ABSTRACT

The US Navy systems may have unexpected significant cost growth for many reasons. The Office of the Chief of Naval Operations (OPNAV) manually and periodically reviews big data (structured and unstructured data) that were created within the Department of Defense requirements process to identify the programs that create excessive cost or cost growth. This research explores two questions:

1: What are the common elements of requirements that create excessive cost growth in Navy systems?

2: Assuming the elements are identified, what is the risk (likelihood and magnitude) of cost growth from common elements for both procurement and sustainment costs?

We applied classic data sciences and business intelligence tools towards a more advanced artificial general intelligence framework to analyze structured and unstructured data and identify elements and factors that create excessive cost growth. We found patterns and deep causes for high cost or cost growth programs using lexical link analysis, natural language processing (NLP) tools, a semantic network analyzer, anomaly detection, and causal learning concepts. Programs with anomalous characteristics can lead to high costs or high growth. These tools provide counterfactual and drill-down discovery of the key words that explain the deep causes of cost growth. The recommendations are to apply these tools for the total benefits of analyzing Navy programs and requirements of post mortem data, towards modernizing the OPNAV's Program Budget Information System (PBIS) to become a knowledge system that can effectively learn from historical data to make better risk predictions and decisions for the future Program Objectives Memorandum (POM).

I. INTRODUCTION

The US Navy's Office of the Chief of Naval Operations (OPNAV) is charged, among other responsibilities, with executing the Planning, Programming, Budgeting, and Execution (PPBE) process through a series of concurrent annual planning cycles guided by a Program Objectives Memorandum (POM), collectively referred to as POM-Year X (C. Marsh, email to author, November 4, 2022).

Navy systems may have unexpected significant cost growth for many reasons. The US Navy's OPNAV is charged, among other responsibilities, with executing the planning, programming, budgeting, and execution (PPBE) process through a series of concurrent annual planning cycles guided by a Program Objectives Memorandum (POM), collectively referred to as POM-Year X (C. Marsh, email to author, November 4, 2022).

The objective is to leverage advanced analytics to help the OPNAV understand the common elements and causes of existing Navy systems that have significant cost growth from historical data, requirements documents, and open-source media.

The research questions are:

1: What are common elements of requirements that create excessive cost growth in Navy systems?

2: Assuming the elements are identified, determine the risk (likelihood and magnitude) of cost growth from common elements for both procurement and sustainment costs?

The PBIS has been modernized as an authoritative knowledge system including historical data of planned and executed POM information and spending each year. Data relevant to PBIS include structured data and unstructured data. For example, structured data include number of platforms procured and procurement and sustainment costs for Navy systems. Budget Exhibits (BE) contain PPBE information as well as unstructured data of unclassified high-level program descriptions and their elements. Initial capability documents (ICDs), key performance parameters (KPPs), or key-systems attributes (KSAs) from capability development documents (CDDs) and operational requirements documents (ORDs) are classified data sources from previous requirements processes that

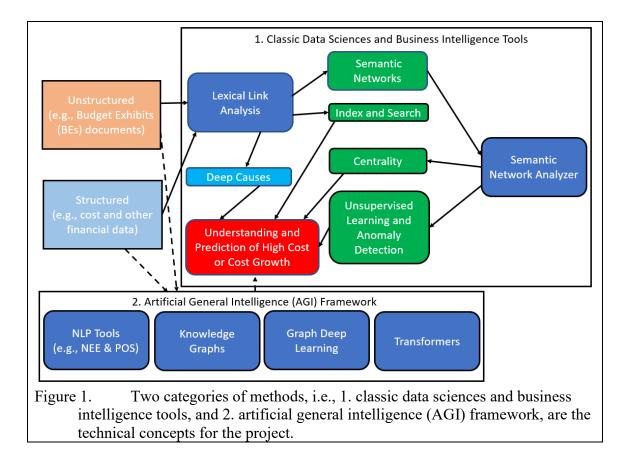

may have contributed to excessive cost growth. These data can be structured, such as KPPs and KSAs, and unstructured, such as BEs, ICDs, and CDDs.

