A Multi-modal Garden Dataset and Hybrid 3D Dense Reconstruction Framework Based on Panoramic Stereo Images for a Trimming Robot

Can Pu, Chuanyu Yang, Jinnian Pu, Radim Tylecek, Robert B. Fisher

Abstract

Recovering an outdoor environment’s surface mesh is vital for an agricultural robot during task planning and remote visualization. Image-based dense 3D reconstruction is sensitive to large movements between adjacent frames and the quality of the estimated depth maps. Our proposed solution for these problems is based on a newly-designed panoramic stereo camera along with a hybrid novel software framework that consists of three fusion modules: disparity fusion, pose fusion, and volumetric fusion. The panoramic stereo camera with a pentagon shape consists of 5 stereo vision camera pairs to stream synchronized panoramic stereo images for the following three fusion modules. In the disparity fusion module, rectified stereo images produce the initial disparity maps using multiple stereo vision algorithms. Then, these initial disparity maps, along with the intensity images, are input into a disparity fusion network to produce refined disparity maps. Next, the refined disparity maps are converted into full-view (360°) point clouds or single-view (72°) point clouds for the pose fusion module. The pose fusion module adopts a two-stage global-coarse-to-local-fine strategy. In the first stage, each pair of full-view point clouds is registered by a global point cloud matching algorithm to estimate the transformation for a global pose graph’s edge, which effectively implements loop closure. In the second stage, a local point cloud matching algorithm is used to match single-view point clouds in different nodes. Next, we locally refine the poses of all corresponding edges in the global pose graph using three proposed rules, thus constructing a refined pose graph. The refined pose graph is optimized to produce a global pose trajectory for volumetric fusion. In the volumetric fusion module, the global poses of all the nodes are used to integrate the single-view point clouds into the volume to produce the mesh of the whole garden. The proposed framework and its three fusion modules are tested on a real outdoor garden dataset to show the superiority of the performance. The whole pipeline takes about 4 minutes on a desktop computer to process the real garden dataset, which is available at: <https://github.com/Canpu999/Trimbot-Wageningen-SLAM-Dataset>.

1 Introduction

An economical but robust online 3D reconstruction approach for outdoor environments is vital for the remote visualization of the scene and robot task planning. Recovering the dense 3D structure (e.g. mesh) of an outdoor garden with only image input quickly and robustly is challenging because of lighting changes, texture similarity, shadow interference, limited computation and network resources, etc. Figure 1 (a) shows a real outdoor garden for our gardening robot Trimbot’s¹ navigation and plant pruning. In real applications, there are two big challenges² for image-based dense 3D reconstruction with high fidelity: 1) Movement (rotation or translation) between adjacent

¹Trimbot2020 project URL: <http://trimbot2020.webhosting.rug.nl/>

²For more description about the challenges in the real world, please read the following file: <https://github.com/Canpu999/Trimbot-Wageningen-SLAM-Dataset/blob/main/Real-challenges.pdf>

42 frames is big because of e.g. a gardening robot’s fast speed (1 m/s translation or 90 deg/s rotation),
43 the temporal downsampling ratio of the frames³ (1/10), and the image sensors’ low frame rate (12
44 FPS); 2) Disparity maps⁴ from existing methods in real outdoor environments are not accurate,
45 dense and robust enough because of texture similarity, lighting changes, and shadows.

46 According to a recent survey (Chen et al., 2022), SLAM⁵ systems are classified by the input
47 data source or the sensors used. Figure 2 shows the SLAM classification results. Given that the
48 input data to our proposed framework is from a newly-designed panoramic stereo camera (see
49 Figure 1 (b), Figure D.1 or Figure D.3) and there is no existing similar work as far as we know,
50 we have defined a new branch in the pure visual SLAM class called ‘Panoramic Stereo SLAM’
51 with abbreviation ‘PS-SLAM’. **Panoramic stereo SLAM is a class of pure visual SLAM**
52 **methods with panoramic stereo images as input (e.g. our ring of stereo vision cameras**
53 **to achieve 360° perception).** Our proposed framework belongs to PS-SLAM which is in the
54 pure visual SLAM area.

55 Instead of following the existing main-stream pure visual SLAM technique [pose recovery by
56 feature extraction and mapping (e.g. Campos et al. (2021); Schonberger and Frahm (2016)); pose
57 recovery by minimizing the pixel-wise photo-metric error (e.g. Engel et al. (2017))], we start a new
58 approach (slightly similar to the RGB-D SLAM algorithm Kinectfusion (Izadi et al., 2011)) to do
59 pose recovery by using the point clouds rather than the features or pixel intensities (which are
60 sensitive to illumination, scene appearance, and shadows). To guarantee point cloud quality out-
61 doors, a new disparity fusion algorithm is first introduced into the SLAM pipeline, whose outputs
62 are then improved by some practical techniques. To deal with fast motion or rotation of the robot,
63 an innovative multi-stage pose trajectory estimation method with joint information (Algorithm 1)
64 is developed based on loop closure (LC), view switching, and global & local information transi-
65 tion. The integration of multi-level fusion modules, various supporting algorithms and different
66 innovative strategies make the proposed hybrid framework unique and able to cope with the real
67 challenges mentioned above, on which the traditional SLAM frameworks (e.g. Orbslam3 (Campos
68 et al., 2021), Open3D reconstruction system (Zhou et al., 2018), and the commercial software
69 ‘ContextCapture’) perform badly.

70 More specifically, to solve the two big challenges above in a real garden for the trimming robot,
71 the TrimBot2020 project team designed a new hardware configuration called the ‘panoramic stereo
72 camera’ along with a novel 3D reconstruction software framework containing three fusion modules
73 to compute accurate disparity maps, estimate relative pose, and geometrically integrate the maps.
74 Figure 1 (b) shows the panoramic stereo camera which is mounted on the TrimBot2020 robot,
75 and which is primarily used for navigation and visual servoing when the vehicle is near to plants
76 to be trimmed. The diagram in Figure 1 (b) shows the panoramic stereo camera with 5 stereo
77 vision cameras (10 image sensors ‘Cam0’ - ‘Cam9’) arranged in a pentagon shape. The panoramic
78 stereo camera streams the synchronized panoramic stereo images (see Figure 1 (c)) from the 10
79 image sensors (‘Cam0’ - ‘Cam9’) for the following three modules to deal with. First, in the
80 disparity fusion module, rectified stereo images are combined to compute the initial disparity
81 maps by multiple stereo vision algorithms. Then the initial disparity maps along with the image
82 information are input into a disparity fusion network to produce a refined disparity map. Next,
83 the refined disparity map is converted into a full-view (360°) point cloud or a single-view (72°)
84 point cloud for the pose fusion module (see Algorithm 1). In the first stage of pose fusion, each
85 two 360° local point clouds are registered by a global point cloud matching algorithm to get the
86 corresponding transformation for the global pose graph’s edge, which realizes loop closure (LC)
87 essentially. The global pose graph is then optimized to produce a coarse global pose trajectory of
88 the robot’s path through the garden. In the second stage, a refined pose graph is computed based

³Because of the mobile network speed, we pick one out of every ten frames to transfer to the server for online 3D reconstruction.

⁴In a stereo configuration, disparity and depth are interchangeable measures: $depth = focal.length \times baseline/disparity$. When input data is from a depth sensor like Lidar or time of flight sensor, the depth information can be converted into disparity information by using a constant baseline and focal length. Thus, in this paper we regard the two terms as the same and won’t distinguish them.

⁵The abbreviations in this manuscript are listed in Appendix A List of Abbreviations. And the frequently-used symbols in this manuscript are listed in Appendix B List of Symbols.

(a) The TrimBot2020 test garden

(b) A panoramic stereo camera

(c) 10 synchronized images from the panoramic stereo camera consisting of 5 stereo vision cameras (10 image sensors in total)

Figure 1: Figure (a) shows the TrimBot2020 outdoor test garden; Figure (b) shows the newly-designed ‘panoramic stereo camera’ hardware, which is mounted on the trimming robot. The panoramic stereo camera with a pentagon shape consists of 5 stereo vision cameras (10 image sensors, ‘Cam0’ - ‘Cam9’). Figure (c) shows ten synchronized raw images from the 5 stereo camera pairs (the left image sensors in the stereo configuration are color cameras and the right image sensors are gray scale). The images in this figure are from the Trimbot2020 project. For viewing small details in this figure, readers are recommended to view the electronic version.

89 on the coarse global pose graph. Local point cloud registration along with the coarse global pose
90 trajectory from the first stage jointly update all the available edges in the refined pose graph, which
91 is then optimized to estimate an accurate global sensor pose trajectory. Lastly, in the volumetric
92 fusion module, the global poses of all the nodes in the refined pose graph are used to integrate
93 the corresponding depth maps or point clouds into a volume to produce the surface mesh of the
94 whole garden, which could be used for task planning and the remote visualization. Figure 3 gives
95 an overview of the whole fusion pipeline.

96 In conclusion, there are three major contributions which could be regarded as the foundation
97 of the PS-SLAM approach. The **major contributions** are :

98 (1) First real garden dataset (Figure 6) for future PS-SLAM research, which contains the
99 ground truth of the fully-dense depth maps, the semantic maps, the global poses, the rectified
100 stereo images, sparse Lidar scans, and the semantic 3D model;

101 (2) First hybrid 3D dense reconstruction framework based on panoramic stereo images, which
102 could be regarded as the initial baseline framework (Figure 3) for future PS-SLAM research;

103 (3) First two-stage full-view-to-single-view global-coarse-to-local-fine pose trajectory estima-
104 tion method (Algorithm 1), which is robust to fast or large transformations between adjacent
105 frames.

106 Additionally, there are three notable minor contributions to solve the related problems or
107 improve the related performance in this paper:

108 1) Theoretical proof (Appendix C.1) that the Frobenius-norm-based transformation difference
109 loss function (Equation 4) is a special case of the maximum likelihood loss function when applied
110 to the pose graph optimization problem;

111 2) Two practical strategies (in Section 3.1.2) with the theoretical proof (Appendix C.2) to
112 improve the disparity fusion accuracy by setting the maximum distance of interest (denoted by
113 ‘Maximum Distance’) and up-and-down resolution transformation (denoted by ‘High Definition’);
114

115 3) Three rules (in Section 3.2.2) to optimize the edge set which constrains the pose graph’s
116 loss function, boosting the estimated pose’s accuracy.

117 The remainder of this paper is structured as follows. Section 2 presents previous research
118 about SLAM classification, influence factors, and the dataset. Section 3 presents the proposed
119 multi-level fusion framework including the disparity fusion module, the pose fusion module, and
120 the volumetric fusion module. Section 4 describes the real garden dataset and demonstrates the
121 performance of the fusion framework including the disparity fusion module, the pose fusion module
122 and the volumetric fusion module on the real garden dataset. Section 5 presents a discussion and
123 summary of the work.

124 2 Related Works

125 This section reviews the existing SLAM classification and positioning the proposed new SLAM
126 framework within it. Secondly, we analyse factors which influence the framework’s performance.
127 Lastly, the outdoor datasets used for visual SLAM are reviewed.
128

129 2.1 SLAM Classification

130 According to a recent survey (Chen et al., 2022), SLAM systems are classified by the input data
131 source or the sensors used. Figure 2 shows the classification of different SLAM systems. SLAM
132 systems have been divided into two main categories: Lidar SLAM (e.g. Lego-Loam (Shan and
133 Englot, 2018)) and visual SLAM. Within the visual SLAM category, there are two sub-categories:
134 semantic visual SLAM (e.g. Blitz-slam (Fan et al., 2022)) and traditional visual SLAM. RGB-D
135 SLAM (e.g. Kinectfusion (Izadi et al., 2011), Elasticfusion (Whelan et al., 2016)), pure visual
136 SLAM and visual-inertial SLAM (e.g. Vins-mono (Qin et al., 2018)) constitute the traditional
137 visual SLAM family. Monocular SLAM with a single image sensor (e.g. Colmap (Schonberger and

Figure 2: The figure shows SLAM classification (Chen et al., 2022) based on the input data source or the used sensors. As far as we know, our proposed framework is the first work in the branch ‘Panoramic Stereo SLAM’.

138 Frahm, 2016)), stereo SLAM with a stereo vision camera (e.g. Stereo LSD-SLAM (Engel et al.,
 139 2015)), and our proposed framework with a panoramic stereo camera belong to the pure visual
 140 SLAM class.

141 While the newly-designed panoramic stereo camera (a ring of 5 synchronized stereo vision
 142 cameras mounted in a pentagon shape) extends the category of stereo SLAM, there are significant
 143 differences which stem from the specifics of the panoramic arrangement of multiple cameras. Thus,
 144 we define a new traditional pure visual SLAM branch ‘Panoramic Stereo SLAM’ (PS-SLAM),
 145 which uses a panoramic stereo camera - a ring of synchronized stereo vision cameras - to input
 146 a 360° view. Although there is a stereo panoramic vision system (Guo et al., 2022) that uses a
 147 stereo vision camera containing two panoramic vision sensors with a wide field of view (FOV) ,
 148 that approach still largely follows the classic stereo SLAM concept with some improvements to
 149 the stereo SLAM framework. As far as we know, our proposed framework (Figure 3) is the first
 150 true PS-SLAM research.

