Mechanism of liver regeneration: 20-year bibliometric analyses

Jingshu Qi¹, Yunkai Dai¹, Xin Sun¹ and Chenghai Liu^{1,2,3*}

¹Institute of Liver Diseases, Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China, ²Shanghai Key Laboratory of Traditional Chinese Clinical Medicine, Shanghai, China, ³Key Laboratory of Liver and Kidney Diseases, Ministry of Education, Shanghai, China

Objectives: The study aims to explore the most influential countries, institutions, journals, authors, “research hotspots,” and trends in the study of the mechanism of liver regeneration (MoLR) in the last 20 years using bibliometric analyses.

Methods: The literature associated with the MoLR was retrieved from the Web of Science Core Collection on 11 October 2022. CiteSpace 6.1.R6 (64-bit) and VOSviewer 1.6.18 were used for bibliometric analyses.

Results: A total of 18,956 authors from 2,900 institutions in 71 countries/regions published 3,563 studies in different academic journals on the MoLR. The United States was the most influential country. The University of Pittsburgh was the institution from which most articles on the MoLR were published. Cunshuan Xu published the most articles on the MoLR, and George K. Michalopoulos was the most frequently co-cited author. *Hepatology* was the journal in which most articles on the MoLR were published and the most frequently co-cited journal in this field. The research hotspots for the MoLR were origin and subsets of hepatocytes during LR; new factors and pathways in LR regulation; cell therapy for LR; interactions between liver cells in LR; mechanism of the proliferation of residual hepatocytes and trans-differentiation between cells; and prognosis of LR. The emerging topic was the mechanism of regeneration of a severely injured liver.

Conclusion: Our bibliometric analyses provide (i) a comprehensive overview of the MoLR; (ii) important clues and ideas for scholars in this field.

KEYWORDS

mechanism, liver regeneration, CiteSpace, VOSviewer, bibliometric

Introduction

“Liver regeneration” (LR) refers to autonomous restoration of the mass and function of a damaged liver. LR includes the induction of cytoprotective mechanisms, deletion of mortally wounded cells, repair of less damaged surviving cells, liver cell proliferation to replace the cells that have died, deposition of new matrix, and tissue remodeling (Diehl, 2002). Of these actions, hepatocyte proliferation is the central event. As a powerful inherent ability of the liver, LR can occur in liver injury caused by partial hepatectomy, acute liver injury induced by chemical agents or viruses, liver fibrosis, etc. (Shang et al., 2016; Clemens et al., 2019; Yagi et al., 2020). The repair of a damaged liver and maintenance of liver homeostasis are extremely important. Moreover, understanding the MoLR can aid the treatment and prognosis of various types of liver diseases.

Research on the MoLR has been relatively deep, but quantitative data are lacking. Although some scholars have used meta-analysis to discuss studies with conflicting data

(Asnaashari et al., 2021), the depth of discussion has been relatively limited and subjective. In addition, research on the MoLR by many scholars has, in general, been limited to literature reading and summaries of personal clinical experience.

“Bibliometrics” is a discipline that uses mathematical, statistical, and other quantitative methods to analyze and describe relevant literature. The research content includes not only descriptive statistics (e.g., countries/regions, institutions, journals, authors, keywords, and references) but also network analysis (e.g., links between authors and institutions, “literature clusters”) (Ninkov et al., 2022).

We wished to systematically review and identify the “research hotspots” and development trends in LR. Two visualization tools, VOSviewer and CiteSpace, were used to review and analyze the literature on LR from 2003 to 2022.

Materials and methods

The data analyzed in this study were retrieved on 11 October 2022 from two influential databases: Web of Science Core Collection and Science Citation Index Expanded.

Then, advanced retrieval was undertaken according to the following search strategy: [TS = (“liver regeneration” OR “hepatic regeneration” OR “hepatocyte proliferation”) AND TS = (mechanism)] OR [TS = (promote OR enhance OR facilitate OR “contribute to”) AND TS = (“liver regeneration” OR “hepatic regeneration” OR “hepatocyte proliferation”)]. The time span was 11 October 2003 to 11 October 2022.

The inclusion criteria for the literature were as follows: (i) the theme of the article was relevant to the MoLR; (ii) the document type was Article or Review; and (iii) the language of the literature was English.

The exclusion criteria for the literature were as follows: (1) Web Of Science categories that were unrelated to the digestive system, medicine, or biology (e.g., respiratory system, chemistry, physics, and polymer science); (2) the theme of the article was not relevant to the MoLR.

The results of retrieval were selected in the form of “Full Record and Cited References” and downloaded in the document format of “Plain Text.”

CiteSpace software (<http://cluster.cis.drexel.edu/~cchen/citespace/>) was developed by Professor Chao-Mei Chen (Drexel University, Philadelphia, PA, United States). It can be used to visualize and analyze the scientific literature in a certain field to discover the research hotspots and main research directions in that research area (Chen and Song, 2019). In the present study, annual publication trends were analyzed by CiteSpace 6.1.R6 (64-bit) and visualized by Excel™ 2019 (Microsoft, Redmond, WA, United States). Countries/regions and institutions, co-cited references, “reference bursts” (i.e., the surge in citations of an article within a period of time after publication), and dual-map overlays of journals were analyzed and visualized by CiteSpace 6.1.R6 (64-bit).

The parameters for CiteSpace were set. “Time-slicing” was chosen from November 2003 to December 2022, and the year per slice was 1. Node types were selected once each time. Term source, links, and selection criteria were left as defaults. VOSviewer

(www.vosviewer.com/) is a type of bibliometric analytical software developed by Nees Jan van Eck and Ludo Waltman at Leiden University (Leiden, the Netherlands). VOSviewer is employed for mapping knowledge and visualizing keywords and authors (van Eck and Waltman, 2010). In the present study, journals and co-cited journals, authors and co-cited authors, and keywords were analyzed and visualized by VOSviewer 1.6.18.

Results

The flowchart of bibliographic retrieval and research steps in this study are illustrated in Figure 1.

