

THE FOREST VEGETATION OF THE TOLFA-CERITI MOUNTAINS (NORTHERN LATIUM – CENTRAL ITALY)

Romeo DI PIETRO¹, Mattia M. AZZELLA² & Laura FACIONI²

Abstract

The forests of the Tolfa-Ceriti mountains (Latium, central Italy) were investigated through a phytosociological approach. 249 relevés were performed and treated with multivariate analysis. 13 woodland communities were identified, of which 7 belong to *Quercetalia pubescenti-petraeae*, 1 to *Fagetalia sylvaticae*, 1 to *Populetalia* and 4 to *Quercetalia ilicis*. The thermophilous Turkey oak-forests occurring on the trachytic hills of the Ceriti Mountains and on the flysch substrates of the Tolfa Mountains were included in *Rubio peregrinae-Quercetum cerridis* ass. nova. *Quercus cerris* and *Fraxinus angustifolia* subsp. *oxycarpa* woodland communities of the foot-slopes have been ascribed to *Fraxino oxycarpae-Quercetum cerridis*, while the widespread mesophilus Turkey oak forests have been ascribed to *Melico-Quercetum cerridis*. *Cephalanthero longifoliae-Quercetum cerridis* has been restricted to acid and oligotrophic soils. *Quercus petraea* woodlands, occurring on trachytic substrates have been described as a new association named *Carici olbiensis-Quercetum petraeae* ass. nova. All these mixed oak woods have been included in the alliance *Crataego laevigatae-Quercion cerridis* Arrigoni 1997. The nomenclatural problems concerning the prior name *Teucrio siculi-Quercion cerridis* Ubaldi 1988 are also discussed. The beech forests of the higher altitudes have been included in *Fraxino orni-Fagetum sylvaticae*, while the *Alnus glutinosa* ravine woodlands have been described as belonging to the new association *Polysticho setiferi-Alnetum glutinosae*. Secondary communities of *Acer monspessulanum* and *Acer campestre* developed on flysch substrates, and of *Erica arborea* and *Arbutus unedo* (*Erico-Arbutetum unedonis*) developed on trachytic substrates, have also been identified. Finally two types of *Quercus ilex* wood have been identified: *Cyclamino repandi-Quercetum ilicis*, on sandstones, and the new association *Arbuto unedonis-Quercetum ilicis* ass. nova on volcanic soils. This latter community can be considered as a coenological and geographical vicariant in central Italy of the sicilian *Erico-Quercetum ilicis*.

Key words: forest vegetation, ICPN, peninsular Italy, phytosociology, syntaxonomy.

Izvleček

Fitocenološko so bili raziskani gozdovih na pogorju Tolfa-Ceriti (Lacijs, osrednja Italija). Izdelano je bilo 249 fitocenoloških popisov, ki so bili obdelani z multivariantimi metodami. Ugotovljenih je bilo 13 gozdnih združb, od katerih jih 7 uvrščamo v red *Quercetalia pubescenti-petraeae*, 1 v red *Fagetalia sylvaticae*, 1 v red *Populetalia* in 4 v red *Quercetalia ilicis*. Termofilni cerovi gozdovi, ki jih najdemo v gričevnatem svetu pogorja Ceriti in se razvijejo na flisu v pogorju Tolfa, so vključeni v asociacijo *Rubio peregrinae-Quercetum cerridis* ass. nova. Gozdovi cera (*Quercus cerris*) in ozkolistnega jesena (*Fraxinus angustifolia* subsp. *oxycarpa*) na vznožjih so uvrščeni v združbo *Fraxino oxycarpae-Quercetum cerridis*, medtem ko so široko razširjeni mezofilni cerovi gozdovi uvrščeni v združbo *Melico-Quercetum cerridis*. Združba *Cephalanthero longifoliae-Quercetum cerridis* je razširjena le na grušču na kislih in oligotrofnih tleh. Gradnovi gozdovi, ki se pojavljajo na trahičnem substratu, so uvrščeni v novo asociacijo *Carici olbiensis-Quercetum petraeae*. Vsi obravnavani mešani hrastovi gozdovi so vključeni v zvezo *Crataego laevigatae-Quercion cerridis* Arrigoni 1997; poleg tega pa obravnavamo tudi starejše ime *Teucrio siculi-Quercion cerridis* Ubaldi 1988. Bukove gozdove, ki se pojavljajo na večjih nadmorskih višinah, uvrščamo v združbo *Fraxino orni-Fagetum sylvaticae*, medtem ko jelševe gozdove, ki jih najdemo po grapah, uvrščamo v novo asociacijo *Polysticho setiferi-Alnetum glutinosae*. Ugotovili smo tudi

sekundarni združbi, in sicer na flišu združbo trokrpega javorja (*Acer monspessulanum*) in maklena (*Acer campestre*) ter na trahičnem substratu združbo drevesaste rese (*Erica arborea*) in jagodičnice (*Arbutus unedo*) – *Erico-Arbutetum unedonis*. Ugotovili smo tudi dva tipa gozdov črnicevja (*Quercus ilex*): *Cyclamino repandi-Quercetum ilicis* na peščenjakih in novo asociacijo *Arbuto unedeonis-Quercetum ilicis ass. nova* na vulkanskih tleh, ki jo lahko obravnavamo kot cenološko in geografsko vikariantno združbo združbe *Erico-Quercetum ilicis*, ki jo najdemo na Siciliji.

Ključne besede: gozdna vegetacija, ICPN, Apeninski polotok, fitocenologija, sintaksonomija.

1. INTRODUCTION

The hilly-mountainous range known as “Comprensorio Tolfetano-Cerite” is the southernmost limit of an ecological and biogeographical area which finds its centre in south-western Umbria and southern-Tuscany. Being an isolated sub-coastal low-mountainous massif this area exhibits some particular litho-stratigraphical and bioclimatical features that give rise to a quite unique potential vegetation pattern. Although the highest peaks of the Tolfa-Ceriti mountains do not exceed 600 m, the entire altitudinal woodland zonation occurring in the central Apennines (from thermophilous holm-oakwoodlands to beech woodlands) can be found as one moves inland from the Thyrrenian coastline. Since ancient times, however, man has significantly influenced the woodland potential vegetational landscape as a result of a variety of activities, from forestry-grazing to mineral mining. The previous vegetational studies concerning the Tolfa-Ceriti mountains (Anzalone 1961a, 1961b; Montelucci 1962; Spada 1975; Scoppola & al. 1990; Scoppola & Caporali 1996, 1998; Pignatti 1998), were restricted to very specific issues and suffered from the lack of a phytosociological overview and of a relevés database regarding the woodland pattern. In the present paper a complete coenological and syntaxonomical analysis of both the evergreen and deciduous woodland communities was carried out and updated to take account of the main recently-published syntaxonomical European revisions on forest vegetation.

2. STUDY AREA

The Tolfa-Ceriti Mountains are a volcanic group in the Latium Anti-Apennines, central Italy (Fig. 1). They are bounded by the Tyrrhenian Sea coast on the West, by the Monti Sabatini on the East, and the Monti Cimini and the Mignone river on

the North (Fig. 1). The Tolfa-Ceriti mountains are formed mostly of trachyte stones from the Eocene and the early Pleistocene, which markedly characterise the landscape of the study area in the form of a complex of acid domes. These volcanic edifices give rise to the rugged morphology which characterises the higher altitude zones of the study area (the highest peak of Tolfa mountains is the Monte della Grazie, 616 m) and which makes them easily distinguishable from the surrounding hilly zones which are formed by older sedimentary deposits of flyschoid origin (Devoto & Lombardi 1977; Contoli & al. 1980; Angelelli

Figure 1: Study area.

Slika 1: Preučevano območje.

& Faramondi 1995; Lombardi 2000). Particularly important are the reservoirs of alunite, a mineral discovered here in the 15th century, and which has been extensively mined since then. According to Blasi (1994), the study area is included in two bioclimatic units: a narrow territorial fringe which runs parallel to the coastal line which belongs to the Mediterranean Region, and a higher altitude zone which belongs to the Transition Mediterranean Region (upper meso-Mediterranean thermotype, upper subhumid- lower humid umbrotype).