151 Compared with mainstream panoramic SLAM algorithms (Chen et al., 2021, 2019; Ji et al.,
 152 2020; Wang et al., 2022; Zhang and Huang, 2021; Zhao et al., 2022; Zhu et al., 2019), one difference
 153 between ours and theirs is that they cannot provide dense global depth information because there
 154 is only one monocular camera at each viewpoint inside their panoramic camera whereas in our
 155 case multiple stereo images from different perspectives create the panoramic image. The second
 156 difference is that they still follow the typical visual SLAM pipeline (e.g. SFM (Schonberger
 157 and Frahm, 2016), Orb-slam (Mur-Artal et al., 2015)): feature extraction and mapping, pose
 158 estimation by triangulation, loop closure detection, and global optimization, which makes them
 159 sensitive to lighting changes unlike our proposed method. Additionally, these algorithms only
 160 produce a sparse reconstruction of the scene based on matched feature points as compared to our
 161 dense reconstruction.

162 Meanwhile, some researchers (Ahmadi et al., 2023; Kang et al., 2021) projected the point
 163 clouds from a Lidar scanner to the image plane of a panoramic image from a panoramic camera
 164 to form a panoramic RGB-D image first. Then, the panoramic RGB-D images were input into
 165 OpenVSLAM (Sumikura et al., 2019), an open-source third-party library containing commonly
 166 used visual SLAM algorithms (e.g. RGB-D SLAM algorithm in Orb-slam framework (Campos
 167 et al., 2021; Mur-Artal and Tardós, 2017)). Compared with our solution, their Lidar sensor
 168 is expensive and does not produce a dense point cloud. In summary, the existing panoramic
 169 SLAM algorithms follow the traditional visual SLAM pipeline and ours has a different theoretical
 170 framework. Based on our newly-designed panoramic stereo camera, we provide an economic dense
 171 reconstruction solution which is robust to light changes and scene appearance.

172 Different from previous frameworks (Chen et al., 2022; Kazerouni et al., 2022; Xu et al.,
 173 2022; Zhang et al., 2021), the proposed framework is designed specifically for a panoramic stereo
 174 camera set and concentrates on depth quality improvement under some challenging conditions

175 (illumination changes, similar texture, etc.) and accurate global pose trajectory estimation while
176 coping with the robot’s fast motion or rotation. Thus, some new features are proposed to enhance
177 the SLAM framework, such as the disparity fusion module, the field of view switching (360° versus
178 72°), the novel multi-stage global pose trajectory estimation algorithm 1.

179 To summarize, the proposed framework is the first to do 3D dense reconstruction in the PS-
180 SLAM research subfield, and so is a baseline to facilitate the progress of PS-SLAM. Compared
181 with the popular SLAM frameworks (e.g. OrbSLAM3 (Campos et al., 2021), Open3D reconstruc-
182 tion system (Zhou et al., 2018), and the commercial software ‘ContextCapture’), the integration
183 of multi-level fusion modules, various supporting algorithms, and different innovative strategies
184 makes the proposed framework both unique and capable of performing well even given the two
185 real challenges facing any real outdoor robot: depth data quality and fast robot motion.

186

187 2.2 Performance Factors

188

189 2.2.1 Depth Quality

190 Compared with Lidar scanners (expensive and their point cloud is sparse) and ToF sensors
191 (sensitive to infrared light outdoors), etc., image-based depth estimation methods (e.g. stereo
192 vision algorithms) are economical and produce dense depth map indoors and outdoors robustly.
193 In our proposed framework, the stereo vision algorithms estimate the raw disparity maps and the
194 disparity fusion algorithm is used to refine the raw disparity maps from the stereo vision algorithms
195 to get a refined disparity map.

196 The most well-known classical stereo vision algorithm is the semi-global matching method (Hirschmuller,
197 2005), which conducts pixel-wise matching using mutual information with a global smoothness ap-
198 proximation. With the rise of deep neural networks, FlowNet (Dosovitskiy et al., 2015) is the first
199 to use an end-to-end convolutional neural network to estimate the disparity map between two im-
200 ages. A recent survey (Poggi et al., 2021) gives an overview of the latest progress of stereo vision
201 algorithms. Although stereo vision algorithms have made huge progress recently, a single stereo
202 vision algorithm still has different advantages and disadvantages, and fails to estimate disparity
203 maps accurately at all pixels in all scenes. Disparity fusion is a good method for refining the
204 initial raw disparity maps (from the same viewpoint) from several individual disparity estimation
205 algorithms to estimate a more accurate and robust disparity map based on their complementary
206 properties. The majority of classical disparity fusion methods (Marin et al., 2016; Poggi et al.,
207 2019; Zakeri et al., 2020) share the same pipeline: estimate the disparity map and a confidence
208 map from different sensors, and then use a specific fusion method to fuse the disparity maps
209 using the confidence maps as weights. Because it is hard to estimate the confidence map and
210 disparity distribution accurately, these classical methods have a lower precision compared with
211 deep-learning-based methods (Pu and Fisher, 2019; Pu et al., 2019; Sandström et al., 2022). To
212 highlight, Sdf-man (Pu et al., 2019) is the first to input multiple initial disparity maps with aux-
213 iliary information (e.g. RGB, gradients) into the refiner network to produce a refined disparity
214 map. It used a discriminator to classify the refined disparity map and the ground truth disparity
215 map as real or fake to improve the refined disparity map’s accuracy.

216 In existing SLAM system surveys (Chen et al., 2022; Kazerouni et al., 2022; Xu et al., 2022;
217 Zhang et al., 2021), the emerging concept of ‘disparity fusion’ was not mentioned and we saw
218 no mention of using a disparity fusion algorithm in the SLAM system to improve the 3D dense
219 reconstruction accuracy. We are the first to encode the disparity fusion part in the front end of our
220 proposed SLAM system based on Sdf-man (Pu et al., 2019). Although Sdf-man achieved state-
221 of-art real-time performance in an outdoor garden, its error rate still lies at ~ 10 cm level. In this
222 paper, we propose two new practical strategies (Section 3.1.2) along with a proof (Appendix C.2)
223 to improve the disparity fusion accuracy, as demonstrated by experiments in Section 4.2.

2.2.2 Pose Accuracy

Compared with image feature matching (e.g. SIFT (Ng and Henikoff, 2003), ORB (Rublee et al., 2011)) to estimate the 6D pose between different views, estimation based on point clouds can produce a more reliable and accurate result. Currently, there are three classes of point cloud matching algorithms to estimate the relative 6D pose. A recent survey (Huang et al., 2021) has an overview. The first class of algorithms (e.g. Gu et al. (2022); Junior et al. (2022); Segal et al. (2009)) is derived from ICP (Besl and McKay, 1992), which calculates the relative 6D pose between two point clouds by finding the closest corresponding points in two point clouds and minimizing their Euclidean distance. Exactly corresponding points seldom exist in the real cases, so the ICP-based methods have low accuracy (and initialization issues). The second class is feature-based algorithms (Ao et al., 2021; Wu et al., 2021; Zeng et al., 2017; Zhou et al., 2016). They extract local descriptors from two point clouds first and then do feature matching to estimate the relative 6D pose between the two point clouds. This class is sensitive to noisy and sparse point clouds which may lead to inaccurate local descriptors and could even make the algorithm collapse when the density is too sparse or the noise is too strong. The third class (Huang et al., 2022; Liu et al., 2021; Myronenko and Song, 2010; Pu et al., 2018) treats point cloud registration as a probability matching problem. They use probabilistic models to describe the geometric distribution of the two point clouds first and then maximize the likelihood of two probabilistic models overlap to calculate the relative 6D pose of the two point clouds. This class of algorithms aligns point clouds more accurately and robustly compared with the previous two classes, but is slow because of their computational complexity.

Pairwise point cloud registration algorithms only compute the relative 6D pose between two local segments within a whole pose trajectory, and do not guarantee estimation of the global optimum of the whole global pose trajectory. That is, registering point clouds sequentially produces a sensor pose trajectory which inherently drifts over time because of the accumulated error. Building an optimized pose graph (Barath et al., 2021; Grisetti et al., 2010; Mendes et al., 2016) could reduce the accumulated error and give an optimized global solution. Ordinarily, loop closure helps resolve this issue, but here the 360 degree point clouds allow many overlapping point sets. Based on the full-view and single-view point clouds, we are the first to develop a two-stage full-view-to-single-view global-coarse-to-local-fine pose trajectory estimation method (Algorithm 1), which can cope well with the fast motion of the real robot outdoors.

2.2.3 Volumetric Fusion

With a range of depth maps and their corresponding global poses, volumetric fusion methods (Curless and Levoy, 1996; Zhou and Koltun, 2013) integrate the surface geometry information into a volume that represents the 3D space in the world coordinate system. Using volumetric integration to build the 3D model of the garden and the marching cube technique (Grosso and Zint, 2022; Lewiner et al., 2003) to extract the surface mesh and its corresponding point cloud is a good option to remove outliers and noise, which could result in good quality when reconstructing the 3D garden model. We use an existing volumetric fusion technique (Section 3.3) for completeness and visualization purposes and do not claim a contribution for this part.

2.3 Dataset

There are multiple outdoor datasets for visual SLAM research, such as Kitti (Geiger et al., 2013; Menze and Geiger, 2015) and Cityscapes (Cordts et al., 2016) for autonomous driving in the city. Besides our dataset, some other datasets (e.g. Alam et al. (2022); Chebroly et al. (2017); Hu et al. (2022); Polvara et al. (2022)) for agricultural robots have recently been announced. For example, LettuceMOT (Hu et al., 2022) and TobSet (Alam et al., 2022) have only semantic information for lettuce, tobacco crop, weed detection and tracking. The Sugar Beets Dataset (Chebroly et al., 2017) contains the data from an RGB-D sensor (Kinect v2), a 4-channel multi-spectral camera

Figure 3: The proposed hybrid multi-level fusion framework based on panoramic stereo images for 3D dense reconstruction

(JAI AD-130GE), two on-board Lidar scanners (Velodyne VLP-16 Puck) and two GPS sensors (Leica RTK GPS and Ublox GPS) as well as wheel encoders to facilitate the research relevant to plant classification, localization and mapping in a sugar beet field. The BLT Dataset⁶ (Polvara et al., 2022) contains the data from two RGB-D sensors (ZED), an IMU (RSX-UM7), a 2D Lidar scanner (SICK MRS1000) and a 3D Lidar scanner (Ouster OS1-16) for long-term mapping and localization in a vineyard.

Compared with all the previous datasets, the obvious difference in our dataset is the inclusion of fully dense ground truth depth maps, a fully dense ground truth semantic 3D model and the synchronized joint panoramic stereo information (including RGB & intensity, fully-dense depth, semantic labels, sparse laser scan and global pose) for the first time. Our released dataset could facilitate multiple research topics in SLAM, including sensor calibration, depth estimation, semantic segmentation, pose estimation, and all types of SLAM frameworks (Lidar SLAM, semantic visual SLAM, and traditional visual SLAM). To the best of our knowledge, this is the first public dataset (Section 4.1) in the panoramic stereo SLAM domain.

3 Methodology

Figure 3 shows the proposed hybrid 3D dense reconstruction framework based on images from a panoramic stereo camera rig. Five calibrated binocular cameras inside the panoramic stereo camera (each with a FOV of 72°) stream five pairs of rectified stereo images from the related left and right cameras synchronously into the disparity fusion module. The stereo image pairs are fed into two separate stereo vision algorithms to compute disparity maps in the same view. The disparity maps are used by the disparity fusion algorithm to produce the refined disparity map, which can be converted into the corresponding full-view (FOV = 360°) or single-view (FOV = 72°) point cloud. The point clouds' outliers are removed by post-processing.

In the pose fusion module, the full-view point clouds from different frame times are first registered with each other by a global point cloud matching algorithm for a coarse global pose

⁶BLT dataset: <https://lcas.lincoln.ac.uk/wp/research/data-sets-software/blt/>

298 estimate, which becomes the corresponding edge’s transformation in the global pose graph. Then,
299 the global pose graph is optimized to produce a coarse global sensor pose trajectory. In the
300 second pose fusion stage, the refined pose graph is initialized by the global pose graph. Each
301 pose graph edge’s transformation is an input into q local point cloud registration algorithm to
302 obtain a more accurate global pose, which will be used to update each edge’s transformation in
303 the refined pose graph. Finally, the refined pose graph is optimized to output a more accurate
304 global pose trajectory, which transforms each single-view point cloud (or depth map) into the
305 global coordinate system in the volumetric fusion module to create a mesh of the whole garden.

306 In the following, Section 3.1 introduces the disparity fusion module including the stereo vision
307 algorithms, the disparity fusion algorithm, and the post-processing step. Section 3.2 introduces
308 the pose fusion module, including the global pose graph and refined pose graph. Section 3.3
309 introduces the volumetric fusion module.

310 **3.1 Disparity Fusion Module**

311 **3.1.1 Disparity Estimation**

312 In this stage, stereo vision algorithms with complementary properties estimate the initial dispar-
313 ity maps from the stereo images. Based on common sense and experience, classical stereo vision
314 algorithms (e.g. Hirschmuller (2005)) perform better at the edges and small objects while the
315 methods based on deep learning (e.g. Mayer et al. (2016)) perform better at other aspects (e.g.
316 flat planes, close shots). We have chosen DispNet (Mayer et al., 2016) and Semi-global match-
317 ing (Hirschmuller, 2005) as suitable representatives to compute the initial disparity maps in our
318 project, but other stereo vision algorithms can be used as well. In the following, the initial dispar-
319 ity maps and auxiliary information (intensity and gradient information) are fed into the disparity
320 fusion network to get a refined disparity map.