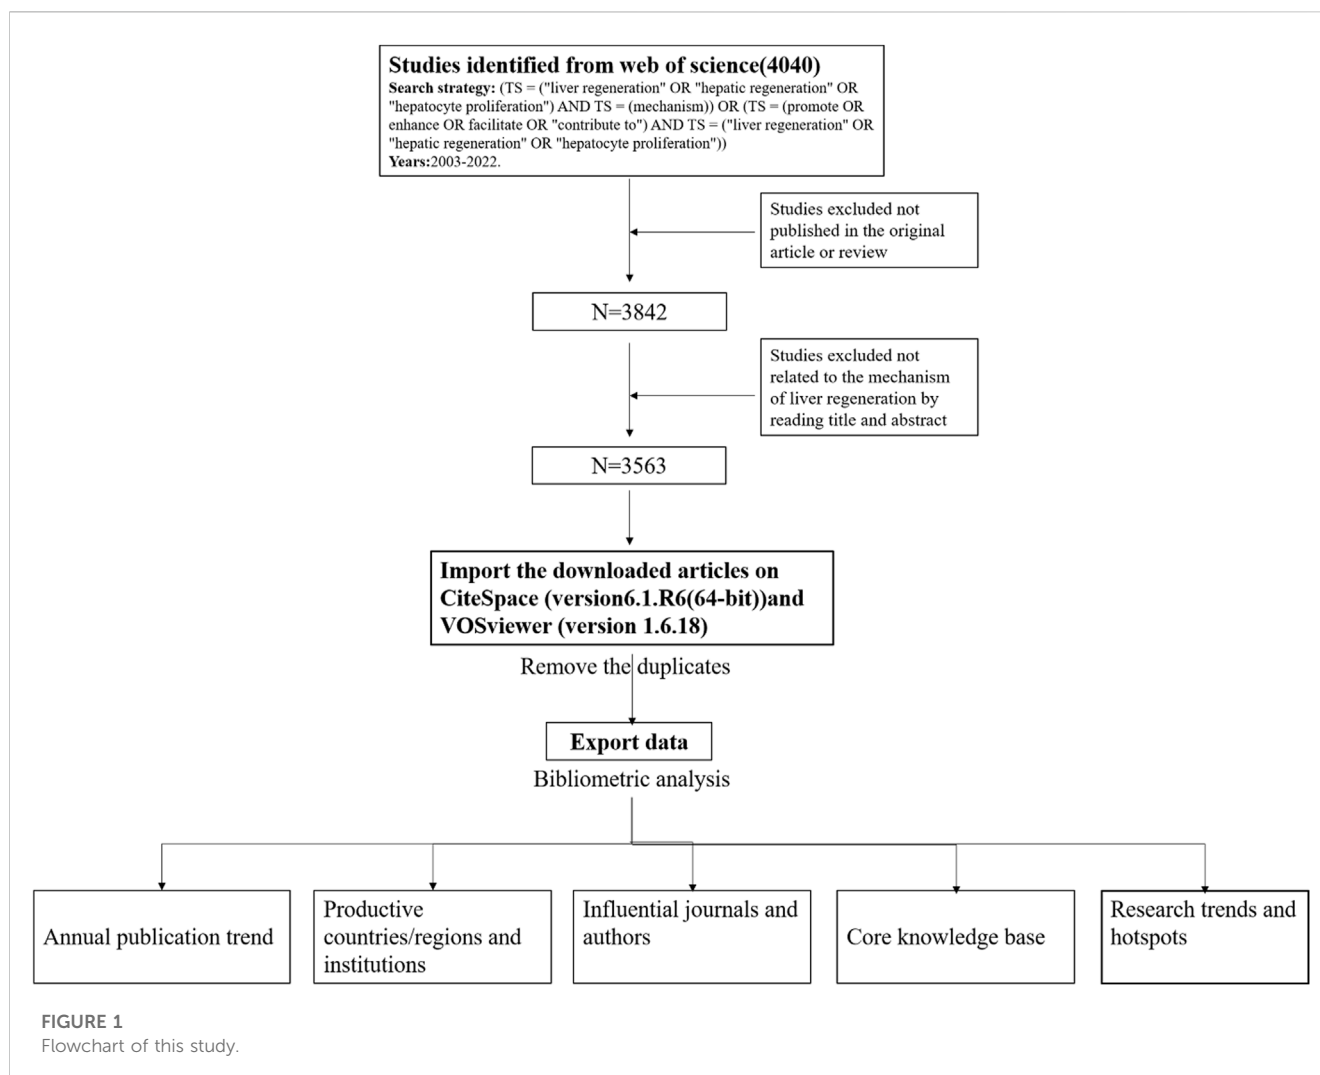

Annual growth trend of publications

According to the criteria for data selection, 3,563 studies involving the MoLR from 2003 to 2022 were retrieved from Web of Science Core Collection: 3,040 original articles (85.32%) and 523 reviews (14.68%). An overall fluctuating upward trend in the number of articles on the MoLR was observed (Figure 2). The highest number of articles was published in 2015 (236), and the lowest number of articles was published in 2003(7). This observation may have been made because the literature search was started in November 2003.

Countries/regions and institutions

The 3,563 articles related to the MoLR were written from 2,900 institutions from 71 countries/regions. The United States ($n = 1,102$, accounting for 30.91% of the total) ranked first in the number of published studies, followed by China ($n = 977$, 27.42%), Japan ($n = 505$, 14.17%), Germany ($n = 342$, 9.60%), and Spain ($n = 151$, 4.24%) (Table 1). The United States and China contributed 58.35% of total publications, far more than any other country. China was the only developing country among the top 10 countries. The United States had the highest centrality (i.e., centrality is a parameter used to measure the importance of nodes in a visual graph. The higher the centrality of a node, the closer it is to other nodes and the more important it is. In CiteSpace, nodes with centrality >0.1 are critical nodes.). The other countries/regions with centrality >0.1 were Japan (0.24), Germany (0.17), China (0.16), England (0.15), Spain (0.13), France (0.13), and Switzerland (0.12). Among the top 10 countries/regions in which most articles on the MoLR were published, the United States had 63,702 citations, far more than all other countries, and it also had the highest ratio of citation:publication (57.81), indicating that it published a large number of studies of high quality. China ranked second in the number of citations (18,204), but its ratio of citation:publication was 18.62, the lowest among the 10 countries evaluated.

With regard to institutions, the University of Pittsburgh ($n = 98$, accounting for 2.75% of the total) ranked first in the number of published articles, followed by Shanghai Jiao Tong University ($n = 73$, 2.05%), Zhejiang University ($n = 73$, 2.05%), Henan Normal University ($n = 65$, 1.82%), and Tokyo University ($n = 54$, 1.52%). Three-fifths of the top 10 institutions were from China. However,

the only institutions with centrality >0.1 were the University of Pittsburgh (0.21) and Chinese Academy of Sciences (0.11). The ratio of citation:publication of Harvard University was 90.4, though it was not in the top five in terms of the number of publications.