We applied two categories of methods: 1. classic data sciences and business intelligence tools and 2. an artificial general intelligence framework to address the needs and research questions to analyze structured and unstructured data together and correlate them with excessive cost or cost growth of Navy systems. Specifically, we applied LLA, a semantic network analyzer, anomaly detection, and causal learning to discover patterns and deep causes that can lead to high cost or cost growth.

We analyzed two unclassified data sets provided by the topic sponsors. The first data set included seven PE documents that are processed using the LLA, artificial general intelligence NLP named entity extraction (NEE) and parts of speech (POS) tagging tools. POS features include extracted noun and verb word features. NEE features include extracted person, organization, location, product, money, event, law, language, date, time, percent, ordinal, cardinal, quantity, nationality or religious group, infrastructure, and work of art.

To discover the anomalous characteristics, we first applied LLA to compute the similarity of every two pairs of programs, then applied community finding and centrality calculation algorithms to discover the programs that are far away from community centers or on the edges of the semantic networks, which are indicators of anomalies. We used a semantic network analyzer to visualize that these Navy systems located in the center or edge of the semantic networks. The number of links are also indicators of system independences represented in the word feature networks discovered by LLA. Less linked BEs are anomalous via the unsupervised learning because they may have more unique features or innovations. We also used LLA's drill-down search capability and counterfactual reasoning of causal inferences to narrow down the key words as potential causes for the anomalous characteristics.

Some data and meta-data for the project are in the secret level. We documented the methodology and demonstrated the approaches using a subset of unclassified data downloaded from public domains, i.e., Budget Exhibits (BE), in this report. The deliverables are also based on the unclassified data.

II. APPROACHES

Figure 1 shows that centered around understanding and prediction high cost or cost growth for Navy systems, the author considers two categories of methods, i.e., 1. classic data sciences and business intelligence tools, and 2. artificial general intelligence (AGI) framework to address the needs. The classic data sciences and business intelligence tools are the focus of the paper. The author first reviews each method and element in the following sections.

A. STRUCTURED AND UNSTRUCTURED DATA

Program Budget Information System (PBIS) has been modernized as an authoritative knowledge system including historical data of planned and executed POM information and spending each year. Data relevant to PBIS include structured data and unstructured data. For example, structured data include number of platforms procured, procurement and sustainment costs for Navy systems. Program elements or Budget Exhibits (BEs) contain PPBE information as well as unstructured data of unclassified high-level descriptions of the programs and their elements. Data from Initial Capabilities Documents (ICDs) and CDDs structured data attributes of Key Performance Parameters (KPP), or Key-Systems Attributes (KSA) from CDDs, which are mostly classified, may have contributed to cost growth. Some requirements documents (ICDs) are unclassified, although none of the pilot programs.

B. LEXICAL LINK ANALYSIS (LLA)

LLA is a data-driven text and data mining method. In an LLA, a complex system can be expressed in a list of attributes or features with specific vocabularies or lexicon terms to describe its characteristics. LLA is data-driven text analysis. For example, word pairs or bi-grams as lexical terms can be extracted and learned from a document repository. LLA automatically discovers word features, links, and groups and displays them as networks. Nodes are words and bi-grams are the links between words. Bi-gram also allows LLA to be extended to numerical or categorical data. This allows the study of the numeric metrics and structured data attributes such as Key Performance Parameters

(KPP), or Key-Systems Attributes (KSA) integrated with the word features and characteristics of capability requirements linked to the cost growth.

LLA is related to but significantly different from bag-of-words (BOW) methods, Latent Semantic Analysis (LSA, Dumais, Furnas, Landauer, & Deerwester, 1988; Probabilistic Latent Semantic Analysis (PLSA, Hofmann, 1999), WordNet (Miller, 1995), Automap (CASOS, 2009), and Latent Dirichlet Allocation (LDA) (Blei, Ng, & Jordan, 2003).

C. SEMANTIC NETWORKS, SEMANTIC NETWORK ANALYZER, CENTRALITY, UNSUPERVISED LEARNING, AND ANOMALY DETECTION

LLA outputs semantic networks. It divides word node features into three categories by applying network community finding algorithms:

- Authoritative or popular (P) themes: These themes resemble eigenvalue centrality measures in network sciences. These represent the main topics in a data set.
- Emerging (E) themes: These themes tend to become popular or authoritative over time.
- Anomalous (A) themes: These themes may not seem to belong to the data domain as compared to others. They are interesting and could be high-value for further investigation.

