19

20 **Abstract**

21 **Aims**

22 Psychotropic medication may be associated with adverse effects, including among people with  
23 diabetes. We conducted a systematic review of observational studies investigating the association  
24 between antidepressant or antipsychotic drug prescribing and type 2 diabetes outcomes.

25 **Methods**

26 We systematically searched PubMed, EMBASE, and PsycINFO to 15<sup>th</sup> August 2022 to identify eligible  
27 studies. We used the Newcastle-Ottawa scale to assess study quality and performed a narrative  
28 synthesis.

29 **Results**

30 We included 18 studies, 14 reporting on antidepressants and four on antipsychotics. There were 11  
31 cohort studies, one self-controlled before and after study, two case-control studies, and four cross-  
32 sectional studies, of variable quality with highly heterogeneous study populations, exposure  
33 definitions, and outcomes analysed. Antidepressant prescribing may be associated with increased  
34 risk of macrovascular disease, whilst evidence on antidepressant and antipsychotic prescribing and  
35 glycaemic control was mixed. Few studies reported microvascular outcomes and risk factors other  
36 than glycaemic control.

37 **Conclusions**

38 Studies of antidepressant and antipsychotic drug prescribing in relation to diabetes outcomes are  
39 scarce, with shortcomings and mixed findings. Until further evidence is available, people with  
40 diabetes prescribed antidepressants and antipsychotics should receive monitoring and appropriate  
41 treatment of risk factors and screening for complications as recommended in general diabetes  
42 guidelines.

43

44

45

46 **1. INTRODUCTION**

47 Antidepressant and antipsychotic drugs are common psychotropic medications used in treating  
48 mental illness such as major depression, bipolar disorder, and schizophrenia [1, 2], with prescribing  
49 having increased in high income countries in recent years [3, 4]. This may be partly driven by longer  
50 treatment duration, but also by more frequent use, including for other indications (such as agitation  
51 and aggression in autism spectrum disorder and dementia [5], and chronic pain, migraines, and  
52 insomnia [6]). This increased use of psychotropic drugs is of particular concern given that they  
53 appear to be associated with risk factors for cardiovascular disease and type 2 diabetes such as  
54 obesity, insulin resistance, and dyslipidaemia [7, 8], as well as major cardiovascular events such as  
55 coronary heart disease and stroke [9, 10].

56 These adverse effects must be considered in the context of their use among people with diabetes,  
57 including the bidirectional links between mental illness and diabetes [11] and the use of tricyclic  
58 antidepressants (TCA) to treat neuropathic pain occurring as a complication of diabetes [12].

59 Previous reviews have summarised evidence from experimental studies on the effect of  
60 antidepressants on outcomes including cardiometabolic risk factors in people with diabetes [13, 14].  
61 Although these reviews concluded that some antidepressant subtypes may be associated with  
62 improved glycaemic control, the overall evidence was inconclusive, in part due to low study quality,  
63 small sample sizes, and insufficient follow-up to adequately investigate longer-term outcomes such  
64 as vascular morbidity or mortality.

65 To our knowledge there is no previous systematic review of observational studies reporting the  
66 association between antidepressant or antipsychotic drugs and diabetes outcomes. We therefore  
67 conducted a systematic review of observational studies in people with diabetes that examined the  
68 association between antidepressant or antipsychotic drug prescribing and diabetes outcomes  
69 including cardiometabolic risk factors, macrovascular and microvascular disease complications, and  
70 mortality.

71

72 **2. Materials and methods**

73 This review is reported in accordance with the PRISMA guidelines. The review protocol was not  
74 registered

75 **2.1 Data sources and searches**

76 We searched PubMed, EMBASE, and PsycINFO from point of inception to August 15<sup>th</sup> 2022 using a  
77 comprehensive electronic search strategy (Supplemental Appendix 1).

78 **2.2 Study selection**

79 We included cohort, case-control, self-controlled, or cross-sectional studies conducted among adults  
80 with type 2 diabetes that examined the association between prescribing of any antidepressant  
81 and/or antipsychotic drug versus no prescribing in relation to diabetes outcomes (cardiometabolic  
82 risk factors [glycaemic control; blood pressure; or lipid levels], macrovascular or microvascular  
83 disease; and all-cause or cause-specific mortality). See Supplemental Table 1 for a detailed summary  
84 of the inclusion criteria. We did not limit our search to studies published in the English language, but  
85 ultimately only included English language articles.

86 Two reviewers (CRLG and HWP or MFI and CAJ) independently screened titles and abstracts and the  
87 full-text of potentially eligible articles and extracted information on study and population  
88 characteristics, exposure and outcome/case definitions, statistical methods, and results from  
89 included articles. Disagreements about suitability for inclusion or data extracted were resolved  
90 through discussion with a third reviewer (CAJ or SHW).