In addition to observing the number of published articles by the size of nodes or finding high-centrality (>0.1) nodes (purple rings in Figures 3A, B), the cooperation between countries/regions or institutions could also be found by the connection between nodes.

Productive journals and co-cited journals

Statistical analyses suggested that the 3,563 studies were published in 707 academic journals. Table 2 shows the top 10 most prolific and co-cited journals associated with the MoLR. *Hepatology* (234 articles, 6.57%) published the most documents in this field, followed by the *Journal of Hepatology* ($n = 112$, 3.14%), *PLOS One* ($n = 98$, 2.75%), and *World Journal of Gastroenterology* ($n = 70$, 1.96%). In addition, there were three journals in the Q1 Journal Citation Report (JCR) division (i.e., the journal performed better than $\geq 75\%$ of journals in that category based

on its impact factor (IF) score), and the IF of *Gastroenterology* was the highest (33.883).

With respect to the co-cited journals in Table 2, *Hepatology* ($n = 14,986$) ranked first, followed by the *Journal of Biological Chemistry* ($n = 6,400$), *Journal of Hepatology* ($n = 5,143$), *Proceedings of the National Academy of Sciences of the United States* ($n = 4,945$), and *Gastroenterology* ($n = 4,814$). In addition, eight journals were located in the Q1 JCR division, and the journal with the highest IF was *Nature* (IF = 69.504).

Figures 4A, B detail the density views of productive journals and co-cited journals. The density view is particularly useful to obtain an overview of the general structure of a map and to draw attention to the most important areas in a map. Moreover, word size and the shade of yellow were positively correlated with frequency.

The dual-map overlay of journals shows the position of a research subject relative to the main research discipline. Each point on the map represents a journal, and the map is divided into two parts, a citation map on the left and the cited map on the right, and the curves are citation lines. As shown in Figure 5, the mapping identifies three colored primary citation pathways, meaning that research studies published in journals in the field of Molecular/Biology/Genetics and Health/Nursing/Medicine were

FIGURE 2

primarily cited by research studies published in Molecular/Biology/Immunology and Medicine/Medical/Clinical journals.

Productive authors and co-cited authors

Bibliometric analyses showed that the 3,563 articles were written by 18,956 authors. Cunshuan Xu was top ($n = 35$) in terms of the number of articles published, followed by Wei An ($n = 24$), Udayan

Apte ($n = 23$), Dieter Haeussinger ($n = 23$), and Stuart J Forbes ($n = 22$) (Table 3).

According to Price’s Law, the minimum number of papers published by core authors in a certain field (m) is given by

$$m = 0.749 \times \sqrt{n_{\max}}$$

which is ≈ 5.92 ,

where n_{\max} represents the number of papers with the most productive authors in the field. Hence, the core authors of the literature written in English in the present study had to write ≥ 6 publications. Then,