Community detection algorithms have been illustrated by Newman in terms of a quality function as the "modularity" measure for a community (cluster) and optimized using a dendrogram-like greedy algorithm (Newman, 2003) as if word features or objects (e.g., programs) in a social community. In a network theory, the most connected nodes, i.e., nodes with higher measures of centrality, are typically considered the most important nodes (Newman, 2006). However, the uniqueness of LLA is that it extracts emerging and anomalous information (word features) which might be more interesting for anomaly detection such as detecting programs with excessive cost growth, and then rank programs with significant cost growth. For example, in the context of the proposed research, emerging and anomalous word features in the capability requirement data might correspond to the innovativeness and uniqueness of a capability requirement. This relates to unsupervised learning algorithms such as K-means, Principal Component Analysis (PCA), and spectral clustering (Ng, Jordan, & Weiss, 2002) for anomaly detection in classic data sciences. Bi-gram also allows LLA to be extended to structured data (Zhao & Zhou, 2014), where a word is an attribute combined with its possible values. LLA

automatically discovers word feature networks of social and semantic for extremely large number of word features, scalable to the data attributes and their possible values, similar to the Generative Pre-trained Transformer 3 (GPT-3) model (Brown, 2020), which can handle about 175 billion word features.

Related research questions are listed as follows:

- How does the cost growth correlate with the popular, emerging, and anomalous categories and common elements of the requirement data?
- Does the cost growth correlate with the innovativeness of the requirements?

LLA can be jointly used with NEE and PoS methods (Section 1.6) to address the

following questions:

- Do the numbers of people and organizations detected in the requirements correlate with the cost growth?
- Do the number of verbs (actions) and nouns (concepts) detected in the requirement data correlate with the cost growth?
- Do the subsystem independences represented in the word feature networks correlate with the cost growth?

D. CAUSAL LEARNING AND DEEP CAUSES

Anomaly detection often needs to understand causes behind any anomalous behaviors such as excessive cost and/or cost growth (observable effects). This calls a systematic approach of causal machine learning. The key factors for causal learning include the three layers of a causal hierarchy - association, intervention, and counterfactuals (Pearl, 2018; Pearl, & Mackenzie, 2018). A typical causal machine learning method needs to select a cause (C) that maximizes the counterfactual difference P(E|C) - P(E|Not C), where the effect *E* is observable data and cause C is actionable and controllable variable, which might be hidden inside big data (structured or unstructured). If causal learning can reason and detect the causes for good or bad effects, decision makers might be able to fix the causes, avoid bad effects, and achieve desired effects. Interventions are often tested as causes since they are actionable and their effects can be measured. LLA allows a causality analysis. LLA uses causal learning and computes counterfactual proportion difference, *i.e.*,

$$cf = [P(E|C) - P(E|Not C)] \times (pooled sample size)$$
(1)

as the strength of the link of two word feature nodes, where P(E|C) is the probability of event E if event C occurs. The pooled sample size is an average number of historical event E and C occur together normalized by the priors. *cf* is a z-score (PSU, 2021) and we use *cf* > 1.96 for *p*-value < 0.05 as the statistical significance for the link strength of the nodes. With the computation, the network nodes are linked causally.

E. INDEX AND SEARCH

LLA is used to index and search for structured and unstructured data sources implemented in a set of collaborative learning agents (CLAs). For a single CLA, it first indexes and data-mines the data and allows search and retrieve data based on causal knowledge patterns discovered from data. The key difference is that LLA search and a typical search engine is that it can address the question of sorting and ranking important and interesting information based on the different needs. Traditionally in knowledge graph analysis (e.g., semantic networks), the importance of a network node is a form of high-value information. Among various centrality measures, sorting and ranking information based on authority is compared with page ranking of a typical search engine. Current automated methods such as graph-based ranking used in PageRank, require established hyperlinks, citation networks, social networks (e.g., Facebook), or other forms of crowd-sourced collective intelligence. However, these methods are not applicable to situations where there exist no pre-established relationships among network nodes such as intelligence analysis. This makes the traditional centrality measures or PageRank-like methods difficult to apply. Furthermore, current methods mainly score popular information that are important for marketing applications, however, emerging and anomalous information are important for discovering anomalies, e.g., for intelligence data analysis. Patterned, emerging, and anomalous themes in the LLA search is used to sort and rank important information based on the needs of different applications.

