20  
21    **Abstract:** The increase of 1.09°C in global temperature resulted in significant  
22    catastrophes because of the extreme climate. The climate change rate can be slowed  
23    down by reducing the levels of CH<sub>4</sub> and CO<sub>2</sub> in the atmosphere. The solar chimney  
24    power plant integrated with a honeycomb photocatalytic reactor (SCPP-HPCR) uses  
25    the photocatalytic technology to remove atmospheric CH<sub>4</sub>. In addition, CO<sub>2</sub> emissions  
26    can be reduced from coal fired power plant due to the generating capacity of the system.  
27    In this paper, the influence of the geometric parameters of the reactor on the turbine  
28    efficiency and overall performance of the SCPP-HPCR are studied by numerical  
29    simulation. The obtained results showed that the flow resistance inside the system was

30 mostly caused by the HPCR at low turbine speed, and primarily by the turbine at high  
 31 turbine speed. Reducing the pore diameter of the reactor could improve the  
 32 photocatalytic performance of the SCPP-HPCR more than increasing the turbine speed.  
 33 The SCPP-HPCR having a pore diameter of 3 mm, porosity of 0.85, and constant  
 34 turbine speed of 180 rpm, built in Qianyanzhou, China, could remove 2.38 kg of CH<sub>4</sub>  
 35 and reduce 375.52 kg of CO<sub>2</sub> in one day.

36

39

<b>Nomenclature</b>	
$B, B_1, B_2$	Constants for reaction rate calculation
$C_{1\varepsilon}, C_{2\varepsilon}$	Constants for turbulent model
$c_1$	CH <sub>4</sub> concentration, $mol \cdot m^{-3}$
$c_2$	O <sub>2</sub> concentration, $mol \cdot m^{-3}$
$r_m$	Reaction rate of CH <sub>4</sub> , $mol \cdot W^{-1} \cdot m^{-1} \cdot s^{-1}$
$G$	Solar radiation, $W \cdot m^{-2}$
$q$	Heat flux of ground, $W \cdot m^{-2}$
$SSA$	Specific surface area, $m^{-1}$
$\vec{J}_i$	Diffusion flux of species $i$ , $mol \cdot s^{-1} \cdot m^{-3}$
$Q_m$	Mass flow rate, $kg \cdot s^{-1}$
$m_1$	Mass fraction of CH <sub>4</sub> at the entrance
$m_2$	Mass fraction of CH <sub>4</sub> at the exit
$P_t$	Output power of the system, $kW$
$S_\phi$	Momentum loss term, $N \cdot m^{-3}$
$S_i$	Additional rate owing to the discrete phase, $kg \cdot m^{-3} \cdot s^{-1}$
$\dot{m}1_{CO_2}$	Reduction rate of CO <sub>2</sub> emission from the coal-fired power station, $kg \cdot h^{-1}$
$\dot{m}2_{CO_2}$	Reduction rate of CO <sub>2</sub> equivalent from photocatalytic CH <sub>4</sub> , $kg \cdot h^{-1}$
$\dot{C}_{eq}$	CO <sub>2</sub> reduction rate, $kg \cdot h^{-1}$
<i>Greek symbols</i>	
$\nu$	Kinetic viscosity, $m^2 \cdot s^{-1}$
$\beta$	Coefficient of thermal expansion, $K^{-1}$
$\rho$	Gas density, $kg \cdot m^{-3}$
$\tau$	Shear stress, $N \cdot m^{-2}$
$k$	Karman Constant

*Abbreviations*

<i>GWP</i>	Global warming potential
<i>SCPP</i>	Solar chimney power plant
<i>HPCR</i>	Honeycomb photocatalytic reactor
<i>IPCC</i>	Intergovernmental panel on climate change

40

41 **1. Introduction**

42 The global climate change caused by the increasing global temperature was a  
43 significant challenge for this century. The maximal temperature increase that the Earth  
44 could withstand should be limited to 2 °C when compared with the pre-industrial  
45 periods, and it should not exceed 0.1 °C each decade (Vellinga and Swart, 1991).  
46 According to the Intergovernmental Panel on Climate Change (IPCC) (Masson-  
47 Delmotte et al., 2021), the global average temperature in 2020 was 1.09 °C warmer than  
48 that in the 20<sup>th</sup> century, with an increase of 1.59 °C on land and 0.88 °C in ocean.  
49 Extreme events caused by climate anomalies, such as localized droughts or heavy  
50 rainfall, forest fires, and biological extinctions, were frequently occurred (Wang et al.,  
51 2022). In addition, other terrifying events prompted by global warming had the potential  
52 to bring great danger to people in the future, such as the loss of seasonal snowpack,  
53 glacier melting, permafrost thawing, and decrease in summer Arctic sea ice (Witze,  
54 2019). To achieve the Paris Agreement's target of restricting global warming to 1.5°C,  
55 the greenhouse gas emissions should be promptly and significantly decreased.

56 It was widely believed that removing CO<sub>2</sub> from the atmosphere could significantly  
57 mitigate climate change. Many active greenhouse gas mitigation technologies, such as  
58 carbon capture, utilization, and storage (CCS) (Bui et al., 2018), bioenergy with carbon  
59 capture and storage (BECCS) (Sanchez et al., 2018), and direct air capture (DAC)  
60 (House et al., 2011) were proposed. CH<sub>4</sub> owns a global warming potential (GWP) 84  
61 times higher than CO<sub>2</sub>. Although the concentration of CH<sub>4</sub> in the atmosphere was low,  
62 it had a contribution of 16 % of the global warming impact. The greenhouse effect  
63 caused by CH<sub>4</sub> had attracted global attention as the atmospheric CH<sub>4</sub> concentration was  
64 increasing from pre-industrial of 0.76 ppm to 1.8 ppm today, with an increasing rate  
65 much higher than that of CO<sub>2</sub>. Almost 40 % of CH<sub>4</sub> emission was from natural sources,

66 such as wetlands and termites. In addition, other 60% were from anthropogenic, such  
67 as ruminants, rice agriculture, fossil fuel extraction, landfills, and biomass burning  
68 (Allen, 2016). The atmospheric persistence of CH<sub>4</sub> was short, and therefore reducing  
69 the emissions could achieve a substantial climate mitigation effect in a short time frame  
70 (Kuylenstierna et al., 2021). Moreover, 90 % of the atmospheric CH<sub>4</sub> was oxidized by  
71 hydroxyl radicals, which promoted the ozone production and affected the oxidation  
72 performance of the tropospheric (Galpern, 2021). Furthermore, high ozone levels could  
73 endanger human health, affect plant and animal growth, and cause photochemical haze.

