

THE RELATIVE HELLER OPERATOR AND RELATIVE COHOMOLOGY FOR THE KLEIN 4-GROUP.

JONATHAN ELMER

ABSTRACT. Let G be the Klein Four-group and let \mathbb{k} be an arbitrary field of characteristic 2. A classification of indecomposable $\mathbb{k}G$ -modules is known. We calculate the relative cohomology groups $H_\chi^i(G, N)$ for every indecomposable $\mathbb{k}G$ -module N , where χ is the set of proper subgroups in G . This extends work of Pamuk and Yalcin to cohomology with non-trivial coefficients. We also show that all cup products in strictly positive degree in $H_\chi^*(G, \mathbb{k})$ are trivial.

1. INTRODUCTION

Let G be a finite group and \mathbb{k} a field of characteristic $p > 0$. If $p \nmid |G|$, then every representation of G over \mathbb{k} is projective. Thus, by decomposing the regular module $\mathbb{k}G$ we can obtain all isomorphism classes of $\mathbb{k}G$ -modules immediately.

From now on assume $p \mid |G|$. Then the above is no longer true. However, it is well-known that, given a $\mathbb{k}G$ -module M , we can find a projective module P_0 and a surjective $\mathbb{k}G$ -morphism

$$\pi_0 : P_0 \rightarrow M.$$

If we choose P_0 and π_0 so that P_0 has smallest possible dimension, then this pair is unique, and known as the projective cover of M . The kernel of π_0 is denoted $\Omega(M)$. This is known as the Heller shift of M . $\Omega(-)$ can be viewed as an operation on the set of $\mathbb{k}G$ -modules which takes indecomposable modules to indecomposable modules.

This construction can be iterated. For each $i > 0$, let $\pi_i : P_i \rightarrow \Omega^i(M)$ be the projective cover of $\Omega^i(M)$. By composing these maps with the inclusions $\Omega^i(M) \rightarrow P_{i-1}$, we obtain an exact sequence

$$(1) \quad \dots P_i \rightarrow P_{i-1} \rightarrow \dots \rightarrow P_0 \rightarrow M \rightarrow 0.$$

This is an example of a projective resolution for M . If N is any $\mathbb{k}G$ -module, then the above induces a complex

$$0 \rightarrow \text{Hom}_{\mathbb{k}G}(P_0, N) \rightarrow \dots \rightarrow \text{Hom}_{\mathbb{k}G}(P_i, N) \rightarrow \dots$$

which is not exact in general. The homology groups of this complex are by definition the groups $\text{Ext}_{\mathbb{k}G}^i(M, N)$. A special case is

$$H^i(G, N) := \text{Ext}_{\mathbb{k}G}^i(\mathbb{k}, N).$$

We call this the *cohomology of G with coefficients in N* .

There is a long and fruitful history of study of the cohomology groups $H^i(G, N)$ in modular representation theory. Further, one may define a pairing

$$\smile : H^i(G, \mathbb{k}) \otimes H^j(G, \mathbb{k}) \rightarrow H^{i+j}(G, \mathbb{k})$$

Key words and phrases. cohomology of groups, relative cohomology, modular representation theory, cup product.

which gives $H^*(G, \mathbb{k})$ the structure of a graded-commutative graded ring. A celebrated theorem of Evens (see [3, Theorem 4.2.1]) states that, for any G , the ring $H^*(G, \mathbb{k})$ is finitely generated.

Now let χ be a set of proper subgroups of G . A $\mathbb{k}G$ -module M is said to be *projective relative to χ* if M is a direct summand of $\bigoplus_{X \in \chi} M \downarrow_X \uparrow^G$. Other equivalent definitions will be given in section 2. It is less well-known, but still true, that every $\mathbb{k}G$ -module has a unique relative projective cover with respect to χ . This is defined to be a $\mathbb{k}G$ -module Q_0 of smallest dimension such that

- (1) Q_0 is projective relative to χ ;
- (2) There is a surjective $\mathbb{k}G$ -morphism $\pi_0 : Q_0 \rightarrow M$ which splits on restriction to each $X \in \chi$.

The kernel of π_0 is denoted $\Omega_\chi(M)$ and called the relative Heller shift of M with respect to χ . We can mimic the construction of (1) to obtain a relative projective resolution of M , that is, an exact sequence

$$(2) \quad \dots Q_i \rightarrow Q_{i-1} \rightarrow \dots \rightarrow Q_0 \rightarrow M \rightarrow 0.$$

of $\mathbb{k}G$ modules which are projective relative to χ and in which the connecting homomorphisms split over each $X \in \chi$. Given any $\mathbb{k}G$ -module N , the above induces a complex

$$0 \rightarrow \text{Hom}_{\mathbb{k}G}(Q_0, N) \rightarrow \dots \rightarrow \text{Hom}_{\mathbb{k}G}(Q_i, N) \rightarrow \dots$$

which is in general no longer exact. The homology groups of this complex are by definition the relative Ext-groups $\text{Ext}_{\mathbb{k}G, \chi}^i(M, N)$. The relative cohomology of G with respect to χ with coefficients in N is the special case

$$H_\chi^i(G, N) := \text{Ext}_{\mathbb{k}G, \chi}^i(\mathbb{k}, N).$$

Further, one may define a pairing

$$\smile : H_\chi^i(G, \mathbb{k}) \otimes H_\chi^j(G, \mathbb{k}) \rightarrow H_\chi^{i+j}(G, \mathbb{k})$$

which gives $H_\chi^*(G, \mathbb{k})$ the structure of a graded-commutative graded ring.

Computations of $H_\chi^i(G, N)$ are rare in the literature. It is notable that the ring $H_\chi^*(G, \mathbb{k})$ is not finitely generated in general. This was first discovered by Blowers [4], who showed that if G_1 and G_2 are finite groups of order divisible by p , and χ_1, χ_2 are sets of subgroups of G_1, G_2 respectively with order divisible by p , then all products of elements of positive degree in $H_\chi^*(G, \mathbb{k})$ are zero, where $G = G_1 \times G_2$ and $\chi = \{G_1 \times X : X \in \chi_2\} \cup \{X \times G_2 : X \in \chi_1\}$. See also [5].

For the rest of this section, let $G = \langle \sigma, \tau \rangle$ denote the Klein four-group, and let \mathbb{k} be a field of characteristic 2. We set $\chi = \{H_1, H_2, H_3\}$, the set of all proper nontrivial subgroups of G , where $H_1 = \langle \sigma \rangle, H_2 = \langle \tau \rangle, H_3 = \langle \sigma\tau \rangle$.

The cohomology groups $H_\chi^i(G, \mathbb{k})$ were computed, by indirect means, by Pamuk and Yalcin [10]. In the present article we recover their result, and also compute $H_\chi^i(G, N)$ for any $\mathbb{k}G$ -module N . Our methods are more direct; we compute an explicit relative projective resolution for each N . Of course we are helped enormously by the fact that the representations of G are completely classified. Our first main result is:

Theorem 1. *Let M be an indecomposable $\mathbb{k}G$ -module, which is not projective relative to χ . Then we have*

$$\Omega_\chi(M) \cong \Omega^{-2}(M)$$

if M has odd dimension, and

$$\Omega_\chi(M) \cong M$$

otherwise.