3. DATA AND METHODS

Field research was carried out in the period from 2004 to 2005. Altogether 249 phytosociological relevés were made following the standard methods of the Zurich-Montpellier approach (Braun-Blanquet 1964). The row matrix (249 rel. x 330 species) was subjected to multivariate analysis procedures (cluster analysis), using the chord distance algorithm to produce the dissimilarity matrix and the minimum variance in new clusters as agglomeration criterion (package Syntax

2000 program, Podani 2001). The following scale was adopted to transform the Braun-Blanquet values of the matrix into numerical values (van der Maarel 1979): r = 1; + = 2; 1 = 3; 2 = 5; 3 = 7; 4 = 8; 5 = 9. Species nomenclature is according to Conti & al. (2005). The new syntaxa were named according to the International Code of Phytosociological Nomenclature (ICPN, Weber et al. 2000). Species which occur only once were excluded from the phytosociological table and were reported in Appendix 1. Place and date of relevés were listed in Appendix 2.

4. RESULTS AND DISCUSSION

4.1 MULTIVARIATE ANALYSIS

The cluster analysis dendrogram based on quantitative data, transformed through the van der Maarel conversion scale, is shown in Fig. 2. Three main clusters were identified; cluster A, which included the thermophilous communities only, was composed of three sub-clusters: secondary *Erica arborea* and *Arbutus unedo* high shrublands (1), mixed woods of *Quercus ilex* and thermophilous

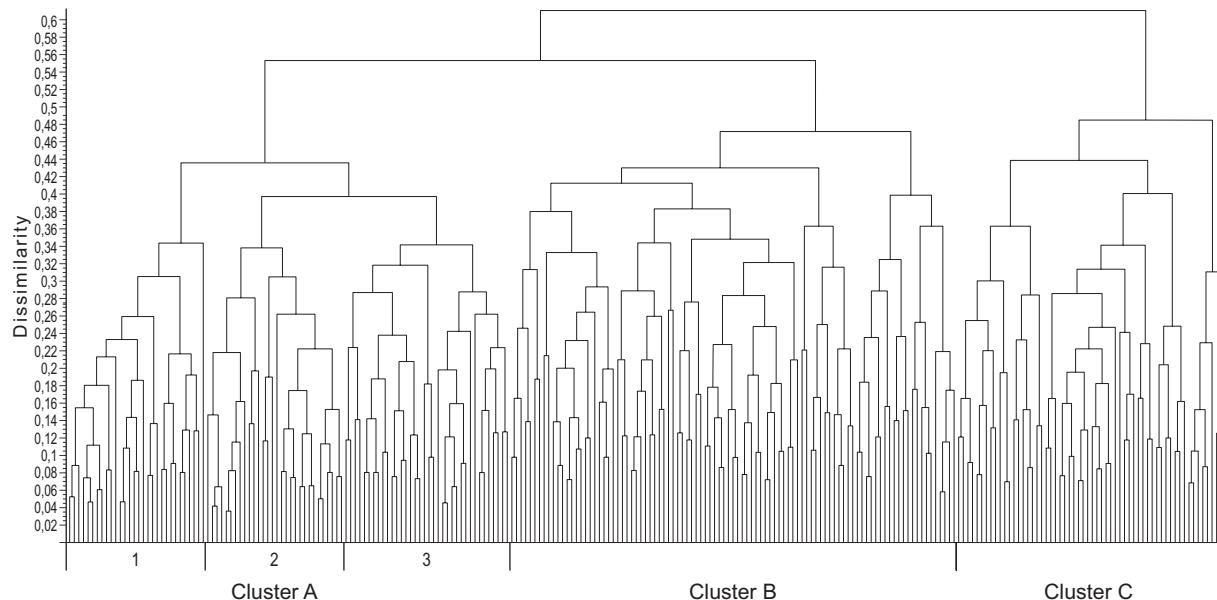

Figure 2: Cluster analysis dendrogram based on quantitative data, transformed through the van der Maarel conversion scale, and computed using the chord distance algorithm to produce the dissimilarity matrix and the minimum variance in new clusters as an agglomeration criterion.

Slika 2: Dendrogram klastrske analize: kvantitativni podatki, pretvorjeni z van der Maarlovo skalo in izračunani z uporabo algoritma tetivne razdalje za izdelavo matrike različnosti in kopiranja na osnovi minimalne varianc.

deciduous tree species developed on the flysch substrates of Tolfa mountains (2), and those developed on the volcanic trachytic substrates of the Ceriti hills (3). In the latter sub-cluster the evergreen *Quercus suber* woodlands and the thermophilous *Quercus cerris* woodlands were also classified. Cluster B included all the mesophilous *Quercus cerris* woodlands developed both on volcanic and flysch substrates, as well as the *Acer monspessulanum* secondary woodlands. Cluster C includes the ravine *Alnus glutinosa* woodlands and the woodlands communities developed at higher altitudes; *Quercus cerris* acidic oligotrophic woods, *Quercus petraea* woods, *Castanea sativa* woods and *Fagus sylvatica* woods. In most of the cases all these woodlands types are relic and are restricted to small areas.

4.2 VEGETATION

Rubio peregrinae-Quercetum cerridis ass. nova hoc loco (Table 1, 2)
(Holotypus rel. 3 in Table 1 hoc loco)

Distribution and structure: Thermophilous *Quercus cerris* woodlands are developed on the marly-calcareous hills, especially on south-western slopes, and are interposed between the sclerophylllic vegetation of the coastal side and the mesophilous *Quercus cerris* woodlands of the inner areas. These woodlands are usually coppiced and are mostly dominated by *Quercus cerris* and in some cases co-dominated by *Quercus pubescens* s.l. In the lower tree-layer the constant presence of *Acer monspessulanum* and *Fraxinus ornus* is found, while the undergrowth is very rich in Mediterranean species (*Osyris alba*, *Pistacia lentiscus*, *Rhamnus alaternus*, *Rosa sempervirens*, *Viburnum tinus*, *Smilax aspera*, *Asparagus acutifolius*, *Rubia peregrina*, *Lonicera implexa* and *Clematis flammula*), which enable these turkey oak woodlands to be distinguished from those occurring in the inner areas and/or at higher altitudes.

Syntaxonomy: These thermophilous *Quercus cerris* woodlands sampled in the Tolfa-Ceriti mountains exhibit strong similarities to those included in the subassociation *Roso-Quercetum pubescantis quercetosum cerridis* proposed by Arrigoni & al. (1997) for some thermophilous oak-woods of central and southern Tuscany (Table 17). However, it is evident that both communities are *Quercus cer-*

ris communities and not *Quercus pubescens* communities mixed with *Quercus cerris*. Moreover, *Roso-Quercetum pubescantis quercetosum cerridis* Arrigoni & al. 1997 is different (physiognomically and coenologically) from the original diagnosis of *Roso-Quercetum pubescantis* provided by Biondi in 1986 and subsequently in Biondi & al. (2002) and Allegrezza & al. (2002). As a consequence the inclusion of our relevés within *Roso-Quercetum pubescantis* was not considered in the present study. Allegrezza & al. (2002) came to the same conclusion and included the subassociation *Roso-Quercetum pubescantis quercetosum cerridis* (sensu Arrigoni & al. 1997) in a *Quercus cerris* forest association, *Lonicero xylostei-Quercetum cerridis* as a new subassociation (*Lonicero-Quercetum cerridis loniceretosum etruscae*). In our opinion the use of the name *Lonicero xylostei-Quercetum cerridis* raises some coenological and nomenclatural problems. From a coenological point of view the association *Lonicero xylostei-Quercetum cerridis* (formerly *Lonicero xylostei-Carpinetum orientalis* Taffetani & Biondi 1995) exhibits a highly unusual floristic combination which is very different from those of the other types of thermophilous *Quercus cerris* woodlands of central Italy. In addition to the abundance of *Carpinus orientalis* there is the simultaneous presence of a species, *Lonicera xylosteum*, which is typical of mesophilous oak-hornbeam woodlands (*Erythronio-Carpinion*) or thermophilous beech woodlands (Ubaldi 1988; Oberdorfer 1994; Di Pietro & Tondi 2005), along with several *Quercetea ilicis* species, such as: *Smilax aspera*, *Rosa sempervirens*, *Viburnum tinus*, *Quercus ilex*. Therefore *Lonicero xylostei-Quercetum cerridis* cannot be considered a widely-distributed community, and must necessarily be restricted to the few zones of the hilly (Adriatic) sector of Marches region where these unusual coenological features were identified (Taffetani & Biondi 1995). Certainly it is not appropriate to include a community such as *Roso-Quercetum quercetosum cerridis*, which was described for the Tyrrhenian side of central Italy and in a geographical context which is external to the distributional range of *Carpinus orientalis*, and what is more in a coenological context in which the character species *Lonicera xylosteum* is absent. From a nomenclatural viewpoint the name *Lonicero xylostei-Quercetum cerridis* is to be considered invalid (Art. 39 ICPN, Weber & al. 2000), in spite of the arguments provided in Biondi & al. (2002). In addition, the new combination of the subass. *Roso-Quercetum pubescantis quercetosum cerridis* Ar-

rigoni 1997 (Arrigoni & al. 1997) in the form of the new subass. *Lonicero xylostei-Quercetum cerridis loniceretosum etruscae* is to be considered *nom. illeg.* (Art. 26 ICPN).