321 **3.1.2 Disparity Fusion**

322 In order to obtain a more accurate disparity map robustly, fusing disparity maps from multiple
323 sources is a good solution considering cost and performance, under the assumption that the initial
324 disparity inputs are from the same viewpoint at the same time. Fusing multiple input disparity
325 maps to get a refined disparity map output is called disparity fusion, and we base it on Sdf-man (Pu
326 et al., 2019) with some small differences, motivated by a machine learning ensemble approach. As
327 demonstrated in (Pu et al., 2019), the disparity fusion algorithm Sdf-man can refine the initial
328 disparity inputs effectively and produce a more accurate disparity map robustly compared with
329 its initial disparity inputs, even where the disparity inputs are inaccurate on their own.

330 Similar to the GAN approach, Sdf-man (Pu et al., 2019) consists of two adversarial networks
331 (refiner and discriminator) to perform a mini-max two-player game strategy to make the refiner
332 network output a more accurate disparity map. However, unlike standard GANs (Goodfellow
333 et al., 2014), the input is the initial disparity maps plus intensity and gradient information rather
334 than random noise, and its output is deterministic during inference.

335 For the sake of readability, we summarize the Sdf-man (Pu et al., 2019) method; more back-
336 ground and details can be found in the original paper.

337 The refiner neural network R (which is similar to the generator G in (Goodfellow et al., 2014))
338 is trained to output a refined disparity map that is not classified as “fake” by the discriminator
339 network D . The discriminator network D is trained simultaneously to conclude that the input
340 disparity map from the ground truth is real and the input disparity map from the refiner network
341 R is fake. With a minimax two-player game strategy, it leads the output distribution from the
342 refiner to approximate the real disparity data distribution. The full system pipeline is shown in
343 Figure 4.

344 To train the refiner network and discriminator network, the following loss function is used in
345 a fully supervised way:

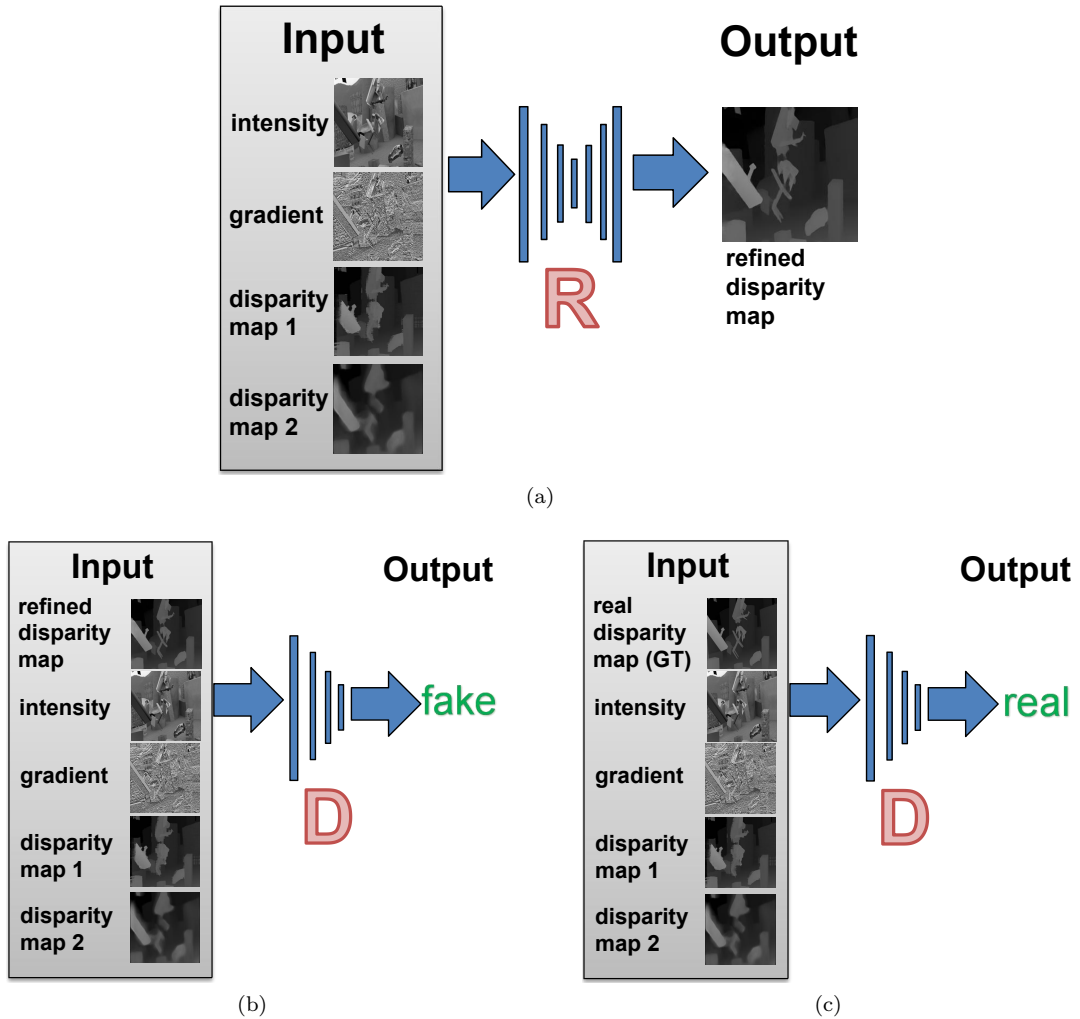

Figure 4: Overview of the disparity fusion algorithm Sdf-man. The refiner network R is trained to map initial disparity maps (*disparity map 1* and *disparity map 2*) from two stereo vision algorithms to the ground truth disparity map based on the corresponding image information (intensity, gradient). The refiner network R attempts to produce a refined disparity map, which is closer to the ground truth. The discriminator network D attempts to discriminate whether its input is the real (real disparity map (GT) from the ground truth) or a fake (refined disparity map from R). The refiner network and discriminator network are updated alternately. (a) Refiner: a network to produce a refined disparity map; (b) Negative examples (fake): a discriminator network with refined disparity maps as input; (c) Positive examples (real): a discriminator network with real disparity maps (GT) as input. For small details in this figure, readers are recommended to view the electronic version.

$$\begin{aligned} \mathcal{L}(R, D) &= \theta_1 \mathcal{L}_{L_1}^{Ld}(R) \\ &+ \theta_2 \mathcal{L}_{sm}^{Ld}(R) + \theta_3 \sum_{i=1}^M \mathcal{L}_{GAN}^{Ld}(R, D_i) \end{aligned} \quad (1)$$

where $\theta_1, \theta_2, \theta_3$ are the weight values of the different loss terms. M is the number of scale levels used. R represents the refiner network and D represents the discriminator network. $\mathcal{L}_{L_1}^{Ld}(R)$ is a gradient-based L_1 distance training loss, which applies a bigger weight to the disparity information at the scene edges to avoid blurring at scene edges. $\mathcal{L}_{sm}^{Ld}(R)$ is a gradient-based smoothness term, which is used to propagate more accurate disparity values from scene edges to other areas, assuming that the disparity values of neighboring pixels should be close if their image intensities are similar. $\mathcal{L}_{GAN}^{Ld}(R, D_i)$ is a disparity relationship training loss, which assists the refiner in outputting a disparity map whose distribution is closer to the real distribution. Ld is the labelled data, which is fed in the supervised learning process.

In this paper, we updated the original method (Pu et al., 2019) to improve its performance in the real robot application with the following two practical strategies:

(1) **Maximum Distance** strategy: The disparity fusion network does not require to output all the disparity information in the source stereo images because the mobile robot needs more accurate depths of the nearby surroundings (rather than the remote scene). Thus, a maximum distance threshold max_dist constrains the output of the disparity fusion network rather than the maximum disparity threshold max_disp . More specifically, in the initial stages, at the end of the refiner network, it uses the function \tanh to output an intermediate map w and uses the function $initial_disp = \frac{max_disp \cdot (w+1)}{2}$ to convert the intermediate map w into the disparity map $initial_disp$. The intermediate map’s size (width, height, channel) is identical to the disparity map’s. In this paper, the difference is that we use a modified function $new_disp = \frac{2fb}{max_dist \cdot (w+1)}$ to map the \tanh output to the new disparity map new_disp where f and b are the focal length and baseline of the stereo vision camera. This strategy effectively reduces the disparity fusion error (see the experiments in Section 4.2). The theoretical proof can be found in Appendix C.2.

(2) **High Definition** strategy: The initial disparity fusion network (Pu et al., 2019) outputs a disparity map with the same resolution as that of the stereo images, which will result in small details being lost in the fused disparity map. To produce a more detailed result in the fused disparity map, the new disparity fusion network is required to output an HD (High Definition) disparity map first. The ratio between the HD width resolution and the initial width resolution is ϕ_w and the ratio between the HD height resolution and the initial height resolution is ϕ_h . Then the HD disparity map is downsampled to the initial resolution (same as the input stereo images). The refiner and the discriminator from Sdf-man are able to adjust their networks adaptively to any resolution of images, as shown in Sdfman (Pu et al., 2019) (Figures 2,3). What is done differently here is: 1) upscaling the data input first and then inputting the upscaled data into the networks to train autonomously; 2) downscaling the disparity output from the refiner network to the resolution of the initial stereo images as the final result. The reason why the up-and-down resolution transformation strategy works is that Sdf-man will include more neurons in the refiner and discriminator network structure to capture more small details autonomously when the input resolution becomes higher. Experiments in Section 4.2 demonstrate this is an effective strategy.

After disparity fusion, a refined disparity map is produced registered to the left view in the stereo configuration. Given that there are still some outliers in the refined disparity map, the refined disparity map is converted into a local point cloud with the outliers removed in the next stage.

3.1.3 Post-processing

The disparity post-processing part consists of three steps: 1) converting the disparity map into a depth map; 2) converting the depth map into a local point cloud using the camera calibration parameters; 3) removing the point cloud outliers.

In the first step, the refined disparity map is converted into the depth map using Equation 2.

$$depth = \frac{focal_length \times baseline}{disparity} \quad (2)$$

393 In the second step, the depth map is back-projected into a 3D point cloud using the camera
 394 intrinsic parameters (Szeliski, 2010). In Equation 3, (u, v) is the coordinate of the 2D point on
 395 the image plane and (X, Y, Z) is the corresponding 3D point in the camera space. f_x, f_y are the
 396 focal lengths on the x, y axes and c_x, c_y are the coordinates of the principle point on the x, y axes.
 397 D is the depth value.

$$D \begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = \begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} \quad (3)$$

398 In the third step, any points that 1) have less than N_p neighboring points in a given sphere
 399 with the radius *radius* or 2) are farther away from their N_n neighboring points than a threshold
 400 distance ratio *dist_ratio* (which is equal to the mean distance to their N_n neighboring points
 401 divided by the distance standard deviation to the N_n neighboring points) are treated as outliers
 402 and are removed.

403 After post-processing stage, the local single-view (72°) and full-view (360°) point clouds in the
 404 current frame are produced and used in the following pose fusion module.

405 3.2 Pose Fusion Module

406 3.2.1 First Stage: Global Pose Graph

407 As a single-view point cloud (72°) has limited features for point cloud matching, we combine
 408 the local point clouds from five views (5 stereo vision cameras) at the same time to form a
 409 full-view (360°) point cloud for point cloud registration. This representation improves tracking
 410 robustness against fast or big transformations, by using the full-view (360°) point clouds for global
 411 registration. The full-view (360°) point cloud X_i^m , the single-view (72°) point cloud X_i^s and their
 412 corresponding global pose P_i in the world frame will constitute a pose graph node V_i . The global
 413 pose P_i is also the pose of the node V_i . Every pair of nodes V_i and V_j have an edge E_{ij} containing
 414 a transformation matrix T_{ij} that aligns their full-view point clouds X_i^m and X_j^m . The nodes V_i
 415 and the edges E_{ij} form a global pose graph $G(V, E)$. V is the set of nodes and E is the set of
 416 edges.

Every pair of full-view point clouds in different nodes are registered to get the corresponding
 edge’s transformation matrix by using the feature-based fast global registration algorithm (Zhou
 et al., 2016), which essentially implements loop closure (LC). The global pose graph $G(V, E)$ is
 then optimized to produce a coarse global pose trajectory $\{P_1, \dots, P_n\}$ by minimizing loss:

$$\mathcal{L}(G(V, E)) = \arg \min_{\{P_1, \dots, P_n\} \in SE(3)^n} \sum_{(i, j) \in E} \|T_{ij} - P_i P_j^{-1}\|_F^2 \quad (4)$$

417 $\|\bullet\|_F$ is the Frobenius norm, $SE(3)$ is the special Euclidean group in 3 dimensions and n is the
 418 number of the pose graph nodes. The loss function represented by Equation 4 derives from the
 419 maximum likelihood estimation formula in (Moreira et al., 2021a) when setting the uncertainty
 420 of the translations to be identical to the rotations. We use the optimization method in (Moreira
 421 et al., 2021a) to minimize the loss function based on the implementation available at: <https://github.com/gabmoreira/maks>.
 422

423 The derivation and proof of Equation 4 can be found in Appendix C.1. The same deduction
 424 and optimization methods can be applied to Equation 6 below.

3.2.2 Second Stage: Refined Pose Graph

The global pose graph has edges between every pair of nodes possibly, even if there is little or no overlap between their corresponding single-views. This can lead to local distortions. This stage optimizes the global pose graph by using the poses from overlapping views. The refined pose graph $\tilde{G}(\tilde{V}, \tilde{E})$ is initialized by the global pose graph $G(V, E)$.