The ring structure of $H_\chi^*(G, \mathbb{k})$ was not considered in [10]. Note, however, that if χ' is a subset of χ with size 2, then all products in $H_{\chi'}^*(G, \mathbb{k})$ are zero, by a special case of Blowers' result. It is perhaps not surprising, therefore, that we have

Theorem 2. *Let $\alpha_1, \alpha_2 \in H_\chi^*(G, \mathbb{k})$, where both have strictly positive degree. Then $\alpha_1 \smile \alpha_2 = 0$.*

This paper is organised as follows. In section 2 we define relative projectivity and derive the results we will need to do the computations in later sections. This section follows [9, Section 2] fairly closely. As most proofs can be constructed by adapting familiar results on projectivity to the relative case, they are omitted. In section 3 we describe the classification of modules for the Klein-four group and prove Theorem 1. We also compute $H_\chi^i(G, N)$ for every $\mathbb{k}G$ -module N and prove Theorem 2.

1.1. Notation. All groups under consideration are finite groups, and for any group G , by a $\mathbb{k}G$ -module we mean a finitely-generated \mathbb{k} -vector space with compatible G action. The one-dimensional trivial $\mathbb{k}G$ -module will be denoted by \mathbb{k}_G or simply \mathbb{k} when the group acting is obvious, and for $n \in \mathbb{N}$ and M a $\mathbb{k}G$ -module we write nM for the direct sum of n copies of M .

Acknowledgements. Thanks to an anonymous referee for some helpful suggestions.

2. RELATIVE PROJECTIVITY

In this section, let $p > 0$ be a prime and let G be a finite group of order divisible by p . Let \mathbb{k} be a field of characteristic p and let χ be a set of subgroups of G . Now let M be a finitely generated $\mathbb{k}G$ -module. M is said to be *projective relative to χ* if the following holds: let $\phi : M \rightarrow Y$ be a $\mathbb{k}G$ -homomorphism and $j : X \rightarrow Y$ a surjective $\mathbb{k}G$ -homomorphism which splits on restriction to any subgroup of $H \in \chi$, then there exists a $\mathbb{k}G$ -homomorphism ψ making the following diagram commute.

$$\begin{array}{ccc}
 & M & \\
 & \swarrow \psi & \downarrow \phi \\
 X & \xrightarrow{j} & Y \longrightarrow 0
 \end{array}$$

Dually, one says that M is *injective relative to χ* if the following holds: given an injective $\mathbb{k}G$ -homomorphism $i : X \rightarrow Y$ which splits on restriction to each $H \in \chi$ and a $\mathbb{k}G$ -homomorphism $\phi : X \rightarrow M$, there exists a $\mathbb{k}G$ -homomorphism ψ making the following diagram commute.

$$\begin{array}{ccccc}
 0 & \longrightarrow & X & \xrightarrow{i} & Y \\
 & & \downarrow \phi & & \swarrow \psi \\
 & & M & &
 \end{array}$$

These notions are equivalent to the usual definitions of projective and injective $\mathbb{k}G$ -modules when we take $\chi = \{1\}$. We will say a $\mathbb{k}G$ -homomorphism is χ -split if it splits on restriction to each $H \in \chi$. Since a $\mathbb{k}G$ -module is projective relative to H if and only if it is also projective relative to the set of all subgroups of H , we often assume χ is closed under taking subgroups.

We denote the set of G -fixed points in M by M^G . For any $H \leq G$ there is a $\mathbb{k}G$ -map $M^H \rightarrow M^G$ defined as follows:

$$\mathrm{Tr}_H^G(x) = \sum_{\sigma \in S} \sigma x$$

where $x \in M$ and S is a left-transversal of H in G . This is called the relative trace or transfer. It is clear that the map is independent of the choice of S . If $H = 1$ we usually write this as Tr^G and call it simply the trace or transfer. For any set of subgroups χ of G we define the subspace

$$M^{G,\chi} := \sum_{H \in \chi} \mathrm{Tr}_H^G(M^H)$$

and quotient

$$M_\chi^G := \frac{M^G}{M^{G,\chi}}.$$

Now let N be another $\mathbb{k}G$ -module. We can define an action of G on $\mathrm{Hom}_{\mathbb{k}}(M, N)$:

$$(g \cdot \phi)(x) = g\phi(g^{-1}x) \text{ for } g \in G, x \in M.$$

Notice that with this action we have $\mathrm{Hom}_{\mathbb{k}}(M, N)^G = \mathrm{Hom}_{\mathbb{k}G}(M, N)$. Further, the transfer construction gives a map

$$\mathrm{Tr}_H^G : \mathrm{Hom}_{\mathbb{k}H}(M, N) \rightarrow \mathrm{Hom}_{\mathbb{k}G}(M, N).$$

There are various ways to characterize relative projectivity:

Proposition 3. *Let G be a finite group of order divisible by p , χ a set of subgroups of G and M a $\mathbb{k}G$ -module. Then the following are equivalent:*

- (i) M is projective relative to χ ;
- (ii) Every χ -split epimorphism of $\mathbb{k}G$ -modules $\phi : N \rightarrow M$ splits;
- (iii) M is injective relative to χ ;
- (iv) Every χ -split monomorphism of $\mathbb{k}G$ -modules $\phi : M \rightarrow N$ splits;
- (v) M is a direct summand of $\bigoplus_{H \in \chi} M \downarrow_H \uparrow^G$;
- (vi) M is a direct summand of a direct sum of modules induced from subgroups in χ ;
- (vii) There exists a set of homomorphisms $\{\beta_H : H \in \chi\}$ such that $\beta_H \in \mathrm{Hom}_{\mathbb{k}H}(M, M)$ and $\sum_{H \in \chi} \mathrm{Tr}_H^G(\beta_H) = \mathrm{id}_M$.

The last of these is called *Higman's criterion*.

Proof. The proof when χ consists of a single subgroup of G can be found in [2, Proposition 3.6.4]. This can easily be generalised. \square

For homomorphisms $\alpha \in \mathrm{Hom}_{\mathbb{k}G}(M, N)$ we have the following:

Lemma 4. *Let M, N be $\mathbb{k}G$ -modules, χ a collection of subgroups of G , and $\alpha \in \mathrm{Hom}_{\mathbb{k}G}(M, N)$. Then the following are equivalent:*

- (i) α factors through $\bigoplus_{H \in \chi} M \downarrow_H \uparrow^G$.
- (ii) α factors through some module which is projective relative to χ .
- (iii) There exist homomorphisms $\{\beta_H \in \mathrm{Hom}_{\mathbb{k}H}(M, N) : H \in \chi\}$ such that $\alpha = \sum_{H \in \chi} \mathrm{Tr}_H^G(\beta_H)$.