Over the last thirty years many other *Quercus cerris* woodland associations have been proposed for the Tyrrhenian district of central Italy (*Asparago-Quercetum cerridis* Scoppola & Filesi 1995, *Carpino orientalis-Quercetum cerridis* Blasi ex Taffetani & Biondi 1995; *Rubio peregrinae-Quercetum cerridis* (Pignatti & Pignatti 1968) Bas Pedroli in Pignatti 1998) and some of them show similarities with *Quercus cerris* thermophilous woodlands of the Tolfa-Ceriti mountains (Table 17). Unfortunately we cannot classify these communities into any of the existing described syntaxa. *Asparago tenuifolii-Quercetum cerridis* (Scoppola & Filesi 1995) is not suitable owing to the complete absence of *Asparagus tenuifolius* (guide species of the association) and the scarcity of *Echinops ritro* subsp. *siculus*, *Bromus ramosus* and *Malus florentina* (character species in the original diagnosis). *Carpino orientalis-Quercetum cerridis* is to be excluded owing to the absence of *Quercus frainetto* (codominant with *Quercus cerris* in the lectotypus of the association provided in Taffetani & Biondi 1995) and the negligible presence of *Carpinus orientalis* in the entire Tolfa-Ceriti mountains area¹.

The association *Rubio-Quercetum cerridis* deserves a separate treatment. The name *Rubio peregrinae-Quercetum cerridis* was proposed (invalidly, Art. 2, Art. 5) in Pignatti & Pignatti (1968) for describing sub-acidophilous woodlands in southern Tuscany. This association was further recognized by other authors (Stortelder & al. 1986; Bas Pedroli & al. 1988) for some types of *Quercus cerris* woodlands of southern Tuscany, despite the lack of a phytosociological table in the original publication from which to extrapolate a type-relevé. The name *Rubio peregrinae-Quercetum cerridis* was proposed again in Pignatti (1998) together with an appropriate synecological and synchorological diagnosis, a list of the character species and a synoptic table listing the high-frequency species only. On the basis of Pignatti's new coenological

description of *Rubio-Quercetum* together with the wide distribution of the characteristic species it can be deduced that this association has a very extensive distribution area. According to Pignatti (1998) *Rubio-Quercetum* includes the majority of the thermophilous *Quercus cerris* woodlands currently described for the Tyrrhenian district of central Italy (e.g. the associations *Asparago tenuifolii-Quercetum cerridis*, *Coronillo emeri-Quercetum cerridis*, *Carpino orientalis-Quercetum cerridis*, *Erico-Quercetum cerridis* were considered in the form of syntaxonomical synonyms).

Nevertheless, this new version of the association is also to be considered invalid (Art. 5), since in Pignatti (1998) it was reported as *Rubio-Quercetum cerridis* Bas Pedroli 1989, although in the publication of Bas Pedroli & al. (1988) there was neither an indication of the nomenclatural-type of the association nor a phytosociological table from which to extrapolate a type-relevé. These nomenclatural gaps, however, do not nullify the statement that Pignatti's *Rubio-Quercetum cerridis* covers a coenological space for which no other existing validly described syntaxa currently correspond. For this reason, and in order to avoid the proliferation of new names, we think it appropriate to keep the reference to the name *Rubio peregrinae-Quercetum cerridis*, however in the form of a new association (*Rubio peregrinae-Quercetum cerridis* ass. nova hoc loco). The proposal of this new association is necessary not only for purely nomenclatural reasons, but also because, even if it corresponds almost entirely to the ecological diagnosis provided by Pignatti (1998), it is in disagreement with most of the syntaxonomical synonymies he proposed. As a consequence, the type-relevé of the new association is defined ex-novo and hoc loco (rel. 3 Table 1 of the present paper) and is no way related to any of the associations published to date which are considered by other authors as syntaxonomical synonyms of *Rubio-Quercetum cerridis*. In this new form *Rubio-Quercetum cerridis* becomes a sort of "base-association" ("Torso-gesellschaft" sensu Poldini 1988) which includes all those *Quercus cerris* thermophilous woodlands of central and western Italy which are developed on sub-acid and/or flyschoid substrates, and which are markedly influenced by the Mediterranean bioclimate. The following species are included in the characteristic component of this new association: *Rubia peregrina*, *Smilax aspera*, *Asparagus acutifolius*, *Stachys officinalis*, *Melittis melissophyllum* and *Hedera helix*.

¹ The name *Carpinus orientalis-Quercetum cerridis* was described invalidly in Blasi (1984) (Art. 3). The further validation of the name made in Taffetani & Biondi (1995) as *Carpino orientalis-Quercetum cerridis* Blasi ex Taffetani & Biondi 1995 is a *nom. illeg.*, owing to the presence of a prior validly described nomenclatural synonym in the Balkan phytosociological literature (*Carpino orientalis-Quercetum cerridis* Oberd. 1934) (Horvat & al. 1974).

In addition to the typical aspect of the *Rubio-Quercetum cerridis*, a thermophilous subassociation named *Rubio-Quercetum cerridis ericetosum arboreae* subass. nova hoc loco (holotypus Table 2 rel. 4), has been identified in the study area. It consists of relatively open woods which occur mostly on the SW facing slopes of the Ceriti hills where trachitic substrates are to be found, and also less frequently on the driest areas of the Tolfa mountains flysch substrates. The upper tree layer is dominated by *Quercus cerris* with *Quercus ilex* and *Quercus suber* also very frequent. The shrub layer is characterised by the presence of many evergreen sclerophylllic species, mainly *Phillyrea latifolia* and *Quercus ilex* and less frequently *Erica arborea*, *Arbutus unedo*, *Myrtus communis*, *Clematis flammula*, *Asparagus acutifolius*, *Rubia peregrina*, *Smilax aspera*. The thermophilous deciduous tree component is composed of *Fraxinus ornus*, *Quercus pubescens* s.l., *Acer monspessulanum*, and *Sorbus domestica*, while *Ostrya carpinifolia* is more sporadic, being restricted to the bottom of small gorges where moister conditions occur. *Luzula forsteri*, *Melica uniflora*, *Ruscus aculeatus*, *Brachypodium sylvaticum* and *Carex distachya* are the most common species in the herb-layer. The presence of this thermophilous subassociation *Rubio-Quercetum* can be explained by the drying out of soils, in its turn the result of coppicing and extensive grazing, which led to increased competitiveness of the evergreen steno-Mediterranean species. The differential species of *Rubio-Quercetum cerridis ericetosum arboreae* are *Erica arborea*, *Myrtus communis*, *Arbutus unedo*, *Quercus suber* and *Quercus ilex*.