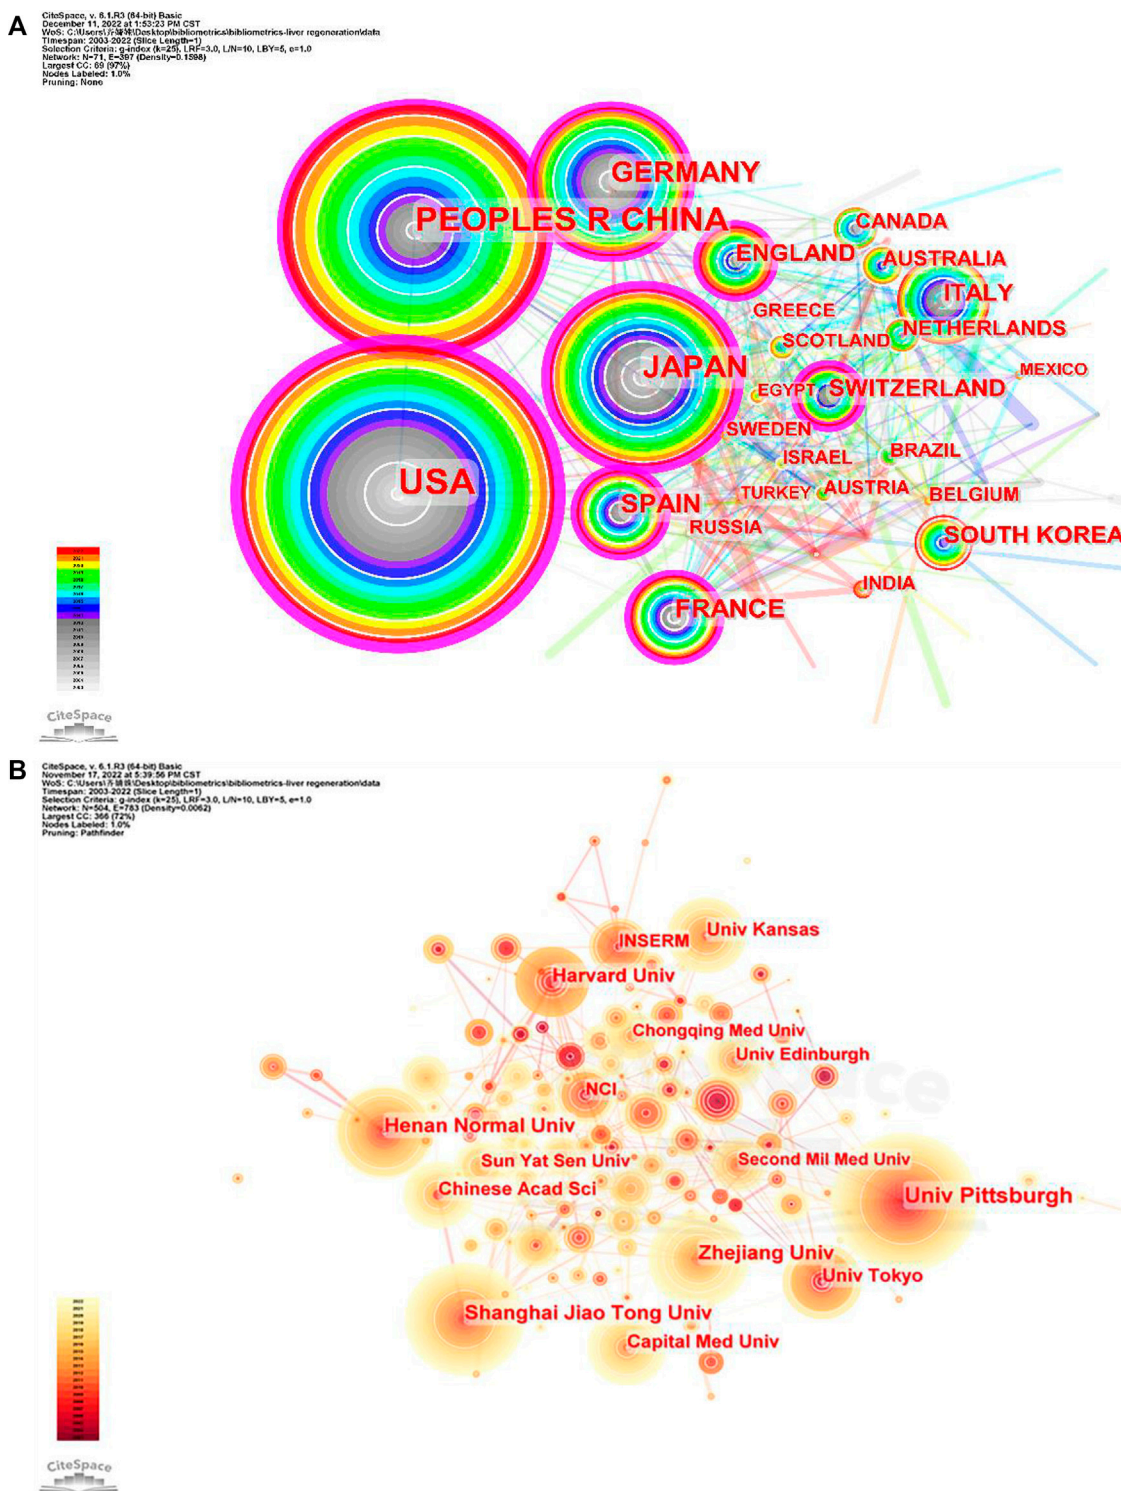

FIGURE 3 Co-occurrence maps for (A) countries and (B) institutions. The size of each node represents the co-occurrence frequency and the links reflect the co-occurrence relationships. The color of each node and line indicate different years.

282 core authors were identified through VOSviewer to draw a cooperation network map. As shown in Figure 6A, each node represents an author, and different colors represent different clusters. Authors who collaborated closely are presented in the same color, such

as Cunshuan Xu and Shi Yin, Wei An and Qi Liu, Udayan Apte, and Sucha Singh.

“Co-cited authors” are ≥ 2 authors who are cited simultaneously in ≥ 1 subsequent article. In our study, 65,625 co-authors were

IF, impact factor; JCR, Journal Citation Reports.

searched. George K Michalopoulos ($n = 1,599$) ranked first, followed by Nelson Fausto ($n = 1,258$), Rebecca Taub ($n = 542$), D. E. Cressman ($n = 368$), and Gregory M. Higgins ($n = 454$) (Table 3). In addition, authors ($n = 1,248$) with co-citations ≥ 20 were identified to draw a density map (Figure 6B) which could also show the most co-cited authors in LR.

Keyword co-occurrence and network clusters

A total of 718 keywords were obtained from the 3,653 studies through analyses of VOSviewer. In terms of frequency, the keywords “liver regeneration” ranked first ($n = 1457$), followed by “expression” ($n = 824$), “partial hepatectomy” ($n = 612$), “hepatocellular carcinoma” ($n = 442$), “activation” ($n = 420$), “mice” ($n = 405$), “regeneration” ($n = 403$), “mechanism” ($n = 347$), “rat liver” ($n = 325$), and “cell” ($n = 302$) (Table 4), which indicated the research hotspots of the MoLR. Then, a keyword co-occurrence map was established (Figure 7) with the 270 most influential keywords chosen by the criteria of “minimum number of occurrences of a keyword ≥ 20 .”

Figure 7 also presents the result of network cluster analyses of keywords. In this map, five clusters represented five research directions and scopes. Among them, cluster 1 (red) was the largest, followed by the clusters 2 (green), 3 (blue), 4 (yellow), and 5 (purple). Specifically, cluster 1 comprised 73 items, including “expression,” “activation,” and “hepatocellular carcinoma.” Cluster 2 contained 66 items, including “mechanism,” “apoptosis,” and “injury.” Cluster 3 consisted of 60 items, including “regeneration,” “transplantation,” and “stem cell.” Cluster 4 comprised 45 items, including “liver regeneration,” “partial hepatectomy,” and “growth factors.” Cluster 5 contained 26 items, including “rats,” “hepatectomy,” and “resection.”

Co-cited references and burst references

CiteSpace was used for analyses of co-cited references and burst references related to the MoLR. A total of 568 co-cited

references on the MoLR in the past 20 years were found through co-occurrence analyses of “co-cited literature” (i.e., two literature works appear together in the citation of a third literature). According to the 10 most frequently co-cited articles (Table 5), “Liver regeneration” by Fausto et al. (2006) (149 co-citations) published in *Hepatology* (IF = 17.298) was the most co-cited article. In addition, the 568 references were classified into 16 clusters through cluster analyses of the co-cited literature in Figure 8 (0 = ductular reaction, 1 = action analysis, 2 = pericentral hepatocyte, 3 = mesenchymal stem cell, 4 = partial orthotopic liver transplantation, 5 = molecular basis, 6 = bile acid, 7 = hepatocyte proliferation, 8 = reperfusion injury, 9 = signaling pathway, 10 = mitochondrial intermembrane space, 11 = antioxidant response element, 12 = tumor necrosis factor receptor, 13 = portal vein ligation, 14 = advanced liver diseases, and 15 = mesenchymal stem cell transplantation). The smaller the cluster number, the greater the influence of that cluster. The top two clusters are shown in Table 6.

Reference burst refers to the surge in citations of an article within a period of time after publication, indicating that scholars have paid great attention to the relevant topic. In this study, 191 burst references were found with the selection criteria in which the minimum duration is ≥ 2 , and the top 50 references are shown in Figure 9. With regard to the strongest burst reference, a review entitled “Liver regeneration” with a strength of 63.12 was published in *Hepatology* by Fausto et al. (2006). In addition, 10 references were considered to still be burst references in 2022.

