CD4⁺ effectors Tbet⁺ ($p=0.0014$) and ROR γ ⁺ ($p=0.0016$) were detected in
272 significantly higher proportions in vehicle-treated females compared to males while DHT
273 treatment in females led these cells to reach the proportions that they display in males
274 (Supplementary Fig. 9b). In the spinal cord, the most important sexual dimorphism regarded
275 microglia and macrophages. Vehicle-treated females displayed as much microglia (46 \pm 4%) as
276 macrophages (53 \pm 4%) whereas males displayed predominant microglia (86 \pm 1%) compared to
277 macrophages (9 \pm 1%) (Supplementary Fig. 9c). In the same line, resting microglia largely
278 predominate in females whereas similar proportions of resting- and activated- microglia could
279 be detected in males. It should be also noted that despite comparable levels of the pro-
280 inflammatory cytokine IL1- β in vehicle-treated EAE females and males, the level reached upon
281 DHT-treatment was significantly lower in females ($p=0.0008$) than in males. Altogether, these
282 data provide evidence for major discrepancies regarding both immune cells and pro-
283 inflammatory cytokines in EAE female and male animals. They also support a strong anti-
284 inflammatory activity of DHT in EAE females, but not males.

285 **Sex-dependent regulation of local inflammatory cells in EAE spinal cord**

286 Given the anti-inflammatory activity of DHT observed only in females and because
287 local inflammatory cells also drive the level of neuroinflammation in the spinal cord, we

288 visualized parenchymal immune cells and astrocytes in EAE vehicle and DHT-treated animals
289 when the neurological scores start to significantly differ (Fig. 9a). In vehicle-treated females
290 and males (Fig. 9b, c, i, j), Iba1-expressing microglia/macrophages were abundantly detected
291 in the white matter at a significantly higher level in males (Supplementary Fig. 10a, $p=0.0013$)
292 whereas DHT treatment strongly decreased the labeling in both sexes but still maintained a
293 higher level in males (Supplementary Fig. 10h, $p=0.0054$). Iba1⁺ cells co-expressed the anti-
294 inflammatory marker Arg-1 in males and females in the vehicle condition (reflecting
295 spontaneous remyelination) with a notable scattering of the cells throughout the whole white
296 matter in females compared to their restricted localization at the periphery of the white matter
297 in males (Fig. 9b, c, i, j). Iba1⁺Arg-1⁺ staining in vehicle-treated females were detected at a
298 significantly lower level than in males (Supplementary Fig. 10b; $p=0.017$) suggesting a
299 spontaneous response to immune-mediated demyelination depending on the sex but not on
300 sexual hormones since animals were gonadectomized. DHT reduced Arg-1 staining in parallel
301 with Iba1 in the whole white matter leading to only a few Arg-1⁺ spots consistent with the
302 detection of a restricted number of demyelinated areas, as indicated by the higher level of MBP
303 staining observed in the white matter of DHT-treated females ($p<0.0001$) and males ($p=0.0008$)
304 (Fig. 9h, o) compared to the vehicle. We characterized also microglia inside each remaining
305 lesion rather than in the whole white matter. There, Iba1 and Arg-1 expression were still higher
306 in males than in females in the vehicle condition (Supplementary Fig. 10c, d; $p=0.0002$ and
307 $p=0.0001$, respectively). However, DHT increased Arg-1 expression in female mice ($p<0.0001$)
308 but did not regulate it in males (Fig. 9d, e, k, l and Supplementary Fig. 10j, k) in agreement
309 with our LPC data.

310 Unlike microglia, GFAP⁺ astroglia expression was significantly higher in vehicle-
311 treated female- than male mice in both the white ($p=0.0090$) and grey ($p=0.0002$) matter
312 (Supplementary Fig. 10e, f). DHT led to a comparable regulation of astrocytes, i.e. the decrease
313 of GFAP staining in the grey matter and its increase in the white matter, but it maintained the
314 higher GFAP staining previously observed in females under vehicle condition (Fig. 9f, g, m, n
315 and Supplementary Fig. 10e, f, l, m). Conversely, while demyelination level was higher in
316 females than in males under the vehicle ($p=0.0002$), DHT led to a more potent increase of MBP
317 staining in females ($p=0.0392$; Supplementary Fig. 10g, n). Thus, DHT is involved in the global
318 decrease of microglia/macrophages in the spinal cord white matter as well as in the balance of
319 astrogliosis between the grey and white matter in both sexes. However, a sexual dimorphism
320 exists in the response of microglia/macrophages inside the few lesions persisting under DHT

321 treatment since DHT clearly regulates microglia phenotype towards the expression of the anti-
322 inflammatory Arg-1 only in females consistent with a more potent remyelinating effect induced
323 by DHT in female mice.

324 **Sexually dimorphic molecular mechanisms induced by DHT in EAE animals**

325 The sexual dimorphism mentioned above led us to investigate the molecular
326 mechanisms putatively involved. We performed a transcriptomic comparison, by bulk RNA
327 sequencing (RNA-Seq) of the spinal cords derived from EAE female and male mice treated or
328 not (control) with DHT (Fig. 10a). After dataset normalization (Supplementary Fig. 11), we
329 found that both DHT-treated females and males were clearly separate from their respective
330 controls by principal component and clustering analyses indicating a clear effect of DTH
331 treatment (Fig. 10b, c and Supplementary Fig. 12a-d). A large number of differentially
332 expressed genes (DEGs) was found in DHT-treated compared to control, both in females (3285
333 up- and 4185 down-regulated) and males (2061 up- and 1720 down-regulated) by using
334 stringent statistical criteria (FDR <0.05) indicating strong gene expression changes upon DHT
335 treatment in both sexes Supplementary Fig. 11b; Supplementary Dataset 1). To assess the
336 impact of DTH-treatment in oligodendrogenesis and myelination, we used OligoScore
337 (<https://oligoscore.icm-institute.org/>), a resource using a knowledge-driven scoring procedure
338 for gene sets involved in oligodendrogenesis and (re)myelination, as described in Methods.
339 Given that EAE model is characterized by the co-existence of demyelinating and remyelinating
340 plaques (as in MS), genes either promoting or inhibiting the oligodendroglial processes could
341 be detected among the DEGs (Supplementary Fig. 13a-j; Supplementary Datasets 2-5). This
342 analysis indicated that myelination was the main process impacted by DHT treatment, both in
343 females and males (Fig. 10d,e), whereas the global changes on other processes of
344 oligodendrogenesis remained rather faint, except on proliferation for which gene changes
345 resulted in an inhibitory effect specifically in females. Thus, DTH treatment mostly results in
346 the promotion of myelin biogenesis in both sexes with however a sex-dependent signature since
347 besides the regulation of 25 shared genes, DHT specifically controlled 69 and 25 genes in
348 female and male mice, respectively (Supplementary Fig. 13k, l).

349 Gene ontology (GO) analysis of DEGs, showed that in both sexes, upon DTH-treatment,
350 the top processes involving up-regulated genes were enriched in terms promoting neuronal
351 activity, confirming our above-mentioned immunofluorescence and functional analyses.
352 However, the top processes enriched in down-regulated genes showed sexual dimorphism, in

353 females related to the immune system and inflammation and in males related to lipid metabolic
354 processes (Fig. 10f-i, Supplementary Dataset 6 and Supplementary Fig. 12e). These molecular
355 features are thus fully consistent with the remyelinating effects and the functional improvement
356 of female and male animals induced by DHT and also corroborate the differential capacity of
357 DHT to regulate the inflammatory process in female and male demyelinated tissues.