74 The existing methods for atmospheric CH<sub>4</sub> removal include zeolites, soil  
75 amendments, iron salt aerosols, biofilters, and photocatalysts. Forest soils were  
76 considered as significant CH<sub>4</sub> sink, neutralizing 13 % of anthropogenic carbon  
77 emissions (Price et al., 2004). However, developing effective CH<sub>4</sub> removal methods  
78 was crucial due to the fact that it could take too long for ecosystems to naturally  
79 decompose the atmospheric CH<sub>4</sub>. Brenneis et al. (Brenneis et al., 2021) synthesized a  
80 Cu-dropped zeolite as a thermocatalyst, which removed 100 % of CH<sub>4</sub> at atmospheric  
81 levels, at a reaction temperature of 310 °C. Although this catalyst could sustain high  
82 activity after 300 h of recycling, the high temperature environment required for the  
83 reactions restricted the large-scale development of this technology. Iron-salt aerosols  
84 could remove atmospheric CH<sub>4</sub> by increasing the level of Cl<sup>-</sup> in the air. However, more  
85 studies should be conducted to evaluate the feasibility of this technology (Ming et al.,  
86 2021a). Moreover, some new removal methods were being investigated (Wang et al.).  
87 CH<sub>4</sub> could be converted to less potent greenhouse gas CO<sub>2</sub> under sunlight at room  
88 temperature and pressure, using the photocatalytic semiconductor technology (de  
89 Richter et al., 2017).

90 The solar chimney power plant (SCPP), which is a green thermal wind power  
91 generating system, can develop a steady upward airflow inside the chimney. However,  
92 it had a low overall effectiveness (Vazquez-Ruiz et al., 2022). Many researchers tried  
93 to improve the solar energy utilization efficiency of the SCPP, or used it for other  
94 objectives, such as the desalination of saltwater (Zuo et al., 2020) and the drying of  
95 food (Maia and Silva, 2022). Some economic evaluation and internal optimization

96 methods had also been extensively studied (Zuo et al., 2021; Zuo et al., 2022). The  
97 SCPP also performed well in terms of cleaning urban air. It produced a stable airflow  
98 with physical filtering to purify the particulates in the city air (Cao et al., 2015). Cao et  
99 al. (Cao et al., 2018) designed and constructed the first haze removal tower in Xi'an,  
100 China, with a collector size of 43 m × 60 m and a chimney height of 60 m, which  
101 confirmed the viability of improving urban air quality with the SCPP from an  
102 engineering standpoint.

103 The IPCC highlighted de Richter's proposal (de Richter et al., 2017) of combining  
104 the SCPP with photocatalysis as a practicable strategy for removing CH<sub>4</sub> on a large  
105 scale (Fuss et al., 2018; Minx et al., 2018). The types of reactors and the photocatalytic  
106 were the critical factors affecting the photocatalytic performance of the system. The  
107 honeycomb photocatalytic reactor (HPCR) having a large specific surface area is an  
108 efficient photocatalytic reactor. In addition, the internal flow field was rectified by  
109 placing the HPCR within the collector (Zhang et al., 2022). Many laboratory tested for  
110 CH<sub>4</sub> between 50 ppm and 1000 ppm demonstrated that its conversion rate and product  
111 selectivity were significantly improved by the addition of noble metals to the TiO<sub>2</sub>  
112 (Ahmed et al., 2022; Li, Y. et al., 2019; Li, Z. et al., 2019; Sekar et al., 2021). It was  
113 important to mention that Ag/ZnO, which was a novel photocatalyst, could be activated  
114 by sunlight and it can convert CH<sub>4</sub>, with a concentration of 50 ppm, to CO<sub>2</sub> in 20 min.  
115 The catalytic efficiency was even better with lower concentration (Chen et al., 2016).  
116 Ming et al. (Ming et al., 2021b) conducted numerical simulations to first study the  
117 factors affecting the performance of the SCPP-HPCR without considering the power  
118 generation. The output power of the system can be reliably estimated by converting the  
119 3-D turbine to the surface of pressure drop (Pastohr et al., 2004). However, the real  
120 fluid trace inside the system could not be simulated. Guo et al. (Guo et al., 2014) more  
121 precisely evaluated the performance of the SCPP by considering both the 3-D turbine  
122 and the solar radiation model. For the SCPP-HPCR, the main performances of the  
123 system are the degradation of atmospheric CH<sub>4</sub> by the reactor and the turbine power  
124 generation. Both could affect the flow of air in the SCPP-HPCR, and knowing the  
125 relationship between them can significantly improve the system performance.

126 In this paper, a numerical model is first developed to study the overall performance  
127 of the SCPP-HPCR considering 3-D turbine. The parameters of the reactor including  
128 the pore diameter, porosity, and operating conditions of the turbine are optimized. This  
129 provides a reference for the future design and construction of the SCPP-HPCR.  
130 Furthermore, taking into account the CH<sub>4</sub> removal and renewable electricity generation,  
131 the equivalent CO<sub>2</sub> emission reduction of the SCPP-HPCR is discussed.

132

## 133 **2. Computation model**

### 134 *2.1 Geometric model*

135 The dimension of the geometric model match that of the Spanish prototype (Haaf,  
136 W, 1984). The radius of the collector is 120 m, and its height linearly varies from 2 m  
137 at the entrance to 6 m at the bottom of the chimney. The chimney has a radius of 5 m  
138 and a height of 200 m. The CLARK-Y airfoil is used in the axial turbine, which is  
139 located at the bottom of the chimney at a height of 7 m above the ground (Tingzhen et  
140 al., 2008), as shown in Fig. 1.

141 The starting of the HPCR is at 10 m from the entrance inside the canopy. The  
142 reactor is made of perspex with good light transmission. The P25 photocatalyst is  
143 uniformly distributed on the inner wall of the honeycomb channel. Note that P25 is  
144 selected due to the fact that it is cheap and stable, and it has a good film formation  
145 property (Ma and Yang, 2010). It is more efficient to remove CH<sub>4</sub> by increasing the  
146 reactor length. However, the HPCR length is kept at 5 m in this study, because a longer  
147 reactor can diminish the ability of the ground to absorb solar energy.

Fig. 1. Schematics of the geometrical model.