91 **2.3 Quality assessment**

92 Two reviewers (CRLG and HWP or MFI and CAJ) assessed methodological study quality using the  
93 Newcastle-Ottawa scale [15]. This assesses the quality of observational studies across eight items  
94 within three domains: (i) the selection of the study groups; (ii) the comparability of the groups; (iii)  
95 the ascertainment of either the outcome or exposure of interest, where relevant.

96 **2.4 Data synthesis and analysis**

97 We performed a narrative synthesis since substantial clinical and methodological heterogeneity  
98 between studies precluded meta-analysis.

99

## 100 **3 RESULTS**

### 101 **3.1 Study characteristics**

102 Our search yielded 11,216 articles, with 19 eligible articles representing 18 studies ultimately  
103 included (Figure 1).

104 Study characteristics are described in Table 1. Details of the antidepressant and antipsychotic drugs  
105 included within each study are given in Supplemental Table 2. Eleven studies were cohort [16-26],  
106 one was a self-controlled before and after study [27], two were case-control [28, 29], and four were  
107 cross-sectional [30-33]. Two studies included overlapping study populations [21, 27], but adopted  
108 different study designs to address a similar question and so both were included in the narrative  
109 synthesis. There was considerable heterogeneity between studies in terms of study population,  
110 exposure definitions, and outcomes analysed. All studies were from high-income countries. Study  
111 populations were most frequently derived from people with newly diagnosed diabetes in the general  
112 population, with two studies conducted in low-income study populations [30, 31]. Two studies  
113 included a study population with comorbid mental illness and diabetes (one with depression [25]  
114 and one with schizophrenia [24]).

### 115 **3.2 Quality assessment**

116 Methodological study quality ranged from three to eight out of nine stars (Supplemental Table 3).  
117 Concerns arising in some studies included: poor comparability due to insufficient adjustment for  
118 relevant confounders including confounding by indication; use of self-report for exposure and/or  
119 outcome assessment; poor representativeness of the population; low precision due to small sample  
120 sizes; and no description of the response rate and/or attrition (where applicable).

### 121 **3.3 Antidepressant prescribing and diabetes outcomes**

#### 122 **3.3.1 Glycaemic control**

123 Of 14 studies reporting on antidepressant prescribing, six studies reported outcomes in relation to  
124 glycaemic control [16, 21, 22, 27, 29, 31], with mixed findings. Of the three cohort studies, two  
125 reported no statistically significant difference in the association between antidepressant prescribing  
126 and optimal glycaemic control [21, 22]. The third study reported that antidepressant prescribing was  
127 associated with reduced risk of sub-optimal glycaemic control [16]. Interestingly, a pre-post study  
128 reported lower HbA1c levels following antidepressant medication initiation [27]. One cohort study  
129 also reported that antidepressant prescribing was associated with increased odds of prescribing of  
130 glucose lowering drugs (GLDs) [21]. Similarly, a case-control study found that among people with  
131 newly diagnosed diabetes, current receipt of selective serotonin reuptake inhibitor (SSRI)  
132 antidepressant prescriptions was associated with more than two-fold increased risk of insulin  
133 prescription [29]. Similar associations were observed for other antidepressant subtypes and for  
134 other durations, with no associations observed for past prescriptions (Table 2). A cross-sectional  
135 study among people from low-income areas found that antidepressant prescribing from multiple  
136 subtypes was associated with higher values of HbA1c, after adjustment for depression severity [31],  
137 whereas there was no association between individual antidepressant subtype prescribing and HbA1c  
138 levels.

### 139 **3.3.2 Other cardiometabolic risk factors**

140 One cohort study found that antidepressant prescribing was associated with abnormal lipid profiles  
141 or receipt of lipid-lowering medication [22], whereas a second reported that antidepressant  
142 prescribing may have a small protective effect on cholesterol levels [21]. Findings were broadly  
143 consistent by prescription timing and across antidepressant subtypes (Supplemental Table 5a).

### 144 **3.3.3 Macrovascular and microvascular disease complications and mortality**

145 Eight studies reported associations with macrovascular and microvascular disease complications of  
146 diabetes, comprising six cohort [17-20, 25, 26] and two cross-sectional studies [30, 33] (Table 2 and  
147 Supplementary Table 4a). Outcomes were heterogeneous and findings were mixed.