F. ARTIFICIAL GENERAL INTELLIGENCE (AGI) FRAMEWORK - NATURAL LANGUAGE PROCESSING (NLP)

An AGI framework typically contains large-scale machine learning models with billions of parameters to learn and recognize patterns from multimodality of data such as imagery, text, geospatial information, video, acoustics, radio frequencies, and time series.

In an AGI framework, natural language processing (NLP) of text analysis include indexing/search, topics and theme extraction, summarization, categorization,

sentiment analysis, entity extraction (e.g., people and locations), and sorting/ranking importance of topics and themes. The tool spaCy and prodigy (Explosion, 2016, 2021) are used for many of these analyses. For example, Air Force uses the combination for monitoring AI and Autonomy research: they are using spaCy to track public AI/autonomy papers, patents, compare them with the internal air force project descriptions. The system is called Landscapes for Autonomy using the tool prodigy. Orange (UOL, 2021) has a text mining package including sentiment analysis. Some text analysis tools are supervised machine learning, some are unsupervised machine learning methods. However, if one wants specific automation to extract keywords related to "fundamental understanding" and "utility," it may be difficult to categorize automatically for the semantic categories and need at least some data with manual labels.

Named Entity Extraction (NEE) (Explosion, 2016; NIST, 2022; Stanford NLP, 2019) and Parts of Speech (PoS) tagger (Toutanova K. & Manning, C., 2000; Explosion, 2016; NIST, 2022) are the techniques used as pre-processing tools. An entity can be a person, organization, location, money, and dates, etc. The tool can also extract PoS such as nouns and verbs which are important to the application in this paper.

G. TRANSFORMERS

An AGI framework typically includes a category of algorithms so-called Transformers. AGI Transformers include deep neural network models and contain large number of parameters (e.g., billions, Generative Pre-trained Transformer (GPT) Neo (Eleuther.ai, 2022; OpenAI, 2022) or Bidirectional Encoder Representations from Transformers (BERT, Devlin, Chang, Lee, & Toutanova, 2018), pre-trained from big data (e.g., the entire internet), can use much less data (few-shots) and better understand and make sense unstructured data. Fine-tuning GPT Neo or BERT can adapt the models to the domain specific data such as exercise logs, intelligence analysis and reports, and Navy systems and programs data.

H. KNOWLEDGE GRAPHS AND GRAPH DEEP LEARNING

In recent years, knowledge graphs (Turing Institute, 2022) revive as knowledge databases that use graph-structured data models or topologies to integrate data can store interlinked descriptions of entities – objects, events, situations or abstract concepts (Wiki, 2022). The generalization of AGI Transformers to knowledge and graph domain is

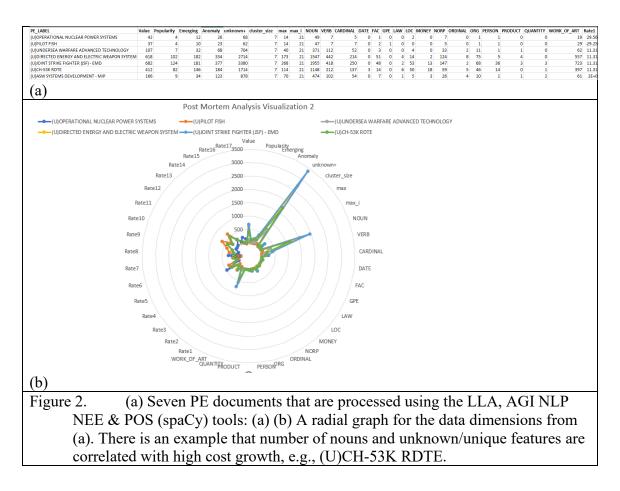

termed Geometric neural network (GNN) or Graph deep learning (GDL) (Bronstein, 2021). Learning from knowledge graphs can model the broad class of data that has objects (treated as nodes) with some known relationships (treated as edges). Knowledge graphs represented as knowledge networks and combine structured, unstructured, and multi-modality data via embedding and encoder techniques for nodes and edges (Barp et al. 2022).