Melico uniflorae-Quercetum cerridis Arrigoni, in Arrigoni, Mazzanti & Ricceri 1990 (Tables 3, 4, 5)

Distribution and structure: The mesophilous *Quercus cerris* woodlands are the most widespread woodland type in the study area, where it occurs on both Flysch and volcanic substrates. These woodlands usually exhibit long-turn coppicing and have a diverse vertical structure. The upper tree-layer is dominated by *Quercus cerris*, and *Acer monspessulanum* and *Fraxinus ornus* are also present. *Acer campestre*, *Sorbus torminalis*, *S. domestica* and *Malus sylvestris* occur in secondary tree layer. The most common shrub species are *Cornus mas*, *Crataegus monogyna*, *C. laevigata*, *Euonymus europaeus*, *Hedera helix*, *Lonicera etrusca* and *Ruscus*

aculeatus. In the herb layer the presence of mesophilous species such as *Melica uniflora*, *Euphorbia amygdaloides*, *Oenanthe pimpinelloides*, *Brachypodium sylvaticum* and *Lathyrus venetus* differentiates these forests from thermophilous forests of *Rubio-Quercetum cerridis*.

Syntaxonomy: In the phytosociological literature of central Italy there are several studies concerning turkey oak woods developed in the ecological conditions described in the previous paragraph (Ubaldi e Speranza 1982; Blasi 1984; Blasi & al. 1993; Arrigoni & al. 1990; Arrigoni 1998; Foggi & al. 2000; Scoppola 1998, Scoppola & Filesi, 1998). Here, the mesophilous *Quercus cerris* woodlands of the Tolfa-Ceriti mountains have been included in the association *Melico uniflorae-Quercetum cerridis* which was first described for southern Tuscany by Arrigoni & al. (1990) and was also recognised in other areas such as the Mount Rufeno Reserve (Scoppola & Filesi 1998) and the Cecina River Basin (Foggi & al. 2000). In addition to the typical aspect of the *Melico-Quercetum* two further types were identified in the study area. On the moister soils of the N-facing footslopes *Melico-Quercetum* woods are characterised by the co-dominance of *Carpinus betulus* in the dominated tree layer and by the abundance of *Fagellalia* species in the undergrowth (*Melico-Quercetum carpinetosum betuli*) (Table 5). On steeper slopes with stony substrates *Ostrya carpinifolia* becomes co-dominant with *Quercus cerris* (*Melico-Quercetum ostryetosum carpinifoliae*) (Table 4).

Fraxino oxycarpa-Quercetum cerridis (Scoppola & Filesi 1995) Foggi, Selvi & Viciani in Foggi, Selvi, Viciani, Bettini & Gabellini 2000 (Table 6)

Distribution and structure: This woodland type is developed on the marly-calcareous substrates of the plain whose ground water table occurs very close to the surface. These woodlands are in spatial contact with *Melico-Quercetum cerridis* and serial contacts with the secondary thick woods of *Acer monspessulanum* and *Acer campestre*. The dominant layer is composed of *Quercus cerris* and *Fraxinus angustifolia* subsp. *oxycarpa*, whereas the dominated tree-layer mainly of *Fraxinus ornus* and *Acer monspessulanum* together with *Acer campestre*, *Ulmus minor* and *Malus sylvestris*. The herb layer is not substantially different from that of *Melico-Quercetum cerridis*.

Syntaxonomy: In the Tolfa-Ceriti mountains area *Fraxinus angustifolia* subsp. *oxyacarpa* does not occur in riparian environments, as instead is the case for the rest of the Latium region and indeed most of the peninsular Italy (Pedrotti & Gafta 1996; Blasi & al. 2002). Scoppola & Filesi (1995) described the subassociation *Asparago tenuifolii-Quercetum cerridis fraxinetosum oxyacarpae* for the Mount Rufeno Natural Reserve. This subassociation was subsequently identified in south-western Tuscany (Foggi & al. 2000) and raised to the rank of association with the name *Fraxino oxyacarpace-Quercetum cerridis*. The rank of association has been adopted in the present paper too.

Acer monspessulanum and *Acer campestre* community (Table 7)

Distribution and structure: These are secondary woods which mainly occur on flysch substrates on gentle slopes. *Acer monspessulanum*, and to lesser extent *Acer campestre*, are the dominant species of tree layer and are accompanied by *Fraxinus angustifolia* subsp. *oxyacarpa*, *F. ornus*, *Quercus cerris*, *Q. pubescens* s.l. and *Malus sylvestris*. These woodlands are subjected to extensive wild grazing and this is testified by the high cover of edge species such as *Stellaria media* and *Geranium purpureum*. These *Acer*-dominant woods are developed in ecological conditions which are similar to those of *Fraxino oxyacarpace-Quercetum cerridis*, so it can be assumed that these woodlands are the successional stage which precedes *Fraxino-Quercetum* in the dynamical series. According to Portoghesi & al. (2008) the prevalence of *Acer monspessulanum* in these areas must be viewed as the consequence of two factors: on the one hand, frequent coppicing and wild grazing, causing intensive soil erosion and accentuating the effects of summer drought; on the other hand a high content of calcium carbonate in the soil, derived from the sedimentary lithotypes (Tolfa flysch) occurring in the southern part of the Tolfa Mountains. So it seems plausible that the progressive drying out of the soil has disadvantaged *Quercus cerris* and especially *Fraxinus angustifolia* subsp. *oxyacarpa* which is more sensitive to ground water level fluctuations.

This study is probably the first carried out in peninsular Italy in which *Acer monspessulanum* is not only a forest species involved in reforestation processes of *Quercus cerris* potential forests, but is also the dominant species in various secondary

forest types. The dynamical role of *Acer monspessulanum* on the flyschoid substrates of the Tolfa mountain (coastal northern Latium) is very similar to that of *Carpinus orientalis* on the limestone substrates of the Ausoni-Aurunci mountains (coastal southern Latium) where this species is dynamically linked to *Quercus pubescens* thermophilous woodlands (Blasi & Di Pietro 1998; Blasi & al. 2001).

Syntaxonomy: As *Acer monspessulanum* has a wide ecological niche, it is hard to classify its wood stands within known syntaxa. The nearest example occurring in the national phytosociological literature is probably that of *Cercidi-Aceretum monspessulanii* described in Pignatti (1998). This reference, however, is not proposable for Tolfa communities since it is a sort of tall-shrub community which is characterised by the co-dominance of *Carpinus orientalis* in the upper tree layer and by the abundance of *Cercis siliquastrum*. Therefore, for the moment, we would provisionally classify the *Acer*-dominant communities from the study area as “*Acer monspessulanum* and *Acer campestre* community”, stressing however that further phytosociological research is needed.

Cephalanthero longifoliae-Quercetum cerridis Scoppola & Filesi 1998 (Table 8)

Distribution and structure: This woodland type occurs exclusively on trachytic substrates on the western slopes of M. Urbano and M. Madonna, at altitudes around 600 m. These are typical impoverished acidic woodlands developed on relatively shallow soils which are dominated by *Quercus cerris*, with minor occurrence of *Fagus sylvatica*, *Quercus petraea*, *Castanea sativa* and *Fraxinus ornus*. In the lower tree-layer *Ilex aquifolium* and *Sorbus torminalis* were found, while in the herb-layer *Cephalanthera longifolia*, *Hieracium racemosum*, *Solidago virgaurea* and *Cruciata glabra* were the most common species.

Syntaxonomy: Three relevés are certainly too few to provide a definite syntaxonomical classification. Nevertheless, classification into the association *Cephalanthero longifoliae-Quercetum cerridis* (Scoppola & Filesi 1998), which was described for the acidic sandstones of Mount Rufeno, appears the most suitable.

Carici olbiensis-Quercetum petraeae ass. nova hoc loco (Table 9)
(Holotypus relege 7 in Table 9 hoc loco)

Distribution and structure: A discontinuous belt of *Quercus petraea* woodlands was recognizable within the north-western sector of the Tolfa mountains at altitudes between 450 and 600 m. The Sessile oak woodlands were normally developed on relatively deep soils on gentle slopes (10–15°), where they came into spatial contact with beech woodlands at higher altitudes and mesophilous turkey oak woodlands at lower altitudes. *Quercus petraea* woodlands are normally characterised by a very dense canopy which prevents development of the shrub-layer, while the herb-layer is always well developed. In addition to *Quercus petraea* (dominant) the upper tree-layer was composed of *Fagus sylvatica*, *Carpinus betulus* and *Ostrya carpinifolia*. The lower tree-layer was mainly characterised by *Ilex aquifolium*, *Mespilus germanica* and *Acer opalus* subsp. *obtusatum*. *Hedera helix* and *Ruscus aculeatus* were the most frequent species of the herb layer where *Carex olbiensis*, *Daphne laureola*, *Cruciata glabra*, *Solidago virgaurea*, *Festuca heterophylla* and *Melica uniflora* also occur.