148 Receipt of antidepressant prescriptions, in comparison to no record of antidepressant prescribing,  
149 was associated with higher crude incidence of myocardial infarction (MI) [20] and of a composite  
150 macrovascular outcome [25]. However, lack of adjustment for age, sex and other factors that may  
151 differ between groups limits conclusions from these studies. A third cohort study found that SSRI  
152 antidepressant prescribing was associated with increased risk of 30-day post-stroke mortality [26],  
153 with the excess risk greatest for people whose SSRI prescription was initiated shortly before stroke.  
154 A cross-sectional study of older men of low-income from one treatment centre reported greater  
155 odds of a composite cardiovascular morbidity outcome and of MI specifically in crude analyses  
156 without control of confounding factors [30]. In contrast, a cohort study with a median of 9.6 years  
157 follow-up derived from post-hoc analyses of a clinical trial for a weight loss intervention [19]  
158 reported that antidepressant prescribing was associated with reduced cardiovascular morbidity or  
159 mortality in women, but not men. Risk of peripheral artery disease was reported to be similar in  
160 those with diabetes prescribed versus not prescribed antidepressants [18]. Finally, the only cohort  
161 study to describe microvascular complications reported higher crude incidence of a composite  
162 microvascular outcome in people prescribed antidepressants among a Taiwanese cohort of people  
163 newly treated for diabetes [25], whilst a small cross-sectional study of people with a diagnosis of  
164 diabetes or with HbA1c 6.5% who took part in the National Health and Nutrition Examination Survey  
165 in the US found that self-reported antidepressant use was associated with lower odds of retinopathy  
166 compared to people not reporting antidepressant use, after adjusting for sociodemographic and  
167 clinical characteristics [33] (Table 2). Supplemental Table 5a includes details of additional results  
168 reported in some studies, including investigations of variations of composite outcomes, interactions,  
169 and associations by antidepressant subtypes, with findings generally consistent with primary results.

170

### 171 **3.4 Antipsychotic prescribing and diabetes outcomes**

#### 172 **3.4.1 Glycaemic control**

173 Just four studies reported on antipsychotic prescribing in relation to diabetes outcomes. Two studies  
174 reported a link between that antipsychotic prescribing and poorer glycaemic control [23, 28], and  
175 one reported the opposite [32]. The only cohort study [23] found that receipt of an antipsychotic  
176 prescription within the first two years of diabetes diagnosis was associated with a two-fold increased  
177 risk of first insulin prescription, which attenuated to a 30% increased risk after adjustment for other  
178 drug prescriptions (Table 3). In a case-control study of older adults, receipt of an antipsychotic  
179 prescription in the previous 180 days was associated with an increased risk of hospitalisation for  
180 hyperglycaemia, regardless of diabetes medication type [28]. This effect was strongest among those  
181 receiving a first prescription of antipsychotics (Table 3) and consistent across antipsychotic subtypes  
182 (Supplemental Table 4b). In contrast, a cross-sectional study found that mean HbA1c values were  
183 significantly lower in people prescribed antipsychotics for more than 12 months in total compared  
184 with those who never received antipsychotics [32].

#### 185 **3.4.2 Other cardiometabolic risk factors**

186 Antipsychotic prescribing was also associated with significantly lower systolic and diastolic blood  
187 pressure and total cholesterol in one study, though absolute differences were small (Supplemental  
188 Table 5b) [32].

#### 189 **3.4.3 Macrovascular or microvascular disease complications and mortality**

190 Two studies reporting on the association between antipsychotic prescribing and macrovascular or  
191 microvascular disease complications of diabetes used population-based national registers [24, 32]. A  
192 cohort study of people with schizophrenia found that, compared to no antipsychotic prescribing,  
193 regular antipsychotic prescribing was associated with a 20% and 27% reduced risk of cardiovascular  
194 morbidity, and all-cause mortality, respectively [24] (Table 3). There was no clear evidence of an  
195 association between antipsychotics and microvascular complications. When stratifying by metabolic  
196 risk of antipsychotics, the authors found that drugs considered to have an intermediate or high  
197 metabolic risk were associated with a significantly reduced risk of all complications including  
198 cardiovascular and microvascular morbidity (Supplemental Table 5b).

199 A second, cross-sectional, study found that the prevalence of retinopathy was lower in people who  
200 had been prescribed antipsychotics for a total of more than 12 months than in a comparison group  
201 matched for age, sex, diabetes type and duration, body mass index, and smoking status that had not  
202 been prescribed antipsychotics (Table 3) [32].

203

#### 204 **4. DISCUSSION**

205 Our review revealed that few observational studies have investigated the association between  
206 antidepressant and antipsychotic drug prescribing and diabetes outcomes. Studies describing  
207 associations with cardiometabolic risk factors other than glycaemic control and microvascular  
208 disease or the association between antipsychotic prescribing and any diabetes outcomes were  
209 particularly limited. The published studies are highly heterogeneous, in terms of the study  
210 population, exposure definitions, and outcomes. Lack of comparability and study shortcomings  
211 highlight key gaps and limit conclusions. Tentative conclusions are that, among people with diabetes,  
212 antidepressant prescribing may be associated with an increased risk of cardiovascular morbidity or  
213 mortality, and both antidepressant and antipsychotic prescribing may be linked to poorer glycaemic  
214 control. However, evidence is mixed.