## 2.2 Numerical model

The Rayleigh number ( $R_a = \frac{g\beta\Delta TH^3}{\alpha\nu}$ ) is a dimensionless number associated with buoyancy-driven convection. The flow in the SCPP-HPCR is fully turbulent due to  $R_a \geq 10^{10}$  (Tingzhen et al., 2006). The governing equations, including the continuity, momentum, energy, RNG  $k$ - $\epsilon$ , and transport equations, are expressed as:

*Continuity equation*

$$\frac{\partial(\rho u_i)}{\partial x_i} = 0 \quad (1)$$

*Momentum equation*

$$\frac{\partial(\rho u_i u_j)}{\partial x_j} = \rho g - \frac{\partial p}{\partial x_i} + \frac{\partial \tau_{ij}}{\partial x_j} \quad (2)$$

*Energy equation*

$$\frac{\partial(\rho c_p u_j T)}{\partial x_j} = \frac{\partial}{\partial x_j} \left( \lambda \frac{\partial T}{\partial x_j} \right) - \tau_{ij} \frac{\partial u_i}{\partial x_j} + \beta T \left( \frac{\partial p}{\partial x_j} + u_j \frac{\partial p}{\partial x_j} \right) \quad (3)$$

*Equation for the turbulent kinetic energy ( $k$ )*

$$\frac{\partial}{\partial x_i} (\rho k u_i) = \frac{\partial}{\partial x_j} (\alpha_k \mu_{eff} \frac{\partial k}{\partial x_j}) + G_k + G_b - \rho \epsilon - Y_M \quad (4)$$

*Equation for the energy dissipation ( $\epsilon$ )*

$$\frac{\partial}{\partial x_i}(\rho \varepsilon u_i) = \frac{\partial}{\partial x_j}(\alpha_\varepsilon \mu_{eff} \frac{\partial \varepsilon}{\partial x_j}) + G_k C_{1\varepsilon} \frac{\varepsilon}{k} - C_{2\varepsilon} \rho \frac{\varepsilon^2}{k} \quad (5)$$

166 *Component transport equation*

$$\nabla \cdot (\rho \vec{v} Y_i) = -\nabla \cdot \vec{J}_i + R_i + S_i \quad (6)$$

168 where  $\tau_{ij}$  is the viscous shear stress ( $\tau_{ij} = \mu \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)$ ),  $\mu_{eff}$  is the effective  
169 kinematic viscosity ( $\mu_{eff} = \mu + \mu_t$ ),  $G_k$  represents the generation of turbulence  
170 kinetic energy (can be defined as  $G_k = -\rho \overline{u_i' u_j'} \frac{\partial u_j}{\partial x_i}$ ),  $\alpha_k$  and  $\alpha_\varepsilon$  are the turbulent  
171 Prandtl numbers for  $k$  and  $\varepsilon$  ( $\alpha_k = \alpha_\varepsilon = 1.3$ ),  $C_{1\varepsilon}$  and  $C_{2\varepsilon}$  are two constants of the  
172 turbulent model ( $C_{1\varepsilon} = 1.44$  and  $C_{2\varepsilon} = 1.92$ ),  $\vec{J}_i$  represents the diffusion flux of  
173 species ( $\vec{J}_i = -\rho D_{i,m} + R_i$ ),  $R_i$  is the amount of component  $i$  produced or consumed  
174 in the reaction,  $S_i$  is the additional rate, and  $Y_M$  denotes the total dissipation rate due  
175 to the variable dilatation incompressible turbulence.

176 The Multiple Reference Frame (MRF) model is used to model the turbine region.  
177 It determines the velocity of the moving region by adding the rotation velocity on the  
178 original translational velocity. The velocity in the rotational region is given by:

$$\vec{v}_r = \vec{v} - \vec{\omega} \times \vec{r} \quad (7)$$

180 The governing equations of flow in the MRF model are modified as:

181 *Continuity equation*

$$\nabla \cdot (\rho \vec{v}_r) = 0 \quad (8)$$

183 *Momentum equation*

$$\nabla \cdot (\rho \vec{v}_r \vec{v}_r) + \rho (2\vec{\omega} \times \vec{v}_r + \vec{\omega} \times \vec{\omega} \times \vec{r}) + \rho \frac{\partial \vec{\omega}}{\partial t} \times \vec{r} = \nabla \cdot (\mu \nabla \vec{v}_r) + S_{\vec{v}_r} \quad (9)$$

185 where  $\vec{v}$  is the absolute velocity,  $\vec{\omega}$  is the angular velocity vector, and  $\vec{r}$  is the  
186 position vector.

187 The output power ( $P_t$ ) can be computed as:

$$P_t = \frac{2\pi n M}{60} \quad (10)$$

189 where  $n$  is the rotation speed and  $M$  represents the total blade moments of the turbine.

190 The HPCR is simplified as a porous media. The governing equations of the HPCR  
191 region are expressed as:

192 *Continuity equation:*

193 
$$\nabla \cdot (\gamma \rho \vec{v}) = 0 \quad (11)$$

194 *Momentum equation:*

195 
$$\nabla \cdot (\gamma \rho \vec{v}) = -\gamma \nabla p(\gamma \vec{\tau}) + \gamma \rho \vec{g} + S_\phi \quad (12)$$

196 where  $\gamma$  is the porosity,  $\vec{\tau}$  is the viscous stress tensor, and  $S_\phi$  denotes the momentum  
197 loss term ( $S_\phi = -\left(\frac{\mu}{K} \vec{v} + \frac{C}{2} \rho |\vec{v}| \vec{v}\right)$ ).

198 The permeability ( $K$ ) and inertia coefficient ( $C$ ) are respectively defined in  
199 Equations (13) and (14) (Wang et al., 2014).

200 
$$K = \frac{D_p^2}{150} \frac{\gamma^3}{(1-\gamma)^2} \quad (13)$$

201 
$$C = \frac{3.5(1-\gamma)}{D_p^2 \gamma^3} \quad (14)$$

202 where  $D_p$  is the pore diameter.

203 The oxidation rate of CH<sub>4</sub> is given by (Haeger et al., 2004):

204 
$$r_m = B \cdot \frac{B_1 c_1}{1+B_1 c_1} \frac{B_2 c_2}{1+B_2 c_2} \cdot SSA \quad (15)$$

205 where  $r_m$  is the reaction rate of CH<sub>4</sub> of the HPCR,  $c_1$  and  $c_2$  are respectively the  
206 concentrations of CH<sub>4</sub> and O<sub>2</sub>,  $B, B_1,$  and  $B_2$  are respectively equal to  $5.37 \times 10^{-7},$   
207 2.42, and 4.60, and  $SSA$  is the specific surface area of the HPCR ( $SSA = \frac{6(1-\gamma)}{D_p}$ )  
208 (Ming et al., 2021b).