Syntaxonomy: According to Pignatti (1998) *Quercus petraea* woodlands of the Tolfa mountains are included in two associations: *Hieracium racemosi-Quercetum petraeae* Pedrotti & al. 1982 and *Ilici-Quercetum petraeae* Brullo 1983 which were both classified into the alliance *Quercion robori-petraeae* and in the order *Quercetalia robori-petraeae*. This syntaxonomical interpretation, however, gives rise to several doubts. In fact, it is highly unlikely that two different *Quercus petraea* associations could find adequate ecological space in a relatively small area, where the climate is mainly meso-Mediterranean and the typically scattered potential areas for *Quercus petraea* are restricted to a narrow belt between *Quercus cerris* and *Fagus sylvatica* forests. Furthermore, it was found (Table 19) that the majority of the characteristic species of both *Hieracio racemosi-Quercetum petraeae* and its higher syntaxonomical ranks are absent in the Tolfa-Ceriti mountains. This absence is due to lithological and ecological dissimilarities which become strikingly evident when the alluvial Umbrian plain of Gubbio (locus classicus of *Hieracio-Quercetum petraeae*) is compared to the Tolfa mountain slopes.

In contrast, the ecological and biogeographical context which characterises *Ilici-Quercetum petraeae* is completely different. This association was described for the montane belt of the Madonie mountains in Sicily and consequently the majority of its diagnostic species (*Geranium versicolor*, *Doronicum orientale* etc.) are restricted to southern Italy (Table 19). In a recent syntaxonomical revision (Ubaldi 2003) *Ilici-Quercetum petraeae* was lowered to the rank of a subassociation of *Anemono-Fagetum* of which it was considered as a previous secondary syndynamical stage. In our opinion this hypothesis is not correct for the Tolfa-Ceriti mountains area where the sessile-oak woodlands are a potential vegetation type and are physiognomically and coenologically distinguishable from the surrounding woodlands. As a consequence they can not be defined using the rank of "variant" or "subassociation". Instead they have to be considered as a sort of residual potential woodland which at present are "trapped" (due to both natural and anthropic causes) between *Quercus cerris* and *Fagus sylvatica* potential areas. Nevertheless *Quercus petraea* woodlands maintain a typical core area which is floristically and coenologically autonomous and, as a consequence, perfectly distinguishable in terms of association. As far as syntaxonomy is concerned, the high number of Mediterranean species occurring alongside several *Fagetales* species is unusual for the woodland syntaxonomical context of central Italy. Hence a new association named *Carici olbiensis-Quercetum petraeae* ass. nova is here proposed. The character species of this association are *Carex olbiensis*, *Ilex aquifolium*, *Hedera helix*, *Mespilus germanica* and *Rubia peregrina*. This new syntaxonomical reference could be further extended to the adjacent *Quercus petraea* woodlands of the Cimini volcanic mountains (Blasi & al. 1990) and to the hilly area of south-western Umbria. In central and southern Tuscany this association is vicaried by *Frangulo alni-Quercetum petraeae*, which shows similar structural and physiognomical features. This association, however, has a floristic component which includes diagnostic species that find their southernmost limit in southern Tuscany (*Physospermum cornubiense*, *Teucrium scorodonia*, *Cytisus nigricans*), or which simply do not occur in Tolfa-Ceriti sessile-oak forests (*Frangula alnus*, *Anemone nemorosa*, *Molinia caerulea* subsp. *arundinacea*, *Erica scoparia*, *Genista pilosa*, *G. germanica* etc.).

Castanea sativa woodlands (Table 10)

Distribution and Structure: The Tolfa mountains chestnut forests are floristically poor as is typical of such plantations. The upper tree-layer is often monospecific while the shrub and herb layers show very low cover values. The co-existence of companion species such as *Fagus sylvatica*, *Quercus petraea*, *Fraxinus ornus*, *Ilex aquifolium*, *Quercus ilex*, *Arbutus unedo*, however, reflects the peculiar coenological features of Tolfa-Ceriti mountains.

Syntaxonomy: The chestnut woods of central Italy can be considered the result of human exploitation and substitution of mixed mesophilous and acidophilous *Quercus cerris* and *Quercus petraea* woodlands, in which it is likely that *Castanea sativa* originally played the role of companion species. Arrigoni & Viciani (2001) identify five *Castanea sativa* forest types occurring in Tuscany including mixed deciduous woodlands, coppiced and monodominant chestnut woods exploited for timber and/or for fruit. In our opinion it is not methodologically correct to assign a syntaxonomical rank to a silvicultural plantation. However, given the wide diffusion of chestnuts woods on the Tolfa mountains and adjacent areas it seems interesting to speculate what the natural forest types which were replaced by chestnut groves were most likely to have been. In fact some authors (Spada 1975; Contoli & al. 1980) hypothesised a previous *Fagus sylvatica* stage. The abundance of *Fagus sylvatica* in the shrub-layer of the chestnut woods would suggest a possible natural dominant role of this species. The presence of *Castanea sativa* in the relevés of *Quercus cerris* and *Quercus petraea* woods (Table 3, 4, 9), however, suggests that these forest types, too, provided portions of their potential area for chestnut plantations.

Remarks on *Crataego laevigatae-Quercion cerridis* Arrigoni 1997

According to the most recent revision of *Quercetalia pubescenti-petraeae* (Blasi & al. 2004) all the associations described in this paper are included in the alliance *Teucrio-Quercion cerridis* Ubaldi 1988 and in the suballiance *Teucrio-Quercenion cerridis* Blasi, Di Pietro & Filesi 2004. According to the ICPN, this name is no longer valid.

The name *Teucrio siculi-Quercion cerridis* was proposed invalidly by Ubaldi (1988) as a new

alliance of the order *Lathyro nigri-Quercetalia cerridis*. Some years later (1995) the same author did not recognize this alliance and included *Teucrio-Quercion* in the alliance *Lonicero etruscae-Quercion pubescensis* Arrigoni & Foggi in Arrigoni, Mazzanti & Ricceri 1990, as a syntaxonomical synonym. However, according to Blasi & al. (2004), the name *Lonicero-Quercion pubescensis* is to be considered invalid (Art. 5) because this alliance overlaps with *Carpinion orientalis* Horvat 1958. In 2003, Ubaldi proposed the alliance *Teucrio siculi-Quercion cerridis* once again in the form “*Teucrio siculi-Quercion cerridis* Ubaldi 1998 em. Scoppola & Filesi 1995” all. nov. From a strictly nomenclatural viewpoint the new name *Teucrio-Quercion* had several problems. First, the reference to the year of the publication of *Teucrio-Quercion* (1998 vs. 1988) was wrong. Second, the new alliance *Teucrio-Quercion* Ubaldi included the alliance *Lathyro montani-Quercion cerridis* Scoppola & Filesi 1995. Although the latter was described invalidly in 1995, it was validated later in Scoppola & Filesi (1998). As a consequence the name *Teucrio siculi-Quercion cerridis* Ubaldi 2003 is to be considered a superfluous name (art. 29c). In addition, the alliance did not coincide syntaxonomically with the *Teucrio-Quercion* Ubaldi 1988 nom. inval. because a significant part of the coenological and geographical range of the *Teucrio-Quercion* Ubaldi 1988 is included in other alliances, namely *Quercion frainetto* Horvat 1954 and *Mespilo-Carpinion betuli* Ubaldi 2003.

Thanks to the appropriate choice of the nomenclatural binomial and to the shared floristic, coenological and synchorological diagnosis of the first version of the alliance *Teucrio siculi-Quercion cerridis* Ubaldi 1988, the name has been widely used by the majority of Italian phytosociologists over the last twenty years. As a consequence Blasi & al. (2004) proposed this name to be maintained as nomen conservandum. This proposal was not allowed by ICPN as *Teucrio siculi-Quercion cerridis* Ubaldi 1988 is an invalid name.