Since the fast global registration algorithm (Zhou et al., 2016) is not accurate enough compared with local registration algorithms (e.g. GICP (Segal et al., 2009), DUGMA (Pu et al., 2018)), we input each edge’s transformation matrix T_{ij} (from E_{ij} in the global pose graph $G(V, E)$) into the local registration algorithm GICP (Segal et al., 2009) as a global initialization to align the corresponding single-view (72°) point clouds⁷ X_i^s and X_j^s . The local registration algorithm GICP (Segal et al., 2009) outputs a new estimated transformation matrix T_{ij}^l for the corresponding edge.

Then, every pair of point clouds X_i^s and X_j^s are transformed into the same coordinate system using the transformation matrix T_{ij}^l . We calculate the number of the corresponding point pairs within a distance threshold (similar to finding corresponding closest point pairs in ICP). The overlap percentage of one point cloud after registration is equal to the number of the corresponding pairs divided by the number of the points in the point cloud. The overlap percentage of the pair of point clouds after registration is equal to the overlap percentage of the point cloud with the fewest points. Based on the registration results above and the coarse global pose trajectory from the first stage, the edges \tilde{E}_{ij} in the refined pose graph are updated using the following three rules:

(1) **Prune**: If the overlap percentage of the two point clouds after registration is lower than the threshold OL_{min} , prune the edge (remove the edge between the two nodes).

(2) **Update**: If the overlap percentage of the two point clouds after registration is higher than threshold OL_{max} and if the transformation $P_i P_j^{-1}$ (whose 6D pose is denoted as the 6D vector \vec{v}_P) between the two nodes (V_i, V_j) is similar to the newly calculated transformation T_{ij}^l (whose 6D pose is denoted as the 6D vector \vec{v}_T), update the edge.

(3) **Keep**: As for the ‘else’ case, keep but do not update the edge transformation.

Equation 5 gives the precise logic for the three rules above:

$$\tilde{T}_{ij} = \begin{cases} Null & \beta < OL_{min} & [rule1] \\ T_{ij}^l & \beta > OL_{max} \ \& \ |\vec{v}_P - \vec{v}_T| < \vec{v}_{th} & [rule2] \\ T_{ij} & else & [rule3] \end{cases} \quad (5)$$

In Equation 5, \tilde{T}_{ij} is the transformation matrix of the edge \tilde{E}_{ij} in the refined pose graph. β is the overlap percentage of the two point clouds after registration. \vec{v}_{th} is 6D pose threshold in vector format and $|\bullet|$ means getting the absolute value of each element to form a new vector. *Null* denotes “deleting this edge”. The two rules (Prune and Update) act on the edge set to constrain the loss function - Equation 6. An accurate constraint could give a more accurate global pose estimation, which is demonstrated by the ablation study in Section 4.3.1. After edge refinement, the refined pose graph $\tilde{G}(\tilde{V}, \tilde{E})$ is optimized using Equation 6 to produce a more accurate global pose trajectory $\{\tilde{P}_1, \dots, \tilde{P}_n\}$. The refined accurate global pose \tilde{P}_i of each node \tilde{V}_i and their corresponding single-view point cloud (or depth map) will be used in the volumetric fusion process to construct the surface mesh of the whole garden.

$$\mathcal{L}(\tilde{G}(\tilde{V}, \tilde{E})) = \arg \min_{\{\tilde{P}_1, \dots, \tilde{P}_n\} \in SE(3)^n} \sum_{(i,j) \in \tilde{E}} \|\tilde{T}_{ij} - \tilde{P}_i \tilde{P}_j^{-1}\|_F^2 \quad (6)$$

To conclude, we have proposed a two-stage full-view-to-single-view global-coarse-to-local-fine pose trajectory estimation method in this subsection. We name this proposed method for pose tra-

⁷When using the extrinsic transformation matrices to merge the point clouds from the five stereo vision cameras on the camera ring, the error from the extrinsic parameters will cause the full-view (360°) point cloud to be not as accurate as the single-view point cloud.

465 jectory estimation as ‘Multi-stage Pose Trajectory Estimation with Joint Information (MPTEJI)’.
 466 Algorithm 1 shows the pseudocode of the proposed algorithm MPTEJI, which gives a formal
 467 overview of the whole proposed method.

Algorithm 1 Multi-stage Pose Trajectory Estimation with Joint Information (MPTEJI)

Input: single-view (72°) and full-view (360°) point clouds

- 1: **procedure** WITH **full view** \triangleright 1st stage
- 2: **global** registration (feature-based) \rightarrow Loop Closure
- 3: **coarse** pose graph $G(V, E)$ \leftarrow Equation 4
- 4: **procedure** WITH **single view** \triangleright 2nd stage
- 5: pose graph inheritance $\leftarrow G(V, E)$
- 6: **local** registration (ICP-based) $\leftarrow T_{ij}$
- 7: edge refinement \leftarrow Equation 5
- 8: **refined** pose graph $\tilde{G}(\tilde{V}, \tilde{E})$ \leftarrow Equation 6

Output: an accurate global pose trajectory $\{\tilde{P}_1, \dots, \tilde{P}_n\}$

468

469 3.3 Volumetric Fusion Module

470 Fusing the range images (containing depth information) into a voxel-based volumetric scene repre-
 471 sentation is called volumetric fusion (Curless and Levoy, 1996). The refined accurate global pose
 472 trajectory $\{\tilde{P}_1, \dots, \tilde{P}_n\}$ gives where to integrate the associated RGB-D range images projected from
 473 the single-view point clouds into a voxel-grid-based TSDF (Truncated Signed Distance Field) vol-
 474 ume. The value of each voxel here represents the signed distance to the closest surface interface
 475 in the global space, which is in turn used to obtain the mesh of the reconstructed scene, using the
 476 marching cubes (Lorensen and Cline, 1987) algorithm.

477 More specifically, the single-view point clouds are projected back into the image planes to get
 478 the related depth maps first, creating again RGB-D images. We use the refined single-view point
 479 clouds to compute the depth maps rather than use the original depth maps from the disparity
 480 fusion (Section 3.1.2) directly because the single-view point clouds after the third step ‘outlier
 481 removal’ in the post-processing section (Section 3.1.3) are more accurate. Then the pairwise data
 482 (the RGB-D images and the corresponding global poses) are integrated into the global TSDF
 483 volume using the technique from Izadi et al. (2011); Zhou and Koltun (2013). Finally, we extract
 484 the surface mesh using marching cubes (Lewiner et al., 2003; Lorensen and Cline, 1987), based on
 485 a publicly available implementation⁸.

486 The volumetric fusion module produces a smooth and watertight 3D mesh of the reconstructed
 487 scene in the global coordinate system. The corresponding dense 3D point cloud of the reconstructed
 488 scene can be produced by extracting all the vertexes of the 3D mesh above. Simply put, the
 489 volumetric fusion performs like a weighted average filter in the 3D global space to reduce the noise
 490 and remove the outliers from multiple local segments by using the joint global information in the
 491 global coordinate system. That is the reason why we use the volumetric fusion to extract the mesh
 492 and the corresponding point cloud sequentially, rather than stitching the single-view point clouds
 493 together using their corresponding pose directly.

494 4 Experiments

495 All the experiments in this section are conducted on a machine with Intel Core i7-12700KF pro-
 496 cessor (12 cores, 20 threads, 25 MB cache, up to 5 GHz) and Nvidia GeForce GTX 1080 Ti.
 497 Section 4.1 gives the description of the real outdoor garden dataset we released and used in this

⁸ <https://github.com/qianyizh/ElasticReconstruction/tree/master/Integrate>

(a) Manually labeled 3D semantic model of the whole garden. Legend: grass (bright green), rail fence (blue), tree (dark green), hedge (brown), board fence (soil color), rose (red), boxwood (dark blue), potted plant (light blue) (Sattler et al., 2017)

(b) The robot platform used for collecting data

(c) Route for the training & testing dataset in the garden

Figure 5: Figure (a) shows the 3D model of the real garden; Figure (b) shows the robot platform for collecting data; Figure (c) shows the routes for training and testing dataset.

498 paper. Section 4.2 evaluates the performance improvement of the disparity fusion module
 499 quantitatively compared with the initial disparity inputs (Hirschmuller, 2005; Mayer et al., 2016), the
 500 ground truth of DSF (Poggi and Mattoccia, 2016) and the initial version of Sdf-man (Pu et al.,
 501 2019). Section 4.3 evaluates the global pose trajectory’s accuracy from the pose fusion module
 502 quantitatively compared with ORB-SLAM3 (Campos et al., 2021) and the “reconstruction system”
 503 in the latest version (0.15.1) of Open3D (Zhou et al., 2018). Section 4.4 gives a view of
 504 the reconstructed point cloud from the volumetric fusion module qualitatively and quantitatively
 505 compared with Open3D (Zhou et al., 2018).

506 4.1 Dataset Description

507 Figure 5 shows the 3D model of the outdoor garden, the robot platform and the route path for
 508 collecting the raw data. All the data in our dataset were recorded within the same half day to
 509 avoid interference from vegetation growth. The raw data is from the “test_around_garden” bagfile⁹
 510 in the Trimbot Garden 2017 dataset (Sattler et al., 2017; Tylecek and Fisher, 2020). The raw data
 511 was divided into two parts in the post-processing step: one for network training and one for testing.
 512 Figure 5 (c) shows the robot navigation path for the training and testing datasets. In Figure 5
 513 (c), the “route 1” trajectory (black loop curve) around the whole garden is for the SLAM testing
 514 and the “route 2” trajectory¹⁰ (red curve) is for the network training (e.g. depth estimation,
 515 semantic segmentation, etc.). We use a robot (See Figure 5 b) equipped with a ring of 5 stereo
 516 vision cameras (for live operations), Velodyne Puck (VLP-16) Lidar sensor (for sparse lidar scans

⁹<https://www.research.ed.ac.uk/en/datasets/trimbot2020-dataset-for-garden-navigation-and-bush-trimming>.

¹⁰All the scenes in “route 1” can be seen in “route 2”.

517 collection), STIM300 IMU sensor and Topcon PS Series Robotic Total Station position tracking
518 system (for ground-truth positions) to collect the raw images, sparse Lidar scans and the global
519 pose of the robot. The raw stereo vision images are calibrated and rectified using the Kalibr
520 package¹¹. The sparse Lidar scan from the Velodyne Puck (VLP-16) Lidar sensor is projected
521 to the camera plane of each left camera in the 5 stereo settings. Robot navigation poses were
522 recorded in the coordinate system of Topcon PS Series Robotic Total Station along with STIM300
523 IMU sensor first and then transformed into each image sensor’s global pose. Structure-from-
524 motion (Schonberger and Frahm, 2016) is used to refine each image sensor’s pose subsequently.
525 The 3D model of the whole garden is collected using Leica ScanStation P15 equipment and is
526 semantically labelled manually. Figure 5 (a) shows the semantic 3D model of the whole garden.
527 Using the semantic 3D model and each camera’s pose in the garden, the dense depth map and
528 semantic map are acquired by projecting the semantic 3D model into each camera’s plane. More
529 details about the data collection process can be found in Appendix D.

Table 1: Parameters of the *Trimbot Wageningen SLAM Dataset*

Parameter Name	Parameter Value
The number of panoramic stereo camera rigs	1;
The number of stereo vision cameras	5;
The number of image sensors	10;
The number of panoramic frames - 360°	In the training subset: 68; In the test subset: 67;
The number of stereo vision frames - 72°	In the training subset: 340; In the test subset: 335;
Image resolution	752 × 480 pixels (width × height);
The mean relative pose between adjacent frames ([translation on x axis, translation on y axis, translation on z axis, roll, pitch, yaw])	[0.29 m, 0.21 m, 0.00 m, 9.04 deg, 0.97 deg, 1.16 deg];
The standard deviation of the relative pose between adjacent frames ([translation on x axis, translation on y axis, translation on z axis, roll, pitch, yaw])	[0.18 m, 0.18 m, 0.00 m, 13.32 deg, 0.76 deg, 0.89 deg];
The maximum translation value on each axis between adjacent frames	X axis: 0.47 m; Y axis: 0.67 m; Z axis: 0.02 m;
The maximum rotation value on each axis between adjacent frames	X axis: 81.64 deg; Y axis: 3.21 deg; Z axis: 4.46 deg;
Data support	RGB — intensity, dense depth, sparse lidar, semantics, pose, point cloud, calibration.

530 Figure 6 shows frames from the new dataset “The Trimbot Wageningen SLAM Dataset”, which
531 is the augmentation of the Trimbot Garden 2017 dataset used in the semantic reconstruction
532 challenge of ICCV 2017 workshop “3D Reconstruction meets Semantics” (Sattler et al., 2017). In
533 the new Trimbot Wageningen SLAM dataset, we release all the rectified images from the 10 image
534 sensors (5 stereo vision cameras) ranging from cam_0 to cam_9 (See Figure 1b for the position of
535 the 10 image sensors). The newly released sparse Lidar scan (from the onboard Lidar sensor -
536 Velodyne Puck (VLP-16)), dense depth map and semantic map are in the coordinate system of
537 each left image sensor (Cam 0, Cam 2, Cam 4, Cam 6, Cam 8). Each image sensor’s global pose in
538 the garden, their intrinsic parameters and distortion models are available in the new dataset. We
539 subsample one out of every 10 frames from the initial raw data bagfile to form the new dataset.
540 Table 1 lists the key dataset properties and their corresponding values in the Trimbot Wageningen
541 SLAM Dataset. Figure 6 gives an overview of the new dataset. See the dataset website for more
542 details: <https://github.com/Canpu999/Trimbot-Wageningen-SLAM-Dataset>.