Proof. This is easily deduced from [2, Proposition 3.6.6]. \square

The above tells us that $\mathrm{Hom}_{\mathbb{k}}(M, N)^{G,\chi}$ consists of the $\mathbb{k}G$ -homomorphisms which factor through a module which is projective relative to χ . We write

$$\underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(M, N) := \mathrm{Hom}_{\mathbb{k}}(M, N)_\chi^G.$$

Let M be a $\mathbb{k}G$ -module and let X be a $\mathbb{k}G$ -module that is projective relative to χ . It is easily shown, using Proposition 3, that $M \otimes X$ is projective relative to χ . For example, the module $M \otimes X$ where $X = \bigoplus_{H \in \chi} \mathbb{k}_H \uparrow^G$ is projective relative to χ . Moreover, with X as defined above, the natural map $\sigma : M \otimes X \rightarrow M$ given by

$$\sigma(m \otimes x) = m$$

is a χ -split $\mathbb{k}G$ -epimorphism (to see the splitting, use the Mackey Theorem). It follows that for each M , there exists a $\mathbb{k}G$ -module Q_0 which is projective relative to χ and a χ -split $\mathbb{k}G$ -epimorphism $\pi_0 : Q_0 \rightarrow M$.

Let $\pi_0 : Q_0 \rightarrow M$ and $\pi'_0 : Q'_0 \rightarrow M$ be two such pairs. The proof of Schanuel's Lemma (see [2, Lemma 1.5.3, Lemma 3.9.1]) extends more or less verbatim to the relative case; if $K_0 = \ker(\pi_0)$ and $K'_0 = \ker(\pi'_0)$ then $K_0 \oplus Q'_0 \cong K'_0 \oplus Q_0$.

If we choose among all such pairs, one in which the dimension of Q_0 is minimal, the kernel K_0 is defined uniquely. This pair (Q_0, π_0) is called the relative projective cover of M . For this choice we set $\Omega_\chi(M) = K_0$. We can iterate this construction, setting $\Omega_\chi^i(M) = \Omega_\chi(\Omega_\chi^{i-1}(M))$. Minimality implies that if K'_0 is the kernel of any other χ -split $\mathbb{k}G$ -epimorphism $Q'_0 \rightarrow M$, then $K'_0 \cong \Omega_\chi(M) \oplus (\text{rel. proj})$, where (rel. proj) is some module which is projective relative to χ .

Dually, we always have that M is a submodule of $M \otimes X$ with $X = \bigoplus_{H \in \chi} \mathbb{k}_H \uparrow^G$, and the inclusion $\rho : M \rightarrow M \otimes X$ splits on restriction to each $H \in \chi$. It follows that for each M , there exists a $\mathbb{k}G$ -module J_0 and a χ -split $\mathbb{k}G$ -monomorphism $\rho_0 : M \rightarrow J_0$.

Let $\rho_0 : M \rightarrow J_0$ and $\rho'_0 : M \rightarrow J'_0$ be two such pairs. Again, by the relative version of Schanuel's Lemma, if $C_0 = \text{coker}(\rho_0)$ and $C'_0 = \text{coker}(\rho'_0)$ then $C_0 \oplus J'_0 \cong C'_0 \oplus J_0$.

If we choose among all such pairs, one in which the dimension of J_0 is minimal, the cokernel C_0 is defined uniquely. The pair (J_0, ρ_0) is called a relative injective hull of M with respect to χ . For this choice we set $\Omega_\chi^{-1}(M) = C_0$. We can iterate this construction, setting $\Omega_\chi^{-i}(M) = \Omega_\chi^{-1}(\Omega_\chi^{-(i-1)}(M))$. Minimality implies that if C'_0 is the kernel of any other χ -split $\mathbb{k}G$ -monomorphism $M \rightarrow J_0$, then $C'_0 \cong \Omega_\chi^{-1}(M) \oplus (\text{rel. proj})$, where (rel. proj) is some module which is projective relative to χ .

The following gives some properties of the operators Ω_χ^i .

Proposition 5. *Let M_1, M_2 be $\mathbb{k}G$ -modules without summands which are projective relative to χ , and i, j nonzero integers. Then:*

- (i) $\Omega_\chi^i(M_1 \oplus M_2) \cong \Omega_\chi^i(M_1) \oplus \Omega_\chi^i(M_2)$;
- (ii) $\Omega_\chi^i(M)^* \cong \Omega_\chi^{-i}(M^*)$;
- (iii) $M \cong \Omega_\chi(\Omega_\chi^{-1}(M)) \oplus (\text{rel. proj}) \cong \Omega_\chi^{-1}(\Omega_\chi(M)) \oplus (\text{rel. proj})$.

Proof. (i) is obvious. (ii,iii) are easily deduced from the relative version of Schanuel's Lemma. □

(i) above shows that Ω_χ^i is a well-defined operator on the set of indecomposable $\mathbb{k}G$ -modules which are not relatively projective to χ . Note that (iii) does not say that $\Omega_\chi \circ \Omega_\chi^{-1}$ is the identity in general. If we define $\Omega_\chi^0(M)$ to be the direct sum of all summands of M which are not projective relative to χ , then we have $\Omega_\chi^{i+j} = \Omega_\chi^i \circ \Omega_\chi^j$ for all i and j .

The following result is sometimes useful.

Lemma 6. *Let M be a $\mathbb{k}G$ -module which is projective relative to a set χ of subgroups of G . Then $M^G = \sum_{H \in \chi} \text{Tr}_H^G(M^H)$.*

Proof. See [9, Lemma 2.9] □

As a consequence of the above, if $M = N \oplus$ (rel. proj.), we get that $M_\chi^G = N_\chi^G$. The operators Ω_χ^i extend in a natural way to homomorphisms between modules. Let $f \in \text{Hom}_{\mathbb{k}G}(M, N)$. Let $(Q, \pi), (Q', \pi')$ be the relative projective covers of M, N . Then the relative projectivity of Q ensures the existence of a homomorphism $\bar{f} \in \text{Hom}_{\mathbb{k}G}(Q, Q')$ making the following diagram commute

$$\begin{array}{ccccccc} \Omega_\chi(M) & \longrightarrow & Q & \xrightarrow{\pi} & M & \longrightarrow & 0 \\ \downarrow \Omega_\chi(f, \bar{f}) & & \downarrow \bar{f} & & \downarrow f & & \\ \Omega_\chi(N) & \longrightarrow & Q' & \xrightarrow{\pi'} & N & \longrightarrow & 0 \end{array}$$

and an easy diagram chase shows that the image of $\Omega_\chi(f, \bar{f}) := \bar{f}|_{\ker(\pi)}$ is contained in $\ker(\pi')$. In this way, f induces a homomorphism

$$\Omega_\chi(f, \bar{f}) \in \text{Hom}_{\mathbb{k}G}(\Omega_\chi(M), \Omega_\chi(N)).$$

Moreover, this homomorphism factors through a relative projective if and only if f does so.

The homomorphism $\Omega_\chi(f, \bar{f})$ depends, as the notation suggests, on the choice of \bar{f} in general. However, if \bar{f} and $\tilde{f} \in \text{Hom}_{\mathbb{k}G}(Q, Q')$ are both homomorphisms making the diagram commute, then one can show that

$$\Omega_\chi(f, \bar{f}) = \Omega_\chi(f, \tilde{f})$$

factors through a relative projective.