Discussion

General information

The 3,563 articles analyzed in our study were published in 707 journals by 18,956 authors from 2900 institutions from 71 countries/regions.

The number of publications every year suggests that the MoLR received considerable attention in the past two decades, but it also illustrates that there are unsolved problems in this field.

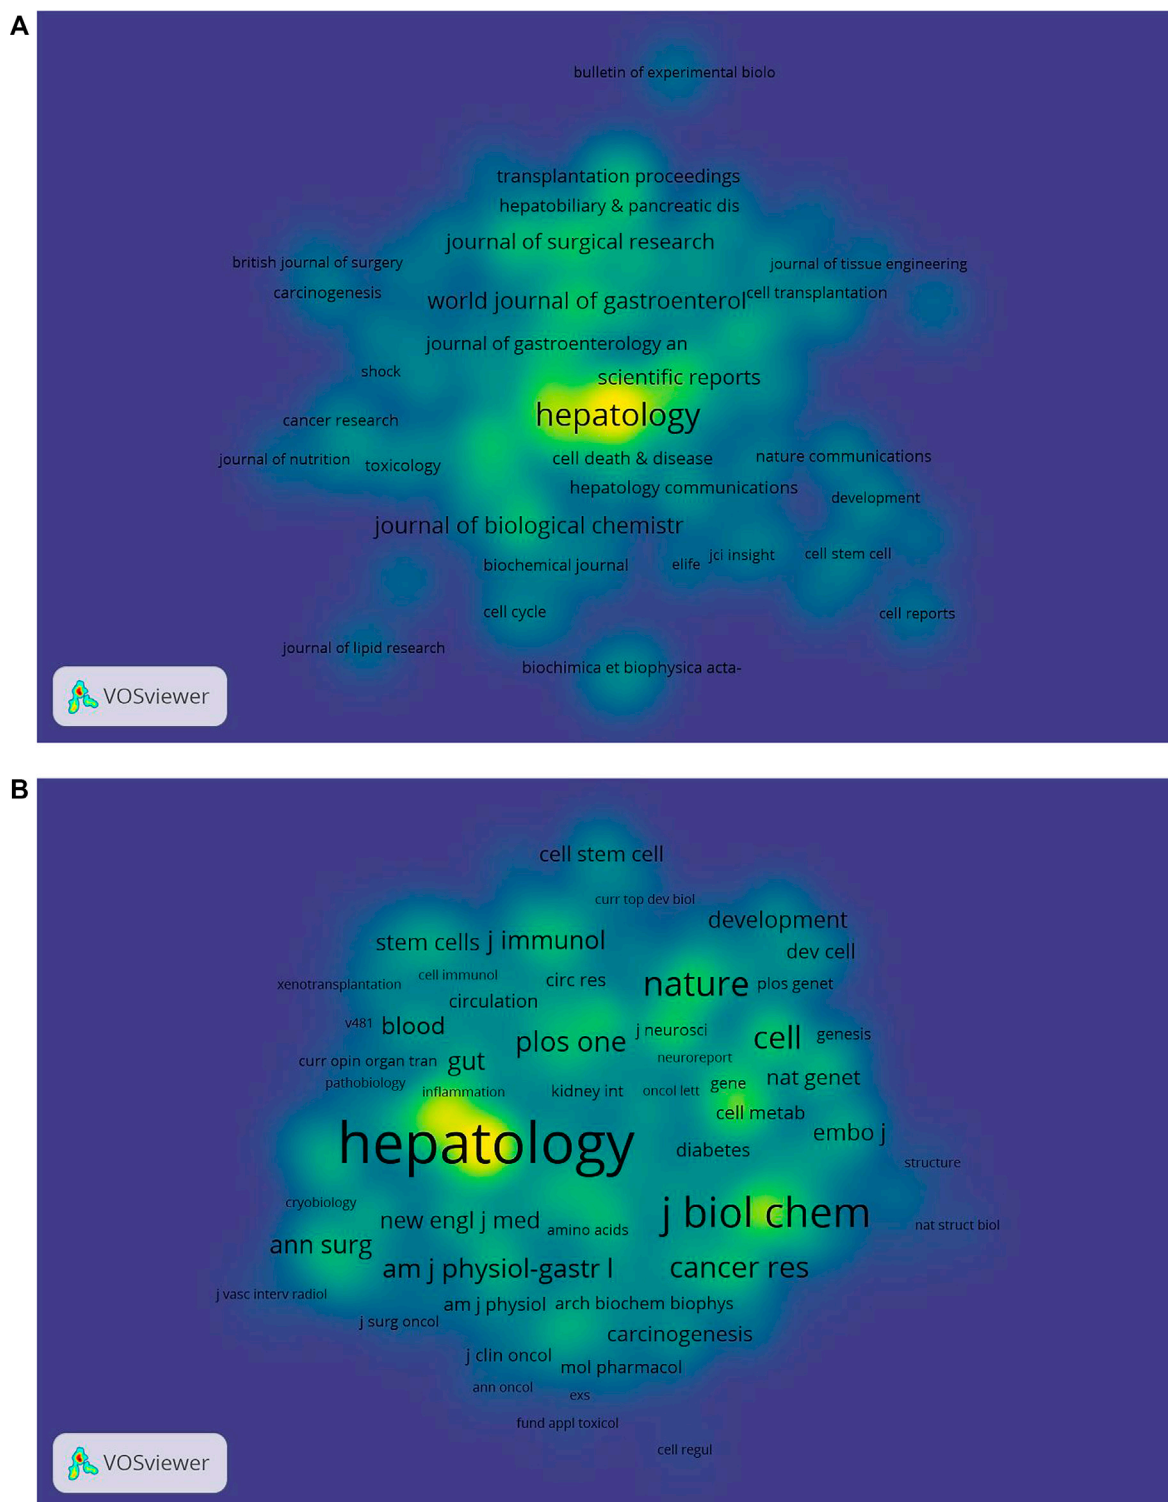

FIGURE 4
Density maps of (A) journals and (B) co-cited journals. The size of the word and circle and the opacity of yellow are positively associated with the frequency of co-citation.