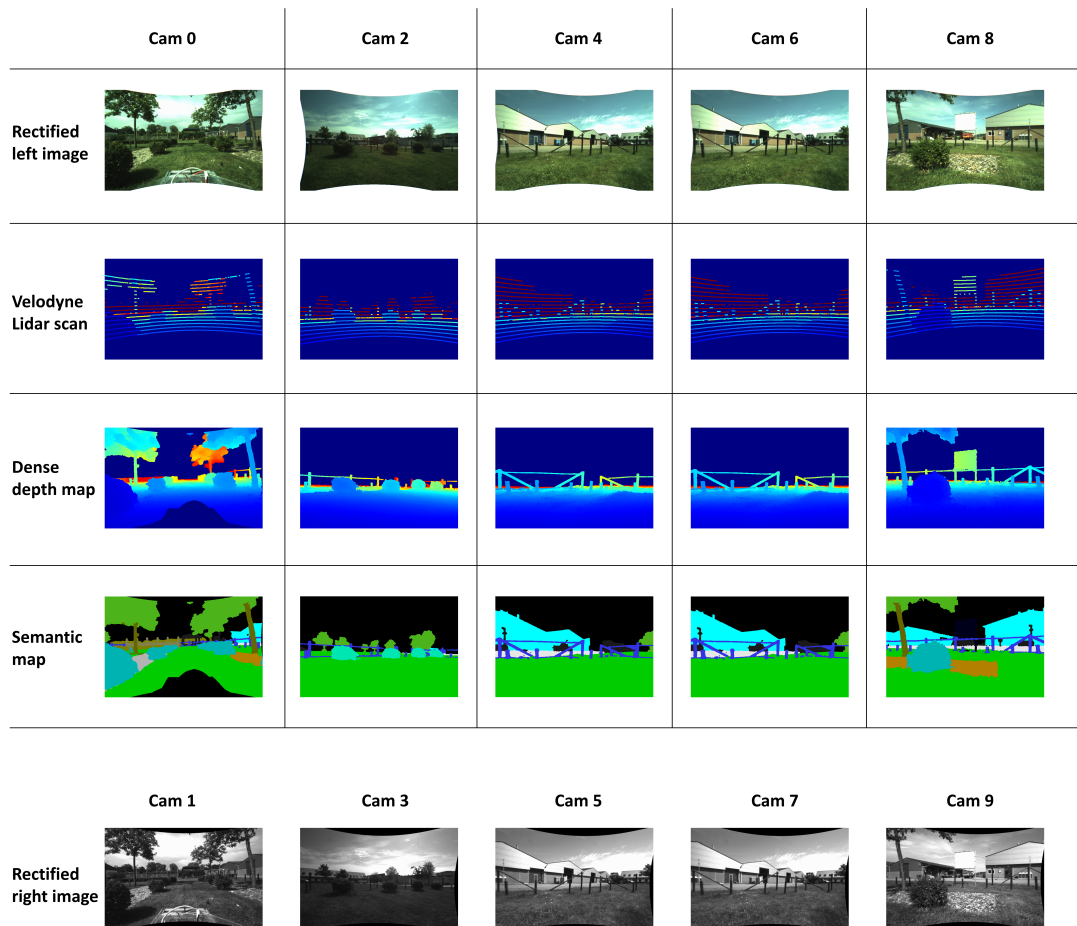

Figure 6: Trimbot Wageningen SLAM Dataset

4.2 Disparity Fusion Module

In the disparity fusion module, we use the SGM (Hirschmuller, 2005) (with Matlab implementation¹²) and Dispnet¹³ (Mayer et al., 2016) stereo vision algorithms to get the initial disparity maps. With the initial disparity maps and auxiliary information (left intensity image and left gradient information), we train our supervised disparity fusion network on our outdoor real garden dataset - "Trimbot Wageningen SLAM Dataset". All 340 samples ($\approx 50\%$) in the training set are used to train and all 335 samples ($\approx 50\%$) in the test set are used to test. The initial supervised method (Pu et al., 2019) is named "Sdfman-initial" and the updated method using the two practical strategies presented in Section 3.1 is named "Sdfman-star". The parameter max_dist is set to 5 meters¹⁴. The parameters ϕ_w and ϕ_h (resolution ratio between the HD and initial image width and height) are set to 2. Disparity fusion algorithms DSF (Poggi and Mattoccia, 2016) and "Sdfman-initial" (Pu et al., 2019) are compared to the new method "Sdfman-star". Additionally, an ablation study is conducted by adding two internal comparison algorithms ("Sdfman-max-dist" and "Sdfman-HR"). "Sdfman-max-dist" is an internal comparison algorithm that only applies the "Maximum Distance" strategy to "Sdfman-initial". "Sdfman-HR" is an internal comparison algorithm that only applies the "High Definition" strategy to "Sdfman-initial". Table 2 summarizes the algorithms' names with the corresponding strategies.

Table 2: Algorithm definition.

Algorithm Name	Strategy
Sdfman-initial	Default
Sdfman-max-dist	Maximum Distance
Sdfman-HR	High Definition
Sdfman-star	Maximum Distance + High Definition

When calculating the error of each algorithm, we omit the pixels whose ground truth depth exceeds the maximum distance threshold $max_dist = 5$ m. Table 3 shows the accuracy of each algorithm. We use meter (m) rather than pixel disparity as the units for the error to give a more intuitive sense of the error magnitudes. With the initial input (Matlab SGM (Hirschmuller, 2005), Dispnet (Mayer et al., 2016)), DSF (Poggi and Mattoccia, 2016) reduces the mean absolute depth error from 0.40 m (Matlab SGM) and 0.24 m (Dispnet) to 0.18 m (DSF), which is larger than that of Sdfman-initial (0.09 m). Compared with Sdfman-initial (0.09 m), Sdfman-max-dist, Sdfman-HR and Sdfman-star are more accurate, which demonstrates that each of the proposed strategies contributes to improving the fusion accuracy. Algorithm Sdfman-star performs best with the mean absolute depth error (0.03 m) and achieves this at 34.21 frames per second. In the following experiments, we omit the two internal algorithms (Sdfman-max-dist and Sdfman-HR) because they are only used for the ablation study.

Table 3: Mean absolute depth error of the disparity fusion on Trimbot Wageningen SLAM Dataset (SD=Sdfman)

	Inputs		Comparison		Ablation Study		
	Matlab SGM	Dispnet	DSF	SD-initial	SD-max-dist	SD-HR	SD-star
Error	0.40 m	0.24 m	0.18 m	0.09 m	0.07 m	0.08 m	0.03 m

Figure 7 (a) compares the mean absolute error of each frame's depth map in the test dataset from all the algorithms. The accuracy of Sdfman-star is better than the other algorithms at all

¹²Matlab Implementation URL:<https://www.mathworks.com/help/vision/ref/disparitysgm.html>

¹³The authors of Dispnet (Mayer et al., 2016) were our project partners and they trained Dispnet on the project dataset to get their best performance.

¹⁴As the focal length and baseline are fixed, depth estimation is inversely proportional to its corresponding disparity value - see Equation 2. When the depth is 5 meters, the corresponding disparity is about 3 pixels. Estimated depth values larger than 5 meters (i.e. disparity value smaller than 3 pixels) have a larger error compared with depths closer than 5 meters.

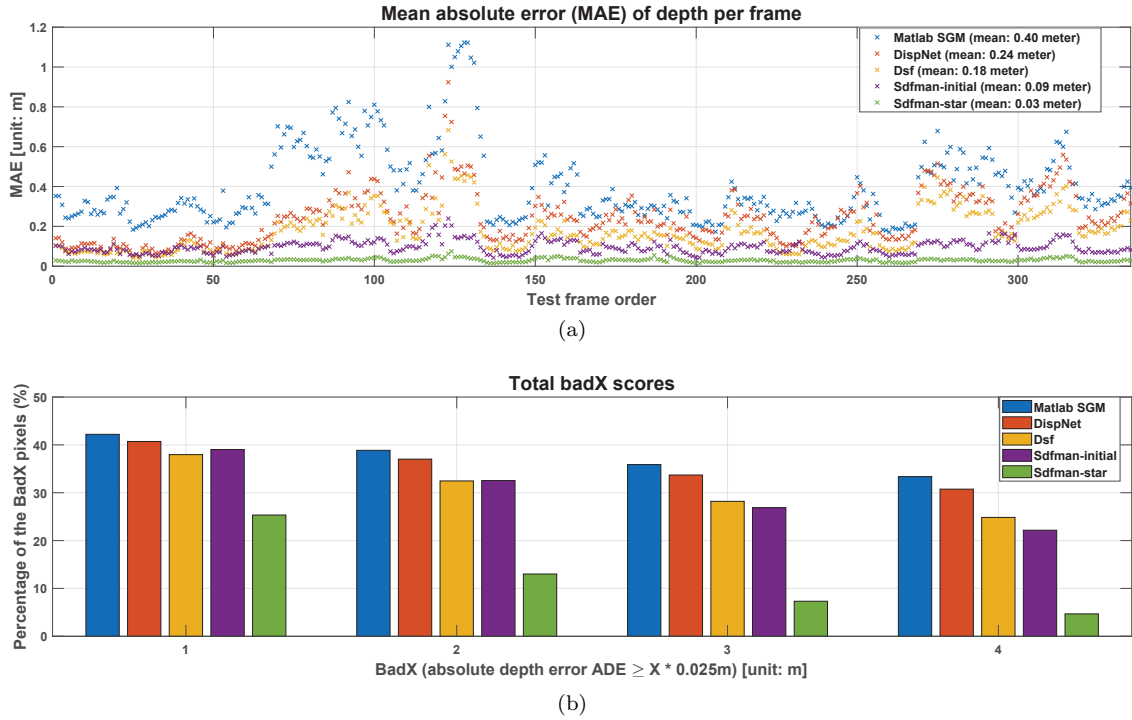

Figure 7: The mean absolute error (MAE) of the estimated depth map per frame and the total bad X scores

574 frames, which shows the robustness of Sdfman-star. Define parameter badX to be the percentage
 575 of pixels whose absolute depth errors in the depth map are bigger than $X * 0.025$ m (X is a positive
 576 number). Figure 7 (b) shows the percentage of badX pixels for different badX thresholds (values
 577 of X). Compared with the other algorithms, Sdfman-star has fewer pixels whose absolute depth
 578 error is bigger than 0.025 m, 0.05 m, 0.075 m and 0.1 m respectively. More than 95% of the pixels
 579 (bad4) from Sdfman-star have an absolute depth error less than 0.1 m.

580 Figure 8 shows one qualitative result from one image sensor (Cam 0). Compared with the other
 581 algorithms, Sdfman-star is more accurate globally and also preserves small details more vividly
 582 (e.g. object edges, the trees' trunks).

Figure 8: *See Continuation*

Figure 8: One qualitative result for disparity fusion. The lighter pixels in (d,f,h,j) represent bigger depth error.

583 In the post-processing step, N_p is set as 20 and *radius* is set as 0.05 m. N_n is set as 20 and
 584 *dist_ratio* is set as 1.5. Figure 9 shows one example of the point clouds from the depth maps after
 585 outlier removal. Compared with the ground truth, the remote objects (e.g. trunk) in the point
 586 clouds from Sdfman-star are noisy, which can be expected.

587 4.3 Pose Fusion Module

588 Section 4.3.1 presents results from an ablation study to show that the strategies proposed in Sec-
 589 tion 3.2 are effective. Section 4.3.2 compares Orbslam3 (Campos et al., 2021) and Open3D (Zhou
 590 et al., 2018) with the proposed pose fusion method.

591 Two methods are used to evaluate the 6D pose estimate accuracy. The first one uses the 6D
 592 pose vector $[tx, ty, tz, r, p, y]$ ([translation on X axis, translation on Y axis, translation on Z axis,
 593 roll, pitch, yaw]). The unit for tx, ty, tz is meters and the unit for r, p, y is degrees. The absolute
 594 difference between the ground truth and the estimated 6D vector is a measure of the 6D pose’s
 595 **accuracy on each axis**. The second method uses the rotation matrix and translation vector.
 596 The **overall accuracy** of the 6D poses is computed using Equation 7 and Equation 8 (Huynh,
 597 2009)

$$E_R = \|\mathbf{I} - \mathbf{R}_{gt}\mathbf{R}_{est}^{-1}\|_F \quad (7)$$

$$E_t = \|\mathbf{t}_{gt} - \mathbf{t}_{est}\|_F \quad (8)$$

598 where $\|\bullet\|_F$ is the Frobenius norm. $\mathbf{R}_{gt}, \mathbf{t}_{gt}$ are the ground truth and $\mathbf{R}_{est}, \mathbf{t}_{est}$ are the estimated
 599 values, respectively. Equation 7 does not have a physical unit although smaller is better and is
 600 a measure of better point cloud overlap. Equation 8 is the distance between the two coordinate
 601 systems’ origins (the ground truth and estimated coordinate system) and its unit is meter. Both
 602 ways of the above methods evaluate the 6D pose’s accuracy, although their error values and their
 603 error estimation methods are different.

(k) Single-view point cloud from Sdfman-star

(l) Single-view point cloud from ground truth

(m) Full-view point cloud from Sdfman-star

(n) Full-view point cloud from ground truth

Figure 9: A single-view (72°) and full-view (360°) point cloud from Sdfman-star and ground truth

604 **4.3.1 Ablation Study**

Table 4: Model definition.