##### 215 **4.1 Interpretation of findings in relation to other studies**

216 Our findings on antidepressant prescribing and reduced risk of cardiovascular morbidity or mortality  
217 in people with diabetes contrast with previous reviews which report the opposite in general  
218 populations (those that include both people with and without diabetes) [9, 34]. These contrasting  
219 findings may reflect key differences in associations for different population sub-groups. Indeed,  
220 pooled results of only studies including people with, or at high risk of, cardiovascular disease  
221 similarly found that antidepressant use or prescribing was associated with a statistically non-  
222 significant reduced risk of cardiovascular morbidity [34]. Systematic reviews of trials suggest that  
223 SSRI use can improve short-term glycaemic control in people with diabetes [13, 14]. Some of the  
224 observational studies we identified found similar results, but others found no differences in

225 glycaemic control between groups, perhaps related to study population, design, sample size, and  
226 approaches to control of confounding.

227 The association between antipsychotic prescribing and reduced mortality risk in people with  
228 schizophrenia and diabetes described in a single cohort study [24] aligns with findings on  
229 antipsychotic prescribing and reduced long-term mortality risk in people with schizophrenia,  
230 including both people with and without diabetes [35, 36]. The findings from this cohort study [24] do  
231 however contrast with previous reports of a link between antipsychotic prescribing and increased  
232 cardiovascular disease risk in general populations [10, 37]. Although counter-intuitive, given their  
233 adverse metabolic and cardiovascular effects [8, 38, 39], antipsychotic use alongside psychological  
234 support in people with severe mental illness (SMI) may improve physical and psychosocial  
235 functioning, thereby improving adherence to lifestyle modification and treatment, which in turn  
236 could reduce risk of diabetes complications. The few studies on antipsychotic prescribing suggest an  
237 association with poorer glycaemic control, which aligns with established adverse glycaemic effects of  
238 some antipsychotics [40].

#### 239 **4.2 Strengths and limitations**

240 To the best of our knowledge, this is the first systematic review of observational studies reporting  
241 associations between antidepressant or antipsychotic drug prescribing and outcomes including  
242 cardiometabolic risk factors, macrovascular and microvascular disease complications, and mortality  
243 in people with diabetes. Other strengths include our use of a detailed and comprehensive search  
244 strategy applied to three bibliographic databases, independent screening and data extraction by two  
245 reviewers, and assessment of study quality.

246 A limitation of this review is the exclusion of outcomes related to weight changes and obesity, that  
247 have previously been linked to antidepressant and antipsychotic use [38, 41], as these outcomes  
248 were beyond the scope of our review. Also beyond our scope were studies which reported on  
249 progression of diabetes complications or compared prescribing of different psychotropic drugs. The  
250 latter point is particularly important when investigating adverse effects of antidepressant and

251 antipsychotic prescribing in people with SMI, where given the clinical need to prescribe,  
252 consideration of the risk and benefits of individual drugs is crucial. Finally, cross-sectional studies  
253 were included in our review because of the limited work in this area. However, as diabetes  
254 complications may lead to psychotropic medication prescribing further prospective studies are  
255 required.

256 Further limitations reflect the limitations of existing studies. Some studies were small, with low  
257 precision of effect estimates. Many had insufficient control of confounding factors, including lifestyle  
258 behaviours, socioeconomic status, and critically, are prone to confounding by indication, particularly  
259 for mental illness. Mental illness is associated with higher risk of poor diabetes outcomes [42-44],  
260 partly through higher prevalence of unhealthy lifestyle factors, including overweight/obesity, lower  
261 socioeconomic status [45], poorer treatment adherence, and in some settings, receipt of sub-  
262 optimal care [45]. Conversely, in other settings, people with diabetes comorbid with mental illness  
263 may be more likely than people with diabetes without mental illness to receive optimal routine  
264 monitoring of certain care indicators [46], perhaps due to more frequent visits to their primary care  
265 practitioner [47]. Social desirability and recall bias may have affected studies where exposure status  
266 was identified using interviews or assessment visits, leading to dilution of effect estimates. Whilst  
267 information bias and loss to follow-up will have been minimised in studies based on electronic  
268 health records, prescribing records may not necessarily reflect actual drug use. Moreover, some  
269 studies based on routine data may not have had information on outcomes where patients were not  
270 admitted to hospital.