Analyses of countries/regions and institutions focused mainly on three indicators: the number of publications, centrality, and average citation. These indicators can reflect the influence of a country/region and institution in a research field. In the present

study, the country with the highest number of publications on LR was the United States ($n = 1102$), followed by China ($n = 977$) and Japan ($n = 505$) (Table 1). Moreover, the United States had the highest centrality (0.4), indicating that it played an important part as

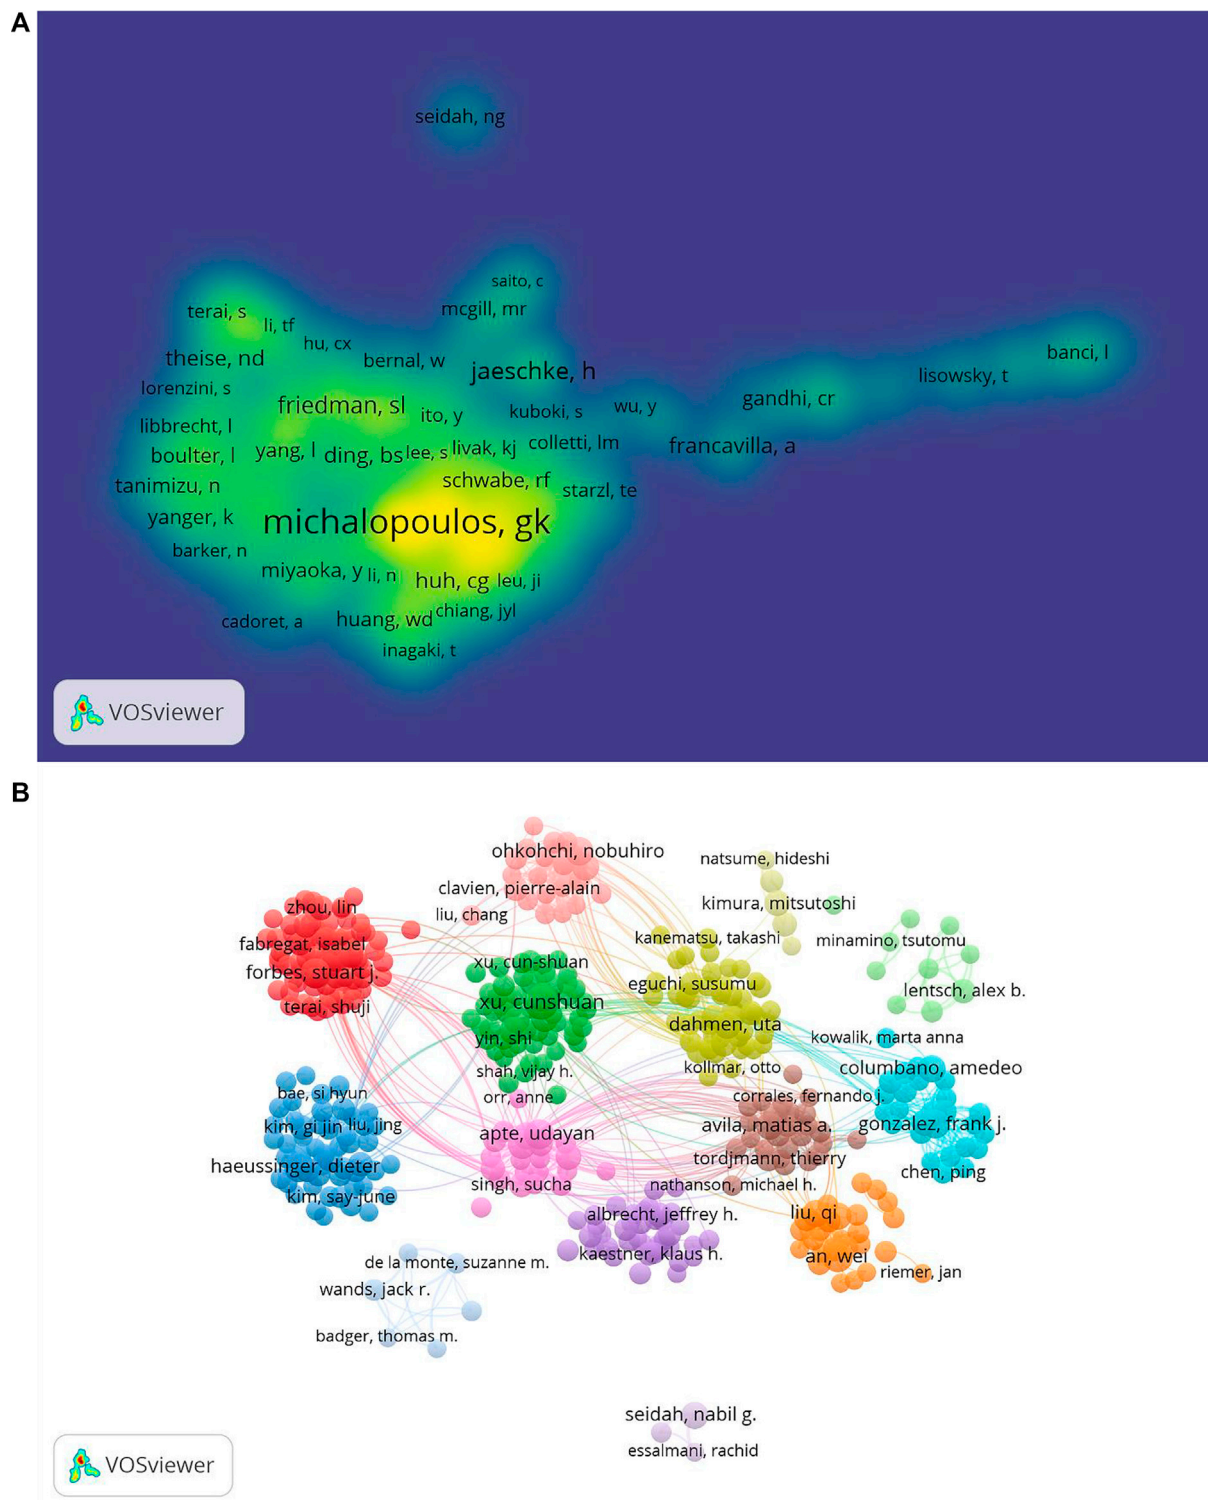

FIGURE 6

suggested that new hepatocytes generated during liver homeostasis and acute hepatocyte injury originated from preexisting hepatocytes. Yanger et al. (2014) concluded that hepatocytes were the main source of hepatocyte renewal/regeneration in the adult liver

regardless of the type of injury. They employed a 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) and choline-deficient ethionine-supplemented diet, CCL₄, and an α-naphthylisothiocyanate diet in mice. Wang et al. (2015) identified a subset of

hepatocytes that maintained the homeostasis of hepatocyte self-renewal in the normal liver: axis inhibition protein 2⁺ hepatocytes. Font-Burgada et al. (2015) discovered hybrid periportal hepatocytes, which replenish hepatocytes after their chronic depletion. Raven et al. (2017) demonstrated that bile duct cells can act as facultative liver progenitor cells in a model using DDC, methionine- and choline-deficient diet combined with thioacetamide, and CCL₄-induced liver injury in tandem with inhibition of hepatocyte proliferation.