209 The CH<sub>4</sub> removal performance of the SCPP-HPCR is evaluated by the  
210 photocatalytic efficiency (Equation (16)) and purification rate (Equation (17)) of CH<sub>4</sub>.

211 
$$\varepsilon_{methane} = \frac{J_1 - J_2}{J_1} \times 100\% \quad (16)$$

212 
$$\dot{m}_{methane} = Q_m (m_1 - m_2) \quad (17)$$

213 where  $J_1$  and  $J_2$  are respectively the CH<sub>4</sub> concentrations at the inlet and outlet of the  
214 reactor,  $m_1$  and  $m_2$  are respectively the mass fractions of CH<sub>4</sub> at the entrance and  
215 exit, and  $Q_m$  is the mass flow rate of the SCPP-HPCR.

216

### 217 2.3 Boundary conditions

218 The SCPP-HPCR is powered by natural convection driven by the solar radiation.  
219 The boundary conditions for the collector inlet and chimney outlet are the pressure inlet  
220 and outlet, respectively. The collector surface is a convective heat transfer boundary,

221 and the coefficient is related to the ambient wind speed. The coefficient can be set to a  
 222 constant value of  $10 \text{ W}/(\text{m}^2 \cdot \text{K})$  while ignoring the ambient wind effect (Tingzhen et al.,  
 223 2006). The surfaces of the chimney and turbine are adiabatic. The conversion of solar  
 224 radiation to heat flux of the ground is an economical and effective method (Tingzhen et  
 225 al., 2008). The conversion coefficient is related to the location of the area, air quality,  
 226 and other factors. For example, the coefficient is 0.7 in a desert in northwest China,  
 227 which indicates that the ground heat flux is almost  $600 \text{ W}/\text{m}^2$ , corresponding to a solar  
 228 radiation of  $857 \text{ W}/\text{m}^2$  (Ming et al., 2012). The details of the boundary conditions are  
 229 presented in Table 1.

230

Table 1. Boundary conditions

Location	Type	Value
Inlet of SCPP-HPCR	Pressure inlet	$p = 0 \text{ Pa}, T = 293 \text{ K}$
Outlet of SCPP-HPCR	Pressure outlet	$p = 0 \text{ Pa}$
Surface of ground	Heat flux	$q = 200 - 600 \text{ W}/\text{m}^2$
Surface of canopy	Convection	$T = 293 \text{ K}, h = 10 \text{ W}/(\text{m}^2 \cdot \text{K})$
Surface of chimney	Adiabatic	$q = 0 \text{ W}/\text{m}^2$
Turbine	MRF	$\omega = 0 \sim 200 \text{ rpm}$
HPCR	Porous media	

231

#### 232 2.4 Grid system and numerical procedure

233 The structured grid system has high better computational stability and shorter  
 234 solution time. Structured grids are used for the whole computational domain, except the  
 235 3-D turbine, whose structure is complex. Moreover, the local grids of blade surface and  
 236 HPCR region are densified to more correctly simulate the mass transfer process. The  
 237 grid system as shown in Fig 2.

238

239

(a)

240

241

(b)

242

Fig 2 Grid system of the SCPP-HPCR: (a) Front view on the surface of  $Y = 0$  m

243 and (b) grid distribution on the surface of the turbine.

244

245 The grid-independent is checked using three grid systems with grid numbers of  
246 4,071,561, 3,112,516, and 2,316,115. The average velocities of the outlet are 8.61, 8.27,  
247 and 8.01 m/s, respectively, under  $G = 857 \text{ W/m}^2$  and  $\omega = 100 \text{ rpm}$ . The relative error  
248 of the simulation results between different grid systems is less than 3.94%. In this study,  
249 the grid system with the number of 3,112,516 is considered in the simulation.

250 The ANSYS FLUENT 19.0 software is used for the numerical simulation. The  
251 SIMPLE algorithm is used for the pressure–velocity coupling scheme. The PRESTO  
252 divergence scheme is used in the pressure term, and the upwind scheme is used in the  
253 other terms. The calculation results converged when the variations of the concentration  
254 of  $\text{CH}_4$  and the velocity at the chimney outlet are less than 0.001, or the maximum  
255 residuals of all the equations are less than  $10^{-5}$ .

256

## 257 2.5 Validation

258 The velocity of the chimney outlet and the photocatalytic efficiency of  $\text{CH}_4$  are  
259 compared with the data presented in the reference (Ming et al., 2021b) to validate the  
260 numerical model at  $G = 857 \text{ W/m}^2$ ,  $\omega = 0 \text{ rpm}$ , and  $\gamma = 0.85$ . The obtained results  
261 are presented in Table 2. It can be seen that the velocity at the chimney outlet increased  
262 while the photocatalytic efficiency decreased with the increase of the pore diameter.  
263 The maximum relative error for the chimney outlet velocity is 8.55% when  $D_p = 2 \text{ mm}$ ,  
264 while the relative errors for other values of  $D_p$  are less than 4%. In fact, the study of  
265 (Ming et al., 2021b) did not build the 3-D turbine causing the grid discrepancy to be the  
266 primary reason for the error. In general, the results of the numerical simulations in this  
267 study are reasonable.

268

269 Table 2. Verification of the simulation results

Simulation results	Date form reference (Ming et al., 2021b)	Relative error (%)
--------------------	---	--------------------

Pore diameter (mm)	Velocity at outlet (m/s)	Photocatalytic efficiency of CH <sub>4</sub> (%)	Velocity at outlet (m/s)	Photocatalytic efficiency of CH <sub>4</sub> (%)	Velocity	Photocatalytic efficiency
2	8.42	96.32	7.70	96.02	8.55	0.31
2.5	8.56	93.56	8.27	92.42	3.39	1.22
3	8.71	89.40	8.56	88.38	1.72	1.14
3.5	9.02	84.97	8.81	84.12	2.33	0.99
4	9.29	80.47	8.92	80.11	3.98	0.44

270

271

### 272 3. Result and analysis

273 In this section, the influence of the pore size on the performance of the SCPP-  
 274 HPCR is first discussed for  $\gamma = 0.85$ . The porosity of HRCR is then optimized to the  
 275 equivalent CO<sub>2</sub> emission. Finally, the solar radiation data of Qianyanzhou, China, are  
 276 considered as example to estimate the CO<sub>2</sub> emission reduction of the system for one  
 277 day.