### 271 **4.3 Implications**

272 Implications for practice are limited by the sparse existing literature in this area, with further  
273 research needed to inform clinical practice. The increased use of antidepressant and antipsychotic  
274 medications in the general population is concerning given the evident lack of understanding of  
275 potential for adverse effects and the increasing prevalence of diabetes. The striking gap in the  
276 evidence on antipsychotic drug prescribing in relation to diabetes outcomes in particular should be

277 urgently addressed. Antidepressant and antipsychotic drugs are an essential component of the  
278 treatment of mental health conditions, and timely treatment in people with diabetes is crucial, given  
279 the poor diabetes outcomes for people with both diabetes and mental illness [48]. It is therefore  
280 important to establish treatment-associated risks of diabetes outcomes within population sub-  
281 groups to inform and enhance drug prescribing and monitoring practices for diabetes and its  
282 complications. To improve upon existing studies and advance our understanding, future studies  
283 should: be well-powered (particularly to investigate differences); include information on mental  
284 illness, lifestyle, and other confounding factors; distinguish between drug subtypes; assess whether  
285 and how risk changes over time; and consider the potential effects of cumulative exposures.

#### 286 **4.4 Conclusions**

287 Few studies have described the association between antidepressant and antipsychotic prescribing  
288 and diabetes outcomes, with shortcomings and mixed findings limiting the ability to draw  
289 conclusions. While future research addresses this evidence gap, at present monitoring  
290 cardiometabolic risk factors and screening for complications in people with diabetes who are being  
291 treated with antidepressant or antipsychotic medication (irrespective of indication) should be  
292 performed at least as frequently as recommended in current guidelines for people with diabetes.

**Supplemental Table 1: Study inclusion and exclusion criteria (PICO framework)**

	<b>Inclusion</b>	<b>Exclusion</b>
<b><u>P</u>opulation</b>	Adults with pre-existing type 2 diabetes mellitus in any location or setting	Children (< 18 years); people with type 1 diabetes mellitus; studies that did not report separately on outcomes in people with diabetes; studies where the study population was selected on the presence of a specific disease of interest and where data on psychotropic medication prescribing was reported for a sub-set of the study population with diabetes but without the provision of key descriptive characteristics of the sub-set
<b><u>I</u>ntervention</b>	All type antidepressant and/or antipsychotic drug use or prescribing	Lithium use or prescribing only
<b><u>C</u>omparison</b>	The absence of antidepressant and/or antipsychotic drug use or prescribing	A second antidepressant and/or antipsychotic drug; no comparison group
<b><u>O</u>utcome</b>	<p><i>Clinical complications (primary)</i>      Cardiovascular morbidity; retinopathy; neuropathy; nephropathy; all-cause mortality; cause-specific mortality</p> <p><i>Cardiometabolic risk factors (secondary)</i>      Glycaemic control (HbA1c, hyperglycaemia, insulin initiation); blood pressure (hypertension, systolic/diastolic); lipid levels (dyslipidaemia, low-density/high-density lipoprotein cholesterol, total cholesterol, triglycerides)</p>	Outcomes related to the progression of clinical complications; weight changes/obesity; outcomes related to mental wellbeing
<b>Study design</b>	Observational studies (cohort, case-control, cross-sectional); accessible in the English language	Case reports; experimental studies; secondary studies (narrative reviews, literature reviews, meta-analyses)

**Supplemental Table 2 (a):** Details of antidepressant drugs included in studies reporting on antidepressant prescribing in relation to diabetes outcomes

Rohde, 2022 [26] Denmark [January 2000 to October 2016]	ATC	Fluoxetine (B03) Citalopram (B04) Paroxetine (B05) Sertraline (B06) Fluvoxamine (B08) Escitalopram (B10)	Imipramine (A02) Clomipramine (A04) Amitriptyline (A09) Nortriptyline (A10)	Mianserin (X03) Mirtazapine (X11) Venlafaxine (X16) Reboxetine (X18) Duloxetine (X21)

\*List not comprehensive, authors specified commonly prescribed drugs only

AD: antidepressant; ATC: Anatomical Therapeutic Chemical; MAOI: monoamine oxidase inhibitor; NR: not reported; SNRI: serotonin–norepinephrine reuptake inhibitor; SSRI: selective serotonin reuptake inhibitor; TCA: tricyclic antidepressant

NB. The ATC classification system is the gold standard for identifying drugs in international drug research. It is maintained by the World Health Organization Collaborating Centre for Drug Statistics Methodology ([www.whocc.no](http://www.whocc.no)). ADs are classified at the third level, N06A, and divided into groups at higher levels according to their therapeutic, pharmacological, and chemical properties. Relevant groups include SSRIs (N06AB-), TCAs (N06AA-), MAOIs, (N06AF/G-), and other (N06AX-). Drugs including venlafaxine (X16) and duloxetine (X21) may also be classified as SNRIs.