Model Name	Strategy
Ours	the proposed method in Section 3.2
Ours-global	disable the refined pose graph in Section 3.2.2
Ours-prune	disable rule 1: "Prune"
Ours-update	disable rule 2: "Update"
Ours-gtdepth	replace the depth from Sdfman-star with the depth from GT depth
Ours-single-stereo	input the stereo images from the front stereo camera only

605 We define six models to compare each proposed strategy’s effectiveness. Table 4 lists the defined
 606 model names and the strategies. The model "Ours" is the proposed method in Section 3.2 with
 607 the point cloud input from Sdfman-star and is the baseline model, from which the other models
 608 are derived by changing only one strategy or factor. Model "Ours-global" disables the second-
 609 stage pose graph - the refined pose graph in Section 3.2.2. Model "Ours-prune" disables rule
 610 1 - "Prune" and thus will not prune any edge, no matter what the edge’s reliability is. Model
 611 "Ours-update" disables rule 2 - "Update" and thus will not update the transformation matrix of
 612 each edge. Model "Ours-gtdepth" replaces the input point clouds from Sdfman-star with the point
 613 clouds from the ground truth depth. Model "Ours-single-stereo" only inputs the stereo images
 614 from the front stereo camera (which consists of image sensors Cam0 and Cam1) rather than the
 615 panoramic stereo images from the ring of synchronized stereo cameras.

616 For all models, the overlapping rate threshold $OL_{min} = 0.33$ and $OL_{max} = 0.35$. The 6D pose
 617 vector \vec{v}_{th} is set to $[0.4 \text{ m}, 0.4 \text{ m}, 0.4 \text{ m}, 15^\circ, 15^\circ, 15^\circ]$ ([translation on X axis, translation on Y
 618 axis, translation on Z axis, roll, pitch, yaw]). Figure 10 shows the 2D trajectories from all the
 619 models when looking downward from above at the whole garden.

620 The trajectory of Ours-gtdepth is closest to the ground truth. The trajectories of Ours and
 621 Ours-prune are similar and rank 2nd together. The remaining models perform worse. In particular
 622 note that Ours-single-stereo did not work correctly in the latter part of the global pose trajectory,
 623 with completely wrong pose estimates. All the models except Ours-single-stereo have similar
 624 performance on the rotation factor, but perform on the translation factor variously. Table 5 shows
 the overall performance of each model by using the metrics in Equation 7 and Equation 8.

Table 5: Ablation study for pose fusion

Metric	Ours	Ours-global	Ours-prune	Ours-update	Ours-gtdepth	Ours-single-stereo
$\overline{E_R}$	0.11	0.08	0.12	0.08	0.08	0.98
σ_{E_R}	0.07	0.04	0.07	0.04	0.05	0.99
$\overline{E_t}$ (m)	0.33	0.48	0.34	0.52	0.27	2.47
σ_{E_t} (m)	0.18	0.32	0.20	0.29	0.16	1.99
Time (s)	233.24	210.86	233.14	233.15	230.41	179.28

625 The running time of all the models are close (about 230 s) except Ours-global (210.86 s) and
 626 Ours-single-stereo (179.28 s). From the quantitative aspect, it is obvious that Ours-single-stereo
 627 fails compared with the other models. Thus, using the panoramic stereo images from the ring of
 628 synchronized stereo vision cameras in the proposed framework is vital to overcome the challenges
 629 of the fast or large transformations between adjacent frames when a real robot navigates in a
 630 real outdoor environment. The reason is that the 360° field of view makes the overlap between
 631

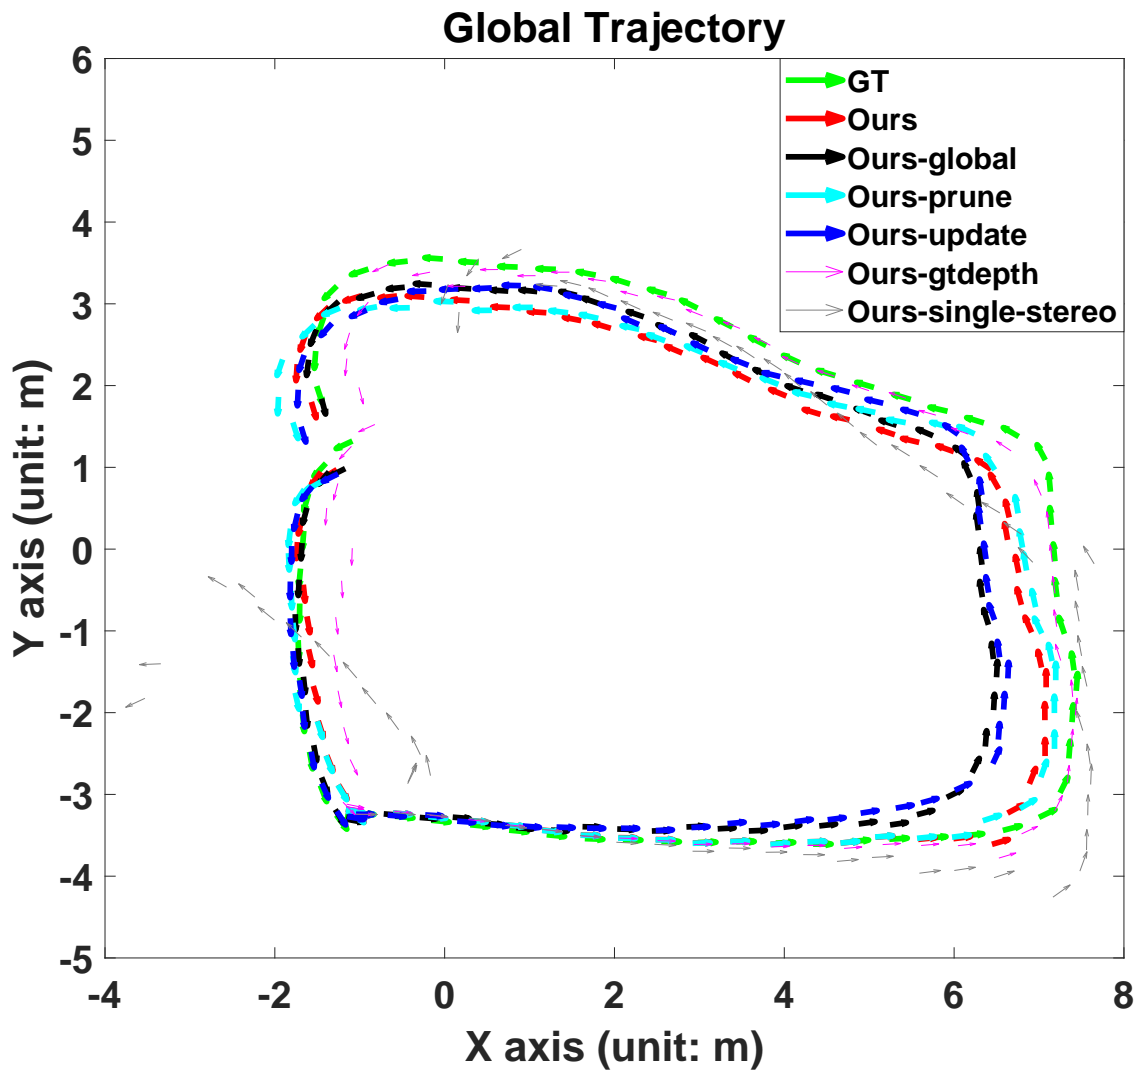

Figure 10: The estimated trajectory using each model

successive views high, which ensures the success of the global point cloud matching in the first stage of the pose fusion - global coarse pose graph optimization - to avoid the possibility of the whole 3D reconstruction framework collapsing. This strongly supports our major contribution (3) because we are the first to combine the two-stage full-view-to-single-view global-coarse-to-local-fine pose graph optimization with a ring of synchronized stereo vision cameras simultaneously to handle the robot’s fast movement in the real world. The performance the other models (except Ours-single-stereo) on the rotation factor are similar (0.08 - 0.12) but the performance on the translation factor fluctuates (0.27 m - 0.52 m). The translation accuracy of the model "Ours-global" and "Ours-update" is much lower than that of the model "Ours", which demonstrates the two-stage from-coarse-to-fine pose graph optimization and rule 2 - "Update" are effective. The accuracy of the model "Ours-prune" is slightly worse than that of the model "Ours" on both rotation and translation factors, which shows that rule 1 - "Prune" is effective. Rule 1 "Prune" and rule 2 "Update" improve the performance because they make the transformation of the edge set \tilde{E} more accurate and reliable which improves the constraint encoded in the loss function (see Equation 6). A more accurate constraint leads to to a more accurate pose estimate. The accuracy of model "Ours-gtdepth" is better than that of the model "Ours", which demonstrates that better recovery of the input point clouds leads to better pose fusion accuracy. Thus, one topic for future work is to continue improving the accuracy of the input point clouds.

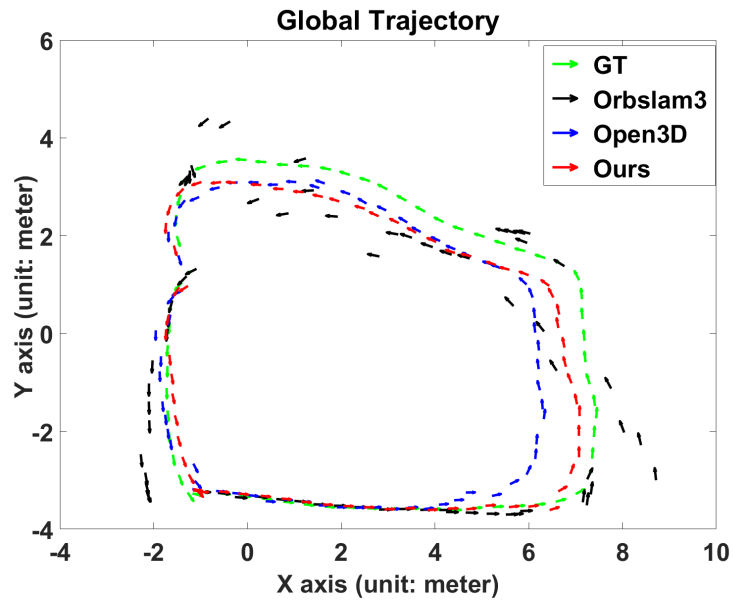

4.3.2 Comparison with Existing Methods

We compare the model "Ours" with existing state-of-the-art algorithms, represented by the RGBD SLAM algorithm in Orbslam3 (Campos et al., 2021) and the reconstruction system in Open3d (Zhou et al., 2018) as available online¹⁵. The depth maps that all the algorithms receive as input are the output from the Sdfman-star fusion algorithm. The parameter setting in model "Ours" is the same as that in Section 4.3.1. For Orbslam3, we set the number of features per image "ORBextractor.nFeatures" as 10000. The number of levels in the scale pyramid "ORBextractor.nLevels" is 15. The fast threshold "ORBextractor.iniThFAST" is 5 and "ORBextractor.minThFAST" is 3. The number of camera frames per second is 1. The rest of the parameters are the same as those in their released code. As the Orbslam3 framework does not support panoramic data, we input the RGB images and the corresponding depth maps from the image sensor 'Cam0' into the RGBD SLAM algorithm in the Orbslam3 framework. To make Orbslam3 work better on the difficult dataset "Trimbot Wageningen SLAM Dataset", we additionally provide the ground truth pose to Orbslam3 when the adjacent frames have a large rotation and Orbslam3 lost tracking (at all the corners of the trajectory). More specifically, at Frames 20, 31, 50, 54, 56, we provide the corresponding ground truth pose to Orbslam3. See Figure 11 (b) and Figure 11 (c) where both the rotation and translation error of Orbslam3 are equal to 0. Open3D failed to work if we only input the single-view point clouds. To make Open3D perform better, we modified its initial code to make it use our full-view and single-view point clouds. We also provide the comparison results under the same conditions in Appendix E.2 Fair Comparison With More Open-source Frameworks. Readers can test their own code on the "Trimbot Wageningen SLAM dataset".

Figure 11 (a) shows the estimated global trajectory from GT, Orbslam3, Open3D, and Ours. Figure 11 (b) and (c) show the rotation and translation error at each frame time in the test dataset using Equation 7 and Equation 8. From Figure 11 we could see Open3D and Ours perform much more accurately and robustly than Orbslam3. Open3D and Ours have similar performance on the rotation and Ours performs more accurately than Open3D on the translation.

If we use the absolute difference between the ground truth and the estimated 6D vector to describe the 6D pose accuracy, Table 6 compares the performance of the algorithms on each axis. Our approach’s mean bias and the related standard deviation of the translation on the x , y , and z axis are generally smaller than those of Orbslam3 and Open3D. The rotation performance of Ours and Open3D on x , y , and z axis is more accurate and robust than that of Orbslam3. Our

687 4.4 Volumetric Fusion Module

688 In this part, we set the maximum depth for integrating as 5 meters. The size of TSDF (Truncated
689 Signed Distance Field) cube is 10 meters. The length of each voxel is 0.01 m (1 cm). The truncation
690 value for the signed distance function (SDF) is set to 0.06.

691 Figure 12 shows the mesh of the reconstructed garden and its details at different sites. Figure 12
692 (a) shows the overview of the reconstructed whole garden. Figure 5 (a) shows the ground truth.
693 Figure 12 (b) (c) (d) (e) show close-up views at sites 1, 2, 3, 4 in Figure 12 (a). The white blank
694 areas in all the figures are regions that have not been scanned during driving. These regions did
695 not have target plants for the trimming robot and thus were not scanned. From the details, the
696 reconstructed scene is good enough for the remote visualization and coarse robot task planning.
697 A video that shows the reconstructed garden is at: https://youtu.be/zGxcj0_NXCA.