358 Given the sex-dependent discrepancies identified above regarding the local
359 inflammatory cells, we further analyzed the RNA-Seq data focusing on these cells. We used
360 gene sets characteristic of the main subpopulations of microglia constituting microglia diversity
361 during aging or neurodegeneration, including homeostatic, activated, disease associated
362 (DAM), and white matter associated (WAM) microglia²⁸⁻³⁵. Two subsets of genes were down-
363 regulated in both DHT-treated females and males compared to their respective controls either
364 without significant difference between female and male controls (including homeostatic genes
365 *Axl*, *Cd68*, *Csf1r*, *Cx3cr1* and *Tmem119*; DAM genes *Axl*, *Trem2*, *Ctsl*, *Fth1*, and *Lyz2*; WAM
366 genes *Anxa5*, *Clqb*, *Cd63*, *Cd74*, *Cst7*, *Ctsz*, *Fam20c*, *Fth1*, *Ftl1*, *H2-D1* and *Lyz2*) or with
367 significant difference between female and male controls (including homeostatic genes *ApoE*,
368 *Clqc*, *Mertk*, *Rxra* and *Trem2*; DAM genes *ApoE*, *Ctsb*, *Ctsd*, *Lpl*, *Timp2* and *Trem2*; WAM
369 genes *ApoE*, *Atp6v0c* and *Ctsb*; Supplementary Datasets 7 and 9) in agreement with the
370 reduction of the inflammatory foci and demyelinated areas previously observed in spinal cord
371 slices. However, another gene subset (34 genes out of 103) was exclusively down-regulated in
372 DHT-treated females without significant differences between female and male controls
373 (including microglia genes *Cd33*, *Fcgr2b*, *Tlr4*, *Tnf*; microglia DAM genes *B2m*,
374 *Ccl6*, *Cd9*, *Clec7a*, *Csfl*, *Csf2*, *Itgax*; microglia WAM genes *Anxa2*, *Clqb*, *Capg*, *Cd52*, *Crip1*,
375 *Ctss*, *Cybb*, *H2-K1*, *Ifitm3*, *Lgals1*, *Lgals3*, *Spp1*, *Tspo*, *Vim*; microglia activated genes *Il1b*,
376 *Rpl14*, *Rpl21*, *Rpl35*, *Rpsa*, *Tmsb4x*; microglia remyelination genes *Ank*, *Fn1*, *Psat1*; pink
377 highlighted in Supplementary Dataset 9; tab DEGs Microglia). Several out of these genes are
378 notable such as the genes encoding TLR4 whose activation leads to the production of pro-
379 inflammatory cytokines³⁶ or the pro-inflammatory cytokine TNF- α , but also *Csf2* and *Il1b*,
380 which encode the well-known pro-inflammatory GM-CSF and IL-1 β , respectively. Quantitative
381 RT-PCR amplification confirmed that *Tnf* and *Csf2* were significantly down-regulated in DHT-
382 treated females (Supplementary Fig. 14). To exclude bias putatively related to changes in
383 microglia cell numbers between conditions, we first took advantage of tools available in the
384 field by using a scRNA-Seq dataset from mouse EAE model³⁷ (GSE113973). Resulting dotplots
385 revealed that 21 genes out of 31 displayed a high average and percent expression mostly in EAE

386 microglia (Supplementary Fig. 15). By combining all microglial gene sets (105 genes), we
387 performed gene set enrichment analysis (GSEA) with these genes ordered by their changes in
388 expression either in female or male comparisons (DHT-treated versus non-treated). In line with
389 previous results, this GSEA analysis showed large enrichment of many gene sets in DHT-
390 treated females but almost none in males, with many of the suppressed gene sets (genes being
391 downregulated) related to immune and inflammatory processes, including ‘lymphocyte
392 mediated immunity’, ‘response to stress’, ‘defense response’, ‘immune system process’,
393 ‘immune response’, and ‘cytokine production’ (Supplementary Fig. 16 ; Supplementary
394 Dataset 10). Therefore, these results agree with those obtained by immunofluorescence analyses
395 supporting a strong anti-inflammatory activity of DHT in EAE female mice, but not males. To
396 try to exclude bias putatively related to changes in cell numbers between conditions, we used
397 Cibersortx, a machine learning method to determine cell type abundance and expression from
398 bulk tissues³⁸, together with a single cell RNA-Seq dataset from mouse EAE model³⁷
399 (GSE113973). This deconvolution of our bulk-RNA-Seq datasets suggested that while
400 microglial clusters did not change in proportions upon DHT-treatment in males, DHT-treated
401 females presented some changes in microglial clusters and EAE immune-OL/OPC clusters³⁷
402 (Supplementary Dataset 11), likely due to the abovementioned dysregulation of
403 microglial/inflammatory genes. Indeed, 21 genes out of 31 downregulated genes only in DHT-
404 treated females are expressed in the EAE microglial cells from this scRNA-Seq dataset
405 (Supplementary Fig. 15). Altogether these results are in agreement with our flow cytometry
406 data, which indicated that DHT did not modify the proportion of microglia/macrophages neither
407 in female nor in male spinal cords compared to their controls (Fig. 8f) and they support the
408 existence of true molecular differences in the effects of DHT in female compared to male mice.

409 Similarly, we used sets of genes previously implicated in the characterization of
410 different astrocyte subsets^{39,40}. Among the 165 DEGs related to astrocytes, 62 were deregulated
411 in both DHT-treated females and males. Most importantly, 83 were deregulated by DHT
412 exclusively in females whereas only 20 were deregulated exclusively in males compared to
413 their own controls. Additionally, most genes (21 out of 26) known to identify activated
414 astrocytes, pro- and anti-inflammatory astroglial phenotypes were exclusively deregulated in
415 DHT-treated females (Supplementary Datasets 8 and 9) further suggesting the ability of DHT
416 to molecularly control astrogliosis in female mice in a specifically different way compared to
417 males.

418

419 **Discussion**

420 Since testosterone is well-known to exert its effects on target cells via AR or ERs after
421 its conversion to estradiol, beneficial effects of estrogens on the course of EAE¹⁰ in males have
422 not been so surprising when reported. In contrast, testosterone involvement in repairing
423 processes in females is more unexpected. However, circulating levels of testosterone in women
424 are far from being insignificant despite a 10-20-fold lower level than in men⁴¹⁻⁴³. Additionally,
425 exacerbation of demyelinating episodes during the postpartum were associated with a decrease
426 in both female and male hormones⁴⁴. Finally, low testosterone levels were previously associated
427 with increased brain lesions and clinical disability in women with MS⁴⁵.

428 Our present data are consistent with those findings as shown by the graphical abstract
429 (Supplementary Fig. 18). Indeed, besides the well-recognized expression of AR in cortical
430 neurons, AR transcripts and protein are also highly expressed in demyelinated areas from
431 female patients and mice. As previously shown in Sertoli cells⁴⁶, both nuclear and non-nuclear
432 AR might participate in androgen signaling during remyelination in females, an observation
433 consistent with the well characterized AR translocation from the cytoplasm to the cell nucleus
434 upon ligand binding^{47, 48}, and the existence of a nucleotide sequence suggesting also AR
435 translocation to the membrane⁴⁹. Although all cell types express AR in the female mouse
436 lesions, AR expression in microglia is widely predominant and functionally critical since
437 conditional AR mutants confer to androgens a direct role in the control of female microglia by
438 promoting a pro-regenerative response to demyelination resulting in OPC differentiation and
439 astrogliosis decrease. However, our data do not allow to exclude that the high AR expression
440 in female neurons might also participate in DHT-induced beneficial response. Indeed, DHT up-
441 regulates genes related to synaptic function and thus promotes neuronal electrical activity, a
442 well-known inducer of myelination^{50, 51}. Moreover, the serine/threonine kinase mTor that we
443 found exclusively up-regulated by DHT in females was previously proposed to maintain the
444 non-reactive state of astrocytes in the cerebral cortex⁵².

445 In male patients and mice, the quite undetectable *AR* expression in the demyelinated
446 lesion supports a fully different remyelinating activity independent of microglia but putatively
447 dependent on neuronal AR expression. These observations are consistent with our previous data
448 showing that microglia is not implicated in AR-mediated remyelinating effect of testosterone^{14,}
449 ²⁰ and with the ability of DHT to up-regulate in male mice (like in females) genes related to
450 purine nucleoside biosynthetic processes known to be required before extra-synaptic release of

451 adenosine, a critical mediator for triggering myelination⁵³. Similarly, neuronal AR activation
452 might also be involved in testosterone-induced increase of astrogliosis previously reported to
453 be AR-dependent in male animals^{15, 20} since in response to neuron-derived active compounds,
454 astrocytes display specific molecular signatures leading to mechanisms of astrocyte-neuron
455 communication including those implicated in migration⁵⁴.