Supplemental Table 2 (b): Details of antipsychotic drugs included in studies reporting on antipsychotic prescribing in relation to diabetes outcomes

First author, publication year, study setting [study period]	Method of identification	FGAs (ATC N05A-)	SGAs (ATC N05A-)
Spoelstra, 2004 [22] Netherlands [January 1991 to June 1999]	ATC	NR	Clozapine (H02) Olanzapine (H03) Quetiapine (H04) Risperidone (X08)
Lipscombe, 2009* [32] Canada [April 2002 to March 2006]	NR	NR	Olanzapine (H03) Quetiapine (H04) Risperidone (X08)
Wake, 2016 [29] UK [2010]	BNF subsection 4.2. <sup>†‡</sup>	NR	NR
Wu, 2016 [23] Taiwan [2001 to 2012]	ATC	Chlorpromazine (A01) Levomepromazine (A02) Promazine (A03) Fluphenazine (B02) Perphenazine (B03) Prochlorperazine (B04) Trifluoperazine (B06) Thioridazine (C02) Pipotiazine (C04) Haloperidol (D01) Flupentixol (F01) Zuclopenthixol (F05) Pimozide (G02) Loxapine (H01)	Clozapine (H02) Olanzapine (H03) Quetiapine (H04) Sulpiride (L01) Amisulpride (L05) Risperidone (X08) Zotepine (X11)

\*Included APs funded by the Ontario Drug Benefit programme during the study period

<sup>†</sup>The BNF is a reference for drug prescribing used in the UK

<sup>‡</sup>Subsection 4.2.1 refers to APs, this excludes: depot injection formulations (BNF subsection 4.2.2); prochlorperazine (B04) and droperidol (D08) (BNF section 4.6, drugs used for vertigo); and asenapine (H05) and lithium (N01) (BNF section 4.2.3, drugs used for mania and hypomania)

AP: antipsychotic; ATC: Anatomical Therapeutic Chemical; BNF: British National Formulary; FGA: first-generation antipsychotic; NR: not reported; SGA: second-generation antipsychotic

NB. The ATC classification system is the gold standard for identifying drugs in international drug research. It is maintained by the World Health Organization Collaborating Centre for Drug Statistics Methodology ([www.whocc.no](http://www.whocc.no)). APs are classified at the third level, N05A, and divided into groups at higher levels according to their therapeutic, pharmacological, and chemical properties. Relevant groups include FGAs and SGAs.

Supplemental Table 3: Assessment of study quality: Newcastle-Ottawa Scale summary

First author, year	Selection	Comparability	Outcome/Exposure	Total stars
<b><i>COHORT STUDIES</i></b>				
Spolstra, 2004 [22]	****	*	***	8/9
Rubin, 2010, 2013 [21]	***	*	**	6/9
Rådholm, 2015 [19]	****		***	7/9
Brieler, 2016 [15]	****	*	***	8/9
Wu, 2016 [23]	****	*	***	8/9
Würtz, 2016 [25]	****		***	7/9
Hazuda, 2019 [18]	***	*	**	6/9
Rohde, 2021 [20]	****	*	***	8/9

Kammer, 2016 [28]		*	**	3/9
Wake, 2016 [29]	****	*	*	6/9

Studies were awarded a maximum of four stars for study selection, two stars for group comparability, and three stars for ascertainment of outcome or exposure, to a maximum total of nine. Separate versions of the scale were used for cohort, case-control, and cross-sectional studies.

Supplemental Table 4 (a): Additional information on adjustment for confounding in statistical models for the association between antidepressant prescribing and outcomes

First author, year	Statistical methods	Confounders adjusted for in analyses	Details of composite outcomes (where relevant)
<b>COHORT STUDIES</b>			
Rubin, 2010, 2013 [22]	GEE	Age; sex; ethnicity; education; HbA1c (prior year); history of CVD; duration of diabetes; AD prescription (prior year); year of follow-up	NA
Rådholm, 2015 [20]	Descriptive	Stratified by age and sex	NA
Brieler, 2016 [16]	GEE	Age; sex; ethnicity; anxiety disorder; obesity; hyperlipidaemia; hypertension; vascular disease; referral to dietary education; smoking; insulin prescription; other GLD prescription; primary care clinic utilisation	NA
Wu, 2016 [24]			CV morbidity (hospitalisation for CHD and stroke; PVD with stent insertion; vascular shunt or bypass; vessel repair procedure), microvascular morbidity (retinopathy; blindness; end-stage renal disease with dialysis; vessel operations for haemodialysis; kidney transplantation; hospitalisation for diabetic foot infection; lower extremity amputations), all-cause mortality
Würtz, 2016 [26]	Cox proportional hazards	Previous MI, atrial fibrillation or flutter; intermittent arterial claudication; dementia; CCI (excluding MI, PVD, and dementia); other drug prescriptions	NA
Hazuda, 2019 [19]	Cox proportional hazards	Age; ethnicity; history of CVD; HbA1c; BMI; waist circumference; insulin prescription; hypercholesterolaemia; hypertension; smoking; estimated exercise stress level; HRT prescription (women only); clinic attended; assigned clinical trial intervention	Non-fatal MI; stroke; angina; CHF; PVD; CABG; carotid endarterectomy; CV and all-cause mortality
Chen, 2021 [17]	Cox proportional hazards	Age; sex; income; urbanisation; hypertension; hypercholesterolaemia; CAD; CKD; heart failure; peptic ulcer; aspirin; clopidogrel (Plavix) prescription	NA
Rohde, 2021 [21]	Cox proportional hazards	Age; sex; marital status; HbA1c (baseline); LDL levels (baseline); obesity; kidney functioning; CCI (excluding diabetes); diabetes complications; alcohol-related disorders; smoking-associated disorders; other drug prescriptions	NA
Wu, 2021 [25]	None	Crude incidence in comparison groups	Macrovascular morbidity (IHD; stroke; PVD; vascular shunts or