III. DATA SETS AND RESULTS

In this section, the author shows two data sets the methods described in Section 1 applied.

A. DATA SET 1

The first data set includes seven budget exhibits documents that are processed using the LLA, AGI NLP NEE & POS (spaCy) tools as shown in Figure 2. Figure 2 (a) show numbers of popularity, emerging, anomaly word features, unknown, and total (value) extracted for the PE documents using LLA. Unknown features are word features do not exist in other programs but uniquely exist in a specific program. POS features include extracted noun and verb word features. NEE features include extracted person, organization (ORG), location (LOC), product, money, event, law, language, date, time, percent, ordinal, cardinal, quantity, nationality or religious group (norp), infrastructure (FAC), work of art. Cost rates are projected for 17 years (Rate1 to Rate17). Figure 2 (b) show a radial graph for the data dimensions from Figure 1 (a). Note that the features extracted do not show deep causes (e.g., key words) for potential high cost growth. In this example, the cost growth does not correlate with the popular, emerging, and anomalous categories of PE documents. Cost growth may correlate with the innovativeness of the programs, there is an example that the number of unknown (e.g. unique) features are correlated with high cost growth, i.e., (U)CH-53K RDTE. The numbers of people and organizations detected in the PE documents do not seem to correlate with the cost growth. The number of nouns (concepts) detected in the data may correlate with the cost growth.

B. DATA SET 2

The second data set includes 14 budget exhibit documents. Figure 3 (a) shows an example where the maximum total program cost, e.g., 5223 million and cost increase 136 percent are used as measures of cost growth for this program and attached to the program folder shown in Figure 3 (b).

Figure 5 shows a semantic network visualization for the data in Figure 4. The nodes represent BEs and edges are the links in Figure 4. More linked BEs which have higher degree centrality locate in the center. Less linked BEs locate outside, which are indicators of anomalies. The number of links are indicators of system independences represented in the word feature networks may correlate with excessive cost or cost growth because less linked BEs locate outside of the network centrality layout are the anomalies via the unsupervised learning.

word features every two programs.

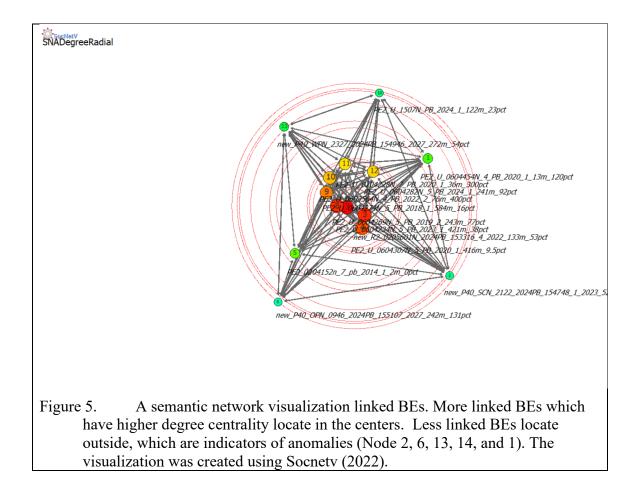

Figure 6, 7, and 8 show the LLA drill-down searches that are performed for the anomalous BEs in Figure 5. Figure 6 shows that "sole source" only show in "P40_SCN_2122_2024PB_154748_1_2023_5223m_136pct," "U 1507N PB 2024 1 122m 23pct," and

"U_0604307N_5_PB_2020_1_416m_9.5pct," which might be causes for the excessive cost or cost growth.