Given the nomenclatural vicissitudes mentioned above, it is understandable that a certain degree of confusion has arisen around the name *Teucrio-Quercion cerridis* in coenological, chorological and nomenclatural terms. As a consequence a new proposal of a nomenclaturally valid version of *Teucrio-Quercion* as “nomen conservandum” does not seem to make sense at present.

For this reason in the place of *Teucrio-Quercion* it is necessary to apply the prior published valid

name. This name is *Crataego laevigatae-Quercion cerridis* Arrigoni 1997. According to its original diagnosis, however, this alliance only partially coincides with *Teucrio-Quercion cerridis* as it is presently used. In fact *Crataego laevigatae-Quercion cerridis* includes only the mesophilous mixed *Quercus cerris* woodlands. The nomenclatural type (*Melico-Quercetum cerridis* Arrigoni in Arrigoni, Mazzanti & Ricceri 1990) and the year of effective publication (1997) confirm that *Crataego laevigatae-Quercion cerridis* has all the necessary nomenclatural qualifications to be considered the valid prior name to be used in place of *Teucrio-Quercion*. Nevertheless both its synchorological range and its character specific component proposed in the original publication of *Crataego laevigatae-Quercion cerridis* are significantly reduced when compared to those of *Teucrio-Quercion cerridis* (e.g. the oak woodlands of southern Italy are completely excluded). For this reason, we have decided to maintain the name *Crataego laevigatae-Quercion cerridis* as the name of the alliance, and to re-propose the division into two “geographical” suballiances as originally made in Blasi & al. (2004): a “northern” *Teucrio-Quercenion cerridis* Blasi, Di Pietro & Filesi 2004 and a “southern” *Ptilostemo-Quercenion cerridis* Bonin & Gamisans 1977. Since the name *Teucrio siculi-Quercenion cerridis* Blasi, Di Pietro & Filesi 2004, is to be considered invalid due to the invalidity status of the alliance *Teucrio siculi-Quercion cerridis*, it is substituted here with the new suballiance *Crataego laevigatae-Quercenion cerridis* Blasi, Di Pietro & Filesi suball. nov. hoc loco. The nomenclatural type of this new suballiance is the same as that of the alliance (*Melico uniflorae-Quercetum cerridis* Arrigoni in Arrigoni, Mazzanti & Ricceri 1990), while its specific character, transgressive and differential species are those already proposed in Blasi, Di Pietro & Filesi (2004) for the invalid version of the suballiance *Teucrio siculi-Quercenion cerridis*. The diagnosis, coenological and synchorological features, as well as character species of the suballiance *Ptilostemo stricti-Quercenion cerridis* remain those which were proposed in Blasi & al. (2004).

Fraxino orni-Fagetum sylvaticae Ubaldi 1995 (Table 11)

Distribution and Structure: The beech woods of the Tolfa mountains are restricted to the N-facing slopes of the upper part of the massif at alti-

tudes ranging between 500 and 600 m. These are old coppices which started to be converted into high-forest stands 50 years ago. *Fagus sylvatica* is the dominant species of a high-cover woodland type having an upper tree-layer co-dominated by *Quercus petraea*, *Carpinus betulus*, *Castanea sativa* and more sporadically by *Ostrya carpinifolia* and *Quercus cerris*. The lower tree-layer is almost completely absent while the shrub-layer is composed of saplings of *Fagus sylvatica*, *Ilex aquifolium*, and scattered individuals of *Mespilus germanica*, *Fraxinus ornus*, *Quercus ilex* and *Acer pseudoplatanus*. The herb layer exhibits a relatively high specific diversity and cover degree (generally exceeding 60 %). Species with high cover values are *Hedera helix* and *Ruscus aculeatus* while *Melica uniflora*, *Festuca heterophylla*, *Pteridium aquilinum*, *Daphne laureola*, *Tamus communis* are very frequent. The occurrence of *Galium rotundifolium* subsp. *rotundifolium* is very interesting because in the central and southern Apennines it is usually restricted to the microthermic beech woodlands of the upper montane belt.

Syntaxonomy: According to several authors (Felioli & Lagonegro 1982; Blasi 1992; Pignatti 1994; Scoppola & Caporali 1996; Fascetti & al. 1996; Scoppola & al. 1993; Scoppola & Caporali 1998) the Tolfa beechwoods are to be included in the association *Anemono-Fagetum* (Gentile 1969) Brullo 1983 which corresponds to the well-known *Aquifolio-Fagetum* sensu Gentile 1969 (*nom. illeg.*). This syntaxonomical diagnosis was mainly due to the frequency of *Ilex aquifolium* in the shrub layer and to the presence of many thermophilous species in the undergrowth. Ubaldi (1995) disagreed with this interpretation and defined a new association, *Fraxino orni-Fagetum sylvaticae*, on the basis of a phytosociological table published by Anzalone (1961a) and composed exclusively of relevés performed in Tolfa beechwoods. *Anemono-Fagetum* is strictly linked to the southern Apennine area due to the presence of species which do not occur in central Italy such as *Geranium versicolor*, *Doronicum orientale*, *Luzula sicula*, *Festuca exaltata* etc. (Gentile 1970; Di Pietro & al. 2004). As a consequence in the present paper too, the Tolfa beech woodlands were included in *Fraxino orni-Fagetum sylvaticae*². As far as the higher syntaxonomical

² In Ubaldi 2003 the association *Fraxino orni-Fagetum* Ubaldi 2005 was considered a syntaxonomical synonym of *Aristolochio-Fagetum* Ubaldi 1987. The name *Aristolochio-*

ranks are concerned this association was (provisionally) included in the *Geranio versicoloris-Fagion* even if this alliance has a southern Apennines centre of distribution which makes its presence in central Italy doubtful. The occurrence in the Tolfa beechwoods of *Anemone apennina*, *Lathyrus venetus*, *Allium pendulinum* and *Cyclamen hederifolium* (which were considered as character species in the original proposal of *Geranio-Fagion*) partially justifies this choice (some authors, e.g. Biondi & al. 2002, however, have recently made reference to it regarding the beechwoods of other central Apennine zones). However there are no doubts about the ranks of order and class which are *Fagetalia* and *Querco-Fagetea*, respectively.

Polysticho setiferi-Alnetum glutinosae ass. nova hoc loco

(Holotypus relevé 1 in Table 12 hoc loco)

Distribution and Structure: These are typical ravine woodlands which are developed on the slopes and at the bottom of the small gorges which characterise the inner zones of the study area. The upper tree-layer is dominated by *Alnus glutinosa* while in the lower tree-layer *Ilex aquifolium*, *Fagus sylvatica* and *Quercus cerris* occur. The herb layer is composed of two components which are easily distinguishable on a physiognomical-spatial scale: a dense carpet of ferns (*Osmunda regalis*, *Athyrium filix-foemina* and *Blechnum spicant*) which occur along the banks of the stream at the bottom of the gorge, and a *Hedera helix*-*Ruscus aculeatus* carpet which provides more or less con-

Fagetum was proposed invalidly in Ubaldi et al. (1990) (art. 3, 5) and subsequently validated in Ubaldi (1995) choosing a type-relevée in the table of beech woodlands relevés published in Anzalone (1961). Amongst the species belonging to the genus *Aristolochia* only the species *Aristolochia longa* var. *pallida* was reported in Table 1 published in Anzalone, 1961. According to Fiori (1923) and Nardi (1984) this variety is to be ascribed to the binomy *Aristolochia pallida*. As a consequence, on the basis of ICPN (Weber & al. 2000) the complete name of the association in Ubaldi, 1995 should be: *Aristolochio pallidae-Fagetum sylvaticae* Ubaldi et al., 1990 ex Ubaldi 1995. According to Conti & al. (2005) the taxon *Aristolochia pallida* is absent from Latium region where it is vicaried by *Aristolochia lutea*. For this reason the name *Aristolochio pallidae-Fagetum sylvaticae* has to be considered as not validly published at the moment, at least until it is proposed in its correct form, *Aristolochio luteae-Fagetum sylvaticae* (art. 43).

tinuous cover of the gorge's steep slopes (30°–45° in the header data of Table 12).

