Cowden and Hallare: Modeling Vegetation-Erosion Dynamics using Differential Equations

1

## Modeling Vegetation-Erosion Dynamics using Differential Equations with Human Factors Mathematica Militaris, Vol. 27, 185, 212023, Art 6 Dr. Maila Hallare (Advisor), C2C Evan Cowden, SPKING 2023 DEPARTMENT OF MATHEMATICS, UNITED STATES AIR FORCE ACADEMY

## **Background and Purpose**

The effects of soil erosion are often devastating. Plants can reduce erosion by slowing runoff and reinforcing soil using its roots. In this project, we investigate the dynamic relationship between vegetation and erosion processes. We assume an inverse relationship between vegetation density and soil erosion: that is, an increase in vegetation cover reverses soil degradation and a decrease in vegetation cover intensifies the problem of erosion. We also assume that human activities (like logging, road-building) affect both vegetation development and resilience against erosion. Our model for the vegetation-erosion dynamics is a two-dimensional nonlinear system of differential equations with logistic growth on both variables. Equilibrium and nullcline analysis methods are applied to determine all possible dynamic scenarios between vegetation and erosion. The resulting parameter conditions can be used to analyze bifurcations on the vegetation and erosion dynamics.

Erosion includes all processes by which the surface of the earth is constantly being worn away, detached and removed of solid particles from their original place.

### Mathematical Model

## Vegetation cover density

E(t) Erosion density Spread of vegetation Damage to the vegetation by erosion Effect of vegetation controlling erosion Human activities that impact vegetation Human activities that cause erosion

The https://cligitalcommoogesmalibrary.org/mathematica-militaris/vol27/iss2/6 spread of the vegetation cover density V and erosion cover density E. Here, the equations have been scaled and the equations are non-dimensional.

## Equilibrium and Stability Analysis Results

Equilibrium analysis shows that there are three boundary and one interior equilibria:

$$\begin{cases} \frac{dv}{dt} = 0\\ \frac{dE}{dt} = 0 \end{cases} \quad \text{that is,} \quad \begin{cases} \mathcal{V}(r(1-\mathcal{V}) - \alpha \mathcal{E}) = 0\\ \mathcal{E}(s(1-\mathcal{E}) - \beta \mathcal{V}) = 0 \end{cases}, \quad \text{or} \begin{cases} \mathcal{V} = 0 \text{ or } r\mathcal{V} + \alpha \mathcal{E} = r\\ \mathcal{E} = 0 \text{ or } \beta \mathcal{V} + s \mathcal{E} = s \end{cases}$$

 $E_0(0,0) \rightarrow$  Vegetation and Erosion are both gone

 $E_1(0,1) \rightarrow$  Vegetation is gone, Erosion is maximized (not desirable equilibrium)  $E_2(1,0) \rightarrow$  Vegetation is maximized, Erosion is gone (desirable equilibrium)  $E^*\left(\frac{s(r-\alpha)}{rs-\alpha\beta},\frac{r(s-\beta)}{rs-\alpha\beta}\right)$ → Coexistence equilibrium

Linear stability analysis  $J(V,E) = \left( \frac{r-2rV-\alpha E}{r} \right)$ requires analyzing the  $s - 2sE - \beta V$ eigenvalues of Jacobian at each equilibrium.

## Vegetation-Erosion Scenarios, Nullcline Analysis

Case	Y-intercepts	X-intercepts	Slopes	
1.1	$r/\alpha > 1$	$s/\beta < 1$	$rs - \alpha\beta < 0$	]
1.2	$r/\alpha > 1$	$s/\beta < 1$	$rs - \alpha\beta > 0$	1
2	$r/\alpha > 1$	$s/\beta > 1$	$rs - \alpha\beta > 0$	
3	$r/\alpha < 1$	$s/\beta < 1$	$rs - \alpha\beta < 0$	1
4.1	$r/\alpha < 1$	$s/\beta > 1$	$rs - \alpha\beta > 0$	1
4.2	$r/\alpha < 1$	$s/\beta > 1$	$rs - \alpha\beta < 0$	]

Nullcline analysis reveals that there are eight cases to consider depending on the relative orientation of the V-nullcline and the E-nullcline.

 $-\alpha E$ 

#### Numerical Simulations

#### **Conclusions and Next Steps**

- ODEs can be used to investigate the dynamics between vegetation and erosion. Resulting model does not fall in the usual math ecology models.
- Equilibrium, stability, and nullcline analysis reveal possible states and scenarios depending on parameter conditions. Numerical simulations illustrate theoretical results.
- Preliminary results on including human factors for Case 3: we recommend choosing parameters so that the new equilibrium position is closer to (1, 0) and choosing initial conditions that lie within the basin of attraction of (1, 0). Such parameter regions can be computed and can be used to guide management decisions on resilience against erosion.
- Future research on this topic includes improving model by considering effects of precipitation on the system, finding real data to test the model, and investigating bifurcations of the system.