Source of bile duct cells in LR

Yanger et al. (2013) found that in the absence/dysfunction of biliary epithelial cells (BECs) in the DDC model and bile duct ligation model in mice, hepatocytes could transform into bile duct epithelial cells. This process required intervention by the Notch signaling pathway. The results obtained by Malato et al. (2011) through bile duct ligation and DDC model argued against the idea that biliary duct injury leads to the conversion of hepatocytes into BECs. Huch et al. (2013) found that liver damage-induced leucine-rich repeat-containing G-protein-coupled receptor 5 liver stem cells could generate hepatocytes and cholangiocytes *in vivo* and could be cloned and expanded into organoids and could differentiate into hepatocytes *in vitro*.

Source of HPCs in LR

In addition to being investigated as a source of hepatocytes/bile duct cells (Lu et al., 2015), the origin of HPCs has also been discussed. Tarlow et al. (2014) used a DDC model in mice. Hepatocytes could be converted to a unique progenitor state that could be reversed upon recovery and, therefore, be the source of HPCs in chronic liver injury.

Mechanism of transformation of HPCs into bile duct cells or hepatocytes

During biliary regeneration, myofibroblasts express Jagged-1, which promotes Notch signaling in HPCs and converts HPCs into bile duct cells. During hepatocyte regeneration, macrophage phagocytosis of hepatocyte debris induces wingless-type (Wnt)3a expression. This action activates the Wnt signaling pathway in nearby HPCs, thereby promoting Numb expression in HPCs and converting HPCs to hepatocytes (Boulter et al., 2012).

In summary, the issue of various liver cell sources in LR is controversial. Accumulating evidence suggests that the origin of regenerated hepatocytes is dependent upon the animal model selected and experimental conditions. Moreover, the proliferation of residual hepatocytes and trans-differentiation between cells are important features of LR.

Part B

Part B was clustered as action analyses, which can be understood as mechanism analyses. Five reviews and five articles were in the top 10 literature works, all of which discussed the MoLR. The related contents are described in the following section.

Cytokines, growth factors, cytokine/growth factor-mediated pathways, and other regulatory factors in LR

Koniaris et al. (2003) summarized the regulatory factors and intracellular pathways in the three stages of LR: initiation,

proliferation, and termination. The regulatory factors included tumor necrosis factor (TNF) and interleukin-6 in the initiation phase; hepatocyte growth factor (HGF), transforming growth factor (TGF)- α , epidermal growth factor, insulin, and epinephrine in the proliferation phase; and activin A, TGF- β , and latency-associated peptide and follistatin in the termination phase. Moreover, the intracellular pathways involved were signaling by the TNF receptor and nitric oxide in the initiation phase; signaling by G-protein-coupled receptors, receptors with intrinsic tyrosine kinase activity, receptors activating the Janus kinase/signal transducer and activator of transcription pathway, and steroid and thyroid hormone receptors in the proliferation phase; and serine and threonine kinase receptors for the TGF-superfamily in the termination phase. Then, Taub (2004) attempted to define regions of overlap between cytokine/growth factor-mediated pathways. For example, the downstream targets that were shared by the two pathways included activator protein 1, Jun amino-terminal kinase, phosphorylated extracellular signal-regulated kinases, CCAAT-enhancer-binding protein- β , and insulin-like growth factor-binding protein 1. Furthermore, five articles (Schwabe et al., 2003; Strey et al., 2003; Borowiak et al., 2004; Berasain et al., 2005; Mitchell et al., 2005) discussed other regulatory factors in LR. These included proteins that trigger LR initiation (e.g., Jun amino-terminal kinase, C3a/C5a, and amphiregulin) and key factors in the proliferative phase of hepatocytes (e.g., mesenchymal-epithelial transition factor and heparin-binding epidermal growth factor).

Cellular mechanisms of LR focusing on the role of hepatocytes, oval cells, or bone marrow cells as the cellular source of LR

As stated in the review by Fausto (2004), in general, replication of existing hepatocytes was the quickest and most efficient way to generate hepatocytes for LR and liver repair. Oval cells replicated and differentiated into hepatocytes only if the replication of mature hepatocytes was delayed or blocked entirely. Bone marrow cells could generate hepatocytes in transplanted livers, but the number of hepatocytes produced was very low. However, bone marrow cells were an important source of nonparenchymal (e.g., Kupffer and endothelial) cells.

Interactions between liver cells in LR

The review written by Michalopoulos and DeFrances (2005) was only one of five reviews that proposed interactions between liver cells in LR. Hepatocytes can produce various growth-regulating cytokines (e.g., TGF α , vascular endothelial growth factor (VEGF), fibroblast growth factor (FGF)-1, FGF-2, angiopoietin-1, angiopoietin-2, and heparin-binding epidermal growth factor) which stimulate the growth of adjacent (e.g., endothelial, stellate, and bile duct epithelial) cells. However, growth factors affecting hepatocytes (e.g., HGF) can also be produced by neighboring stellate cells and endothelial cells. In addition, VEGF produced by replicating hepatocytes can stimulate endothelial cells to produce the hepatocyte mitogen HGF via VEGF receptor 1.

Role of liver metabolism in LR

Fausto et al. (2006) stated that LR was not only related to cytokines and growth factors but also to liver metabolism. Amino

acids regulate hepatocyte proliferation by controlling the expression of cyclin D1. After partial hepatectomy, the activity of p70 S6 kinase increases, and the activity of eukaryotic cell initiation factor 4E-binding protein 1 (translational repressor) decreases, leading to increased translation.