Syntaxonomy: The *Alnus glutinosa* ravine communities of the Tolfa mountains exhibit a slight similarity with the association *Circaeо lutetianae-Alnetum glutinosae* which was described for an adjacent area in Blasi & Frondoni (1996). This association, however, mainly described flooded riparian woodlands developed on the plain, where the substrates were normally not volcanic. Furthermore the name *Circaeо lutetianae-Alnetum glutinosae* is illegitimate (art 31 ICPN) since it had already been used in Fukarek (1979) for the riparian vegetation of Bosnia and Herzegovina. For this reason we propose the new association *Polysticho setiferi-Alnetum glutinosae* ass. nova hoc loco for the ravine woodlands of the Tolfa mountains. This association is typically developed on volcanic substrates. The following characteristic species were selected: *Polystichum setiferum*, *Blechnum spicant*, *Hypericum androsaemum* and *Ilex aquifolium*. Table 12 also includes two relevés (7 and 8) in which the undergrowth is comparable to that of a typical *Alnus* ravine woodland but from which *Alnus glutinosa* is completely missing. *Polysticho-Alnetum glutinosae* could be considered the southern and thermophilous vicariant of the association *Carici pallescenti-Alnetum glutinosae* described by Landi & Angiolini (2008) for various areas of Tuscany. However no sharp geographical or ecological boundaries occur between these two associations. In fact it is not uncommon to find intermediate coenological situations, as we found performing relevés in the thermophilous *Alnus glutinosa* communities of the torrential riverbeds surrounding the area of S. Lorenzo a Merse in central Tuscany (Table 12, relevés 9–10–11). As far as the higher syntaxonomical ranks are concerned the situation is rather complex. It is known that *Alnus glutinosa* ravine woodlands with *Athyrium filix-foemina*, *Blechnum spicant*, *Polystichum setiferum*, *Carex remota* (etc.) occur both in Croatia and Bosnia and Herzegovina (Fukarek 1979; Barudanović 2003; Barudanović & Redžić 2006). At the same time typical thermophilous Mediterranean *Alnus glutinosa-Osmunda regalis* communities are also very frequent in Spain (Rivas-Martínez & al. 2002) and Algeria (Meddour & Laribi 1999).

In our opinion, on the basis of its floristic and bioclimatic features, the new association *Polysticho-Alnetum glutinose* should be included in the

suballiance *Hyperico hircini-Alnenion glutinosae*, and in the submediterranean-atlantic alliance *Osmundo-Alnion*. The inclusion in *Osmundo-Alnion*, however, is to be considered as provisional, since at present this alliance is characterised almost entirely by species having a western-Iberian distribution and, as a consequence, only marginally eligible as a reference for the submediterranean communities of peninsular Italy (Rivas-Martínez & al., 2002; Bardat & al. 2004.). For this reason a new syntaxonomical and synchorological revision of *Osmundo-Alnion* that also includes Peninsular Italy and western Balkans communities is needed.

Cyclamino repandi-Quercetum ilicis Riv.-Mart., Cantò, Fernández-González, Sánchez-Mata 1995 (Table 13)

Cyclamino repandi-Quercetum ilicis querchetosum cerridis subass. nova hoc loco
(Holotypus relevé 14 in Table 13 hoc loco)

Distribution and Structure: This woodland type is found in the coastal area extending from Civitavecchia to Santa Severa and it is restricted to the flyschoid or marly-calcareous substrates occurring on gentle slopes. It is characterised by a single tree-layer where *Quercus ilex* is a dominant tree species and several deciduous species such as *Quercus pubescens* s.l., *Quercus cerris*, *Fraxinus ornus* and *Acer monspessulanum* may also occur. *Phillyrea latifolia*, *Pistacia lentiscus*, *Smilax aspera*, *Rubia peregrina*, *Asparagus acutifolius* and *Osiris alba* are the most frequent species in the shrub layer, while the poor-in-species herb layer is composed of *Tamus communis*, *Cyclamen repandum*, *C. hederifolium*, *Carex hallerana* and *Arisarum vulgare*.

Syntaxonomy: Because of the presence of a strong deciduous woody component the syntaxonomical diagnosis of the holm oak woods on flyschoid substrates of the Tolfa area is rather complex. On the basis of Biondi & al. (2003), the abundance of species such as *Quercus pubescens* s.l., *Fraxinus ornus*, *Acer monspessulanum* and an undergrowth characterised by many ingressive elements from *Rhamno-Prunetea* and *Querco-Fagetea* would suggest the inclusion of the relevés in the association *Cyclamino hederifolii-Quercetum ilicis* (of which more or less the entire characteristic component was found). The scarce presence of Illyrian-Balkan species, however, makes this

reference unsuitable (especially because in its original diagnosis *Cyclamino hederifolii-Quercetum ilicis* was considered a geographical vicariant of *Fraxino ornii-Quercetum ilicis*). On the other hand, the wide occurrence of *Cyclamen repandum* and the location in the north-western coastal sector of the Latium region made us lean towards *Cyclamino repandi-Quercetum ilicis*. According to Rivas-Martínez & al. (1995) and Biondi & al. (2003) this association would take the place of *Viburno-Quercetum ilicis pistacetosum* which was proposed by De Dominicis & al. (1988) for the compact limestone substrates of the Punta Ala promontory in southern Tuscany. For this association the new subassociation *Cyclamino repandi-Quercetum ilicis querchetosum cerridis* was recognised for some *Quercus ilex* stands characterised by the constant presence of *Quercus cerris* in the upper tree-layer, and of slightly mesophilous species such as *Brachypodium sylvaticum*, *Viola alba* subsp. *dehnhardtii*, and *Anemone apennina* in the herb layer.

Arbuto unedonis-Quercetum ilicis ass. nova hoc loco

(Holotypus relevé 7 in Table 14 hoc loco)

Distribution and Structure: These holm-oak woodlands occur exclusively on the trachytic volcanic substrate of the Ceriti mountains where they occupy both steep and gentle slopes. The upper tree-layer is dominated by *Quercus ilex*, and *Quercus cerris* is also well represented, whereas the lower tree-layer is composed completely of *Quercus ilex*. The shrub-layer is mainly composed of *Arbutus unedo*, *Erica arborea* and other species of the evergreen sclerophylllic shrublands.

Syntaxonomy: The abundance of *Erica arborea* and *Arbutus unedo* in the shrub-layer, together with the presence of the *Erico-Arbutetum* as the main woodland regressive successional stage, suggests a possible classification within the association *Erico-Quercetum ilicis* which was described for the island of Pantelleria to the south of Sicily. In fact many other holm oak woodlands of Sicily and southern Italy have already been classified in this association (Brullo & Marcenò 1984; Brullo & al. 2001; Biondi & al. 2003) on the basis of the simultaneous presence of *Erica* and *Arbutus* in their undergrowth. Simply by observing the *locus classicus* of *Erico-Quercetum ilicis* and its original phytosociological table, it is imme-

diately evident that this community is a sort of thermo-Mediterranean tall-maquis, dominated by *Quercus ilex* and by other *Pistacio-Rhamnetalia* species to which extremely xerothermic species (*Chamerops humilis*, *Euphorbia dendroides* etc.) are commonly associated (Table 18). In our opinion these peculiar coenological features restrict the distribution of *Erico-Quercetum ilicis* to Sicily and immediately surrounding areas. Certainly these thermo-xeric bioclimatic conditions are not to be found along most of the Tyrrhenian side of the Italian Peninsula where thermo-Mediterranean thermotypes are completely absent or restricted to coastal cliffs (Blasi & Michetti 2003). Still in Sicily, on acid substrates at higher altitudes *Erico-Quercetum ilicis* becomes substituted by *Teucrio siculi-Quercetum ilicis*, which is a sub-montane and lower-montane evergreen wood rich in *Querco-Fagetea* species. Despite its mesophilous characteristics *Teucrio siculi-Quercetum ilicis* is to be considered as restricted to Sicily and southern Italy due to the presence of species, *Quercus congesta*, *Silene sicula*, *Doronicum orientale* (etc), whose distributional ranges do not extend beyond this area.