278

#### 279 3.1 Analysis of flow field

280 Most of the solar energy is locked in the collector for air heating due to its one-  
 281 way-screen property (Ming et al., 2017). The heated airflow could form a density  
 282 difference with the ambient air, and be gradually collected at the bottom of the chimney  
 283 to develop a strong upward airflow due to the buoyancy effect.

284 Fig. 3 shows the pressure distribution of the plane of  $Y = 0$  m and  $Z = 1$  m. There  
 285 are two main contributors of resistance while the hot air flow is moving. Firstly, the  
 286 porous structure can impede the passage of the airflow, generating a pressure gradient  
 287 of roughly 93.3 Pa. Secondly, the airflow at the bottom of the chimney converts its own  
 288 kinetic energy into mechanical energy, causing the turbine to rotate in to generate  
 289 electricity. The maximum pressure differential is almost 942.7 Pa, with a significant  
 290 positive pressure at the bottom and a negative pressure above the blade.

291

296 Fig. 3. Contours of the pressure distribution of the plane at  $G = 857 \text{ W/m}^2$ ,  $\omega = 100$   
297 rpm, and  $D_p = 4 \text{ mm}$ : (a) plane at  $Y = 0 \text{ m}$  and (b) plane at  $Z = 1 \text{ m}$ .  
298

299 Fig. 4 shows the velocity distribution of the plane of  $Y = 0$  m and  $Z = 1$  m. The  
300 airflow enters at the entrance of the canopy and converges towards the center with  
301 increasing speed. The overall velocity is still modest (not exceeding 2 m/s), while the  
302 velocity at the edge of canopy is just 0.35 m/s, with a major increase only occurring  
303 near the chimney bottom. The airflow overcomes gravity and keeps going upward after  
304 passing through the turbine, and the velocity gradually decreases. However, the velocity  
305 of the air at the center of the wheel remains low.

306

(b)

309

310

311 Fig. 4. Contours of the velocity distribution of the plane at  $G = 857 \text{ W/m}^2$ ,  $\omega = 100$   
 312 rpm, and  $D_p = 4 \text{ mm}$ : (a) plane at  $Y = 0 \text{ m}$  and (b) plane at  $Z = 1 \text{ m}$ .

313

314 Fig. 5 shows the  $\text{CH}_4$  distribution of the plane of  $Y = 0 \text{ m}$  and  $Z = 1 \text{ m}$ . The natural  
 315 convection pulls  $\text{CH}_4$  into the system at a concentration of 1.87 ppm from the  
 316 atmosphere, where it is continually degrading in the HPCR along a distinct  
 317 concentration gradient. The  $\text{CH}_4$  degradation process is confined in, relative to the plate  
 318 reactor (Ming et al., 2022; Xiong et al., 2022), and the distribution appears hierarchical.  
 319 The  $\text{CH}_4$  is evenly distributed and remained unchanged in the system after passing  
 320 through the HPCR. For instance, the  $\text{CH}_4$  concentration at the chimney outlet is 0.27  
 321 ppm and the photocatalytic efficiency is 85.56% at  $G = 857 \text{ W/m}^2$ ,  $\omega = 100 \text{ rpm}$ , and  
 322  $D_p = 4 \text{ mm}$ .

323

324  
325

326  
327

(b)

328 Fig. 5. Contours of the CH<sub>4</sub> distribution of the plane at  $G = 857 \text{ W/m}^2$ ,  $\omega = 100 \text{ rpm}$ ,  
329 and  $D_p = 4 \text{ mm}$ : (a) plane at  $Y = 0 \text{ m}$  and (b) plane at  $Z = 1 \text{ m}$ .

330

331 3.2 Performance analysis of SCPP-HPCR

332 Fig. 6 shows the average velocity at the chimney outlet. The airflow resistance  
 333 through the turbine area increased as the turbine speed increased, so that more kinetic  
 334 energy of the air is transformed into mechanical energy of the turbine. In addition, when  
 335 the  $D_p$  of the honeycomb channel is small, the viscous resistance caused by the porous  
 336 medium can dramatically increase, and the chimney exit velocity can decrease.  
 337 According to the experimental data provided in Haff (Haaf, W., 1984), the exit velocity  
 338 of the chimney was 9 m/s with  $G = 857 \text{ W/m}^2$  and  $\omega = 100 \text{ rpm}$ . The exit velocity loss  
 339 is 8.2% when a reaction zone of  $D_p = 4 \text{ mm}$  is within the canopy, while it is 15.7% for  
 340  $D_p = 2 \text{ mm}$ .

341

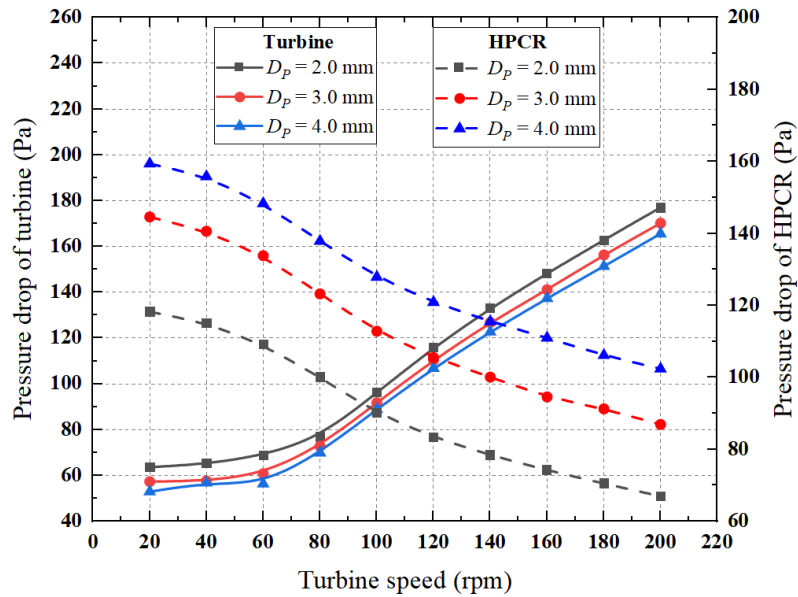

342

343 Fig. 6. Average velocity at the chimney outlet under different turbine speeds at  $G =$   
 344  $857 \text{ W/m}^2$ .