For a given homomorphism $f : M \rightarrow N$, denote by $[f]$ its equivalence class in $\underline{\text{Hom}}_{\mathbb{k}G}^\chi(M, N)$. By the discussion following Lemma 4, the equivalence class

$$[\Omega_\chi(f, \bar{f})] \in \underline{\text{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi(M), \Omega_\chi(N))$$

does not depend on \bar{f} , so we write this as $\Omega_\chi[f]$. In this way, we obtain a well-defined homomorphism

$$\Omega_\chi : \underline{\text{Hom}}_{\mathbb{k}G}^\chi(M, N) \rightarrow \underline{\text{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi(M), \Omega_\chi(N)).$$

In a similar fashion, let $(J, \rho), (J', \rho')$ be the relative injective hulls of M, N respectively. Then relative injectivity of J' ensures the existence of a homomorphism $\tilde{f} \in \text{Hom}(J, J')$ making the following diagram commute,

$$\begin{array}{ccccccc} \Omega_\chi(M) & \longleftarrow & J & \xleftarrow{\rho} & M & \longleftarrow & 0 \\ \downarrow \Omega_\chi^{-1}(f, \tilde{f}) & & \downarrow \tilde{f} & & \downarrow f & & \\ \Omega_\chi^{-1}(N) & \longleftarrow & J' & \xleftarrow{\rho'} & N & \longleftarrow & 0 \end{array}$$

and a diagram chase shows that \tilde{f} induces a homomorphism

$$\Omega_\chi^{-1}(f, \tilde{f}) \in \text{Hom}(\Omega_\chi^{-1}(M), \Omega_\chi^{-1}(N)).$$

Moreover $\Omega_\chi^{-1}(f, \tilde{f})$ factors through a projective if and only if f does so, and although $\Omega_\chi^{-1}(f, \tilde{f})$ depends on the choice of \tilde{f} in general, the equivalence class

$[\Omega_\chi^{-1}(f, \tilde{f})]$ depends only on f , so we write it as $\Omega_\chi^{-1}[f]$. Thus, we obtain a well-defined homomorphism

$$\Omega_\chi^{-1} : \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(M, N) \rightarrow \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^{-1}(M), \Omega_\chi^{-1}(N)).$$

One can show further that, for $[f] \in \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(M, N)$ we have

$$[f] = \Omega_\chi^{-1}\Omega_\chi[f] = \Omega_\chi\Omega_\chi^{-1}[f],$$

which justifies the following:

Proposition 7. *For all $i \in \mathbb{Z}$, $\Omega_\chi^i(-)$ induces an isomorphism*

$$\underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(M, N) \cong \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^i(M), \Omega_\chi^i(N)).$$

As explained in the introduction, the idea of a relatively projective cover can be extended to a relatively projective resolution; that is, an exact complex

$$(3) \quad \dots \rightarrow Q_i \rightarrow Q_{i-1} \rightarrow \dots \rightarrow Q_0 \rightarrow M \rightarrow 0$$

of relatively projective modules in which the connecting homomorphisms split over χ . If

$$(4) \quad \dots \rightarrow Q'_i \rightarrow Q'_{i-1} \rightarrow \dots \rightarrow Q'_0 \rightarrow M \rightarrow 0$$

is another relatively projective resolution, then it turns out that any two chain maps between them are chain homotopic (see [2, Theorem 3.9.3] for the version with χ consisting of one subgroup - the proof of the more general version is the same). Consequently, for any $\mathbb{k}G$ -module N , the homology groups of the induced complex

$$0 \rightarrow \mathrm{Hom}_{\mathbb{k}G}(Q_0, N) \rightarrow \dots \rightarrow \mathrm{Hom}_{\mathbb{k}G}(Q_i, N) \rightarrow \dots$$

are independent of the choice of resolution. The homology groups of this complex are by definition the relative Ext-groups $\mathrm{Ext}_{\mathbb{k}G, \chi}^i(M, N)$. The relative cohomology of G with respect to χ with coefficients in N is the special case

$$H_\chi^i(G, N) := \mathrm{Ext}_{\mathbb{k}G, \chi}^i(\mathbb{k}, N).$$

We will use a minimal relative projective resolution of the trivial module to compute relative cohomology; that is, a relatively projective resolution

$$(5) \quad \dots \rightarrow Q_i \xrightarrow{\partial_{i-1}} Q_{i-1} \rightarrow \dots \xrightarrow{\partial_0} Q_0 \rightarrow \mathbb{k} \rightarrow 0.$$

in which $\ker(\partial_{i-1}) = \Omega_\chi^i(\mathbb{k})$. We can construct this by taking for each i a short exact sequence

$$0 \rightarrow \Omega_\chi^{i+1}(\mathbb{k}) \xrightarrow{\rho_i} Q_i \xrightarrow{\pi_i} \Omega_\chi^i(\mathbb{k}) \rightarrow 0$$

and setting $\partial_i := \rho_i\pi_{i+1}$. For each i let

$$\delta_i : \mathrm{Hom}_{\mathbb{k}G}(Q_i, \mathbb{k}) \rightarrow \mathrm{Hom}_{\mathbb{k}G}(Q_{i+1}, \mathbb{k})$$

denote the map induced by ∂_i .

Our main tool will be the following:

Proposition 8. *Let N be a $\mathbb{k}G$ -module. Then we have*

- (i) $H_\chi^0(G, N) = N^G$;
- (ii) $H_\chi^i(G, N) \cong \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^i(\mathbb{k}), N)$.

The proof is the same as in the case $\chi = \{1\}$, but we give a sketch for lack of a good reference to this proof.

Proof. We first show that for each $i \geq 0$,

$$\ker(\delta_i) \cong \text{Hom}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), N).$$

To see this, let $\phi \in \ker(\delta_i) \subseteq \text{Hom}_{\mathbb{k}G}(Q_i, N)$. For $x \in \Omega_\chi^i(\mathbb{k})$, choose $q \in Q_i$ such that $\pi_i(q) = x$ and define $\hat{\phi}(x) = \phi(q)$. Then $\hat{\phi} \in \text{Hom}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), N)$. The assignment $\phi \rightarrow \hat{\phi}$ is well-defined: for if $q' \in Q_i$ with $\pi_i(q') = x$ and $\tilde{\phi}(x) := \phi(q')$, then since $q - q' \in \ker(\pi_i)$ we get $q - q' \in \text{im}(\partial_i)$ and $\phi(q - q') = 0$ since $\phi \in \ker(\delta_i)$. Conversely, given $\hat{\phi} \in \text{Hom}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), N)$ we can define $\phi = \hat{\phi} \circ \pi_i \in \ker(\delta_i)$. It's easy to see that the two assignments are inverse to each other.