After close examination of the wide phytosociological literature on the syntaxonomy of holm oak forests it is our opinion that there is still no acidophilous *Quercus ilex* association which appropriately describes those woods which behave as bioclimatic and/or biogeographic vicariants of the Sicilian *Erico-Quercetum ilicis* and *Teucrio-Quercetum ilicis*. For this reason we here propose a new association, named *Arbuto unedo-Quercetum ilicis*, which can be used to classify all those acidophilous holm-oak woodlands of the Tyrrhenian sector of peninsular Italy which thrive in sub-mediterranean bioclimatic conditions and which are characterised by a significant deciduous component. This new association is characterised by an abundance of *Erica arborea* and *Arbutus unedo*, while its differential floristic component is made up of *Quercus cerris*, *Acer monspessulanum*, *Fraxinus ornus*.

We here propose classifying both *Cyclamino repandi-Quercetum ilicis* and *Arbuto unedo-Quercetum ilicis* into the alliance *Quercion ilicis*. In fact, other options would have been to include both associations in the recently described alliance *Fraxino orni-Quercion ilicis* (sensu Biondi & al. 2003) or to include in this latter alliance only the association *Cyclamino repandi-Quercetum*, leaving the association *Arbuto-Quercetum ilicis* in *Erico-*

Quercion ilicis (sensu Brullo & al. 1977). However, in our opinion neither of the alliances *Fraxino orni-Quercion ilicis* and *Erico-Quercion ilicis* displays a sufficient floristic autonomy to be substantially distinguished from the older alliance *Quercion ilicis*. According to Biondi & al. (2003) the distribution area of *Quercion ilicis* (sensu Braun-Blanquet) was restricted to the Iberian Peninsula whereas the *Quercus ilex* forests of the entire Italian peninsula (Sicily and Sardinia included) and of the Dinarids have to be ascribed to the amphiadriatic alliance *Fraxino orni-Quercion ilicis*. Obviously this paper is not the suitable place for a revision of the syntaxonomy of *Quercus ilex* woodlands in southern Europe. Nevertheless there are various factors that suggest to us that Tolfa-Ceriti *Quercus ilex* woodlands should be included in *Quercion ilicis* rather than in *Fraxino orni-Quercion ilicis*. First, the locus classicus of *Quercion ilicis* is in the Catalunian-Provincial district, and here *Quercus ilex* woodlands exhibit a clear "eastern" biogeographical character making them very different from those of the rest of the Iberian peninsula, where *Quercus ilex* is almost completely substituted by *Quercus rotundifolia* (Rivas-Martínez 1975; Rivas-Martínez & al. 2002). Second, Provincial *Quercus ilex* woodlands (which are often in spatial contact with *Ostrya carpinifolia* and *Fraxinus ornus* woodlands) share several floristic, coenological and biogeographical similarities with the holm-oak woods of the Tyrrhenian district of the Italian Peninsula, especially with those of Liguria, Tuscany and northern Latium. Third, due to the fact that they mostly occur on volcanic or flyschoid substrates, Tolfa-Ceriti *Quercus ilex* woodlands are extremely impoverished in those SE-European species which should play the role of "differential" species in the *Fraxino orni-Quercion ilicis* alliance and which are usually linked to limestone substrates.

Quercus suber community (Table 15)

Distribution and Structure: Very limited stands of *Quercus suber* forests were identified between 450 and 500 m on volcanic substrates on gentle south-facing slopes. These are mixed evergreen/deciduous communities where *Quercus suber* (slightly dominant) is accompanied by *Quercus cerris*, *Quercus ilex* and *Castanea sativa*. The herb-layer in which thermophilous species such as *Smilax aspera*, *Asparagus acutifolius*, *Arbutus unedo*, *Erica*

arborea, *Lonicera implexa* are mixed together with mesophilous ones such as *Melica uniflora*, *Viola reichenbachiana*, *Brachypodium sylvaticum* (etc.) is highly unusual.

There is no general agreement on whether *Quercus suber* woodlands are native to the Tolfa-Ceriti mountains. Some authors consider these woods to be ancient plantations whereas others think that they are merely the remains of widely distributed *Quercus suber* forests which underwent a regression due to climatic and anthropogenic pressure.

Syntaxonomy: The few available relevés do not allow a classification into the rank of the association, although a slight similarity with the association *Cytiso-Quercetum suberis* sensu Testi & Lucatini (1994) was recognised.

Erico arboreae-Arbutetum unedonis Allier & Lacoste ex Foggi in Foggi & Grigioni 1999. (Table 16)

Distribution and Structure: *Erica-Arbutus* stands are secondary successional stages which are developed exclusively on the acid volcanic soils of the Tolfa-Ceriti mountains. *Erica arborea* and *Arbutus unedo*, form a very intricate structure together with other shrub species such as *Quercus ilex*, *Phillyrea latifolia* and *Crataegus monogyna*. The herb-layer is poor-in-species and mainly composed of *Rubia peregrina* and *Cyclamen repandum*. *Erica-Arbutus* stands are dynamically related to various types of pre-existing woodlands which were over-exploited for timber or which were subjected to frequent fire. Here and there isolated old individuals of *Quercus cerris*, *Q. petraea* and *Q. ilex* break through the compact *Erica-Arbutus* canopy, indicating the potential vegetation type which would be capable of replacing the tall-maquis phase. In spite of their typically Mediterranean character, the majority of *Erica-Arbutus* stands are dynamically linked to mesophilous deciduous forests, in particular *Carici-Quercetum petraeae* or *Melico-Quercetum cerridis*.

Syntaxonomy: These pre-forestal communities are included in the association *Erico arboreae-Arbutetum unedonis*, which is widely known as a secondary maquis type developed on siliceous substrates (Molinier 1937, Allier & La Coste 1980, Foggi & Grigioni 1999). Although many *Erico-Arbutetum* subassociations have been described in

the phytosociological literature, we have decided to express the floristic-coenological pattern occurring in the *Erico-Arbutetum* stands of the study area at the level of "dynamical variants". In particular two different variants were identified: a thermo-xerophilous *Quercus ilex* variant, restricted to the Ceriti mountains and which is dynamically linked to *Arbuto-Quercetum ilicis* or to *Rubio-Quercetum ericotosum arboreae*, and a mesophilous *Quercus petraea* variant, which is restricted to the Tolfa mountains and is dynamically linked to the *Quercus cerris* and/or *Quercus petraea* mesophilous woodlands (and sporadically even to *Fagus* or *Alnus* woodlands). At alliance level *Erico-Arbutetum* is included in the *Ericion arboreae* alliance and in the *Pistacio lentisci-Rhamnetalia alaterni* order.

5. CONCLUSIONS

In this paper several syntaxa of particular interest for forest vegetation of the Italian peninsula have been discussed. In particular the proposition here of the new association *Rubio peregriniae-Quercetum cerridis* represents an important contribution to fill in the gaps in the coenological pattern of *Quercus cerris* thermophilous woodlands in central Italy. The new evergreen sclerophylllic association *Arbuto-Quercetum ilicis* is described as geosynviciant of the association *Erico-Quercetum ilicis* of southern Italy, while *Carici olbiensis-Quercetum petraeae* is the southernmost *Quercus petraea* association so far described for continental Italy. Besides providing further confirmation of the high forest heterogeneity of the studied area, the presence of the new ravine woodland association *Polysticho-Alnetum glutinosae* also represents an additional contribution towards achieving a wider biogeographical and coenological definition of the alliance *Osmundo-Alnion*. Finally, the syntaxonomical-nomenclatural question of the alliance of thermophilous oak woodlands of peninsular Italy was resolved by substituting the invalid name *Teucrio siculi-Quercion cerridis* Ubaldi 1988 with *Crataego laevigatae-Quercion cerridis* Arrigoni 1997.

6. ACKNOWLEDGEMENTS

The authors wish to express their thanks to Carlo Blasi for logistic support and to Goffredo Fibbeck for his help during field-work. We are also grateful to Jean-Paul Theurillat, Laco Mucina for

their help on some critical nomenclatural issues. Thanks also to Daniele Viciani, to the anonymous reviewer and to the Editor-in-chief for their important advice. Jim McManus kindly revised the English language.
