Diabetes Management in Preoperative Hospitalized Patients: Improving Quality Measures on an Orthopedic Trauma and Surgical Unit

Caroline Kinkaid RN

The University of Tennessee, Knoxville

Overview of Problem

- Diabetes mellitus (DM) is a major public health concern as it is the seventh leading cause of death in the United States
- Diabetes adversely affects the outcome of all orthopedic surgery subspecialties including foot and ankle, upper extremity, adult reconstructive, pediatrics, spine surgery, and sports medicine

Clinical significance

- Diabetic patients undergoing surgery are at risk for increased morbidity and longer hospital stays
- Perioperative mortality rate for DM patients is significantly higher than mortality seen in patients without DM
- Patients with complicated DM (neuropathy, PAD, or nephropathy) have seven times higher likelihood of surgical site infection (SSI) and nearly a four times higher likelihood of SSI compared with patients with uncomplicated DM
- Effective diabetes management in patients without comorbidities have similar outcomes to those without diabetes

Project Purpose and Goal

- Purpose
 - To implement nursing education for the staff nurses to improve preoperative patients diabetes management (as defined as holding short acting insulin without an order to do so)
- Goals
 - To improve staff nurses knowledge of preoperative diabetes management
 - To improve outcomes of surgical patients who receive insulin

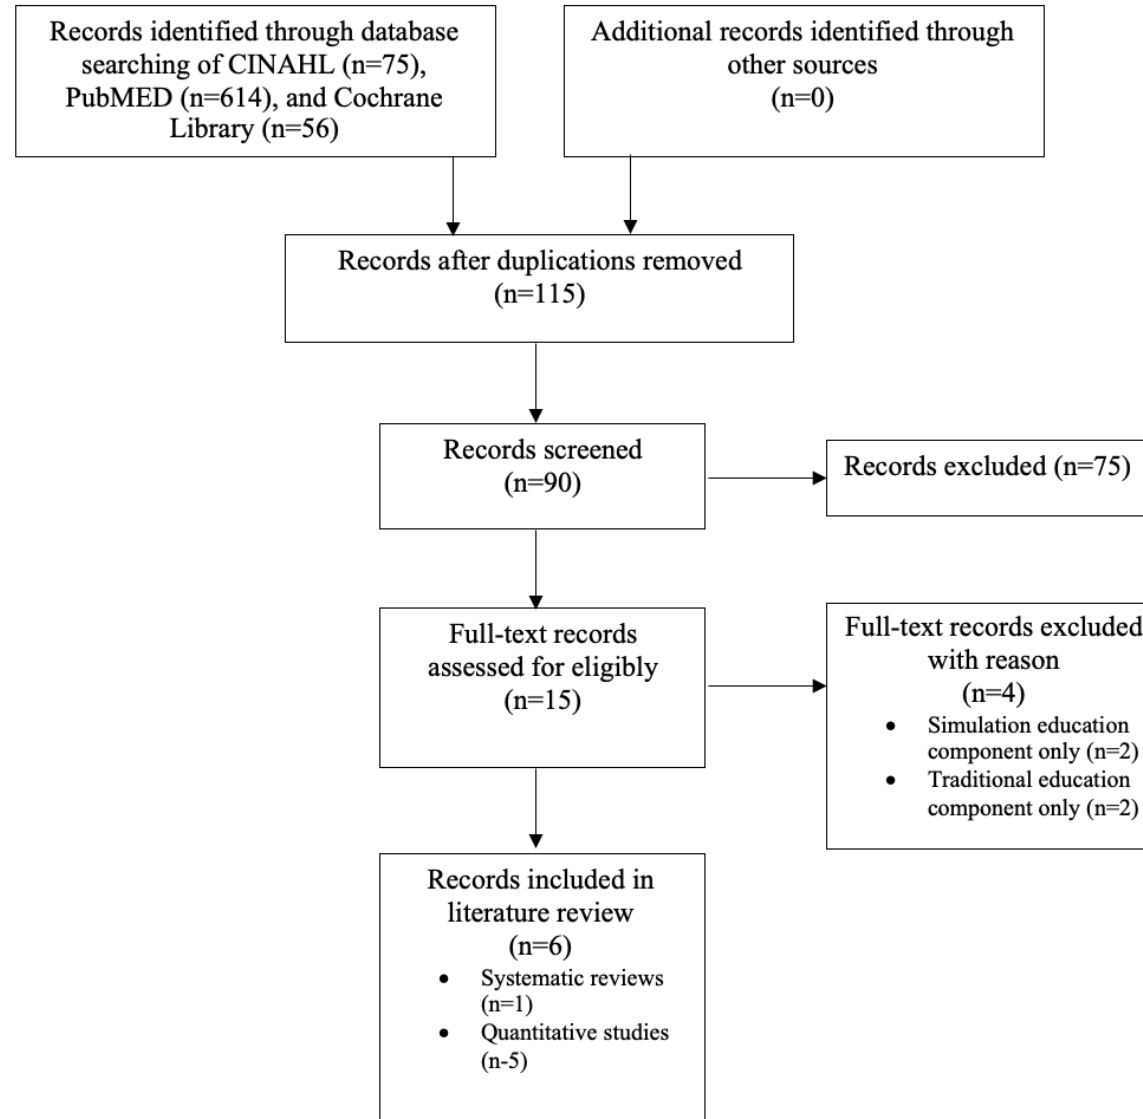

Aims of Recommended Practice Change

- To improve staff nurses knowledge over preoperative diabetes management
- To improve patient outcomes through a reduction of adverse events related to withholding short acting insulin in the preoperative period

PICOT Question

- “In nurses employed on an orthopedic trauma and surgical unit, how does the implementation of unit wide nursing diabetic pre-operative care education affect perioperative diabetes management (as defined as short acting insulin held without an order to do so) over four weeks?”