456 Our work also uncovers other major sex-dependent molecular discrepancies regarding
457 DHT effects upon CNS demyelination. Thus, only DHT-treated female mice are able to down-
458 regulate genes known to identify activated-, pro- or anti-inflammatory astrocytes. One of these
459 genes encodes the critical regulator of astrogliosis STAT3⁵⁵ whose down-regulation is
460 consistent with the decrease of the number of GFAP⁺STAT3⁺ reactive astrocytes induced by
461 DHT in the LPC model in female animals, but not in males (present data and ²⁰). Moreover,
462 only female mice respond to DHT by promoting clear anti-inflammatory effects including the
463 reduction of the pro-inflammatory cytokines IL-1 β / IFN- γ and the down-regulation of the genes
464 encoding TLR4 and TNF- α , which are involved in the pro-inflammatory phenotype of reactive
465 astrocytes⁴⁰. The critical crosstalk existing between astrocytes, microglia and oligodendrocytes
466 during remyelination⁵⁶ might thus be sex-dependent and likely contribute to the differential
467 gene profiles characterizing female and male mouse remyelination as shown for instance for
468 *mTor*. Indeed, known to regulate the initiation of myelination^{57, 58} mTor appears here to be one
469 of the molecular targets of AR-dependent remyelinating effects of DHT in female mice but not
470 in males.

471 Finally, if most genes down-regulated by DHT in female mice are related to
472 inflammation, those predominantly down-regulated in males are related to lipid metabolic
473 processes. However, this discrepancy does not mean that lipid metabolism is not controlled by
474 DHT in females as evidenced by the comparable down-regulation of genes encoding proteins
475 known to link lipid metabolism and remyelination⁵⁹. This is true for *RxR α* , involved in the
476 phagocytic removal of myelin debris deleterious for OPC differentiation⁶⁰ and for *ApoE*,
477 impeding cholesterol accumulation upon myelin debris phagocytosis to prevent phagocytes
478 from becoming inefficient⁵⁹. Though androgens protect against autoimmunity by primarily
479 acting at the level of the thymus in both males and females¹³, the decrease of the
480 encephalitogenic CD4⁺ T cells Th1 and Th17⁶¹ exclusively detected in females suggest a higher
481 level of complexity in the peripheral immune response of the latter. The curative administration
482 of DHT nevertheless interrupts the encephalitogenic process and decreases the need for high
483 spontaneous remyelination in agreement with the down-regulation of *RxR α /ApoE* in both sexes.

484 However, if we consider the anti-inflammatory effects of DHT occurring exclusively in females
485 together with the fact that the peripheral immune response is thought to drive the relapsing-
486 remitting form of MS whereas compartmentalized CNS immune reactions may be more
487 involved in the progression of MS⁶², we may wonder if the well-known worse prognosis of MS
488 in men compared to women might be in part related to improper anti-inflammatory response in
489 the demyelinated male CNS. Thus, besides suggesting the use of appropriate doses of androgens
490 in demyelinated females, this work also uncovers the need for considering the sex-specific AR-
491 mediated control of microglia/macrophage response to demyelination in the therapeutic
492 management of MS.

493 **Methods**

494 **Animals.** All procedures were performed according to the European Communities Council
495 Directive (86/806/EEC) for the care and use of laboratory animals and were approved by the
496 Regional Ethics Committee CEEA26, Ministère de l'Éducation Nationale, de l'Enseignement
497 et de la Recherche. Wild-type intact or gonadectomized C57Bl/6 male and female mice were
498 purchased at the age of 8 to 12 weeks from Janvier Labs Breeding Center (France). *AR^{fl/fl}*⁶³
499 were maintained on a C57Bl/6 background. The mouse strain CX3CR1^{tm2.1}(Cre/ERT2)
500 (thereafter called CX3CR1CreER-YFP) expressing the YFP reporter under the promoter of the
501 chemokine receptor CX3CR1^{64, 65} was provided by Jackson Laboratory. Animals prone to
502 receive hormones were gonadectomized in order to exclude the confounding effects of
503 endogenous gonadal steroid hormones and after validation that *AR* up-regulation was still
504 detected in ovariectomized animals and not related to the mechanical injury induced by the
505 injection (Supplementary Fig. 17). All animals were housed in standard conditions: ambient
506 temperature at 20°C, relative humidity at 45-65%, 12 hours light-dark cycle with food and water
507 *ad libitum*.

508 **Drugs.** Testosterone, dihydrotestosterone, estradiol, flutamide and fadrozole were provided by
509 Sigma-Aldrich (France). Testosterone (0.20 mg/day under a volume of 2.5 µl in each nostril),
510 dihydrotestosterone (0.04 mg/day under a volume of 2.5 µl in each nostril due to its much higher
511 potency in transactivating AR target genes than testosterone⁶⁶) and estradiol (0.0375 mg/day
512 under a volume of 2.5 µl in each nostril) were administered daily per the intranasal route via a
513 proprietary oleogel (MetP Pharma AG, Emmetten, Switzerland)⁶⁷. Flutamide (20 mg/kg) and
514 fadrozole (250 µg/kg) were administered daily per gavage. Tamoxifen (Sigma-Aldrich; 30

515 mg/ml) was dissolved in corn oil (Sigma-Aldrich) and administered by gavage (3 mg/day for 5
516 days) 2 weeks before inclusion of the animals in any experimental protocol.

517 **LPC-induced focal demyelination.** Demyelinating lesions were induced unilaterally by
518 stereotaxic injections of 1.5 µl of a solution containing LPC 1% (Sigma-Aldrich) into the right
519 corpus callosum at the following coordinates (to the bregma): anteroposterior (AP) +1 mm,
520 lateral +1 mm, dorsoventral (DV) -2.2 mm for brain analyses performed at 7, 10 or 14 days
521 postlesion (dpl) after animal perfusion with PFA 4%. The tissue was post-fixed for 4 hrs in
522 fresh 4% PFA solution before being cryopreserved in 30% sucrose, frozen in liquid nitrogen
523 and cryostat sectioned (14 µm). 7dpl was selected as the suitable time when the process of
524 spontaneous remyelination is ongoing and corresponds to the end of OPC recruitment and the
525 beginning of their differentiation into oligodendrocytes^{20, 68}. 10 and 14 dpl were used for MBP
526 immunostaining and electron microscopy analysis of myelin, respectively.

527 **Autoimmune Experimental Encephalomyelitis.** Ovariectomized females or castrated male
528 mice at age of 9-10 weeks were maintained for one week for acclimatization prior to EAE. The
529 pathology was induced by subcutaneous injection of an emulsion of MOG₃₅₋₅₅ peptide in
530 complete Freund's adjuvant⁶⁹. The mice that developed EAE were randomly assigned into
531 vehicle, testosterone or DHT treatment in order to constitute groups with similar time of EAE
532 onset and similar onset scores (n=8-12 animals per group). The mice were scored blindly once
533 a day starting at Day 8 post-immunization (onset of neurological disabilities for all animals)
534 until Day 16 or 38 (as indicated) according to the following scale: 0.0=no obvious changes in
535 motor function; 0.5=tip of tail is limp; 1.0=limp tail; 1.5=limp tail and hind leg inhibition;
536 2.0=limp tail and weakness of hind legs or signs of head tilting; 2.5=limp tail and dragging of
537 hind legs or signs of head tilting; 3.0=limp tail and complete paralysis of hind legs or limb tail
538 with paralysis of one front and one hind leg; 3.5=limp tail and complete paralysis of hind legs
539 and animal unable to right itself when placed on its side; 4.0=limb tail, complete hind leg and
540 partial front leg paralysis with minimal moving and feeding. Drugs were administered at the
541 onset of clinical symptoms for 30 days. The drugs or the vehicle were daily administered via
542 the intranasal route. The spinal cord / vertebrae were removed and lumbar spinal cord /
543 vertebrae samples were either post-fixed in PFA 4% for 24 hrs and sectioned (7 µm) with a
544 microtome for immunostaining or post-fixed in a mixture of PFA 2% and glutaraldehyde 2%
545 for 5 days, then in cacodylate-buffered 1% osmium tetroxide for 1 hr at 4°C and in 2% uranyl
546 acetate for 1 hr at room temperature before embedding in epoxy resin and ultrathin sectioning
547 for electron microscopy.