345

346 The resistance of the turbine and reactor (Fig. 7), as well as the turbine speed, are  
 347 the primary factors that affect the air flow inside the SCPP-HPCR. When the turbine  
 348 speed increases, the pressure drop through the reaction zone constantly decreases, while  
 349 the pressure drop through the turbine increases. An excessively high turbine speed can  
 350 lower the mass flow rate of the system, obstruct airflow inside the canopy, and decrease  
 351 the pressure loss caused by the HPCR. The latter is the primary source of internal

352 resistance when the turbine speed is low, but the turbine area is the primary source at  
 353 high turbine speed. Furthermore, the overall pressure loss inside the system is first  
 354 decreased and then increased. The overall internal pressure loss of the SCPP-HPCR is  
 355 minimized to 176.84 Pa for  $G = 857 \text{ W/m}^2$ ,  $\omega = 80 \text{ rpm}$ , and  $D_p = 2 \text{ mm}$ .  
 356

357  
 358 Fig. 7. Pressure drop of the turbine and HPCR under different turbine speeds at  $G =$   
 359  $857 \text{ W/m}^2$ .  
 360

361 The two performance criteria of the SCPP-HPCR for removing atmospheric  $\text{CH}_4$   
 362 are the photocatalytic efficiency and purification rate, as shown in Fig. 8. The former  
 363 describes the level of  $\text{CH}_4$  molecule purification, while the latter calculates the amount  
 364 of  $\text{CH}_4$  damaged by the system. The photocatalytic efficiency of  $\text{CH}_4$  can be improved  
 365 by increasing the turbine speed or reducing the reactor particle size. However,  
 366 decreasing the mass flow rate of the system sharply reduces the purification rate. The  
 367 photocatalytic performance of the system can be enhanced more by reducing the  
 368 particle size in the honeycomb channel than by speeding up the turbine. For instance,  
 369 the efficiency of the  $\text{CH}_4$  photocatalytic is boosted by roughly 20% when the particle  
 370 size is decreased from 4 mm to 2 mm, but only by 8% when the turbine speed is  
 371 increased to 200 rpm. The impact of the turbine speed on the photocatalytic efficiency

372 becomes insignificant for  $D_p \leq 3$  mm.

373         Increasing the turbine speed can only slightly lower the purge rate of  $\text{CH}_4$ , in the  
374 case where the turbine speed is low. A linear relationship between the turbine speed and  
375 the rate of purification can be observed when the turbine speed is high. The primary  
376 reason for the rate of purification decrease is the loss of mass flow rate brought by the  
377 increased turbine speed. The curves of the purification rate of  $\text{CH}_4$  are pretty close for  
378 reactors having particle diameters of 2.5 mm, 3 mm, and 3.5 mm. Although the reactor  
379 with a smaller particle size seems more effective in lowering the atmospheric  $\text{CH}_4$ , the  
380 large pressure loss can undoubtedly have an adverse effect on the overall performance  
381 of the system. In addition,  $\text{CH}_4$  generally has a high photocatalytic efficiency for  $D_p =$   
382 3 mm.

383

384

(a)

(b)

Fig. 8. Degradation of  $\text{CH}_4$  under different turbine speeds at  $G = 857 \text{ W/m}^2$ : (a) photocatalytic efficiency of  $\text{CH}_4$  and (b) purification rate of  $\text{CH}_4$ .

The primary source of electricity for most countries is still the thermal power plants. Many pollutants are emitted during the burning of fossil fuels, such as  $\text{CO}_2$ , which is released on 0.95 kg for 1 kW of produced energy (Mittal et al., 2012). The SCPP can produce up to 36 kW of power and it is a zero-energy zero-pollution power source, which significantly reduces the  $\text{CO}_2$  emissions from thermal power plants (Pasumarthi and Sherif, 1998).

The SCPP-HPCR is a  $\text{CH}_4$  negative emission technology able to face the climate change using  $\text{CO}_2$  equivalents.  $\text{CH}_4$  had 84 times the GWP of  $\text{CO}_2$  on a 20-year scale, which showed that reducing 1 kg of  $\text{CH}_4$  is comparable to reducing 84 kg of  $\text{CO}_2$  (Jackson et al., 2019). The  $\text{CO}_2$  emission reduction rate of the SCPP-HPCR can be expressed as:

$$C_{eq}^{\cdot} = \dot{m}_{\text{CH}_4} \times 84 + \dot{m}1_{\text{CO}_2} - \dot{m}2_{\text{CO}_2} \quad (18)$$

where  $\dot{m}_{\text{CH}_4}$  is the purification rate of  $\text{CH}_4$ ,  $\dot{m}1_{\text{CO}_2}$  is the reduction rate of  $\text{CO}_2$  emission from coal-fired power station, and  $\dot{m}2_{\text{CO}_2}$  is the generation rate of  $\text{CO}_2$  from photocatalytic  $\text{CH}_4$ .

405 Fig. 9 shows the rate of CO<sub>2</sub> emission reduction of SPCP-HPCR. It can be seen  
 406 that the rate of CO<sub>2</sub> emission reduction increases and then decreases at different reactor  
 407 particle diameters. The emission reduction rate is nearly identical at lower turbine  
 408 speeds, mostly because generating electricity from turbines at lower speeds results in  
 409 less CO<sub>2</sub> reduction. The peak CO<sub>2</sub> reduction rate corresponds to a turbine speed between  
 410 160 rpm and 180 rpm for different particle sizes. In addition, the larger the particle size,  
 411 the greater the reduction rate.