This in particular shows that (i) holds, since $\text{Hom}_{\mathbb{k}G}(\mathbb{k}, N) \cong N^G$. We now show that $\text{im}(\delta_{i-1})$ consists of the homomorphisms in $\text{Hom}_{\mathbb{k}G}(\Omega^i(\mathbb{k}), N)$ which factor through a module which is projective relative to χ . To see this, first suppose $\phi \in \text{im}(\delta_{i-1}) \subseteq \text{Hom}_{\mathbb{k}G}(Q_i, N)$, say $\phi = \psi \circ \partial_{i-1}$ where $\psi \in \text{Hom}_{\mathbb{k}G}(Q_{i-1}, N)$. Then with $x \in \Omega_\chi^i(\mathbb{k})$ and $q, \hat{\phi}$ as before we note that

$$\psi \circ \rho_{i-1}(x) = \psi \circ \rho_{i-1} \circ \pi_i(q) = \psi \circ \partial_i(q) = \phi(q) = \hat{\phi}(x)$$

which shows that $\hat{\phi}$ factors through the module Q_{i-1} which is projective relative to χ . Conversely, if $\hat{\phi} \in \text{Hom}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), N)$ factors through any module which is projective relative to χ , then it factors through Q_{i-1} , because ρ_{i-1} is injective and Q_{i-1} is also an injective module with respect to χ by Lemma 3. \square

One can define a pairing $\smile: H_\chi^i(G, \mathbb{k}) \otimes H_\chi^j(G, \mathbb{k}) \rightarrow H_\chi^{i+j}(G, \mathbb{k})$ in a few different ways. On the one hand, elements of $H_\chi^*(G, \mathbb{k}) = \text{Ext}_{\mathbb{k}G, \chi}^*(\mathbb{k}, \mathbb{k})$ can be viewed as equivalence classes of extensions of \mathbb{k} by \mathbb{k} split over χ , and the usual Yoneda splice gives the required pairing; see [2, Section 2.6, 3.9] for details in the case χ consisting of only one subgroup. Some other constructions in the case $\chi = \{1\}$ are given in [6], and all of these extend in a natural way to arbitrary χ . Happily, all these methods give the same construction. In the present article we will use the following construction: recall that

$$H_\chi^i(G, \mathbb{k}) \cong \underline{\text{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^i(\mathbb{k}), \mathbb{k}).$$

Similarly

$$H_\chi^j(G, \mathbb{k}) = \underline{\text{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^j(\mathbb{k}), \mathbb{k}) \cong \underline{\text{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^{i+j}(\mathbb{k}), \Omega_\chi^i(\mathbb{k}))$$

with the second isomorphism arising from Proposition 7. Therefore we may define a product as follows: for $\alpha \in H_\chi^i(G, \mathbb{k})$ and $\beta \in H_\chi^j(G, \mathbb{k})$ choose $f \in \underline{\text{Hom}}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), \mathbb{k})$, $g \in \underline{\text{Hom}}_{\mathbb{k}G}(\Omega_\chi^j(\mathbb{k}), \mathbb{k})$ representing α, β respectively. Then $\Omega_\chi^i(g) \in \underline{\text{Hom}}_{\mathbb{k}G}(\Omega_\chi^{i+j}(\mathbb{k}), \Omega_\chi^i(\mathbb{k}))$, so that

$$f \circ \Omega_\chi^i(g) \in \underline{\text{Hom}}_{\mathbb{k}G}(\Omega_\chi^{i+j}(\mathbb{k}), \mathbb{k}).$$

We take $\alpha \smile \beta$ to be the cohomology class represented by $f \circ \Omega_\chi^i(g)$. This is called the *cup product* of α and β .

3. REPRESENTATIONS OF $C_2 \times C_2$

In this section, let $G = \langle \sigma, \tau \rangle$ denote the Klein four-group, and let \mathbb{k} be a field of characteristic 2 (not necessarily algebraically closed). We set $\chi = \{H_1, H_2, H_3\}$, the set of all proper nontrivial subgroups of G , where $H_1 = \langle \sigma \rangle, H_2 = \langle \tau \rangle, H_3 = \langle \sigma\tau \rangle$.

Let $X := \sigma - 1 \in \mathbb{k}G$, $Y := \tau - 1 \in \mathbb{k}G$. Then $X^2 = Y^2 = 0$, $\mathbb{k}G$ is isomorphic to the quotient ring

$$R := \mathbb{k}[X, Y]/(X^2, Y^2),$$

and $\mathbb{k}G$ -modules can be viewed as R -modules. We will describe R -modules by means of the diagrams for modules popularised by Alperin in [1]. In these diagrams,

nodes represent basis elements, and two nodes labelled a and b are joined by a south-west directed arrow if $Xa = b$, and by a south-east directed arrow if $Ya = b$. If no south-west arrow begins at a then it is understood that $Xa = 0$, similarly for Y .

Our statement of the classification of $\mathbb{k}G$ -modules resembles that found in [7], which is based on calculations first found in [8]. We recommend the former reference as an easily accessible proof.

Proposition 9. *Let M be an indecomposable $\mathbb{k}G$ -module. Then M is isomorphic to one of the following:*

- (1) The module V_{2n+1} ($n \geq 0$), with odd dimension $2n + 1$ and diagram

- (2) The module $V_{-(2n+1)}$ ($n \geq 0$), with odd dimension $2n + 1$ and diagram

Note that $V_1 \cong V_{-1} \cong \mathbb{k}$, with trivial G -action, but otherwise these modules are pairwise non-isomorphic.

- (3) The module $V_{2n,\infty}$ ($n \geq 1$), with even dimension $2n$ and diagram

- (4) The module $V_{2n,\theta}$ ($n \geq 1$), with even dimension $2n$ and diagram,

Here, $\theta(x) = \sum_{i=0}^n \lambda_i x^{n-i}$ is a power of an irreducible monic polynomial with coefficients in \mathbb{k} and the dotted line labelled by θ indicates that $Xa_1 = \sum_{i=1}^n \lambda_i b_i$.

- (5) The projective indecomposable module P , with dimension 4 and diagram

The following, also taken from [7], may be proved directly from the classification above.

Proposition 10. *Let M be an indecomposable $\mathbb{k}G$ -module. Then we have*

- (1) $M \cong M^*$ if M is even-dimensional.
- (2) $M^* \cong V_{-(2n+1)}$ if $M \cong V_{2n+1}$ is odd dimensional.

- (3) $M^* \cong V_{2n+1}$ if $M \cong V_{-(2n+1)}$ is odd-dimensional.

Clearly (3) follows from (2) above, but we include it for completeness. In addition,

Proposition 11. *Let M be an indecomposable $\mathbb{k}G$ -module. Then we have*

- (1) $\Omega(M) \cong M$ if M is even-dimensional.
- (2) $\Omega^{-1}(M) \cong V_{-(2n+3)}$ if $M \cong V_{-(2n+1)}$ is odd dimensional.
- (3) $\Omega(M) \cong V_{2n+3}$ if $M \cong V_{2n+1}$ is odd-dimensional.

Again (3) follows from (2) when we take into account that $\Omega(M)^* \cong \Omega^{-1}(M^*)$ in general.

3.1. Relative shifts. The goal of this subsection is to prove Theorem 1.

Among the indecomposable $\mathbb{k}G$ -modules listed in the previous section, only four are projective relative to χ . These are the projective indecomposable P , and the three modules $V_{2,\infty}$, $V_{2,x}$ and $V_{2,x+1}$. Here the last two are the indecomposable modules $V_{2,\theta}$ where $\theta(x)$ is the monic irreducible x or $x+1 \in \mathbb{k}[x]$. Note that τ acts trivially on $V_{2,\infty} = \mathbb{k}_{H_2} \uparrow^G$, while σ acts trivially on $V_{2,x} = \mathbb{k}_{H_1} \uparrow^G$ and $\sigma\tau$ acts trivially on $V_{2,x+1} = \mathbb{k}_{H_3} \uparrow^G$. As these three play an important role in what follows, we denote them by Q_τ, Q_σ and $Q_{\sigma\tau}$ respectively. We set $Q = Q_\sigma \oplus Q_\tau \oplus Q_{\sigma\tau}$.