548 **Human tissues:** Post-mortem brain samples from MS and non-neurological control donors
549 were provided by a UK prospective donor scheme with full ethical approval from the UK
550 Multiple Sclerosis Society Tissue Bank (MREC/02/2/39) and from the MRC Edinburgh Brain
551 Bank (16/ES/0084). MS diagnosis was confirmed by neuropathological means by F. Roncaroli
552 (Imperial College London) and Prof. Colin Smith (Centre for Clinical Brain Sciences,
553 University of Edinburgh) and clinical history was provided by R. Nicholas (Imperial College
554 London) and Prof. Colin Smith. Supplementary Tables 1 and 2 include donor characteristics
555 corresponding to the human samples used. Control samples were derived from donors between
556 44 and 88 years old for whom the cause of death was heart disease, pulmonary disease or cancer.
557 MS samples were derived from donors between 44 and 72 years old for whom the cause of
558 death was heart disease, pulmonary disease, cancer or sepsis. Tissue blocks were used as
559 paraffin sections for RNAscope analysis and cut at 4 μ m. White matter lesions were identified
560 and characterised by Anna Williams⁷⁰ using Luxol Fast Blue staining and Oil Red O (for lipids
561 phagocytosed by macrophages). Active lesions have indistinct borders and lipid-laden
562 macrophages/microglia. Chronic active lesions have a ring of lipid-laden
563 macrophages/microglia and a core with few immune cells⁷⁰.

564 **Immunostaining experiments.** The primary antibodies were as follows: Olig2 (rabbit,
565 AB9610, 1:500, Millipore ; mouse, MABN50, 1:500, Millipore), MBP (rabbit, AB980, 1:750,
566 Millipore), Adenomatous Polyposis Coli (APC/CC1) (mouse, OP80, 1:500, Calbiochem), GFAP
567 (mouse, G3893, 1:1500, Sigma), Iba1 (rabbit, W1 W019-19741, 1:500, Wako), Arg-1 (goat,
568 sc-18355, 1:100, Santa-Cruz), PDGFR α (rat, 558774, 1:500, BD Pharmingen), DHT (guinea-
569 pig, GP-DHT1, 1 :200, Synabs), Neurofilament H (NF-H), Non-phosphorylated Smi-32
570 (mouse, 801701, 1 :300, Biolegend), Ki67 (mouse, 550609, 1:150, BD Pharmingen),
571 Aromatase (rabbit, Ab18995, 1:200, Abcam), Claudin-5 (mouse, 35-2500, 1 :700, Invitrogen),
572 pSTAT3 (Tyr705) (rabbit, 9145, 1: 500, Cell Signaling). AR is a home-made antibody (guinea-
573 pig, Aa 283-298 / Aa 406-420 from mus musculus AR Accession NP_038504.1; Eurogentec).
574 The secondary antibodies were: goat anti-rabbit cyanine 3 conjugated (111165003, 1/250,
575 Jackson Immunoresearch); goat anti-mouse Alexa 488 (A11029, 1:250, Thermo Fisher
576 Scientific), goat anti-rabbit Alexa 633 (A21070, 1:750, Thermo Fisher Scientific), goat anti-rat
577 Alexa 633 (A21094, 1:750, Thermo Fisher Scientific), goat anti-rabbit Alexa 488 (A32731,
578 1:350, Thermo Fisher Scientific) ; goat anti-guinea pig cyanine 3 conjugated (106165003,
579 1/500, Jackson Immunoresearch); donkey anti-goat Alexa 488 (A11055, 1:500, Thermo Fisher
580 Scientific).

581 **High-resolution fluorescent *in situ* hybridization in human tissues.** To detect single AR
582 mRNA molecules within microglia/macrophages, the RNAscope Multiplex Fluorescence v2
583 Assay (Bio-Techne) was combined with IBA1 immunofluorescence on 4µm-thick white matter
584 paraffin sections. Briefly, sections were deparaffinised and antigen retrieval was performed
585 using Co-Detection Target Retrieval buffer (Bio-Techne) in a steamer. Endogenous peroxidase
586 activity was quenched with hydrogen peroxide and sections were incubated overnight at 4°C
587 with a monoclonal anti-Iba1 primary antibody (1:250; ab178846, Abcam). The next day,
588 sections were fixed in 10% neutral buffered formalin to cross-link the primary antibody and the
589 RNAscope assay was performed as per manufacturer's instructions. Briefly, sections were
590 digested with protease and hybridised with a human AR probe (Hs-AR-02, Bio-Techne) for 2
591 h at 40°C. Sequential amplifications were performed at 40°C and the mRNA signal was
592 developed by horseradish peroxidase incubation followed by incubation with Opal 570 (1:750;
593 FP1488001KT, Akoya Biosciences). For Iba1 immunofluorescence, sections were then
594 incubated with anti-rabbit Alexa Fluor 647 secondary antibody (1:750; A-21244, Thermo
595 Fischer Scientific), counterstained with DAPI and mounted with ProLong Glass Antifade
596 mounting medium (Invitrogen). The entire sections were imaged using the Opera Phenix Plus
597 system (PerkinElmer) under a 20x water-immersion objective. Image analysis was performed
598 in QuPath software⁷¹. Regions of interest were selected to contain different lesion types in MS
599 samples, or at random in control samples. Iba1⁺ cells that contained AR⁺ puncta were manually
600 counted in at least 3 different regions of interest per lesion type and expressed as percentage of
601 the total number of Iba1⁺ cells.

602 **High-resolution fluorescent *in situ* hybridization in animal tissues.** FISH was performed on
603 frozen brain sections derived from 3 independent animals per group by using RNAscope
604 Multiplex Fluorescent Reagent Kit v2, ACDBio according to the instructions of the provider
605 (Advanced Cell Diagnostics). The probes (Biotechne) and Opal fluorophores (Akoya
606 Biosciences) were as follow : *AR* (316991), *Esr1* (478201) *Esr2* (316121), Opal-570
607 (FP1488001KT, 1 :1500), Opal-620 (FP1495001KT1 :1500).

608 **Image Acquisition and Analysis.** Images were taken using the microscope analyzing system
609 Axiovision 4.2 (Carl Zeiss, Inc.) and the confocal Zeiss LSM 510-Meta Confocor 2. Analyses
610 were performed with ImageJ software. 3-5 sections per mouse were analyzed. For the brains
611 derived from the LPC-injected animals, the immunofluorescent-positive cells or areas were
612 determined in one every other 5 sections throughout the whole demyelinated lesion per mouse
613 and averaged for each animal. The lesion surface was determined by measuring the area of the

614 nuclear densification (correlated with myelin loss visualized by MBP staining) one every other
615 5 slices through the whole demyelinated lesion.

616 For the human post-mortem tissue analysis, the entire sections were imaged using a ZEISS Axio
617 Scan.Z1 slide scanner. All quantifications were performed using Zeiss Zen lite imaging
618 software. For cell density quantification, 3-5 different areas of interest were marked out in
619 control white matter, normal appearing white matter (NAWM) and lesion sites.

620 **Electron microscopy.** Ultrathin sections of lumbar spinal cords were examined using
621 transmission electron microscope (1011 JEOL) equipped with a Gatan digital camera. The g
622 ratio (the ratio between the axon diameter and fiber diameter corresponding to myelin sheath +
623 axon diameter) was estimated by measuring the minimum and maximum axon diameter and
624 fiber diameter for each axon using ImageJ software. 100 to 300 randomly chosen myelinated
625 axons were evaluated for each animal.