			bypasses; vessel repair procedures), microvascular morbidity (retinopathy; end-stage renal disease; diabetic foot infections), all-cause mortality
Chen 2022 [18]	Cox proportional hazards	Age; sex; economic level; urbanisation; CCI score; hypertension; acute MI; hyperlipidaemia; atrial fibrillation; COPD; depression; bipolar disorder; schizophrenia; alcoholism; antithrombotic medication prescriptions*; TCA prescriptions; other AD prescriptions	NA
<b><i>SELF-CONTROLLED STUDIES</i></b>			
Rhode, 2022 [27]	Mean percent change	Individuals serve as their own controls, allowing adjustment for all time-stable confounders; findings externally compared to those from an age-sex matched reference population	NA
<b><i>CASE-CONTROL STUDIES</i></b>			
Noordam, 2016 [29]	Conditional logistic regression	Age; sex; BMI; number of prescribed oral GLDs	NA
<b><i>CROSS-SECTIONAL STUDIES</i></b>			
Higgins, 2007 [30]	Logistic regression	None for relevant analyses	CAD; MI; angioplasty; CABG
Yekta, 2015 [33]	Logistic regression	Age; sex; ethnicity; income; diabetes duration; HbA1c; SBP; TG levels; BMI; smoking	NA
Kammer, 2016 [31]	Linear regression	Age; sex; ethnicity; education; depression severity; BMI; smoking	NA

\*Including: warfarin; acetylsalicylic acid; cilostazol; clopidogrel; prasugrel; ticagrelor; ticlopidine; dabigatran etexilate; apixaban; edoxaban; rivaroxaban

AD: antidepressant; BMI: body mass index; CABG: coronary artery bypass graft; CCI: Charlson Comorbidity Index; COPD: chronic obstructive pulmonary disease; CAD: coronary artery disease; CHD: coronary heart disease; CHF: congestive heart failure; CKD: chronic kidney disease; CV: cardiovascular; CVD: cardiovascular disease; GLD: glucose lowering drug; HbA1c: glycated haemoglobin; IHD: ischaemic heart disease; MI: myocardial infarction; PAD: peripheral artery disease; PVD: peripheral vascular disease; SBP: systolic blood pressure; TCA: tricyclic antidepressant; TG: triglyceride

**Supplemental Table 4 (b):** Additional information on adjustment for confounding in statistical models for the association between antipsychotic prescribing and outcomes

First author, year	Statistical methods	Confounders adjusted for in analyses	Details of composite outcomes (where relevant)
<b>COHORT STUDIES</b>			
Spoolstra, 2004 [23]	Cox proportional hazards	Age at diabetes onset (first prescription of oral GLD); other drug prescriptions in previous 180 days*; calendar year	NA
Wu, 2016 [24]	Cox proportional hazards	Age at diabetes diagnosis; sex; calendar year of diabetes diagnosis; comorbid diagnoses <sup>†</sup> ; other drug prescriptions <sup>#</sup> ; number of/adherence to prescribed oral GLDs; insulin prescription; examination for HbA1c/lipids; number of outpatient visits/hospitalisations	CV morbidity (hospitalisation for CHD and stroke; PVD with stent insertion; vascular shunt or bypass; vessel repair procedure), microvascular morbidity (retinopathy; blindness; end-stage renal disease with dialysis; vessel operations for haemodialysis; kidney transplantation; hospitalisation for diabetic foot infection; lower extremity amputations); all-cause mortality
<b>CASE-CONTROL STUDIES</b>			
Lipscombe, 2009 [28]	Conditional logistic regression	Age; sex; neighbourhood income quintile; diabetes duration; CCI; comorbid dementia, schizophrenia, or other major psychoses; other drug prescriptions in previous 180 days <sup>††</sup> ; health service use history	NA
<b>CROSS-SECTIONAL STUDIES</b>			
Wake, 2016 [32]	Student's t-test/chi-squared test	Exposed and non-exposed people, matched for: birth year; sex; diabetes type; diagnosis date; BMI; smoking	NA