Literature search

Critical Appraisal

- All of the studies were appraised using the Johns Hopkins Nursing Evidence-based Practice Model and Guidelines tool
- After appraisal each study was given a level and quality rating
 - All studies are a level I or II
 - All given quality ratings of A or B indicating good and high quality evidence
- Appraisal of non research evidence like clinical practice guidelines or clinical expertise was graded using the Appraisal of Guidelines for Research and Evaluation (AGREE) II instrument

Synthesis

- E-learning instruction is effective in improving knowledge and provides a convenient way for individuals to receive instruction

Clinical Expertise

- The American Diabetes Association (ADA) recommends a target blood glucose of 80-180 mg/dL (4.4-10.0 mmol/L) in the perioperative period.
- In patients that receive insulin, half of NPH or 75-80% doses of long-acting analog or pump basal insulin should be given.
- Blood glucose should be monitored at least every 2-4 hours while the patient is NPO (nothing by mouth) and dose with short or rapid acting insulin as needed.
- Short acting insulin should not be held routinely

Patient Preferences

- Patients diagnosed with DM prefer treatment that generates benefits with controllable parameters (Gomez-Peralta et al., 2021)
- Some patients are hesitant to continue taking insulin when they are NPO. Properly informing the patient that the ADA does not recommend holding short acting insulin and that their blood sugar will be monitored might help ease their mind (ADA, 2021)
- If the patient is not used to receiving insulin additional education as why the ADA does not recommend withholding short acting insulin might be needed (ADA, 2021).
 - Metformin
 - Non-diabetic receiving insulin

Guiding Theoretical Framework

- Iowa Model
 - This cyclical model begins by identifying problem focused triggers through risk management data, process improvement data, internal or external benchmarking data, financial data, or a clinical problem.
 - After these triggers are identified, the topic is assessed to see if it is a priority for the organization
 - Next, relevant research is collected for critique and critical appraisal for use in practice. If there is a sufficient research base, an EBP project can be conducted.
 - After the outcomes are evaluated, the change to practice is assessed to see if it is appropriate for adoption. If it is not appropriate, the topic is continued to be evaluated and the process will restart.

Recommendations for Practice change

- There is good and consistent evidence to support implementation of an e-learning module to increase preoperative diabetes education in staff nurses

Implementation Process

- Pre posttest
 - 10-questions
 - Targeted at perioperative diabetes management, insulin education, and enhancing patient outcomes
- Educational Module
 - Voiced over PowerPoint embedded into Qualtrics
- Posttest will be made available immediately after completing educational component
- Chart reviews during the 4-week project period
 - Included all diabetic/trauma patients receiving insulin who went to surgery

Findings

- 15 nurses completed the pre-posttest and viewed the educational module. Before analysis, there were 19 responses but four were excluded due to insufficient data
- There was a statistically significant difference in the nurses' examination score pretest [14.00 (1.732)] and posttest [16.00 (1.639)] (paired T-test: $p < 0.004$)
- 66 charts were reviewed that met the criteria (diabetic, receiving insulin, and going to the OR)
 - 48.5% of cases insulin was not required
 - 27.35% of cases insulin was given
 - 16.7% of cases the blood sugar was not checked
 - 7.5% of cases insulin was withheld

Findings

Question	Pretest, n (%)	Posttest score, n (%)
Recommended target blood glucose in perioperative patients is:	5 (33.3)	13 (86.7)
How often should blood glucose be monitored in NPO patients?	5 (33.3)	11 (73.3)
Short acting insulin should be routinely held prior to surgery in NPO patients?	3 (20.0)	11 (73.3)
Complications of poorly controlled diabetes includes:	11 (73.3)	14 (93.3)
Treatment for hypoglycemia should be initiated at:	11 (73.3)	13 (86.7)
The BEST nursing intervention to prevent hyperglycemia in a hospitalized patient is:	5 (33.3)	10 (66.7)
The most appropriate treatment for hypoglycemia in an asymptomatic NPO patient is:	9 (60.0)	7 (46.7)
Reasons for postoperative hyperglycemia include:	8 (53.3)	9 (60.0)
Physicians should be notified when:	6 (40.0)	13 (86.7)
Your patient has been kept NPO for an upcoming surgery. The patient's sugar is 220 at 0900. What is the most appropriate treatment?	7 (46.7)	12 (80.0)

Implications

- The results of this project demonstrated that an e-learning module was an effective tool in educating nurses about perioperative diabetes management as previously shown by evidence
- The educational module took about 15 minutes to the participants to complete and was relatively easy to operate. Based off needs assessments, implementation of e-learning modules with pre-posttests to measure success could be applied to any subject

Limitations

- Staff participation, high nurse turnover rate, and time constraints
 - Identified as a potential barrier and measures including continuous reinforcement and streamlining the pre-posttest e-learning module were implemented

Dissemination Plan

- Key stakeholder presentation
- Presentation to other medical surgical units, stepdown units, and the emergency center at project site

Conclusion

- Management of glycemic levels in the perioperative setting is essential to improve surgical outcomes.
- Evidence and guidelines support keeping target blood glucose at 80-180 mg/dL (4.4-10.0 mmol/L) in the perioperative period and not withholding insulin.
- In the chosen practice, implementation of an e-learning module increased perioperative diabetes management nursing knowledge. This led to a reduction in adverse events consequently improving patient outcomes.