626 **Flow cytometry.** Spleen and lymph node cells were isolated using a digestion solution
627 containing 1 mg ml/ Collagenase A, 100 µg/ml DNase and 1 U/ml Dispase (Roche) in
628 Dulbecco's modified Eagle's medium (DMEM) 37°C 20 min. The mixture obtained was
629 filtered through a Falcon 70 µm nylon cell strainer. The single-cell suspensions were then
630 centrifuged at 600 g and the resulting pellets resuspended in RPMI 1640 culture medium and
631 viable cell numbers were determined using LUNA-FL dual fluorescence cell counter (Logos
632 Biosystems). The spinal cords, which mostly contain non-immune cells unlike the lymphoid
633 organs, were cut in small fragments, mechanically and enzymatically dissociated in a solution
634 containing collagenase A 3mg/ml, DNase 100µg/ml, Dispase 2mg/ml at 37°C for 35 min before
635 being filtrated through Falcon® 70 µm Cell Strainer. The suspension was mixed with 30%
636 Percoll and layered on top of a 70% Percoll solution for cell purification and then centrifuged
637 at 500 g without brake for 30 min. The myelin top layer was removed. Immune cells were
638 isolated from the interface and resuspended in RPMI 1640 culture medium. The concentration
639 and viability of single cell suspensions were determined using automated cell counter (LUNA-
640 FL dual fluorescence counter, Logos Biosystems) and acridine orange and propidium iodide
641 staining (Logos Biosystems). Spleen, lymph node, and spinal cord mononuclear cell
642 suspensions were phenotyped by flow cytometry using 50 ng/ 10⁶ cells of the following
643 fluorescent-conjugated monoclonal antibodies (mAb) directed against the cell surface markers
644 CD90.2/Thy1.2 (clone 53-2.1), B220 (clone RA3-6B2), CD4 (clone GK1.5), CD8α (clone 53-
645 6.7), CD44 (clone IM7), CD45RB (clone C363.16A), CD11b (clone M1/70), CD11c (clone
646 N4/8), Ly-6G (clone RB6-8C5), NK1.1 (clone PK136), CD45 (clone 30-F11), CD206 (clone

647 MR5D3) and the transcription factors Foxp3 (clone FJK-16s), T-bet (clone eBio4BIO) and
648 ROR γ t (clone B2D) (ThermoFisher Scientific, BD Bioscience). The use of a mAb to the mouse
649 Fc γ receptor (clone 93, eBioscience) avoided non-specific antibody binding. At least 20,000
650 events were analyzed for each sample. Cell debris, dead cells, and doublets were gated out using
651 the FSC and SSC parameters. Data acquisition was performed at the Flow Cytometry Core
652 Facility IPSIT (Clamart, France). Flow cytometry data were analyzed using FlowJo (Treestar)
653 software.

654 **Quantification of cytokines.** Spleen lymph nodes and spinal cord were dissected and snap-
655 frozen in liquid nitrogen. Samples were then stored at -80°C until further processing. Frozen
656 tissues were homogenized in cold RIPA lysis buffer (Biorad) according to the manufacturer's
657 instructions in the presence of protease inhibitors (Sigma-Aldrich). The protein extract
658 concentration was measured using the BCA method (Thermo Fisher Scientific) and the
659 expression levels of cytokines (GM-CSF IFN- γ IL-1 β IL-2 IL-4 IL-5 IL-10 TNF- α IL-17)
660 secreted by immune cells from spinal cord, spleen and lymph nodes were determined using the
661 Bio-Plex Pro Mouse Cytokine 8-Plex Immunoassay (Biorad) according to the manufacturer's
662 instructions²⁰.

663 **Bulk RNA sequencing and analysis.** The spinal cords from 4 animals for each group were
664 dissected and frozen in liquid nitrogen for further processing. Total RNA was isolated with the
665 Trizol Reagent protocol (ThermoFisher) from spinal cords and RNeasy Mini Kit (Qiagen)
666 according to instructions of the provider. The RNA-Seq libraries were prepared using the
667 NEBNext Ultra II Directional RNA Library Prep Kit (NEB) and sequenced with the Novaseq
668 6000 platform (ILLUMINA, 32*10⁶ 100bp pair-end reads per sample). Quality of raw data was
669 evaluated with FastQC. Poor quality sequences were trimmed or removed with fastp tool, with
670 default parameters, to retain only good quality paired reads. Illumina DRAGEN bio-IT
671 Platform (v3.6.3) was used for mapping on mm10 reference genome and quantification with
672 gencode vM25 annotation gtf file. Library orientation, library composition and coverage along
673 transcripts were checked with Picard tools. Following analyses were conducted with R
674 software. Female and male datasets were first integrated by using normalization by
675 housekeeping genes⁷² present in the two datasets, as a previously demonstrated strategy to
676 reduce unwanted variation from RNA-Seq data⁷³ (RUVSeq). The integrated data were then
677 normalized with edgeR (v3.28.0) bioconductor packages, prior to differential analysis with glm
678 framework likelihood ratio test from edgeR package workflow. Multiple hypothesis adjusted
679 p-values were calculated with the Benjamini-Hochberg procedure to control FDR. For the

680 differential expression analyses, low expressed genes were filtered, sex was used as covariable
681 (when relevant) and the cut-offs applied were $FDR < 0.05$. Finally, gene ontology (GO)
682 enrichment analysis of biological processes of the differentially expressed genes (DEGs) was
683 conducted with clusterProfiler R package (v3.14.3). R script detailing these analyses has been
684 deposited in [https://github.com/ParrasLab/Androgen-signaling-and-remyelination-Nat-](https://github.com/ParrasLab/Androgen-signaling-and-remyelination-Nat-Commun-paper)
685 Commun-paper (DOI: 10.5281/zenodo.7560637).

686 **Scoring of differentially expressed genes for their impact in oligodendrogenesis.** We used
687 OligoScore (<https://oligoscore.icm-institute.org/>), a resource based on expert curation scoring
688 strategy for gene signatures or transcriptomic studies related to oligodendrogenesis and
689 (re)myelination. This resource currently implicates curation of 430 genes for which loss-of-
690 function and gain-of-function studies have demonstrated their requirement in the main
691 processes of oligodendrogenesis that we categorized in: specification, proliferation, migration,
692 survival, differentiation, myelination, and remyelination. Gene activities are scored in each
693 process from 1 to 3 (low, medium, strong) either positively or negatively (promoting or
694 inhibiting, respectively), depending on the severity of gain- or loss-of-function phenotypes. The
695 large number of references (~1000) used in the scoring are provided per gene and process.

696 **Gene set enrichment analysis (GSEA).** We used *gseGO* function of *Cluster profiler* R
697 package to find gene sets enriched in the gene list of 105 microglial genes (Supplementary
698 Dataset 10) ranged by the differential expression (logarithmic fold change, logFC) in DTH-
699 treated versus non- treated females and males, respectively. We found 219 gene set enriched in
700 females but only 2 in males. *Dotplot* and *gseaplot* functions were used for visualization of
701 enriched gene sets. All gene sets enriched are provided in Supplementary Dataset 10. R script
702 has been deposited in [https://github.com/ParrasLab/Androgen-signaling-and-remyelination-](https://github.com/ParrasLab/Androgen-signaling-and-remyelination-Nat-Commun-paper)
703 Nat-Commun-paper (DOI: 10.5281/zenodo.7560637).

704 **scRNA-Seq analysis.** EAERaw.RData object was obtained from Gonçalo Castelo-Branco's lab
705 and processed in R (4.0) using the following packages: *Seurat* (3.0) for data processing and
706 *ggplot2* (v3.3.6) for graphical plots. Seurat objects were first generated using
707 *CreateSeuratObject* function (min.cells = 5, min.features = 100). Normalized with *sctransform*
708 function. Cell neighbors and clusters were found using *FindNeighbors* (dims = 1:30) and
709 *FindClusters* (resolution = 0.8) functions. *RunPCA*, and *RunUMAP* functions with default
710 parameters. Clusters were annotated based on cell-subtype markers as detailed in the R script,

711 which has been deposited in [https://github.com/ParrasLab/Androgen-signaling-and-](https://github.com/ParrasLab/Androgen-signaling-and-remyelination-Nat-Commun-paper)
712 [remyelination-Nat-Commun-paper](https://github.com/ParrasLab/Androgen-signaling-and-remyelination-Nat-Commun-paper) (DOI: 10.5281/zenodo.7560637).