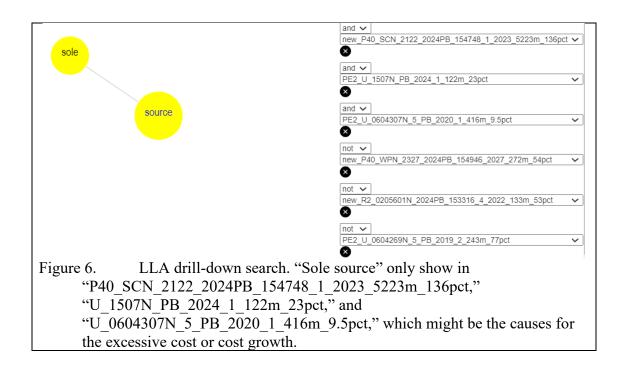

Figure 7 show using LLA search to drill down to word features around "recurring cost," "recurring engineering," "recurring equipment," "recurring procurement," and "recurring swan," which might be causes for the excessive cost or cost growth for anomalous BEs "P40_WPN_2327_2024PB_154946_2027_272m_54pct," "U_1507N_PB_2024_1_122m_23pct," "P40_OPN_0946_2024PB_155107_2027_242m_131pct."

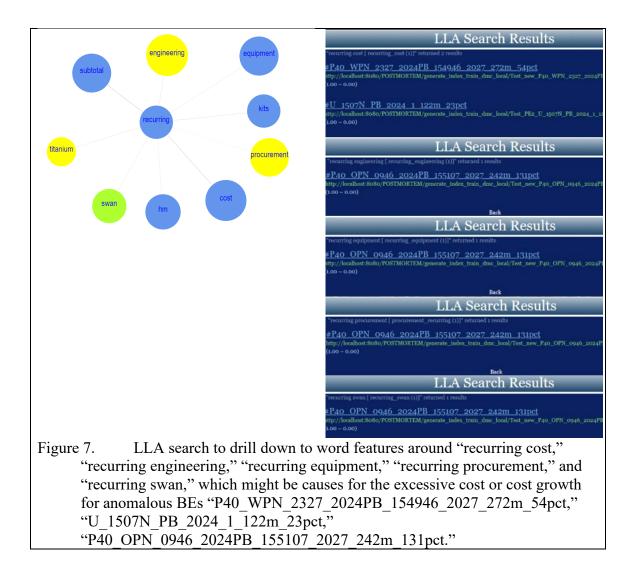

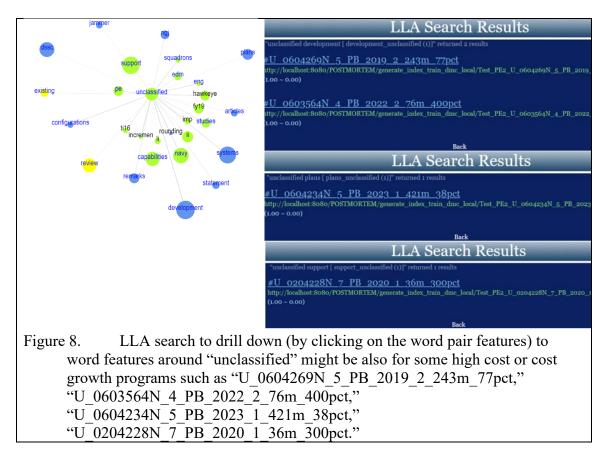

Figure 8 shows a LLA search to drill down to word features around "unclassified"

might be also for some high cost or cost growth programs such as

- "U_0604269N_5_PB_2019_2_243m_77pct,"
- "U_0603564N_4_PB_2022_2_76m_400pct,"
- "U_0604234N_5_PB_2023_1_421m_38pct,"
- "U_0204228N_7_PB_2020_1_36m_300pct."

In summary, in order to understand and eventually predict high cost or cost growth for evaluating new programs, classic data sciences and business intelligence provide immediate tools to drill down and discover deep causes. The future work to scale the concepts up via the tools in the AGI framework for more accurate prediction, however, deep causes may remain hidden. It is vital to combine the classic data sciences and business intelligence and AGI.

IV. CONCLUSIONS AND RECOMMENDATIONS

In this project, we showed the feasibility to apply the classic data sciences and business intelligence tools and artificial general intelligence (AGI) framework to address the common elements and deep causes of Navy programs and systems that create excessive cost growth. We demonstrated the potential to enable a knowledge system of unstructured and structured data that can effectively learn from historical data and environment and make discovery and prediction. The deliverables include the presentation, demonstration shown to the topic sponsors on November 4, 2022 (Appendix A) and submission a paper proposal/abstract to the 20th Annual Acquisition Research Symposium, May, 2023, Monterey (Appendix B).