We begin by considering odd-dimensional modules.

Lemma 12. *Let $n \geq 0$:*

- (1) *The relative projective cover of $V_{-(2n+1)}$ is $Q \oplus nP$.*
- (2) *We have $\Omega_\chi(V_{-(2n+1)}) \cong V_{-(2n+5)}$.*

Proof. Let $M \cong V_{-(2n+1)}$ and let $\pi : N \rightarrow M$ be its relative projective cover with respect to χ . N must decompose as a direct sum of modules of the form P, Q_σ, Q_τ and $Q_{\sigma\tau}$.

Let $a_1, a_2, \dots, a_n, b_0, b_1, \dots, b_n$ be a basis of M , with action given by the diagram as in Proposition 9. Since π is a surjective $\mathbb{k}G$ -map and no a_i is fixed by any element of G , the same must be true of their unique pre-images. The modules Q_σ, Q_τ and $Q_{\sigma\tau}$ all have non-trivial kernels. Therefore N contains at least n copies of P .

On the other hand, we have, for any i ,

$$(6) \quad M \downarrow_{H_i} \cong \mathbb{k}_{H_i} \oplus n\mathbb{k}H_i$$

The restrictions to H_1 of P, Q_τ and $Q_{\sigma\tau}$ contain no trivial H_1 -summands. So N must contain a direct summand isomorphic to Q_σ if π is to split on restriction to H_1 . A similar argument (restricting to H_2, H_3) shows that N must contain summands isomorphic to Q_τ and $Q_{\sigma\tau}$.

We will construct a surjective $\mathbb{k}G$ -homomorphism $Q \oplus nP \rightarrow M$. The following diagrams label the basis elements:

(the diagram for $Q_{\sigma\tau}$ is not as described in Proposition 9, but makes sense, because $Xa_1 = Ya_1 = b_1$ in this case). We now define a linear map $\pi : Q \oplus nP \rightarrow M$ by

- $\pi(w_i) = a_i$ for $i = 1, \dots, n$.
- $\pi(x_i) = b_{i-1}$ for $i = 1, \dots, n$.
- $\pi(y_i) = b_i$ for $i = 1, \dots, n$.

- $\pi(z_i) = 0$ for $i = 1, \dots, n$.
- $\pi(s_i) = 0$ for $i = 1, 2, 3$.
- $\pi(r_1) = \pi(r_3) = a_0$.
- $\pi(r_2) = a_n$.

The reader should check that π is a $\mathbb{k}G$ -homomorphism. The kernel of π is spanned by

$$\{z_i : i = 1, \dots, n\} \cup \{s_1, s_2, s_3\} \cup \{x_i + y_{i-1} : i = 2, \dots, n\} \cup \{x_1 + r_1, x_1 + r_3, y_n + r_2\}.$$

It has dimension $2n + 5$, and the fixed-point space within this module is spanned by $\{z_1, z_2, \dots, z_n, s_1, s_2, s_3\}$, so it has dimension $n + 3$. It is easily checked that no element of the kernel outside of the fixed-point space is fixed by any subgroup H_i . Therefore

$$\ker(\pi) \downarrow_{H_i} \cong \mathbb{k}H_i \oplus (n + 2)\mathbb{k}H_i$$

for any i . This, combined with (6) and the fact that

$$(Q \oplus nP) \downarrow_{H_i} \cong 2\mathbb{k}H_i \oplus (2n + 2)\mathbb{k}H_i$$

shows that π splits on restriction to any H_i . The construction ensures the minimality of $Q \oplus nP$, so $Q \oplus nP = N$, proving (1). Further, $\Omega_\chi(M) = \ker(\pi)$, and the classification of $\mathbb{k}G$ -modules, together with the fact that $\ker(\pi)$ must be indecomposable, implies that $\ker(\pi) \cong V_{-(2n+5)}$, proving (2). \square

The following follows immediately from the above using Propositions 10 and 5(3).

Lemma 13. *Let $n \geq 0$: Then we have $\Omega_\chi(V_{(2n+5)}) \cong V_{(2n+1)}$.*

To complete the picture for odd-dimensional modules, it remains only to show that

Lemma 14. *Let $M \cong V_3$. Then:*

- (1) *The relative projective cover of M is Q ;*
- (2) *We have $\Omega_\chi(M) \cong V_{-3}$.*

Proof. We have $M \downarrow_{H_i} \cong \mathbb{k}H_i \oplus \mathbb{k}H_i$, for $i = 1, 2, 3$, so once more the projective cover must contain a summand isomorphic to Q . We shall construct a $\mathbb{k}G$ -homomorphism $\pi : Q \rightarrow M$. We retain the notation for a basis of Q used in Lemma 12; a basis for M is $\{a_0, a_1, b_1\}$ with action given as in the classification.

Define:

- $\pi(r_1) = a_0$
- $\pi(r_2) = a_1$
- $\pi(r_3) = a_0 + a_1$.
- $\pi(s_1) = \pi(s_2) = \pi(s_3) = b_1$.

The reader should check this is a $\mathbb{k}G$ -homomorphism. The kernel of π is spanned by $\{s_1 + s_2, s_2 + s_3, r_1 + r_2 + r_3\}$, and the fixed-point space of the kernel is two-dimensional, spanned by $\{s_1 + s_3, s_2 + s_3\}$. Noting that

$$X(r_1 + r_2 + r_3) = s_2 + s_3, Y(r_1 + r_2 + r_3) = s_1 + s_3,$$

we see that the kernel of π is indecomposable, and as a $\mathbb{k}G$ -module is isomorphic to V_{-3} . Therefore

$$\ker(\pi)_{H_i} \oplus \mathbb{k}H_i \oplus \mathbb{k}H_i$$

for all i , from which we deduce that π splits on restriction to each H_i . Our construction ensures the minimality of Q , so Q is indeed the relative projective cover of M , proving (1), and $\ker(\pi) = \Omega_\chi(M) \cong V_{-3}$, proving (2). \square

We now turn to even dimensional modules. Note that $V_{2,\infty} = Q_\tau$ is already projective relative to χ , so $\Omega_\chi(V_{2,\infty})$ is not defined.

Lemma 15. *Let $n \geq 2$ and $M \cong V_{2n, \infty}$. Then:*

- (1) *The relative projective cover of M is $2Q_\tau \oplus (n-1)P$;*
- (2) *We have $\Omega_\chi(M) \cong M$.*

Proof. Let $\pi : N \rightarrow M$ be the relative projective cover of M . Notice that

$$(7) \quad M \downarrow_{H_i} = n\mathbb{k}H_i$$

for $i = 1, 3$ whereas

$$(8) \quad M \downarrow_{H_2} = 2\mathbb{k}H_2 \oplus (n-1)\mathbb{k}H_2.$$

So if $\pi : N \rightarrow M$ is to split on restriction to H_2 , N must contain a pair of direct summands isomorphic to Q_τ . On the other hand, retaining the notation from Proposition 9, the basis elements a_1, \dots, a_{n-1} are not fixed by any element of G , so the same must be true of their unique pre-images in N . From this it follows that N must contain $n-1$ direct summands isomorphic to P .