698 In the following, the reconstructed gardens from all the algorithms are compared to the ground
699 truth 3D model of the whole garden in the same world coordinate system. The evaluation method
700 consists of estimating the mean and standard deviation of the minimum distance between each
701 point of the reconstructed garden and its closest point in the ground truth garden model. Thus,
702 this metric measures how close the reconstructed garden is, on average, with respect to the ground
703 truth garden model.

704 Table 8 shows the mean \overline{dist} and standard deviation σ_{dist} of the minimum distance between
705 the corresponding closest points. The mean and standard deviation of the minimum distance's
706 absolute bias on x , y , and z axis are $(\overline{dx}, \sigma_{dx})$, $(\overline{dy}, \sigma_{dy})$ and $(\overline{dz}, \sigma_{dz})$ respectively. The maximum

\overline{dz} (m)	0.20	0.15
σ_{dz} (m)	0.18	0.12
\overline{dist} (m)	0.24	0.18
σ_{dist} (m)	0.19	0.14
Time /s	8.48	8.23

710 Figure 13 (a) (c) (e) show the reconstructed gardens from Open3D, Ours, and the ground
 711 truth garden model. Figure 13 (b) (d) (f) show the details on the same site in the real garden.
 712 Compared with ours, we could see Open3D fails to align the point clouds of the same tree, and
 713 makes it seem that there were two trees on that site.

714 In addition to the experiments above, there are two other experiments. In the first experiment,
 715 the proposed framework is successfully tested with scene appearance and sunlight change. More
 716 details can be found in Appendix E.1. The second experiment compares our proposal with a popu-
 717 lar commercial software application ‘ContextCapture’ on the Trimbot Wageningen SLAM Dataset.
 718 The proposed approach again has better performance. For more details, see Appendix E.3.

719 5 Conclusion and Discussion

720 This paper presented an improved approach for recovering accurate outdoor 3D scene recon-
 721 struction, based on disparity fusion, pose fusion and volumetric fusion, and demonstrated its
 722 performance by reconstructing a real outdoor garden containing a variety of different natural and
 723 man-made structures. Avoiding the need for expensive and sparse Lidar scans, the proposed ap-
 724 proach inputs the disparity maps from two different stereo vision algorithms into a disparity fusion
 725 network to produce accurate disparity maps, which is a cheap, accurate and robust solution to
 726 get higher quality depth data. The depth data is converted into point clouds, whose outliers are
 727 removed, and then input into the pose fusion module. The pose fusion module uses a two-stage
 728 from-global-coarse-to-local-fine pose graph optimization to estimate a more accurate global pose
 729 trajectory. More specifically, in the first stage, we use fast global point cloud registration (Zhou
 730 et al., 2016) and full-view (360°) point clouds to build a coarse global pose graph, which is robust
 731 to fast motion and big transformations between two consecutive frames. In the second stage, a
 732 local point cloud registration algorithm GICP (Segal et al., 2009) extended with three domain
 733 rules optimizes the refined pose graph, which produces a more accurate global pose trajectory.
 734 With the accurate global pose trajectory and the fused depth maps, the mesh of the whole garden
 735 can be reconstructed by volumetric fusion, as demonstrated on a real outdoor dataset.

736 The key to a good 3D reconstruction of the real garden is the accurate depth map and global
 737 pose trajectory. In future work, more advanced disparity fusion networks will be explored to con-
 738 tinue to improve the disparity accuracy. The accuracy of the 6D pose that registers the point clouds
 739 affects the accuracy of the edges in the pose graph, which in turn influence the optimized global
 740 pose trajectory. More advanced and faster global and local point cloud registration algorithms

¹⁶Our trimming robot did coarse global task planning on the reconstructed global model first. When the robot arrives at the specific location for trimming, the robot arm will move the depth cameras on the robot arm to scan the target locally and build the accurate local 3D model with the precise pose update from the robot arm’s joints.

741 that are robust against strong noise and large occlusions will be explored to get more accurate
742 initial 6D pose estimation. The research proposed in this paper is adapted for use by a robot in
743 a garden environment, but it can be generalized to different outdoor application scenarios. How-
744 ever, this requires the related ground truth for the network training and performance evaluation.
745 Expanding into related domains of robot applications is our priority for the near future.

746 **Acknowledgements**

747 Before 2020, the research was funded by the TrimBot2020 project (Grant Agreement No. 688007,
748 URL: <http://trimbot2020.webhosting.rug.nl/>) from the European Union Horizon 2020 pro-
749 gramme. After 2020, the research funding is from Shenzhen Amigaga Technology Co. Ltd. by
750 the Gagabot2022 project (Grant Agreement No. P987001), from the Human Resources and Social
751 Security Administration of Shenzhen Municipality by Overseas High-Caliber Personnel project

764

765 C.1 Loss Function

766 In this subsection, we will prove that Equation 4 in this paper is equal to equation 4 in the
767 paper (Moreira et al., 2021a) under the assumption that the uncertainty of the rotation is the
768 same as the translation’s. Although ‘Equation 1’ in the paper (Moreira et al., 2021a) is similar to
769 our Equation 4, the authors (Moreira et al., 2021a) did not prove that the Frobenius-norm-based
770 transformation difference loss function (Equation 4) is a special case of the maximum likelihood
771 loss function in the pose graph optimization, which is the motivation for this section.

In Equation 4, $G(V, E)$ is a connected pose graph with $|V| = n$ poses (or vertices). The rigid transformation T_{ij} (here, computed using a point cloud registration algorithm) from the i^{th} pose (denoted by P_i) to the j^{th} pose (denoted by P_j) could be written as $\{\tilde{\mathbf{R}}_{ij}, \tilde{t}_{ij}\}$ for the edge $(i, j) \in E$. E is the edge set. $\tilde{\mathbf{R}}_{ij}$ and \tilde{t}_{ij} are the corresponding relative rotation and translation estimates. The i^{th} pose P_i could be written as $\{\mathbf{R}_i, t_i\}_{i=1, \dots, n}$. In the following, we will use block-matrix notation to represent Equation 4.

As the transformation is rigid, thus:

$$\tilde{\mathbf{R}}_{ij}\tilde{\mathbf{R}}_{ij}^T = \mathbf{I}, \mathbf{R}_i\mathbf{R}_i^T = \mathbf{I}, \mathbf{R}_j\mathbf{R}_j^T = \mathbf{I}.$$

Let us write:

$$T_{ij} = \begin{bmatrix} \tilde{\mathbf{R}}_{ij} & \tilde{t}_{ij} \\ \mathbf{0} & 1 \end{bmatrix}, P_i = \begin{bmatrix} \mathbf{R}_i & t_i \\ \mathbf{0} & 1 \end{bmatrix},$$

$$P_j = \begin{bmatrix} \mathbf{R}_j & t_j \\ \mathbf{0} & 1 \end{bmatrix}, P_j^{-1} = \begin{bmatrix} \mathbf{R}_j^T & -\mathbf{R}_j^T t_j \\ \mathbf{0} & 1 \end{bmatrix};$$

Thus, Equation 4 can be transformed into:

$$\begin{aligned} & \arg \min \sum_{(i,j) \in E} \|T_{ij} - P_i P_j^{-1}\|_F^2 \\ &= \arg \min \sum_{(i,j) \in E} \left\| \begin{bmatrix} \tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T & \tilde{t}_{ij} - t_i + \mathbf{R}_i \mathbf{R}_j^T t_j \\ \mathbf{0} & 0 \end{bmatrix} \right\|_F^2 \\ &= \arg \min \sum_{(i,j) \in E} (\|\tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T\|_F^2 + \|\tilde{t}_{ij} - t_i + \mathbf{R}_i \mathbf{R}_j^T t_j\|_F^2) \end{aligned} \quad (\text{C.1})$$

According to the definition, Frobenius norm of a matrix \mathbf{A} is defined as the square root of the sum of the absolute squares of its elements in the matrix, which is equal to the square root of the matrix trace of $\mathbf{A}\mathbf{A}^T$. Additionally, $tr(\mathbf{A}) = tr(\mathbf{A}^T)$.

Expanding the term $\|\tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T\|_F^2$ in Equation C.1:

$$\begin{aligned} & \|\tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T\|_F^2 \\ &= tr\{(\tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T)(\tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T)^T\} \\ &= tr(\tilde{\mathbf{R}}_{ij}\tilde{\mathbf{R}}_{ij}^T + \mathbf{R}_i \mathbf{R}_j^T \mathbf{R}_j \mathbf{R}_i^T - \tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T - \mathbf{R}_i \mathbf{R}_j^T \tilde{\mathbf{R}}_{ij}^T) \\ &= tr(\mathbf{I} + \mathbf{I}) - tr(\tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T) - tr\{(\tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T)^T\} \\ &= 6 - 2tr(\tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T) \end{aligned} \quad (\text{C.2})$$

Substitute the term $\|\tilde{\mathbf{R}}_{ij} - \mathbf{R}_i \mathbf{R}_j^T\|_F^2$ in Equation C.1 with Equation C.2 and neglect the constant term:

$$\begin{aligned} & \arg \min \sum_{(i,j) \in E} \|T_{ij} - P_i P_j^{-1}\|_F^2 \\ &= \arg \min \sum_{(i,j) \in E} \{\|\tilde{t}_{ij} - t_i + \mathbf{R}_i \mathbf{R}_j^T t_j\|_F^2 - 2tr(\tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T)\} \end{aligned} \quad (\text{C.3})$$

In Equation C.3 we minimize the loss function to get the estimated rotation and translation by maximizing its negative. Thus, divide the right part of the equal sign by the negative constant $-2\sigma_R^2$, we get:

$$\begin{aligned} & \arg \min \sum_{(i,j) \in E} \|T_{ij} - P_i P_j^{-1}\|_F^2 \\ &= \arg \max \left\{ -\frac{1}{2\sigma_R^2} \sum_{(i,j) \in E} \|\tilde{t}_{ij} - t_i + \mathbf{R}_i \mathbf{R}_j^T t_j\|_F^2 \right. \\ & \quad \left. + \frac{1}{\sigma_R^2} \sum_{(i,j) \in E} tr(\tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T) \right\} \end{aligned} \quad (\text{C.4})$$

Compare our term Equation C.4 with the log-likelihood term equation 4 in the paper (Moreira

et al., 2021a), which is shown in the following Equation C.5:

$$\begin{aligned}
& \log L(\theta|y) \\
&= -\frac{1}{2\sigma_t^2} \sum_{(i,j) \in E} \|\tilde{t}_{ij} - t_i + \mathbf{R}_i \mathbf{R}_j^T t_j\|_F^2 \\
& \quad + \frac{1}{\sigma_R^2} \sum_{(i,j) \in E} \text{tr}(\tilde{\mathbf{R}}_{ij} \mathbf{R}_j \mathbf{R}_i^T)
\end{aligned} \tag{C.5}$$

772

773 When the noise level for the rotation and translation in the paper (Moreira et al., 2021a) is
774 assumed to be equal (i.e. $\sigma_t = \sigma_R$), Equation C.4 (in our paper) and Equation C.5 (which is
775 same with equation 4 in Moreira et al. (2021a)) are completely the same. Thus, we could use
776 the optimization method¹⁷ in Moreira et al. (2021a) to optimize our error function. Finding the
777 optimum rotation parameters first and then solving for the translation parameters turns it into
778 a least-squares problem. To deduce the Equation C.5, refer to Page 9 - 10 in (URL: [https://
779 drive.google.com/file/d/1ML7mkLSIALm3x5DtID7ozHD3YL7S1iNC/view?usp=sharing](https://drive.google.com/file/d/1ML7mkLSIALm3x5DtID7ozHD3YL7S1iNC/view?usp=sharing)) or the
780 most related papers (Carlone et al., 2015a,b; Moreira et al., 2021a,b).

781 To conclude, Equation 4 can be turned into a maximum likelihood estimation problem under the
782 assumption of the proper noise level for rotation and translation. From another aspect, there is
783 a more intuitive way to express the physical meaning of Equation 4. That is: estimate the pose
784 of each node accurately, which in turn makes the existing relative pose measurements between
785 different nodes closer to the post-calculated relative pose between different nodes based on their
786 estimated global pose.

787 C.2 Maximum Distance

In the initial work Sdf-man (Pu et al., 2019), at the end of the refiner network (see Figure 2 on
page 7 in Pu et al. (2019)) the method uses the function ‘tanh’ to output an intermediate map w
and each value in w is in $(-1, 1)$.

$$\text{initial_disp} = \frac{\text{max_disp} \cdot (w + 1)}{2} \tag{C.6}$$

Then it uses Equation C.6 to convert the intermediate map w to the disparity map initial_disp .
 max_disp is the maximum disparity threshold. Converting the disparity map initial_disp into a
depth map using Equation 2 gives Equation C.7.

$$\text{initial_depth} = \frac{2fb}{\text{max_disp} \cdot (w + 1)} \tag{C.7}$$

788 f and b are the focal length value and baseline value of the stereo vision camera. As w ranges
789 from -1 to 1, the initial_depth values will range from $\frac{fb}{\text{max_disp}}$ to $+\infty$.