713 **Statistical analysis.** Statistical analysis of mouse histological staining was performed with
714 GraphPad Prism 7.0 software (La Jolla, CA). The significance of differences between means
715 was evaluated by two-tailed, unpaired Student's t test for two independent group comparisons
716 and ANOVA followed by Tukey's or Holm-Sidak's post tests for comparisons of more than
717 two groups and/or several variables. In case of absence of distribution normality (analyzed via
718 D'Agostino & Pearson normality test and Shapiro-Wilk normality test), non-parametric tests
719 (Mann-Whitney two-tailed, Kruskal-Wallis with Dunn's post tests for comparison) were used.
720 Appropriate corrections were done according to the determination of the variance of each
721 sample. The values are the means \pm SEM from the number of animals indicated in each plotted
722 graph or as indicated in the corresponding legends. Significance of $p < 0.05$ was used for all
723 analyses. *, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$; ****, $p < 0.0001$. For human histological
724 staining, data were analysed using linear mixed-effects models on R Studio with the lmerTest
725 package, adding diagnosis, sex and lesion type as main effects and accounting for multiple
726 measurements from each sample by the random effects. To determine main effects ANOVAs
727 were used (stats package), and post-hoc comparisons between groups were made using pairwise
728 comparisons in the emmeans package with Tukey method. To ensure data met model
729 assumptions, normal distribution was assessed by Shapiro-Wilk test, and homogeneity of
730 variance by Levene's test. For transcriptomic analyses, multiple testing correction aimed at
731 controlling the false discovery rate (FDR) was performed using the Benjamini-Hochberg
732 method. Cutoff used for FDR was 5%. For differential expression, the workflow used edgeR's
733 quasi-likelihood (QL) pipeline (edgeR-quasi).

734 **Data Availability.** All metadata associated with RNA sequencing generated in the present
735 manuscript are available at <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE225254>.
736 The publicly available independent single-nuclei RNA sequencing database from MS donors is
737 available at https://malhotralab.shinyapps.io/MS_broad/. Human MS data are available at
738 <https://ega-archive.org/studies/EGAS00001006345>. scRNA-Seq dataset from mouse EAE
739 model is available at <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE113973>.
740 Mm10 reference genome (org.Mm.eg.db_3.15.0.) is available at <https://bioconductor.org> (DOI:
741 [0.18129/B9.bioc.BSgenome.Mmusculus.UCSC.mm10](https://doi.org/10.18129/B9.bioc.BSgenome.Mmusculus.UCSC.mm10)). The readers can expect to receive any
742 raw data from their request. Source data are provided with this paper.

743 **Code availability.** Analyses of images were performed with ImageJ-win64 v1.41 software
744 (mouse tissues) at <https://imagej.nih.gov/> or Zeiss Zen lite blue edition 2.3 software (human
745 tissues) available at <https://www.zeiss.fr>. Flow cytometry analysis used FlowJo v10.8.1
746 (Treestar) software available at <https://www.flowjo.com>. Statistical analysis was performed
747 with GraphPad Prism 7.0 software (La Jolla, CA) available at <https://www.graphpad.com>.
748 RNA-seq analyses were conducted with R software available <https://www.r-project.org> and
749 including edgeR (v3.28.0) bioconductor packages for normalization, edgeR package workflow
750 for differential analysis, clusterProfiler R package (v3.14.3) for gene ontology enrichment
751 analysis, gseGO function of Cluster profiler R package used for gene Set Enrichment Analysis.
752 EAE raw.RData GSE113973 were processed in R (4.0) using the packages: Seurat (3.0) for
753 data processing and ggplot2 (v3.3.6) for graphical plots. The deconvolution of our bulk RNA-
754 Seq datasets used the CIBERSORTx tool on the docker (v20.10.12) module
755 Cibersortx/fractions available at <https://cibersortx.stanford.edu>. R script detailing these
756 analyses has been deposited at <https://github.com/ParrasLab/Androgen-signaling-and-remyelination-Nat-Commun-paper> (DOI: 10.5281/zenodo.7560637). Scoring of differentially
757 expressed genes for their impact in oligodendrogenesis used the OligoScore resource has been
758 deposited at <https://oligoscore.icm-institute.org/>.

1019 **Figure Legends**

1020 **Figure 1. The androgen receptor is strongly up-regulated in the LPC-demyelinated corpus**
1021 **callosum from female but not male mice. a** Scheme of the experimental protocol. **b, c**
1022 Differential detection of *AR* transcripts in the corpus callosum (cc), but not cortex (Cx) from
1023 LPC-injected females or males. Dashed lines delineate the demyelinated area. **d** *AR* signal

1024 quantification in the lesions. **e** Double *AR* ISH (left) and Iba1, GFAP or Olig2 immunostainings
1025 (middle) and, merge images (right) in the female demyelinated lesions. The white arrows show
1026 a high number of AR-expressing microglial cells compared to a more restricted number of
1027 *AR*⁺GFAP⁺ astrocytes or *AR*⁺Olig2⁺ oligodendroglia. The white arrowheads indicate AR-
1028 expressing cells clearly devoid of GFAP or Olig2 markers. The boxed areas are magnified in
1029 the insets. **f, g** Visualization of cells co-expressing either the AR protein or the DHT ligand with
1030 Iba1 marker. The white arrows show microglia co-expressing nuclear/perinuclear AR (f) and
1031 nuclear DHT staining (g). In (g), microglial or non-microglial (white and yellow arrowheads,
1032 respectively) cells displaying a perinuclear DHT labeling or cells expressing none of the
1033 markers (yellow arrow) are shown. **h** Quantification of the percentage of Iba1⁺ cells displaying
1034 a nuclear (Nuc) or perinuclear (Perinuc) labeling. **i** Co-visualization of *AR* transcripts with Iba1
1035 or GFAP immunostainings in the demyelinated corpus callosum (dotted line) from LPC-
1036 injected male mice. The boxes are cortical (yellow) and callosal (white) areas magnified in the
1037 corresponding inset. **j, k** Triple labeling of female or male lesions using Iba1 immunostaining
1038 with *Esr1* and *Esr2* ISH. The lesions are delineated by the dashed lines. The boxed areas are
1039 magnified in the insets. *Esr2* can be observed colocalized or not with *Esr1*. **l, m** Quantification
1040 of *Esr1* and *Esr2* signals. Scale bars (μm) : 100 (b, c, i, j, k), 50 (e), 10 (f, g). Data are mean
1041 values±SEM from n=4 (d,l,m) or n=5 (h) animals/condition examined over two independent
1042 experiments. *P* values (**d, h, l, m**) were calculated using the unpaired two-tailed *t*-test with
1043 Welch's correction (**d, l**) ; **, p=0.001 (**d**), p= 0.003 (**l**); ****, p<0.0001 (**h**). Source data are
1044 provided as a Source Data file.

1045 **Figure 2. AR mRNA expression in IBA1⁺ microglia/macrophages is up-regulated in the**
1046 **human female MS brain.** Post-mortem white matter samples from MS and non-neurological
1047 control donors were used to detect AR mRNA expression in fluorescently labelled IBA1⁺
1048 microglia/macrophages. **a** Representative images showing AR mRNA expression (red) within
1049 Iba1⁺ microglia/macrophages (cyan) in white matter from a female control donor and in active
1050 white matter demyelinated lesions from a female and male MS donor. Sections were
1051 counterstained with DAPI (blue). Scale bar 50μm. Magnified regions in inserts show AR⁺
1052 (white arrows) and AR⁻ (yellow arrows) microglia/macrophages. Scale bar 20μm. **b**
1053 Quantification of RNAscope experiment shows a significantly greater proportion of Iba1⁺ cells
1054 expressing AR mRNA in MS samples compared to controls ($F_{1,18} = 8.778$, $p = 0.00821$; post-
1055 hoc pairwise comparison: $t = 2.963$, $p = 0.0083$; control: median 34.70 (CI 30.00, 37.47), 25%
1056 percentile 32.50, 75% percentile 35.98, minimum 25.00, maximum 40.10; MS: median 46.60

1057 (CI 31.92, 52.00), 25% percentile 33.33, 75% percentile 51.43, minimum 25.77, maximum
1058 66.00), with a significant effect of sex, as significantly more Iba1⁺ cells express AR in females
1059 compared to males (linear mixed-effect model: $F_{1,18} = 10.411$, $p = 0.00459$; post-hoc pairwise
1060 comparison: $t = 3.231$, $p = 0.0046$). **c** Within MS donors, female samples show a significantly
1061 greater proportion of AR⁺Iba1⁺ cells compared to males ($F_{1,8} = 28.579$, $p = 0.000494$). No
1062 significant differences were detected among different lesion types ($F_{3,97} = 2.027$, $p = 0.1151$;
1063 WM: median 34.70 (CI 30.00, 37.47), 25% percentile 32.50, 75% percentile 35.98, minimum
1064 25.00, maximum 40.10; CIL: median 45.41 (CI 22.94, 56.00), 25% percentile 32.89, 75%
1065 percentile 52.28, minimum 22.94, maximum 56.00; AL: median 46.60 (CI 25.00, 72.03), 25%
1066 percentile 31.54, 75% percentile 59.94, minimum 25.00, maximum 72.03; NAWM: median
1067 (43.33 (CI 28.26, 52.00), 25% percentile 29.41, 75% percentile 51.36, minimum 27.78,
1068 maximum 64.00; CAL: median 40.54 (CI 26.53, 59.21), 25% percentile 32.64, 75% percentile
1069 54.57, minimum 26.53, maximum 59.21). Data were analysed by linear mixed-effects models
1070 followed by ANOVA to determine main effects and Tukey post-hoc pairwise comparisons.
1071 Each data point represents the average quantification of 5-10 different regions of interest from
1072 the same case (n=10 controls (5M, 5F), n=11 MS (5M, 6F)). AL, active lesion; CAL, chronic
1073 active lesion; CIL, chronic inactive lesion; NAWM, normal-appearing white matter; WM,
1074 white matter from control donors. Source data are provided as a Source Data file.