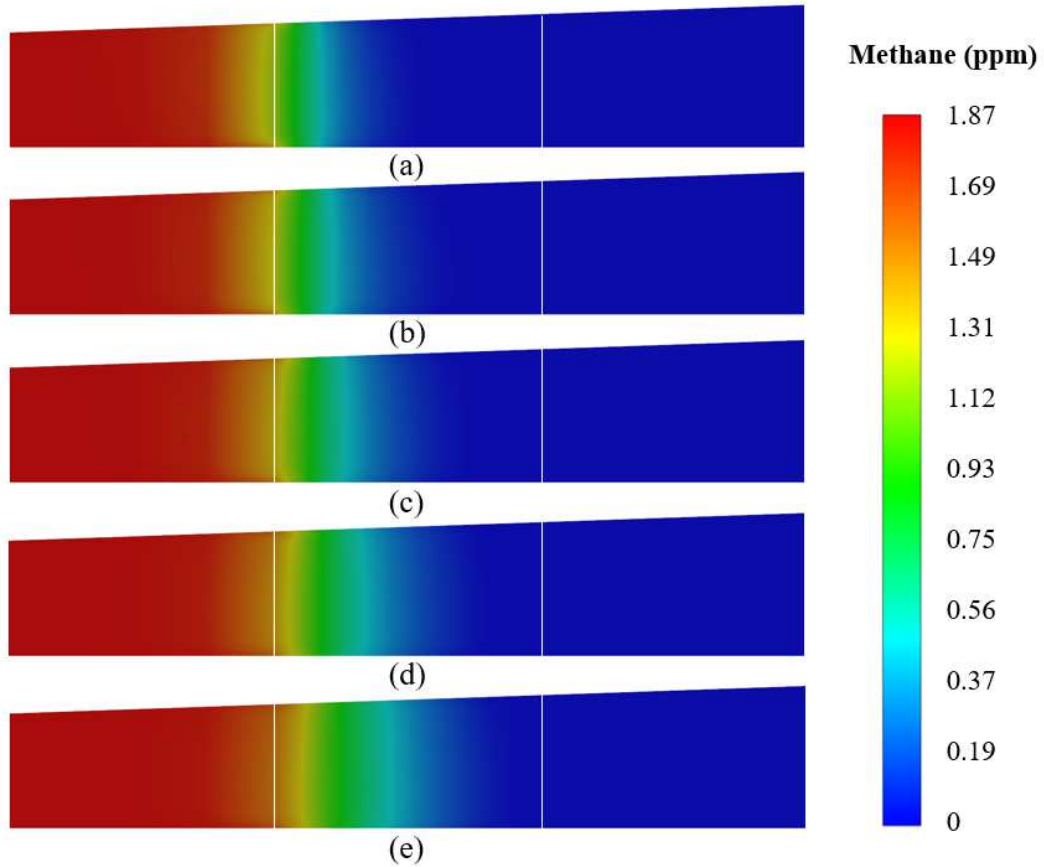

412  
 413 Fig. 9. Rate of CO<sub>2</sub> emission reduction under different turbine speeds at  $G = 857$   
 414  $W/m^2$ .

415  
 416 **3.3 Optimization of the HPCR porosity**

417 Porosity is another crucial factor that affected the overall performance of the  
 418 SPCP-HPCR. The highest photocatalytic efficiency and purification rate are for  $D_p = 3$   
 419 mm, as mentioned in section 3.2. Fig. 10 shows the CH<sub>4</sub> distribution in the HPCR at  $G$   
 420  $= 857 W/m^2$ ,  $\omega = 180$  rpm, and  $D_p = 3$  mm. It is less difficult for atmospheric CH<sub>4</sub>  
 421 to enter the HPCR as the porosity of the reactor increases because of the greater airflow  
 422 resistance. The length of the concentration gradient of CH<sub>4</sub> in the reactor expands as  
 423 the reactor's porosity, and the uniform concentration at the exit of the HPCR.

424

425

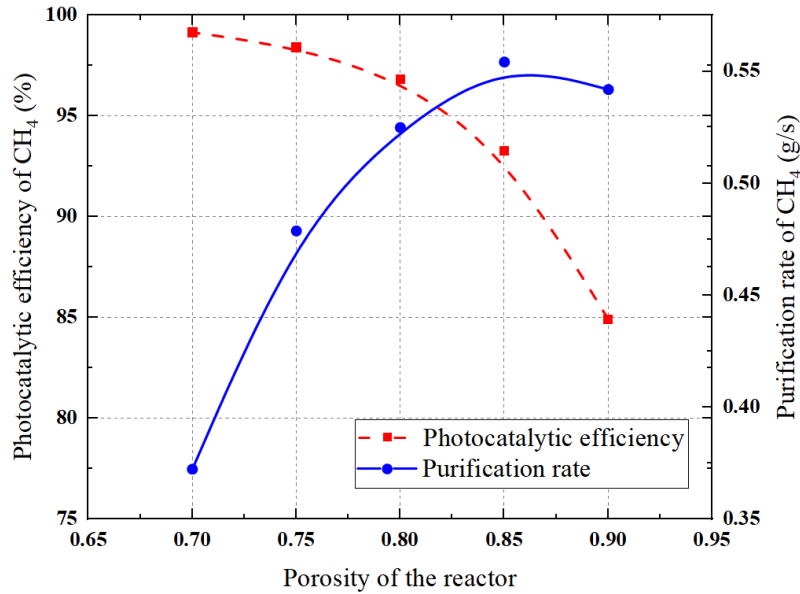

426 Fig. 10. Contours of the CH<sub>4</sub> distribution in the HPCR at  $G = 857 \text{ W/m}^2$ ,  $\omega =$   
 427  $180 \text{ rpm}$ , and  $D_p = 3 \text{ mm}$ : (a)  $\gamma = 0.70$ , (b)  $\gamma = 0.75$ , (c)  $\gamma = 0.80$ , (d)  $\gamma = 0.85$   
 428 and (e)  $\gamma = 0.90$ .

429

430 The impact of reactors with various porosities on the photocatalytic performance  
 431 of the system is studied at  $D_p = 3 \text{ mm}$  (Fig. 11). The HPCR with less porosity can have  
 432 higher the SSA and longer times for CH<sub>4</sub> to contact with the photocatalyst when the  
 433 particle diameter is kept constant. In addition, a decrease in porosity can make the  
 434 porous media more viscous resistant, and impede the flow of gas. The purification rate  
 435 peaks at a porosity of 0.85, while the photocatalytic efficiency decreases with the  
 436 increase in the porosity. The CH<sub>4</sub> photocatalytic efficiency is 93.26% and the  
 437 purification rate is 0.55 g/s at  $G = 857 \text{ W/m}^2$ ,  $D_p = 3 \text{ mm}$ , and  $\gamma = 0.85$ .

438

439

440 Fig. 11. Influence of the porosity on the CH<sub>4</sub> degradation performance of the SCPP-  
 441 HPCR at  $G = 857 \text{ W/m}^2$ .

442

### 443 3.4 Estimation of CO<sub>2</sub> emission reduction

444 Based on solar radiation data from July 24, 2016 (Ming et al., 2021b), the  
 445 performance characteristics of the system for one day of operation were evaluated while  
 446 assuming that an SCPP-HPCR will be built in Qianyanzhou, China.  $D_p = 3 \text{ mm}$ ,  $\gamma =$   
 447  $0.85$ , and a turbine at a constant speed of 180 rpm are chosen as the optimal parameters  
 448 of the SCPP-HPCR. Ten groups of the solar radiation from 7:00 am to 5:00 pm are  
 449 divided, and input parameters are established at one-hour intervals. The volumetric flow  
 450 rate, turbulent pressure drop, output power, and CO<sub>2</sub> emission reduction of the system  
 451 are presented in Table 3. The time-by-time photocatalytic performance curves of the  
 452 system are shown in Fig. 12.