\*Including: beta blockers; diuretics; antiparkinsonian drugs; corticosteroids for systemic use; ADs

<sup>†</sup>Including: hypertension; dyslipidaemia; chronic pulmonary disease; chronic liver disease; malignancy; depression; dementia; anxiety disorders; alcohol-related disorders; substance use disorders

<sup>#</sup>Including: angiotensin system acting agents; beta blockers; calcium channel blockers; diuretics; lipid-lowering agents; antithrombotic agents; non-steroidal anti-inflammatory drugs; anticonvulsants; lithium; ADs; benzodiazepines

<sup>††</sup>Including: cytochrome P-450 2C9 inducers; cytochrome P-450 2C9 inhibitors; thiazide diuretics; corticosteroids for systemic use

BMI: body mass index; CCI: Charlson Comorbidity Index; CHD: coronary heart disease; GLD: glucose lowering drug; HbA1c: glycated haemoglobin; PVD: peripheral vascular disease

						<i>Oral GLD</i> : rate ratio 1.31 (0.90 to 1.90)	↔
						<i>None</i> : rate ratio 3.43 (1.59 to 7.38)*	↑
						<i>Insulin</i> : rate ratio 1.40 (1.06 to 1.85)*	↑
Lipscombe 2009 [28]	Conditional logistic regression	Age; sex; neighbourhood income quintile; diabetes duration; CCI; comorbid dementia, schizophrenia, or other major psychoses; other drug prescriptions in previous 180 days <sup>**</sup> ; health service use history	Hospitalisation for hyperglycaemia	Remote AP	Current FGA (any)  Current SGA (any)	<i>Oral GLD</i> : rate ratio 1.37 (1.12 to 1.67)*	↑
						<i>None</i> : rate ratio 2.37 (1.57 to 3.58)*	↑

Wake, 2016 [32]	Student's t- test/chi- squared test	Exposed and non-exposed people, matched for: birth year; sex; diabetes type; diagnosis date; BMI; smoking	Mean SBP	AP (≥ 12 months in total)	130.7 ± 2.0*	↓
			(mmHg) ± SD	No AP	134.5 ± 1.1	
			Mean DBP	AP (≥ 12 months in total)	74.3 ± 1.2*	↓
			(mmHg) ± SD	No AP	75.1 ± 0.7	
			Mean TC	AP (≥ 12 months in total)	4.2 ± 0.2*	↓
			(mmol/l) ± SD	No AP	4.3 ± 0.1	

\*Denotes significant P < 0.05

†Results given for fully multivariable adjusted or matched models unless otherwise stated

‡No association refers to no statistically significant association at P < 0.05

§Time-dependent with AP prescribing measured in six month intervals

||Including: hypertension; dyslipidaemia; chronic pulmonary disease; chronic liver disease; malignancy; depression; dementia; anxiety disorders; alcohol-related disorders; substance use disorders

¶Including: angiotensin system acting agents; beta blockers; calcium channel blockers; diuretics; lipid-lowering agents; antithrombotic agents; non-steroidal anti-inflammatory drugs; anticonvulsants; lithium; ADs; benzodiazepines

#Drugs considered to have high metabolic risk included: clozapine; olanzapine, drugs considered to have intermediate metabolic risk included: paliperidone; quetiapine; risperidone; zotepine; chlorpromazine; chlorprothixene; clopentixol; clothiapine; loxapine; methotrimeprazine; perphenazine; pipotiazine; prochlorperazine; thioridazine; zuclopentixol, drugs considered to have low metabolic risk included: amisulpride; aripiprazole; sulpiride; ziprasidone; flupentixol; fluphenazine; haloperidol; pimozide; thiothixene; trifluoperazine

\*\*Including: cytochrome P-450 2C9 inducers; cytochrome P-450 2C9 inhibitors; thiazide diuretics; corticosteroids for systemic use

AD: antidepressant; AP: antipsychotic; BMI: body mass index; CCI: Charlson Comorbidity Index; CI: confidence interval; CV: cardiovascular; DBP: diastolic blood pressure; FGA: first-generation antipsychotic; GLD: glucose lowering drug; HbA1c: glycated haemoglobin; HR: hazard ratio; SBP: systolic blood pressure; SGA: second-generation antipsychotic; TC: total cholesterol