- Apply the combined analytic tools explored in this project to the other classified or unclassified, structured and unstructured data sets scale up the combined analytic tools from the OPNAV's Program Budget Information System (PBIS) towards to accurately predict the risk (likelihood and magnitude) of cost growth for future Navy systems.
- Enable the PBIS to become a knowledge system that can effectively learn from human, data, and its surrounding environment to make good assessments and decisions for the future Program Objectives Memorandum (POM).

A. Mission Description and Budget Item Justification

The Next Generation Jammer (NGJ) is the next step in the evolution of Airborne Electronic Attack (AEA) and is a critical capability necessary to address current, emerging, and evolving Electronic Warfare gaps, ensure kill chain wholeness against growing threat capabilities and capacity, keep pace with enemy threat weapon systems' advancements, and support the continuous expansion of the AEA mission areas that exceed the capability of currently fielded systems. NGJ will utilize enhanced techniques and tactics to deliver significantly improved radar and communications jamming effectiveness as well as other classified capabilities. Utilizing an Open Systems Architecture that supports software and hardware updates to rapidly counter emergent and evolving threats, NGJ is a key enabler and force multiplier for operations across the spectrum of missions defined in the Defense Strategic Guidance, including strike warfare, projecting power in highly contested environments, and counterinsurgency/irregular warfare. NGJ will also address the shortfalls in scalability, flexibility, supportability, interoperability, availability, and capability of the existing AN/ALQ-99 Tactical Jamming System.

Presenter Organization Naval Postgraduate School

Presenter Email Address yzhao@nps.edu

Presenter Phone Number 408-218-8484

Abstract Navy systems may have unexpected significant cost growth for many reasons. There is an urgent need to leverage advanced analytics to understand the common elements and causes of significant cost growth from existing requirements documents and open-source media. The need includes identifying the characteristics of capability requirements from Initial Capability Documents (ICD), Key Performance Parameters (KPP), or Key-Systems Attributes (KSA) from Capability Development Documents (CDD) and Operational Requirements from previous requirements processes that may have contributed to cost growth.

The author applied various text analyses, link analysis, network analysis, and causality analysis to the DoD programs requirements data from the operational requirements documents and previous processes. The automatic discovery of the correlations and causations using deep analytics will greatly facilitate the prediction and prevention of the financial risks for building Navy systems in the future.

Research Issue The research issues are listed as follows

1. What are common elements of requirements that create excessive cost growth in Navy systems?

2. Assuming the elements are identified, determine the risk (likelihood and magnitude) of cost growth from common elements for both procurement and sustainment costs.

<u>Research Results Statement</u> The author located the cost growth risks (likelihood and magnitude) in terms of characteristics including capability requirements (unstructured), key performance parameters (structured data), key systems attributes (structured data), keywords, themes, and entities. Tools also included lexical link analysis, spaCy for entity extraction.

The author also applied apply network/graph tools to visualize the risks and capabilities in terms of relations and centralities of the networks of keywords and measures. The author also applied causal sciences and counterfactual calculation in junction with lexical link analysis to discover the key words that are associated with higher cost increase rates for Navy systems.

Ying Zhao

Dr. Ying Zhao is a research professor at the Naval Postgraduate School (NPS). Her research focused on data sciences, machine learning, artificial intelligence, artificial general intelligence methods, including lexical link analysis (LLA), collaborative learning agents (CLA), and reinforcement learning for search, visualization, and analysis, for defense military applications in the areas of semantic and social networks, common tactical air pictures, combat identification, logistics, wargaming, and mission planning. Since joining NPS, Dr. Zhao has been a principal investigator (PI) of many awarded DoD research projects. Dr. Zhao is a co-author of four U.S. patents in knowledge pattern search

from networked agents, data fusion, and visualization for multiple anomaly detection systems. She received her PhD in mathematics from MIT and is the co-founder of Quantum Intelligence, Inc.