453 From 9:00 am until 3:00 pm, the solar radiation is high (more than  $700 \text{ W/m}^2$ ).  
 454 The solar radiation of a day first increased and then decreased. The rate of CO<sub>2</sub>  
 455 reduction and the power generation of the turbine both peaks during this time period.  
 456 The photocatalyst activity is fully stimulated due to the strong UV light in the  
 457 environment, and the photocatalytic efficiency and rate of methane reaches their  
 458 maximum values during this period. 375.52 kg of CO<sub>2</sub> and 2.38 kg of CH<sub>4</sub> can be  
 459 mitigated by the system in one day of operation.

460

461

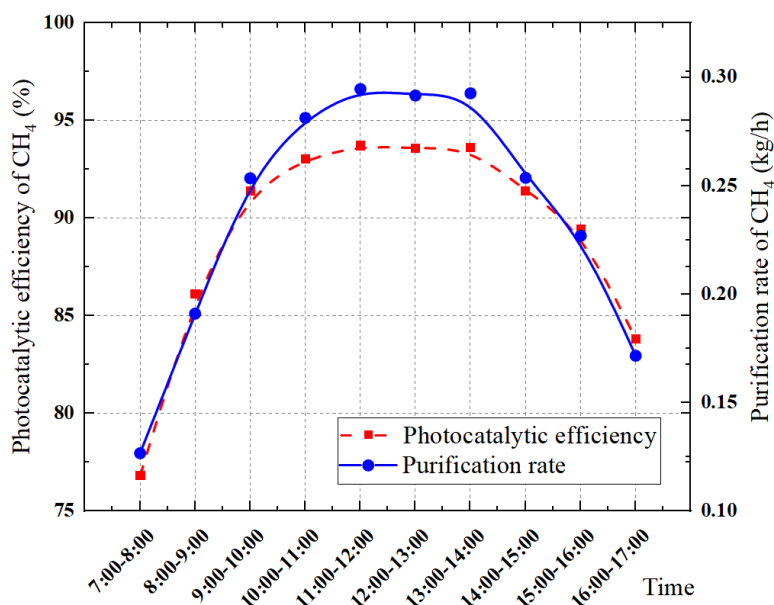

Table 3. Performance parameters of the SCPP-HPCR on July 24, 2016 in

462

Qianyanzhou, China.

Time	Solar radiation (W/m <sup>2</sup> )	Volume flow rate of the system (m <sup>3</sup> /s)	Pressure drop of turbine (Pa)	Output power (kW)	CO <sub>2</sub> emission reduction (kg/h)
7:00-8:00	270	323.98	102.99	8.89	8.46
8:00-9:00	474	416.42	126.41	25.39	24.14
9:00-10:00	715.3	501.12	146.45	43.29	41.15
10:00-11:00	837.5	537.99	154.84	51.86	49.29
11:00-12:00	892.8	555.37	158.82	56.07	53.29
12:00-13:00	884.7	551.57	157.92	55.15	52.41
13:00-14:00	889.2	552.79	158.28	55.45	52.70
14:00-15:00	716.1	501.27	146.50	43.33	41.19
15:00-16:00	607.2	465.49	138.16	35.44	33.68
16:00-17:00	407.5	388.93	119.83	20.21	19.21

463

464

465

Fig. 12. Performance of CH<sub>4</sub> degradation on July 24, 2016 in Qianyanzhou, China.

466

467 As a massive energy storage layer, the soil can turn part of the solar energy into  
468 internal energy at day and release thermal energy at night to heat the air inside the  
469 collector, creating a steady thermal airflow and achieving all-weather intermittent  
470 power generation (Guo et al., 2016). The HPCR cannot perform well due to the lack of  
471 the UV light at night. The capacity of the system to reduce CO<sub>2</sub> can be further improved  
472 if an appropriate UV light source system is constructed around the HPCR (Wang et al.,  
473 2014).

474

#### 475 **4. Discussion**

476 The high construction costs are still a concern to be considered even though SCPP-  
477 HPCR can remove atmospheric CH<sub>4</sub> while simultaneously producing electricity. The  
478 SCPP building cost is around \$1.25 million in the desert, the Gobi, and other regions  
479 where lands are cheap (Abdelsalam et al., 2020). The original investment can be  
480 returned after 15 years of operation owing to the generating power of the system  
481 (Krätzig, 2013). SCPP is a long-term investment that will yield off with an expected  
482 lifespan of 80 years (Harte et al., 2013). It has the advantages of a simple structure and  
483 low maintenance. In comparison to other methods currently used to remove  
484 atmospheric CH<sub>4</sub>, such as photocatalysis, thermal catalysis, electrocatalysis, etc., a  
485 large and continuous amount of energy must be consumed in to achieve the appropriate  
486 reaction conditions and provide steady airflow (Sher Shah et al., 2020). SCPP-HPCR  
487 forms a steady air stream to degrade atmospheric CH<sub>4</sub> by the HPCR and create  
488 economic value by the turbine power generation with no energy usage. In the future,  
489 highly selective photocatalysts can be used to remove other atmospheric pollutants.

490

#### 491 **5. Conclusion**

492 As a novel negative emission technology, the SCPP-HPCR can effectively reduce  
493 the atmospheric CH<sub>4</sub> concentration, ultimately alleviating the global warming effect. In  
494 this paper, the CH<sub>4</sub> degradation and electricity generation performance of the SCPP-  
495 HPCR are studied based on a 3-D numerical model. The impact of the system on the  
496 environment is evaluated by the CO<sub>2</sub> equivalent. The following conclusions can be

497 drawn.

498 (1) The HPCR and the turbine area are the primary sources of internal resistance  
499 for low and high turbine speeds, respectively. The overall internal pressure loss of the  
500 SCPP-HPCR is minimized to 176.84 Pa for  $G = 857 \text{ W/m}^2$ ,  $\omega = 80 \text{ rpm}$ , and  $D_P = 2$   
501 mm.

502 (2) The photocatalytic efficiency of  $\text{CH}_4$  can be enhanced by increasing the turbine  
503 speed or decreasing the  $D_P$  of the reactor. However, the latter can improve the efficiency  
504 more than the former.

505 (3) 375.52 kg of  $\text{CO}_2$  and 2.38 kg of  $\text{CH}_4$  can be mitigated by an SCPP-HPCP  
506 system built in Qianyanzhou, China, in one day for  $D_P = 3 \text{ mm}$ ,  $\gamma = 0.85$ , and  $\omega =$   
507 180 rpm.