We will construct a $\mathbb{k}G$ -homomorphism $2Q_\tau \oplus (n-1)P \rightarrow M$. The following diagram gives the labelling for a basis of the domain:

We define:

- $\pi(w_i) = a_i$ for $i = 1, \dots, n-1$.
- $\pi(x_i) = b_i$ for $i = 1, \dots, n-1$.
- $\pi(y_i) = b_{i+1}$ for $i = 1, \dots, n-1$.
- $\pi(z_i) = 0$ for $i = 1, \dots, n-1$.
- $\pi(r_1) = b_1$.
- $\pi(s_1) = 0$.
- $\pi(r_2) = a_n$.
- $\pi(s_2) = b_n$.

The reader should check that π is a $\mathbb{k}G$ -homomorphism. The kernel of π is spanned by

$$\{z_i : i = 1, \dots, n-1\} \cup \{x_i + y_{i-1} : i = 2, \dots, n-1\} \cup \{s_1, x_1 + r_2, y_{n-1} + s_2\}.$$

This has dimension $2n$. The fixed points within this module are spanned by

$$\{z_i : i = 1, \dots, n-1\} \cup \{s_1\}.$$

These span the fixed points of H_1 and H_3 , while H_2 has a fixed point space of dimension $n+1$, spanned by the above and $y_{n+1} + s_2$. Therefore we have

$$\ker(\pi) \downarrow_{H_i} \cong n\mathbb{k}H_i$$

for $i = 1, 3$ and

$$\ker(\pi) \downarrow_{H_2} \cong 2\mathbb{k}H_2 \oplus (n-1)\mathbb{k}H_2.$$

Note that

$$(2Q_\tau \oplus (n-1)P) \downarrow_{H_i} \cong 2n\mathbb{k}H_i$$

for $i = 1, 3$ and

$$(2Q_\tau \oplus (n-1)P) \downarrow_{H_2} \cong 4\mathbb{k}H_2 \oplus (2n-2)\mathbb{k}H_2.$$

Thus, π splits on restriction to each H_i . The construction ensures the minimality of $2Q_\tau \oplus (n-1)P$, so this is equal to N and we have (1). Further, $\ker(\pi) = \Omega_\chi(M)$ must be indecomposable. By the classification (looking at the dimension of the

fixed point space of each subgroup of G to distinguish among modules of even dimension) we must have $\Omega_\chi(M) \cong M$ as required for (2). \square

Notice that if $\theta(x) = x^n$, then $V_{2n,\theta}$ can be obtained from $V_{2n,\infty}$ by applying the automorphism of G which swaps σ and τ . Similarly if $\theta(x) = (x+1)^n$, then $V_{2n,\theta}$ can be obtained from $V_{2n,\infty}$ by applying the automorphism of G which swaps $\sigma\tau$ and τ . We therefore obtain immediately from Lemma 15 above that $\Omega_\chi(M) = M$ if M is one of these.

It remains only to prove the following:

Lemma 16. *Let $n \geq 1$ and let $M \cong V_{2n,\theta}$, where θ is neither x^n nor $(x+1)^n$. Then:*

- (1) *The relative projective cover of M is nP ;*
- (2) *$\Omega_\chi(M) \cong M$.*

Proof. Observe that $M \downarrow_{H_i} = n\mathbb{k}H_i$ for each i . The proof of [7, Proposition 3.1] shows that the projective (as opposed to relatively projective) cover of M is nP and $\Omega(M) \cong M$, so there is a surjective $\mathbb{k}G$ -homomorphism $\pi : nP \rightarrow M$ with kernel isomorphic to M . Noting that $nP \downarrow_{H_i} \cong 2n\mathbb{k}H_i$ for each i , we see that π splits on restriction to each H_i . On the other hand, if N is a $\mathbb{k}G$ -module having Q_τ (resp. $Q_\sigma, Q_{\sigma\tau}$) as a direct summand then $N \downarrow_{H_i}$ contains a pair of trivial $\mathbb{k}H_i$ -modules as direct summand, and no surjective homomorphism $N \rightarrow M$ may split. This shows the minimality of the dimension of nP among relatively projective modules with a χ -split epimorphism to M , i.e. we have proved (1). We also have

$$\Omega_\chi(M) = \ker(\pi) = \Omega(M) \cong M$$

as required for (2). \square

Remark 17. Combining all the Lemmas in this section with Proposition 11, we obtain Theorem 1.

3.2. Computing Cohomology. In this subsection we will determine $H^i(G, N)$ for all $i \geq 0$ and for all indecomposable $\mathbb{k}G$ -modules N . First observe that if N is projective relative to χ , then $H^i(G, N) = 0$ for all $i > 0$: this is an immediate consequence of Proposition 8(ii). Further, recall from part (i) of the same that $H_\chi^0(G, N) = N^G$ for any $\mathbb{k}G$ -module. It follows that:

Proposition 18. *Let $N \in \{P, Q_\sigma, Q_\tau, Q_{\sigma\tau}\}$. Then,*

$$\dim(H_\chi^i(G, N)) = \begin{cases} 1 & i = 0, \\ 0 & \text{otherwise.} \end{cases}$$

Now we consider even-dimensional modules which are not relatively projective. Recall that for $i > 0$ we have

$$H_\chi^i(G, N) = \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(\Omega_\chi^i(\mathbb{k}), N) \cong \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(\mathbb{k}, \Omega_\chi^{-i}(N)) \cong \underline{\mathrm{Hom}}_{\mathbb{k}G}^\chi(\mathbb{k}, N) \cong N_\chi^G$$

using the fact that, for these modules N , we have $\Omega_\chi^{-i}(N) \cong N$.

We obtain by direct calculation:

Proposition 19. *Let N be an even-dimensional $\mathbb{k}G$ -module which is not projective relative to χ . Then.*

$$\dim(H_\chi^i(G, N)) = \begin{cases} n & i = 0 \\ n - 1 & \text{otherwise} \end{cases}$$

if $N \cong V_{2n,\infty}$ or $N \cong V_{2n,\theta}$ where $\theta(x) = x^n$ or $\theta(x) = (x+1)^n$, while

$$\dim(H_\chi^i(G, N)) = n$$

for any i , if $V \cong V_{2n,\theta}$ for some other choice of θ .

For odd-dimensional modules we proceed as follows. Let N be an odd-dimensional indecomposable module and let $i > 0$. Then

$$H_\chi^i(G, N) = \underline{\text{Hom}}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), N) \cong \underline{\text{Hom}}_{\mathbb{k}G}(\mathbb{k}, \Omega_\chi^{-i}(N)) \cong \underline{\text{Hom}}_{\mathbb{k}G}(\mathbb{k}, \Omega^{2i}(N)) \cong \Omega^{2i}(N)_\chi^G$$

using Theorem 1. Suppose $N \cong V_{2n+1}$ where $n \geq 0$. Then $\Omega^{2i}(N) \cong V_{2(n+2i)+1}$. A basis for $V_{2(n+2i)+1}$ is given by $\{a_0, a_1, \dots, a_{n+2i}, b_1, b_2, \dots, b_{n+2i}\}$, with action given by the diagram in Proposition 9. The b_i are all fixed points, and in addition a_0 is fixed by H_1 , a_{n+2i} by H_2 and $a_0 + a_1 + \dots + a_{n+2i}$ by H_3 . Therefore b_1, b_{n+2i} and $b_1 + b_2 + \dots + b_{n+2i}$ lie in $\Omega^{2i}(N)^{G,\chi}$. We therefore have

Proposition 20. *Let $N \cong V_{2n+1}$ for some $n \geq 0$. Then*

- (1) $\dim(H_\chi^0(G, N)) = n$ if $n > 0$, and 1 if $n = 0$.
- (2) $\dim(H_\chi^i(G, N)) = \max(0, n + 2i - 3)$ for $i > 0$.