1075 **Figure 3. Testosterone and DHT induce a potent regeneration of myelin in female mice. a**
1076 Scheme of the experimental protocol. **b-g** Visualization of OPC proliferation in (**b, c**), OPC
1077 differentiation in (**d, e**) and MBP expression in (**f, g**) evaluated 7 days after LPC injection into
1078 the corpus callosum of ovariectomized females daily treated with the drug vehicle (Veh),
1079 testosterone (T) or dihydrotestosterone (DHT). In (**b**), the white arrows indicate Ki67⁺
1080 PDGFR α ⁺ proliferating OPCs. **h-k** Immunostaining of local inflammatory cells using Iba1 and
1081 Arg-1 antibodies for the detection of the microglial population and the cell subset expressing
1082 the anti-inflammatory marker Arg-1 in (**h, i**) as well as GFAP and STAT3 antibodies, as
1083 markers of astrocytes and their reactive state in (**j, k**). The dashed lines in (**d, f, h, j**) indicate
1084 the lesion. The boxed area in (**f, j**) is magnified in the inset. Scale bars: 50 μ m unless indicated.
1085 Data in (**c, e, g, i, k**) are presented as mean values \pm SEM from n=8 mice / group examined over
1086 2 independent experiments (3-5 slices / animal). **l-o** Scheme of the experimental protocol in (**l**).
1087 Electron microscopy analysis of the spinal cords from Vehicle and DHT-treated EAE females
1088 in (**m**) and determination of the g-ratio values plotted according to axon diameter in (**n**; 100
1089 axons per animal, n=3 / group) as well as the mean value of g-ratios in each group in (**o**; 100

1090 axons per animal, n=3 mice / group). The upper, middle and lower horizontal lines of the
1091 boxplots represent the upper, median and lower quartile, respectively. Whiskers depict the
1092 smallest or largest values within 1.5-fold of the interquartile range. *P* values were calculated by
1093 using the one-way ANOVA test together with Tukey's (c, i, k) or Holm-Sidak's (g) multiple
1094 comparisons test, Kruskal-Wallis test together with Dunn's multiple comparisons test (e), two-
1095 tailed Mann-Whitney test (o). Brown-Forsythe correction was used for (e left, i left, k right).
1096 **, $p \leq 0.01$; ***, $p \leq 0.001$; ****, $p \leq 0.0001$ compared to the control (Veh). ##, $p = 0.0049$
1097 compared to the indicated condition. Source data are provided as a Source Data file.

1098 **Figure 4. The combination of androgens and estrogens in LPC-demyelinated female**
1099 **animals leads to a regeneration process more efficient than the one induced by each**
1100 **molecule used alone. a** Scheme of the experimental paradigm. **b-i** Visualization of OPC
1101 proliferation in (b, c), OPC differentiation (d, e) and MBP immunostaining (f, g) as well as
1102 quantifications carried out 7 days after stereotaxic injection of LPC into the corpus callosum of
1103 ovariectomized female mice daily treated with the drug vehicle (Veh), dihydrotestosterone
1104 (DHT), estradiol (E2) or the combination of these molecules (DHT+E2). **h, i** Immunostaining
1105 of microglial cells by Iba1 and Arg-1 antibodies for the detection of the whole microglial
1106 population and the cell subset expressing the anti-inflammatory marker Arg-1. **j-n** Scheme of
1107 the protocol used for pharmacologically inhibiting the conversion of testosterone to estradiol
1108 by using the aromatase inhibitor, fadrozole (Fad) in (j). MBP in (k, l) and Iba1/Arg-1 in (m, n)
1109 immunostaining experiments were performed and quantified on slices from the different groups
1110 of LPC-demyelinated animals. In (b), the white arrows indicate Ki67⁺ PDGFR α ⁺ proliferating
1111 OPCs. The dashed lines in (d, f, h, k, m) delineate the lesion. Scale bars (μm): 50 in (b), 100
1112 in (d, f, h, k, m). Data are presented as mean values \pm SEM from n=8 mice / group in (c, e, g,
1113 i) examined over two independent experiments and n=4 mice / group in (l, n) examined in a
1114 single experiment (3-4 slices / per animal). *P* values were calculated by using the one-way
1115 ANOVA test together with Tukey's (c) or Holm-Sidak's (e, g, l, n) multiple comparisons test
1116 or Kruskal-Wallis test together with Dunn's multiple comparisons test (i). Brown-Forsythe
1117 correction was used for (e left, l). *, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$; ****, $p \leq 0.0001$
1118 compared to the control (Veh). #, $p \leq 0.05$; ##, $p \leq 0.01$; ####, $p \leq 0.0001$ compared to the indicated
1119 condition. Source data are provided as a Source Data file.

1120 **Figure 5. AR blockade alters spontaneous regeneration in female mice. a** Scheme of the
1121 experimental paradigm. Visualization and quantification of OPC proliferation in (b, c), OPC
1122 differentiation in (d, e) and MBP immunostaining in (f, g) at 7 days after stereotaxic injection

1123 of LPC into the corpus callosum of ovariectomized female mice daily treated with the drug
1124 vehicle (Veh) or the AR antagonist flutamide (Flu). In **(b)**, the white arrows indicate Ki67⁺
1125 PDGFR α ⁺ proliferating OPCs. **h, i** Immunostaining of microglial cells by using Iba1 and Arg-
1126 1 antibodies for the detection of the whole microglial population and the cell subset expressing
1127 the anti-inflammatory marker Arg-1. The dashed lines delineate the lesions. The boxed areas
1128 are magnified in the insets. **(j-m)** Visualization and quantification of MBP in **(j, k)** and
1129 Iba1/Arg-1 in **(l, m)** immunostaining at 10 dpl. Scale bars (μ m): 50 in **(b, j)**, 100 in **(d, f, h, l)**.
1130 Data are presented as mean values \pm SEM from n=6 mice / group in **(c, e, g, i)** and n=4 mice /
1131 group in **(k, m)** (3-4 slices / per animal). *P* values were calculated by using the unpaired two-
1132 tailed t-test **(c, k, m)** or two-tailed Mann-Whitney **(e, g, i)**. Welch's correction was used for **(c**
1133 **left, i right)**. *, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$; ****, $p \leq 0.0001$ compared to the control
1134 (Veh); n.s., non-significant. Source data are provided as a Source Data file.

1135 **Figure 6. Microglial AR is required for DHT-induced control of microglia response to**
1136 **demyelination.** **a** Scheme of the experimental paradigm. **b-g** Visualization and quantification
1137 of Arg-1 expression in Iba1-expressing microglial cells in **(b, c)**, OPC differentiation in **(d, e)**
1138 and GFAP immunostaining of astrocytes **(f, g)** at 7 days after stereotaxic injection of LPC into
1139 the corpus callosum of ovariectomized female mice expressing (AR wt/wt) or not (AR fl/fl) AR
1140 in microglia and treated with the drug vehicle (Veh) or DHT. The dashed lines delineate the
1141 lesions. Scale bars: 50 μ m. Data are presented as mean values \pm SEM from n=6 mice/condition
1142 examined in two independent experiments (3 slices / per animal). *P* values **(c, e, g)** were
1143 calculated by using the two-way ANOVA test together with Tukey's multiple comparisons test.
1144 **, $p=0.0069$ **(e left)**, $p=0.0061$ **(e right)**; ****, $p < 0.0001$ **(c)**, $p=0.0001$ **(g)**; n.s., not significant.
1145 Source data are provided as a Source Data file.