In this paper, the difference is that we use a new Equation C.8 to map the intermediate map
 w to the new disparity map new_disp rather than Equation C.6.

$$\text{new_disp} = \frac{2fb}{\text{max_dist} \cdot (w + 1)} \tag{C.8}$$

max_dist is set as the maximum distance threshold of interest. Converting the new disparity map
 new_disp into the depth map format using Equation 2 gives Equation C.9, whose value domain is
 $(0, \text{max_dist})$.

$$\text{new_depth} = \frac{\text{max_dist} \cdot (w + 1)}{2} \tag{C.9}$$

¹⁷The URL of the released code: <https://github.com/gabmoreira/maks>

790

791 Comparing the value domain of *new_depth* in Equation C.9 and *initial_depth* Equation C.7,
 792 the domain $(\frac{fb}{max_disp}, +\infty)$ of *initial_depth* is larger than the domain $(0, max_dist)$ of *new_depth*
 793 considerably, though their definition domains are the same. Thus, as for noise with the same
 794 granularity in the input, *new_depth* from the proposed strategy will output a more robust and
 795 accurate result. By setting the maximum distance threshold of interest and the new mapping
 796 function Equation C.8, we effectively narrow the value domain of the depth output to increase
 797 depth accuracy. This alternative approach has also been confirmed by the experiment results in
 798 Section 4.2.

799 Appendix D. More Details about Data Collection

800 As Figure 5 (b) shows, the trimming robot Trimbot¹⁸ navigates around the outdoor garden¹⁹ to
 801 collect the raw data. The top of the robot resembles a ‘tower’ (see Figure D.1), which consists
 802 of a prism retroreflector, a Velodyne VLP16, and the panoramic stereo camera (a ring of 5 stereo
 803 cameras).

804 The prism reflector on the robot is used to reflect the laser beam from Topcon PS Series Robotic
 805 Total Station (See Figure D.2), to estimate the robot’s position in 3D space. According to the
 806 datasheet of the Topcon PS Series Robotic Total Station²⁰, the distance measurement accuracy
 807 with the prism could be down to $1.5mm + 2ppm$. To estimate the robot’s orientation [roll, pitch,
 808 yaw], a STIM300 IMU sensor inside the trimming robot is used to record the acceleration and
 809 rotation rate measurements. According to the datasheet of STIM300 IMU sensor²¹, the gyroscope
 810 input range is $\pm 400deg/sec$ and its angular random walk is $0.15deg/\sqrt{hr}$. The accelerometer
 811 range is $\pm 10g$ and its velocity random walk is $0.06m/s/\sqrt{hr}$. The in-run bias stability of the
 812 gyroscope and accelerometer is $0.5deg/hr$ and, $0.05mg$ respectively. Based on the precise mea-
 813 surements from the STIM300 IMU sensor, the orientation of the robot is estimated in an offline
 814 post-processing step by strap-down integration. The 3D position $[tx, ty, tz]$ from Topcon PS Series
 815 Robotic Total Station and the orientation (*roll, pitch, yaw*) are appended to constitute the 6-DoF
 816 pose of the robot. Then, by calibration, the 6-DoF pose of the robot is transformed to get the
 817 pose of each rigidly placed image sensor in the panoramic stereo camera. Finally, structure-from-
 818 motion (Schonberger and Frahm, 2016) is used to refine each image sensor’s pose to form the
 819 ground truth pose of each image sensor, particularly to fix poses where the line of sight between
 820 the Topcon and prism was interrupted by obstacles.

821 The Velodyne VLP16 lidar sensor is mounted on top of the panoramic stereo camera to record a
 822 reference point cloud from the Trimbot robot’s perspective. The lidar sensor has a 360° horizontal
 823 field of view with an angle resolution spanning from 0.1° to 0.4° , which corresponds to the rotation
 824 rate from 5 Hz to 20 Hz. In the Trimbot Wageningen SLAM Dataset, the angular resolution is set
 825 to 0.2° and the rotation rate is set to 10Hz. The Velodyne VLP16 lidar sensor has 16 horizontal
 826 rays, which are distributed within a vertical field of view of $\pm 15^\circ$. According to its datasheet²²,
 827 its scanning range could be up to 100 m with an accuracy of $\pm 3cm$. Then the lidar point cloud
 828 is projected to the image planes of the 10 image sensors in the panoramic stereo camera to form
 829 sparse depth maps.

830 The panoramic stereo camera²³ is built with ten MT9V024 CMOS image sensors from ON-
 831 Semiconductors²⁴. The housing of the panoramic stereo camera has a pentagon shape and is

¹⁸Trimbot’s hardware was mainly developed by our Trimbot2020 consortium member Robert Bosch GmbH based on the Bosch Indigo lawn mower.

¹⁹The garden was constructed by our Trimbot2020 consortium member Wageningen Research in Netherlands.

Figure D.1: Some sensors for collecting the data

Figure D.2: Topcon PS Series Robotic Total Station estimated the robot’s 3D position by emitting laser beams and receiving the beams reflected by the prism reflector on the top of the trimming robot Trimbot.

832 manufactured by 3D printing. Figure D.3 shows the panoramic stereo camera from the top and
 833 side views. The image sensors have 752×480 (*Horizontal* \times *Vertical*) pixels resolution with
 834 global shutter. The maximum frame rate of a single image sensor could be up to 60 FPS at full
 835 resolution. The five synchronized stereo vision cameras (10 image sensors) could only stream the
 836 synchronized panoramic stereo images (10 synchronized images) at 12 HZ because it is limited by
 837 the bandwidth of the panoramic stereo camera’s data bus. The image sensor’s operating tempera-
 838 ture ranges from $-40^{\circ}C$ to $+100^{\circ}C$ ambient. The active imager size is $4.51mm(H) \times 2.88mm(V)$,
 839 whose diagonal size is 5.35 mm. The pixel size is $6.0 \mu m \times 6.0 \mu m$. We calibrated the image sensor
 840 using the *Kalibr* package²⁵ by setting the camera model as pinhole and the distortion model as
 841 radial-tangential. The calibration accuracy of image sensors in terms of a mean reprojection error
 842 was 0.00 pixels on the X and Y axis, with standard deviation ranging from 0.1 pixels to 0.2 pixels.
 843 Given that the image sensors’ temperature and long operating time influences the robustness of
 844 the commercial hardware’s imaging quality, which will possibly influence the calibration accuracy,
 845 more engineering robustness tests would be future work.

846 The 3D point cloud of the whole garden was collected by a Leica ScanStation P15²⁶. The Leica
 847 ScanStation P15 measures the distance by a laser scanner and incorporates the corresponding
 848 RGB data from a color camera into the laser scanner’s coordinate system. The laser scanner’s
 849 working distance range varies from $[0.4m, 40m]$. The 3D position accuracy could be low to 3
 850 mm at 40 meters and the linearity error is smaller than 1 mm. The angular accuracy is 8” in
 851 the horizontal direction and 8” in the vertical direction. Figure D.4 shows the garden’s point
 852 clouds from different views with RGB data and colored height (different colors represent different
 853 heights). As the distance measurement and the RGB measurement are conducted sequentially,

(a) Top View

(b) Side View

Figure D.3: Figure (a) (b) shows the panoramic stereo camera from the top view and side view

854 both measurements are not exactly synchronized. As a consequence, there may be wrong RGB
 855 values on moving objects’ point clouds. A moving leaf’s point cloud (taken at one timestamp)
 856 will show the sky’s color (taken at another timestamp) if the leaf moved at one timestamp (when
 857 the laser scanner was acquiring data) to another place at another timestamp (when the RGB
 858 sensor was acquiring data). Reflectance properties of glossy leaves can also result in color changes.
 859 Thus, in Figure D.4, the tree’s point clouds show a mixed color (green and sky-white). That is
 860 the reason why we did not include the point cloud with RGB data into the Trimbot Wageningen
 861 SLAM Dataset.

862 Appendix E. Additional Qualitative Results

863 E.1 Robustness to Environment Change

864 As sunlight and the scene appearance outdoors will influence an image’s appearance directly, thus
 865 we vary sunlight from different time periods and scene appearance from different places in the
 866 following experiment to demonstrate the robustness of the proposed framework. Figure E.1 shows
 867 the experimental setting for the robustness test. In Scene 1, the robot drove straight along route
 868 A under sunlight A. In Scene 2, the robot drove straightly along route B (whose travelled distance
 869 is same with that of route A) under the same sunlight A. In Scene 3, the robot drove straightly
 870 along the route A, but under the different sunlight B. Since factors other than scene appearance
 871 and lighting should not influence the image appearance directly, we classify the other factors as
 872 Uncontrolled Random Factors. Table E.1 gives the precise value of each factor, and the values of
 873 the uncontrolled random factors are from a weather website ²⁷.

874 Figure E.2 shows the three scenes and the related 3D reconstruction results in surface mesh
 875 format by the proposed framework. As acquiring ground truth requires considerable expense and
 876 effort by a big team, we only show the corresponding qualitative results. Compare the shadows,
 877 trees, posts and bushes in the example images (Figure E.2 a c e) with the corresponding shapes
 878 in the reconstructed 3D meshes (Figure E.2 b d f). The high quality and believable shapes, even
 879 with different lighting and viewpoint, demonstrate the high quality of the 3D reconstruction by
 880 our proposed framework. Further robustness tests against other factors (e.g. temperature, wind
 881 speed, long operating time, humidity, foggy or snowy weather) are future work.

Table E.1: Scene Definition with Different Condition Setting

Scene	Controlled Var			Uncontrolled Random Factors					
	route	sun-light	time	date	temp	wind speed	humid	dew point	pressure
1	A	A	~ 15 : 30	2017-05-17	22.5°C	12.7 km/h	76%	15.7°C	995.6Mb
2	B	A	~ 15 : 30	2017-05-17	22.5°C	12.7 km/h	76%	15.7°C	995.6Mb
3	A	B	~ 11 : 00	2018-06-27	20.5°C	12.7 km/h	75%	12.7°C	1003.4Mb

882 E.2 Fair Comparison with More Open-source Frameworks

883 Orbslam3 (Campos et al., 2021) and Open3D (Zhou et al., 2018) needed hints in Section 4.3.2
 884 to make them work. In this subsection, we will compare all the frameworks when using only
 885 one stereo vision camera (which consists of the image sensor Cam0 and Cam1) without any hints
 886 provided to any framework. We use the initial parameter setting of Open3D for a test (denoted
 887 by Open3D-initial). For Orbslam3, we test their RGBD SLAM algorithm (denoted by Orbslam3-
 888 rgbd), their stereo SLAM algorithm (denoted by Orbslam3-stereo), and their monocular SLAM
 889 algorithm (denoted by Orbslam3-monocular). For the parameter setting of each SLAM algorithm

Figure D.4: Figure (a) (c) (e) (g) show the point clouds with colored height. Figure (b) (d) (f) (h) show the point clouds with registered RGB data. All point clouds are from the Leica ScanStation P15. The images are from our partner Robert Bosch GmbH in the Trimbot2020 project.

Figure E.1: The experiment setting in the robustness test

890 from Orbslam3, please refer to the video at <https://youtu.be/41uADtHNbuA>. In this video²⁸, we
 891 also show the performance of each algorithm from Orbslam3 on our Trimbot Wageningen SLAM
 892 dataset when having a random test²⁹.

893 Figure E.3 shows the global pose trajectory of each framework. The results of Orbslam3 are
 894 from the best trials among tens of random trials. Method "Ours" is the method proposed in this
 895 paper with panoramic stereo images as input. Method "Ours-single-stereo" denotes a method
 896 which is derived from the "Ours" method, but with the input from only one stereo camera.
 897 Figure E.3 shows that all of the algorithms successfully estimate poses initially, but eventually
 898 fail, except "Ours" when traversing the whole dataset. "Ours-single-stereo" seems to work better
 899 compared with the external counterparts, although it still fails at the latter part of the global pose
 900 trajectory. The trajectory of Orbslam3-monocular (cyan trajectory) has only one dot to show at
 901 the starting point, near the coordinate (0 m, -1 m), because Orbslam3-monocular almost lost
 902 tracking every frame. Given the bad performance of each external algorithm, it is meaningless to
 903 calculate the corresponding quantitative results. It is also the reason why we needed to provide
 904 "some extra help" to the external counterparts to get results to compare with in Section 4.3.2.

905 E.3 Comparison with Software 'ContextCapture'

906 Above, we compared our proposed framework with the latest popular frameworks Orbslam3 (Cam-
 907 pos et al., 2021) and Open3D (Zhou et al., 2018). The experimental results have shown our
 908 framework's performance superiority over the two open-source frameworks. Here, we compare the
 909 proposed framework with the commercial software called "ContextCapture Center" from Bent-

²⁸There are many false extracted features near the edge of the robot in the above video. We refined the data input of Orbslam3 by masking more areas near the robot and tuned the parameters to maximize Orbslam3's performance. The modified video (URL: <https://youtu.be/9TaayX14mJ4>) shows the corresponding performance.

²⁹Due to the stochastic property of the algorithm RANSAC (Fischler and Bolles, 1981) in the framework Orbslam3, the results from Orbslam3 are different each time.

Figure E.4: Figures (a) and (b) show the reconstructed models from the professional 3D reconstruction Software ‘ContextCapture’.

910 ley³⁰, which is known for its image-based 3D reconstruction and aerial photogrammetry. Because
 911 the commercial software ContextCapture’s 3D reconstruction framework does not support 360°
 912 image-based 3D reconstruction, we could only input the RGB images from our image sensor Cam0
 913 in our Wageningen SLAM Dataset. Figure E.4 shows the reconstructed meshes from two views.
 914 From the strange reconstruction results, we could easily see that the ContextCapture reconstruction
 915 system failed at our task. The reason is that the real robot’s fast movement and large
 916 transformation between frames when navigating in the real outdoor garden lead ContextCapture
 917 to lose tracking (please read the acquisition report³¹ from ContextCapture). The quality report³²
 918 from the software ContextCapture reveals more reconstruction details about its failure.