Remark 21. This includes [10, Theorem 1.2] as a special case ($n = 0$).

For the remaining odd dimensional modules things are a little more complicated, since $\Omega^{2i}(N)$ eventually moves into the ‘‘positive’’ part of the spectrum. We begin by noting that if $n \geq 0$, then $V_{-(2n+1)}^{H_i} = V_{-(2n+1)}^G$ for all i . Therefore $(V_{-(2n+1)})^{G,\chi} = 0$.

Now let $N \cong V_{-(2n+1)}$ where $n \geq 1$. For $i \leq n/2$ we have $\Omega^{2i}(N) \cong V_{-(2(n-2i)+1)}$. Therefore

$$H_\chi^i(G, N) = \underline{\text{Hom}}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), N) \cong \underline{\text{Hom}}_{\mathbb{k}G}(\mathbb{k}, \Omega_\chi^{-i}(N)) \cong \underline{\text{Hom}}_{\mathbb{k}G}(\mathbb{k}, \Omega^{2i}(N)) \cong \Omega^{2i}(N)_\chi^G.$$

For $i > n/2$ we have $\Omega^{2i}(N) \cong V_{2(2i-n)+1}$. We therefore obtain the following:

Proposition 22. *Let $N \cong V_{-(2n+1)}$ where $n \geq 1$. Then*

$$\dim(H_\chi^i(G, N)) = \begin{cases} n + 1 - 2i & i \leq n/2 \\ \max(0, 2i - n - 3) & i > n/2. \end{cases}$$

3.3. Calculating cup products. The aim of this section is to prove Theorem 2. We begin with a lemma:

Lemma 23. *Let $M \cong V_{-(2m+1)}$ and $N \cong V_{-(2n+1)}$ for some $m > n \geq 0$. Let $\phi \in \text{Hom}_{\mathbb{k}G}(M, N)$. Then*

- (1) $\text{im}(\phi) \subseteq N^G$;
- (2) $M^G \subseteq \ker(\phi)$.

Proof. Note first that $\phi(M^G) \subseteq N^G$ for arbitrary G and $\mathbb{k}G$ -modules M and N . Let $a_1, a_2, \dots, a_m, b_0, b_1, \dots, b_m$ and $a'_1, a'_2, \dots, a'_n, b'_0, b'_1, \dots, b'_n$ be bases of M and N respectively, with action given by the diagrams in proposition 9. Note that if $n = 0$, then (1) is immediate. So suppose $n > 0$ and (1) does not hold: then we can find a maximal $k \geq 1$ such that $\phi(a_k) \notin N^G$.

We claim that $k = m$. To see this, write

$$\phi(a_k) = \sum_{i=1}^n \lambda_i a'_i \quad \text{mod } N^G.$$

Then

$$\phi(b_k) = \phi(Y a_k) = Y \phi(a_k) = \sum_{i=1}^n \lambda_i b'_i.$$

If $k < m$ then also

$$\phi(b_k) = \phi(X a_{k+1}) = X \phi(a_{k+1}) = 0$$

since $\phi(a_{k+1}) \in N^G$. So $\lambda_i = 0$ for all i and $\phi(a_k) \in N^G$, a contradiction.

Now we claim that, for all $0 \leq j \leq n$, we have

$$(9) \quad \phi(a_{m-j}) = \sum_{i=j+1}^n \lambda_i a'_{i-j} \pmod{N^G}$$

and $\lambda_i = 0$ for $i = 1, \dots, j$. We prove this by induction on j . The base case $j = 0$ is true by definition. Assuming the above for some $0 \leq j < n$ and noting that $n < m$, we have

$$\phi(b_{m-j-1}) = \phi(Xa_{m-j}) = X\phi(a_{m-j}) = \sum_{i=j+1}^n \lambda_i b'_{i-j-1}.$$

But

$$\phi(b_{m-j-1}) = \phi(Ya_{m-j-1}) = Y\phi(a_{m-j-1}) \in YN = \langle b'_1, \dots, b'_n \rangle$$

which shows that $\lambda_{j+1} = 0$. Therefore

$$\phi(b_{m-j-1}) = \sum_{i=j+2}^n \lambda_i b'_{i-j-1}$$

which shows that

$$\phi(a_{m-j-1}) = \sum_{i=j+2}^n \lambda_i a'_{i-j-1} \pmod{N^G}$$

proving our claim. Taking $j = n$ in (9) shows that $\phi(a_m) \in N^G$, a contradiction. This proves (1).

For (2), let $x \in M^G$. We may write

$$x = \sum_{i=0}^m \mu_i b_i$$

for some coefficients μ_i . Then

$$\phi(x) = \sum_{i=0}^m \mu_i \phi(b_i) = \mu_0 \phi(Xa_0) + \sum_{i=1}^m \mu_i \phi(Ya_{i-1}) = \mu_0 X\phi(a_0) + Y\phi\left(\sum_{i=1}^m \mu_i a_i\right) = 0$$

by (1). □

The following is immediate:

Corollary 24. *Let $L \cong V_{-(2l+1)}$, $M \cong V_{-(2m+1)}$ and $N \cong V_{-(2n+1)}$ for some $l > m > n \geq 0$. Let $\phi \in \text{Hom}_{\mathbb{k}G}(M, N)$ and $\psi \in \text{Hom}_{\mathbb{k}G}(L, M)$. Then $\phi \circ \psi = 0$.*

We may now proceed with the proof of Theorem 2:

Proof. Let $i, j > 0$. Let $\alpha \in H_\chi^i(G, \mathbb{k})$ and $\beta \in H_\chi^j(G, \mathbb{k})$. Choose $\phi \in \text{Hom}_{\mathbb{k}G}(\Omega_\chi^i(\mathbb{k}), \mathbb{k})$ and $\psi \in \text{Hom}_{\mathbb{k}G}(\Omega_\chi^j(\mathbb{k}), \mathbb{k})$, such that the equivalence classes

$$[\phi] \in \underline{\text{Hom}}_{\mathbb{k}G}^X(\Omega_\chi^i(\mathbb{k}), \mathbb{k}), [\psi] \in \underline{\text{Hom}}_{\mathbb{k}G}^X(\Omega_\chi^j(\mathbb{k}), \mathbb{k})$$

represent α and β respectively. By definition, $\alpha \smile \beta$ is represented by $[\phi \circ \Omega_\chi^i(\psi)]$. By Lemma 12 we have

$$\phi \in \text{Hom}(V_{-(2i+1)}, V_{(-1)}), \Omega_\chi^i(\psi) \in \text{Hom}(V_{-(2i+2j+1)}, V_{-(2i+1)})$$

and by Corollary 24 the composition of these two is the trivial map. □