1146 **Figure 7. Therapeutic administration of androgens mitigates the course of EAE in female**
1147 **mice.** **a** Functional scores derived from EAE ovariectomized female mice treated with the drug
1148 vehicle (Veh), testosterone (T) or dihydrotestosterone (DHT) at onset of the first neurological
1149 symptoms (day 1) for 30 days (two-way ANOVA: treatment: $F(2, 1307)=298.2$, $p < 0.0001$;
1150 time: $F(29, 1307)=33.23$, $p < 0.0001$). **b, c** Smi-32 and MBP IHF performed on spinal cord
1151 slices derived from animals of each group. The boxed areas are magnified in the bottom panels.
1152 Determination of the fluorescent area is shown in the histograms on the right. **d, e** Electron
1153 microscopy analysis of the spinal cords and determination of the g-ratios plotted according to
1154 axon diameter or represented by their mean value. **f, g** Visualization and quantification of
1155 microglia immunostained with Iba1 (red) and Arg-1 (green) as markers of the whole microglia

1156 population and the cell subset that express the anti-inflammatory molecule Arg-1, respectively.
1157 **h, i** Visualization and quantification of astrocytes by using GFAP. **j, k** Detection of the tight
1158 junction protein Claudin-5 in each animal group. The boxed areas are magnified in the insets.
1159 Data are the mean \pm SEM from n=12 animals / condition in (**a**) or from n=8 animals / condition
1160 in (**g, i, k**) examined in a single experiment (3-4 slices / per animal). 600-900 axons from n=3
1161 mice in (**e**) were evaluated. *P* values were calculated by using the Kruskal-Wallis test together
1162 with Dunn's multiple comparisons test (**c, g**) or one-way ANOVA test together with Tukey's
1163 (**e, k**) or Holm-Sidak's (**i**) multiple comparisons test. Brown-Forsythe correction was used in
1164 (**k**). *, $p < 0.05$; **, $p < 0.01$; ***, $p < 0.001$ ****, $p < 0.0001$ versus the control condition. Scale
1165 bars (μm): 200 in (**b top**), 50 (**f, h, j**), 25 (**b bottom**). Source data are provided as a Source Data
1166 file.

1167 **Figure 8. The immune response triggered by DHT in EAE animals is strikingly different**
1168 **in female compared to male mice. a** Scheme of the experimental protocol. **b, c** Scoring of
1169 neurological disabilities in EAE female and male mice (n=8 / group) daily treated with DHT or
1170 the drug vehicle (Veh) at onset of neurological symptoms (day 1) for 8 days. **d-f** The spleen
1171 (n=8 females, 5 males) in (**d**), lymph nodes in (**e**) and spinal cord in (**f**) (n=7 females, 5 males)
1172 from each animal group examined in a single experiment were harvested in order to perform
1173 flow cytometry analysis and dosage of cytokines. Data are presented as mean values \pm SEM.
1174 The gating strategies for flow cytometry analysis are shown in Supplementary Fig. 4-7. Only
1175 the cell types regulated by DHT are shown. In the lymphoid organs and spinal cord, immune
1176 cell types are expressed in percentage of all cells and CD45⁺ leukocytes, respectively. Similarly,
1177 a panel of 9 cytokines has been assessed (as described in Methods). Only cytokines regulated
1178 by DHT are shown in red boxes. *P* values (**d, e, f**) were calculated by using the unpaired two-
1179 tailed t-test or Mann-Whitney tests. Welch's correction was used for IFN γ (**e**) and IL1- β (**f**) in
1180 females. *, $p \leq 0.05$; **, $p \leq 0.01$; ***, $p \leq 0.001$ compared to the control (Veh); n.s, non-
1181 significant. Source data are provided as a Source Data file.

1182 **Figure 9. DHT controls differently the local inflammatory cells in EAE female and male**
1183 **mice. a** Scheme of the experimental protocol. Immunostaining of microglial and astroglial cells
1184 in the spinal cord from vehicle or DHT-treated female in (**b-h**) or male in (**i-o**) mice. **b, c**
1185 Visualization and quantification of microglia in the whole white matter of vehicle-treated
1186 females indicate numerous spots of Arg-1⁺ cells extending deeply into the white matter (white
1187 arrows in **b**) strongly reduced under DHT treatment. **d, e** Visualization and quantification of
1188 Iba1 and Arg-1 staining at the level of an individual lesion indicating that Iba1 staining is still

1189 decreased whereas Arg-1⁺ area is significantly higher under DHT treatment. **f, g** GFAP⁺
1190 astrogliosis is shown in whole spinal cord slices co-labelled by MBP antibody aimed at
1191 visualizing myelin. Numerous spots of demyelinated tissue are shown (white arrows) in the
1192 vehicle- compared to the DHT condition. Magnifications of the boxed areas show that DHT
1193 treatment is accompanied by the decrease of GFAP staining in the grey matter (GM) and
1194 conversely its increase in the white matter (WM). **h** Quantification of MBP⁺ area in the white
1195 matter. **i-l** Visualization and quantification of Iba1 and Arg-1 staining in the spinal cord from
1196 male in the whole white matter in (**i, j**) and at the level of individual lesions in (**k, l**). **m-o**
1197 Visualization of GFAP and MBP staining in (**m**). Quantification of GFAP⁺ fluorescence in the
1198 white (WM) and grey (GM) matter in (**n**) and of MBP in the white matter in (**o**). The boxed
1199 areas in (**b, i**) are magnified in (**d, k**). Data are presented as mean values \pm SEM from n= 8 mice
1200 / group examined in a single experiment (3-4 slices / per animal). *P* values (**c, e, g, h, j, l, n, o**)
1201 were calculated by using the unpaired two-tailed t-test or Mann-Whitney test. Welch's
1202 correction was used for (**e left, j, h**). **, $p \leq 0.01$; ***, $p \leq 0.001$; ****, $p \leq 0.0001$; n.s, non-
1203 significant. Scale bars (μm): 200 in (**b, f top, i**), 50 in (**m**), 25 (**d, f bottom, k**). Source data are
1204 provided as a Source Data file.

1205 **Figure 10. RNA-Seq analysis of the spinal cord derived from EAE mice therapeutically**
1206 **treated with DHT reveal major differences between female and male animals. a** Scheme
1207 of the experimental protocol. **b, c** PCA plot of two first components with their contribution to
1208 the variance depicting clear differences between DHT-treated (DHT, n=3) and control (CT,
1209 n=4) samples in the first PCA component, which contributes for more than half of the variance
1210 of the experiment, in females in (**b**) and in males in (**c**) examined in two independent
1211 experiments. The size of the sample name and the circle indicate the relative contribution to the
1212 total variance. **d, e** Barplots and tables showing the contribution of oligodendroglial curated
1213 DEGs genes to promote (positive) or inhibit (negative) each process of oligodendrogenesis in
1214 females in (**d**) and in males in (**e**). Note that DHT mainly promotes (re)myelination. (**f, g**)
1215 Dotplot representating the top 7 biological processes enriched in up-regulated genes in DHT-
1216 treated females in (**f**) and DHT-treated males in (**g**) compared to their respective controls,
1217 showing similar up-regulation of synaptic and neuronal associated processes in both sexes. **h, i**
1218 Dotplot representating the top 7 biological processes enriched in down-regulated genes in DHT-
1219 treated females in (**h**) and DHT-treated males in (**i**). Note that while down-regulated genes are
1220 implicated in immune processes in females in (**h**), they are implicated in catabolism in males in
1221 (**i**). **j-l** Histograms visualizing the deregulation of genes characterizing homeostatic in (**j**),

1222 Disease-Associated in **(k)** and White matter-Associated in **(l)** microglia by DHT in EAE
1223 females or males. Multiple testing correction aimed at controlling the false discovery rate (FDR,
1224 p-adjust) was performed by using the Benjamini-Hochberg method **(f-i)**. Fisher test was used
1225 as well as multiple testing correction aimed at controlling the false discovery rate (FDR, p-
1226 adjust) performed by using the Benjamini-Hochberg method **(j-l)**. *, FDR<0.05; **, FDR<0.01;
1227 ***, FDR<0.001.