In summary, research on cytokines, growth factors, and their related pathways in LR is detailed, and the discovery of new regulatory factors is a research trend. The related content is not comprehensive, but the topic of interactions between liver cells in LR is a research hotspot because most regulatory factors are secreted by cells.

Analyses of hotspots and emerging topics

Analyses of keywords can provide a glimpse of the topic of an article. The keyword co-occurrence can reflect the research hotspots and trends of a subject in a certain field. The top 20 keywords with high-frequency terms involved in the MoLR are shown in Table 4. We can summarize (approximately) five main areas in this field through the keywords shown in Table 4. The first area is the commonly used model of LR, which was partial hepatectomy in rats/mice. Second, the main source of hepatocytes during LR after acute or chronic liver injury was the proliferation of residual hepatocytes. However, if the liver was severely damaged or hepatocyte proliferation was inhibited, liver stem cells (e.g., liver progenitor cells) could be used as the hepatocyte source. Third, the only treatment for end-stage liver disease was liver transplantation. However, due to the shortage of organs, the practical application of liver transplantation was limited. Primary-cell transplantation is expected to become an alternative method to organ transplantation. Fourth, HGF is a key factor in LR promotion. Fifth, the adverse consequences of LR are the cytokines produced during LR, which can induce the recurrence and metastasis of hepatocellular carcinoma.

Clustering analyses of keywords provided a more intuitive view of the research hotspots in the MoLR, as represented by five clusters (red, green, blue, yellow, and purple) in Figure 7. Cluster 1 focused on the targets that regulated LR. Cluster 2 involved the etiology of liver injury, chronic diseases, and the pathological basis of liver injury. Cluster 3 centered on cell therapies to promote LR. Cluster 4 mainly covered the factors and pathways that regulate LR. Cluster 5 mainly involved the commonly used models of LR, as well as angiogenesis in LR.

Burst references can reflect the emerging research topics in a certain field. Herein, 191 burst references were noted, and the top 50 are shown in Figure 9. Based on the strength of burst references (high to low), 10 references could be focused upon.

The first paper (Michalopoulos, 2017) (strength = 30.35) was a review by George K. Michalopoulos published in *Hepatology*, which summarized the MoLR after partial hepatectomy. The second paper (Raven et al., 2017) (strength = 24.69) was by Alexander Raven et al. published in *Nature* and discussed the knowledge base of LR. The third paper (Forbes and Newsome, 2016) (strength = 20.32) was by Stuart J. Forbes and Philip N. Newsome and published in *Nature Reviews Gastroenterology and Hepatology*. They summarized the animal models used and MoLR (including factors, signaling pathways, and interaction between hepatic cells). They also pointed out that the regeneration mechanism of a severely injured liver is an

important question that warrants investigation. The fourth paper (Deng et al., 2018) (strength = 17.79) was written by Xing Deng and colleagues and published in *Cell Stem Cell*. The results showed that BECs are converted into hepatocytes through a hepatocyte nuclear factor-4 α ⁺ cytokeratin-19⁺ biphenotypic state in severe liver injuries. The fifth paper (Tao et al., 2017) (strength = 14.65) was by Yachao Tao et al. and published in *Mediators of Inflammation*. They reviewed the novel and important signaling molecules involved in LR. The sixth paper (Planas-Paz et al., 2019) (strength = 12.44) was by Lara Planas-Paz and coworkers and published in *Cell Stem Cell*. They demonstrated that signaling by Yes-associated protein and mammalian target of rapamycin complex 1 promoted BEC expansion during DR. G-protein-coupled receptors 4/5-mediated Wnt/ β -catenin signaling is dispensable for promoting DR. The seventh paper (Russell and Monga, 2018) (strength = 12.44) was by Jacquelyn O. Russell and Satdarshan P. Monga and published in *Annual Review of Pathology: Mechanisms of Disease*. That article mainly discussed the Wnt/ β -catenin signaling pathway, its role in cell-cell adhesion and liver function, and the cell type-specific roles of the Wnt/ β -catenin signaling pathway in liver physiology/disease. The eighth paper (Asrani et al., 2019) (strength = 11.74) was a review written by Sumeet K. Asrani and colleagues and published in the *Journal of Hepatology*. They discussed the global epidemiology and prognosis of various acute and chronic liver diseases. The ninth paper (Bird et al., 2018) (strength = 11.74) was by Thomas G. Bird and colleagues and published in *Science Translational Medicine*. They found that severe acute hepatic necrosis induced the spread of senescence to remaining viable hepatocytes, which impaired hepatocyte-mediated regeneration. Furthermore, the spread of senescence was dependent upon a macrophage-derived TGF- β 1 ligand. The tenth paper (Lin et al., 2018) (strength = 11.08) was by Shengda Lin and coworkers and published in *Nature*. They found that hepatocytes with high telomerase expression regenerated hepatocytes and replenished the liver parenchyma during liver homeostasis and liver injury.

Study limitations

The present study had three main shortcomings. First, the literature was obtained from the Web of Science Core Collection. Although this database is representative, some relevant literature may have been overlooked. Second, the articles whose topics were unrelated to the MoLR were excluded manually, but some relevant literature may have been overlooked. In the section on the core knowledge base, we discussed the literature only in the first two clusters.

Conclusion

The MoLR remains a research hotspot worthy of investigation. Our study elicited four main findings. First, the most influential country in study of the MoLR was the United States. It had the highest number of published papers, centrality, and citation:publication ratio. Second, the University of Pittsburgh ranked first in the number of published papers

on LR and centrality. Second, *Hepatology* was the journal in which most articles on LR were published and the most frequently co-cited journal, which indicated its influential status in the study of the MoLR. Third, the most productive author in LR was Cunshuan Xu, and the top co-cited author was George K Michalopoulos. Fourth, the research hotspots related to MoLR were the origin and subsets of hepatocytes during LR; new factors and pathways in LR regulation; cell therapy for LR; interactions between liver cells in LR; mechanism of the proliferation of residual hepatocytes and the trans-differentiation between cells; and prognosis of LR. Fifth, the emerging topic to which attention should be paid is the regeneration mechanism of a severely injured liver.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Material; further inquiries can be directed to the corresponding author.

Author contributions

JQ analyzed the data and wrote the manuscript. YD and XS made revision for the manuscript. CL supervised the study. All authors contributed to the article and approved the submitted version.
